

GAMS – Documentation

Contents

1	GAMS Documentation Center	1
1.1	Model Libraries	1
1.2	Further Help	2
2	Preface	3
2.1	Timeline for documentation released with GAMS software	4
3	Release Notes	7
3.1	Release Types	7
3.2	Release History	7
3.3	38 Distribution	11
3.3.1	38.0.0 Beta release (January 14, 2022)	11
3.4	37 Distribution	22
3.4.1	37.1.0 Major release (November 11, 2021)	22
3.5	36 Distribution	29
3.5.1	36.1.0 Major release (August 02, 2021)	29
3.5.2	36.2.0 Minor release (September 03, 2021)	40
3.6	35 Distribution	41
3.6.1	35.1.0 Major release (April 29, 2021)	41
3.6.2	35.2.0 Minor release (June 02, 2021)	58
3.7	34 Distribution	60
3.7.1	34.1.0 Major release (January 29, 2021)	60
3.7.2	34.2.0 Minor release (February 05, 2021)	72
3.7.3	34.3.0 Minor release (February 25, 2021)	73
3.8	33 Distribution	75
3.8.1	33.1.0 Major release (November 01, 2020)	75
3.8.2	33.2.0 Minor release (December 01, 2020)	84
3.9	32 Distribution	85
3.9.1	32.1.0 Major release (July 31, 2020)	85
3.9.2	32.2.0 Minor release (August 26, 2020)	92
3.10	31 Distribution	94
3.10.1	31.1.0 Major release (May 01, 2020)	94
3.10.2	31.1.1 Maintenance release (May 16, 2020)	106
3.10.3	31.2.0 Minor release (June 19, 2020)	107
3.11	30 Distribution	108
3.11.1	30.1.0 Major release (January 10, 2020)	108
3.11.2	30.2.0 Minor release (February 07, 2020)	114
3.11.3	30.3.0 Minor release (March 06, 2020)	115
3.12	29 Distribution	117
3.12.1	29.1.0 Major release (November 15, 2019)	117
3.13	28 Distribution	122
3.13.1	28.1.0 Major release (August 02, 2019)	122
3.13.2	28.2.0 Minor release (August 19, 2019)	126
3.14	27 Distribution	127
3.14.1	27.1.0 Major release (April 24, 2019)	127
3.14.2	27.2.0 Minor release (May 23, 2019)	134

3.14.3	27.3.0 Minor release (July 04, 2019)	135
3.15	26 Distribution	137
3.15.1	26.1.0 Major release (February 02, 2019)	137
3.16	25.1 Distribution	149
3.16.1	25.1.1 Major release (May 19, 2018)	149
3.16.2	25.1.2 Minor release (August 01, 2018)	157
3.16.3	25.1.3 Minor release (October 30, 2018)	159
3.17	25.0 Distribution	161
3.17.1	25.0.1 Major release (January 17, 2018)	161
3.17.2	25.0.2 Maintenance release (January 31, 2018)	171
3.17.3	25.0.3 Minor release (March 21, 2018)	172
3.18	24.9 Distribution	174
3.18.1	24.9.1 Major release (August 30, 2017)	174
3.18.2	24.9.2 Minor release (November 14, 2017)	184
3.19	24.8 Distribution	187
3.19.1	24.8.1 Major release (December 21, 2016)	187
3.19.2	24.8.2 Maintenance release (January 03, 2017)	197
3.19.3	24.8.3 Minor release (January 28, 2017)	197
3.19.4	24.8.4 Minor release (April 10, 2017)	199
3.19.5	24.8.5 Maintenance release (May 10, 2017)	201
3.20	24.7 Distribution	202
3.20.1	24.7.1 Major release (March 14, 2016)	202
3.20.2	24.7.2 Minor release (July 07, 2016)	205
3.20.3	24.7.3 Maintenance release (July 11, 2016)	208
3.20.4	24.7.4 Minor release (September 19, 2016)	208
3.21	24.6 Distribution	210
3.21.1	24.6.1 Major release (January 18, 2016)	210
3.22	24.5 Distribution	215
3.22.1	24.5.1 Major release (September 23, 2015)	215
3.22.2	24.5.2 Maintenance release (September 29, 2015)	224
3.22.3	24.5.3 Maintenance release (October 01, 2015)	225
3.22.4	24.5.4 Maintenance release (October 15, 2015)	225
3.22.5	24.5.5 Maintenance release (November 25, 2015)	226
3.22.6	24.5.6 Maintenance release (November 27, 2015)	227
3.23	24.4 Distribution	228
3.23.1	24.4.1 Major release (December 20, 2014)	228
3.23.2	24.4.2 Minor release (March 15, 2015)	237
3.23.3	24.4.3 Maintenance release (April 02, 2015)	240
3.23.4	24.4.4 Maintenance release (May 12, 2015)	240
3.23.5	24.4.5 Maintenance release (May 26, 2015)	241
3.23.6	24.4.6 Minor release (June 26, 2015)	242
3.24	24.3 Distribution	243
3.24.1	24.3.1 Major release (July 31, 2014)	243
3.24.2	24.3.2 Minor release (August 29, 2014)	252
3.24.3	24.3.3 Minor release (September 19, 2014)	255
3.25	24.2 Distribution	257
3.25.1	24.2.1 Major release (December 09, 2013)	257
3.25.2	24.2.2 Maintenance release (March 04, 2014)	257
3.25.3	24.2.3 Maintenance release (May 22, 2014)	257
3.26	24.1 Distribution	257
3.26.1	24.1.1 Major release (May 30, 2013)	257
3.26.2	24.1.2 Maintenance release (June 16, 2013)	257
3.26.3	24.1.3 Maintenance release (July 26, 2013)	257
3.27	24.0 Distribution	257
3.27.1	24.0.1 Major release (December 24, 2012)	257
3.27.2	24.0.2 Maintenance release (February 14, 2013)	257
3.28	23.9 Distribution	257
3.28.1	23.9.1 Major release (July 04, 2012)	257

3.28.2	23.9.2	Maintenance release (August 29, 2012)	257
3.28.3	23.9.3	Maintenance release (September 26, 2012)	257
3.28.4	23.9.4	Maintenance release (October 20, 2012)	257
3.28.5	23.9.5	Maintenance release (November 09, 2012)	257
3.29	23.8	Distribution	257
3.29.1	23.8.1	Major release (March 17, 2012)	257
3.29.2	23.8.2	Maintenance release (April 05, 2012)	257
3.30	23.7	Distribution	258
3.30.1	23.7.1	Major release (July 14, 2011)	258
3.30.2	23.7.2	Maintenance release (July 22, 2011)	258
3.30.3	23.7.3	Maintenance release (August 23, 2011)	258
3.31	23.6	Distribution	259
3.31.1	23.6.2	Major release (December 13, 2010)	259
3.31.2	23.6.3	Maintenance release (February 15, 2011)	259
3.31.3	23.6.4	Maintenance release (April 01, 2011)	259
3.31.4	23.6.5	Maintenance release (April 08, 2011)	260
3.32	23.5	Distribution	260
3.32.1	23.5.1	Major release (July 05, 2010)	260
3.32.2	23.5.2	Maintenance release (August 18, 2010)	260
3.33	23.4	Distribution	260
3.33.1	23.4.1	Major release (May 21, 2010)	260
3.33.2	23.4.3	Maintenance release (May 24, 2010)	260
3.34	23.3	Distribution	260
3.34.1	23.3.1	Major release (November 01, 2009)	260
3.34.2	23.3.2	Maintenance release (November 18, 2009)	260
3.34.3	23.3.3	Maintenance release (December 17, 2009)	261
3.35	23.2	Distribution	261
3.35.1	23.2.1	Minor release (August 14, 2009)	261
3.36	23.1	Distribution	261
3.36.1	23.1.1	Major release (July 13, 2009)	261
3.36.2	23.1.2	Maintenance release (July 23, 2009)	261
3.37	23.0	Distribution	261
3.37.1	23.0.2	Major release (February 14, 2009)	261
3.38	22.9	Distribution	261
3.38.1	22.9.2	Major release (December 01, 2008)	261
3.39	22.8	Distribution	261
3.39.1	22.8.1	Major release (August 01, 2008)	261
3.40	22.7	Distribution	261
3.40.1	22.7.1	Major release (May 01, 2008)	261
3.40.2	22.7.2	Maintenance release (May 13, 2008)	261
3.41	22.6	Major release (December 24, 2007)	262
3.42	22.5	Major release (June 01, 2007)	262
3.43	22.4	Major release (February 12, 2007)	262
3.44	22.3	Major release (November 27, 2006)	262
3.45	22.2	Minor release (April 21, 2006)	262
3.46	22.1	Major release (March 15, 2006)	262
3.47	22.0	Major release (August 01, 2005)	262
3.48	21.7	Major release (April 01, 2005)	262
3.49	21.6	Minor release (January 26, 2005)	262
3.50	21.5	Minor release (November 11, 2004)	262
3.51	21.4	Major release (September 06, 2004)	262
3.52	21.3	Major release (January 19, 2004)	262
3.53	21.2	Maintenance release (September 03, 2003)	262
3.54	21.1	Maintenance release (June 02, 2003)	262
3.55	21.0	Major release (May 15, 2003)	262
3.56	20.7	Maintenance release (June 14, 2002)	262
3.57	20.6	Major release (May 25, 2002)	262
3.58	20.5	Maintenance release (January 28, 2002)	262

3.59	20.4 Maintenance release (January 21, 2002)	262
3.60	20.3 Major release (December 24, 2001)	262
3.61	20.2 Maintenance release (November 22, 2001)	262
3.62	20.1 Major release (October 31, 2001)	262
4	User's Guide	263
4.1	Installation and Licensing	263
4.2	Tutorials and Examples	263
4.3	GAMS Language and Environment	264
4.4	Glossary	265
4.5	Supported Platforms	265
4.6	Installation Notes for Mac OS X	266
4.6.1	Installation using the PKG installer (GAMS38.0.0.pkg)	266
4.6.2	Uninstall PKG installation	268
4.6.3	Installation using the self-extracting archive (osx_x64_64_sfx.exe)	268
4.7	Installation Notes for Unix	272
4.7.1	Installation	272
4.7.2	Access to GAMS	273
4.8	Installation Notes for Windows	274
4.8.1	Installation	274
4.8.2	Visual C++ Redistributable Dependency	276
4.8.3	Command Line Use of GAMS	276
4.8.4	Warning from Microsoft SmartScreen Filter	276
4.9	Standard Locations	277
4.9.1	Standard Locations on Mac OS X	277
4.9.2	Standard Locations on Unix	278
4.9.3	Standard Locations on Windows	278
4.10	Licensing	279
4.10.1	General Information	279
4.10.2	GAMS Community License	280
4.10.3	GAMS Licenses	280
4.10.4	Installing or updating a license file	280
4.10.5	License Problems	281
4.10.6	Warnings	282
4.10.7	The GAMS/BASE Module	282
4.10.8	Additional Limits for the Demo and Community License	284
4.11	A GAMS Tutorial by Richard E. Rosenthal	284
4.11.1	Introduction	284
4.11.2	Structure of a GAMS Model	287
4.11.3	Sets	288
4.11.4	Data	289
4.11.5	Variables	292
4.11.6	Equations	293
4.11.7	Objective Function	295
4.11.8	Model and Solve Statements	295
4.11.9	Display Statements	296
4.11.10	The .lo, .l, .up, .m Database	297
4.11.11	GAMS Output	299
4.11.12	Summary	307
4.12	Quick Start Tutorial	307
4.12.1	Three Basic Models	308
4.12.2	Components of the Example Models	310
4.12.3	Running a GAMS Job	314
4.12.4	Examining The Output	315
4.12.5	Exploiting the Algebraic Structure	319
4.12.6	Components of the Revised Example Models	322
4.12.7	Documenting the GAMS Code	326
4.12.8	Guidelines on Ordering GAMS Statements and Formatting GAMS Programs	328

4.12.9	Adding Complexity	329
4.12.10	Advantages of Algebraic Modeling in General	332
4.13	Good Coding Practices	335
4.13.1	Using Longer Names and Descriptive Text	336
4.13.2	Including Comments on Procedures and the Nature and Sources of Data	338
4.13.3	Choosing Raw Data Instead Of Computed Data	339
4.13.4	Avoiding the Universal Set in the Context of Data Input	339
4.13.5	Defining Sets and Subsets Wisely	340
4.13.6	Structuring and Formatting Files to Improve Readability	341
4.13.7	Other Suggestions	342
4.14	Fixing Compilation Errors	343
4.14.1	Preliminary Remarks	343
4.14.2	Resolving Common Compilation Errors	345
4.15	Finding and Fixing Execution Errors and Performance Problems	359
4.15.1	Resolving Execution Errors	360
4.15.2	Small to Large: Aid in Development and Debugging	368
4.15.3	Increasing Efficiency: Reducing GAMS Execution Time	373
4.15.4	Increasing Efficiency: Reducing Memory Use	381
4.16	Comparative Analyses with GAMS	384
4.16.1	Manual Approach	384
4.16.2	An Automated Approach - Avoiding Repeated Work	390
4.16.3	Ranging analysis	393
4.17	Good NLP Formulations	394
4.17.1	Specifying Initial Values	394
4.17.2	Setting Variable Bounds	395
4.17.3	Avoiding Expressions in Nonlinear Functions	396
4.17.4	Scaling Variables and Equations	396
4.17.5	Blocking Degenerate Cycling	397
4.17.6	Reformulating DNLP Models	398
4.18	Data Exchange with Other Applications	401
4.18.1	Data Exchange with Text Files	401
4.18.2	Data Exchange with Microsoft Excel	407
4.18.3	Data Exchange with Databases	414
4.19	Executing GAMS from other Environments	440
4.19.1	Some General Comments	440
4.19.2	Spawning GAMS from VBA	441
4.19.3	Spawning GAMS from C	442
4.19.4	Spawning GAMS from Visual Basic	444
4.19.5	Spawning GAMS from Delphi	445
4.19.6	Spawning GAMS from Visual C++	448
4.19.7	Spawning GAMS from C#	448
4.19.8	Spawning GAMS from Java	448
4.19.9	Spawning GAMS from a Web Server	449
4.19.10	Spawning GAMS from PHP	450
4.20	Using GAMS Studio	451

4.20.22	What does it not do so well?	487
4.21	Introduction	488
4.21.1	Summary	488
4.21.2	The Origins of GAMS	488
4.21.3	Background and Motivation	488
4.21.4	Design Goals and Changing Focus	489
4.22	GAMS Programs	490
4.22.1	Introduction	490
4.22.2	The Structure of GAMS Programs	491
4.22.3	Data Types and Definitions	495
4.22.4	Language Items	496
4.22.5	Summary	506
4.23	Set Definition	506
4.23.1	Introduction	506
4.23.2	Simple Sets	506
4.23.3	The Alias Statement: Multiple Names for a Set	509
4.23.4	Subsets	510
4.23.5	Multi-Dimensional Sets	511
4.23.6	Singleton Sets	515
4.23.7	The Universal Set: * as Set Identifier	516
4.23.8	Set and Set Element Referencing	517
4.23.9	Set Attributes	517
4.23.10	Finding Sets from Data	519
4.23.11	Domain Checking	520
4.23.12	Implicit Set Definition (or: Domain Defining Symbol Declarations)	521
4.23.13	Summary	523
4.24	Dynamic Sets	523
4.24.1	Introduction	523
4.24.2	Assigning Membership to Dynamic Sets	524
4.24.3	Set Operations	527
4.24.4	Using Dollar Controls with Dynamic Sets	528
4.25	Sets as Sequences: Ordered Sets	533
4.25.1	Introduction	533
4.25.2	Ordered and Unordered Sets	533
4.25.3	Sorting a Set	534
4.25.4	Ord and Card Operators	535
4.25.5	Lag and Lead Operators	536
4.25.6	Summary	542
4.26	Data Manipulations with Parameters	542
4.26.1	Introduction	542
4.26.2	The Assignment Statement	543
4.26.3	Expressions	546
4.26.4	Functions	549
4.26.5	Extended Range Arithmetic and Error Handling	563
4.26.6	Predefined Symbols	565
4.26.7	Summary	566
4.27	Data Entry: Parameters, Scalars and Tables	566
4.27.1	Introduction	566
4.27.2	Scalars	567
4.27.3	Parameters	568

4.27.4	Tables	570
4.27.5	Constant Evaluation	574
4.27.6	Data Entry by Assignment	575
4.27.7	Acronyms	576
4.27.8	Summary	577
4.28	Variables	577
4.28.1	Introduction	577
4.28.2	Variable Declarations	577
4.28.3	Variable Attributes	581
4.28.4	Variables in Display and Assignment Statements	585
4.28.5	Summary	588
4.29	Equations	588
4.29.1	Introduction	588
4.29.2	Declaring Equations	588
4.29.3	Defining Equations	589
4.29.4	Expressions in Equation Definitions	594
4.29.5	Equation Attributes	596
4.29.6	Summary and Quick Reference	597
4.30	Model and Solve Statements	598
4.30.1	Introduction	598
4.30.2	The Model Statement	598
4.30.3	The Solve Statement	614
4.30.4	Programs with Several Solve Statements	616
4.30.5	Choosing a Solver	619
4.30.6	Making New Solvers Available with GAMS	620
4.31	Conditional Expressions, Assignments and Equations	620
4.31.1	Introduction	620
4.31.2	The Dollar Condition	621
4.31.3	Logical Conditions	621
4.31.4	Conditional Assignments	628
4.31.5	Conditional Indexed Operations	630
4.31.6	Conditional Equations	631
4.31.7	Filtering Sets	633
4.32	The Display Statement	636
4.32.1	Introduction	636
4.32.2	The Syntax	636
4.32.3	Displaying Multi-Dimensional Identifiers: Label Order	638
4.32.4	Display Controls	640
4.32.5	Conditional Displays	644
4.33	Programming Flow Control Features	645
4.33.1	Introduction	645
4.33.2	The If Statement	645
4.33.3	The Loop Statement	647
4.33.4	The While Statement	651
4.33.5	The For Statement	652
4.33.6	The Repeat Statement	654
4.33.7	The Break Statement	656
4.33.8	The Continue Statement	657
4.33.9	The Abort Statement	658
4.34	The Option Statement	660
4.34.1	Introduction	660
4.34.2	List of Options	661
4.35	System Attributes	673
4.35.1	Introduction	673
4.35.2	System Suffixes	674
4.35.3	System Data	677
4.35.4	Access to Hidden Functions	679
4.36	The Grid and Multi-Threading Solve Facility	679

4.36.1	Introduction	679
4.36.2	The Grid Facility: Basic Concepts	680
4.36.3	The Grid Facility: A First Example	681
4.36.4	Advanced Use of Grid Features	684
4.36.5	Summary of Grid Features	686
4.36.6	The Grid Facility: Architecture and Customization	689
4.36.7	Multi-Threading	690
4.37	Special Features for Mathematical Programs	691
4.37.1	Introduction	691
4.37.2	Special Mixed Integer Programming (MIP) Features	691
4.37.3	Model Scaling - The Scale Option	699
4.37.4	Conic Programming in GAMS	703
4.37.5	Indicator Constraints	707
4.38	GAMS Output	711
4.38.1	Introduction	711
4.38.2	An Illustrative Model	711
4.38.3	Compilation Output	712
4.38.4	Execution Output	719
4.38.5	Model Generation Output	719
4.38.6	The Solution Report	723
4.38.7	Post-Solution Output	729
4.38.8	Error Reporting	730
4.38.9	Customizing the Output File	734
4.39	GAMS Log	736
4.39.1	Introduction	736
4.39.2	Header	736
4.39.3	Compilation Log	738
4.39.4	Execution Output	738
4.40	The GAMS Call and Command Line Parameters	740
4.40.1	The Generic GAMS Call	740
4.40.2	Double Dash Parameters, Compile-Time Variables and Environment Variables	748
4.40.3	Compile-Time Constants	754
4.40.4	GAMS Compile Time and Execution Time Phase	756
4.40.5	List of Command Line Parameters	757
4.40.6	Detailed Descriptions of All Options	761
4.40.7	Executing an External Program	833
4.41	Dollar Control Options	834
4.41.1	Introduction	834
4.41.2	List of Dollar Control Options	835
4.41.3	Detailed Description of Dollar Control Options	841
4.41.4	Conditional Compilation	930
4.41.5	Macros in GAMS	938
4.41.6	Compressing and Decompressing Files	943
4.41.7	Encrypting Files	945
4.42	The Put Writing Facility	949
4.42.1	Introduction	949
4.42.2	The Syntax	949
4.42.3	A First Example	952
4.42.4	Put Files	953
4.42.5	Put File Pages	963
4.42.6	Output Items	969
4.42.7	The Put.Utility Statement	982
4.42.8	Conditional Put Statements	990
4.42.9	Errors Associated with Put Statements	990
4.42.10	Creating a Report for the Model MEXSS	991
4.43	Solver Usage	995
4.43.1	Controlling a Solver via GAMS Options	995
4.43.2	The Solver Options File	996

4.43.3	Starting Point and Initial Basis	998
4.43.4	Trace Features	999
4.43.5	Branch-and-Cut-and-Heuristic Facility (BCH)	1007
4.43.6	Choosing an appropriate Solver	1011
4.44	The Save and Restart Feature	1013
4.44.1	Basic Usage	1014
4.44.2	Use Cases	1017
4.44.3	Secure Work Files	1022
4.44.4	Obfuscated Work Files	1028
4.45	Embedded Code Facility	1030
4.45.1	Motivation	1030
4.45.2	Concept	1030
4.45.3	Simple Example	1031
4.45.4	Syntax	1033
4.45.5	Python	1035
4.46	Extrinsic Functions	1049
4.46.1	Introduction	1049
4.46.2	Using Function Libraries	1050
4.46.3	Libraries that are included in the GAMS Distribution	1051
4.46.4	Build Your Own Library	1058
4.46.5	Extrinsic Functions vs. External Equations	1062
4.47	External Equations	1063
4.47.1	Examples in the GAMS Test Library	1064
4.47.2	Model Interface	1064
4.47.3	Programming Interface	1066
4.47.4	Implementation	1069
4.48	GAMS Return Codes	1074
4.48.1	List of the Error/Return Codes	1076
4.49	GAMS Data eXchange (GDX)	1077
4.49.1	Reading a GDX file	1077
4.49.2	Writing a GDX file	1090
4.49.3	General notes on GDX files	1097
4.49.4	GAMS Data eXchange Tools	1097

GAMS Documentation Center

The GAMS Documentation Center provides you with the technical information on getting started, using and maintaining our GAMS (General Algebraic Modeling System) products.

- [Preface](#)
- [Release Notes - 38.0.0 Beta release \(January 14, 2022\)](#)
- [User's Guide](#)
 - [Installation and Licensing](#) - Guides on installing GAMS for various platforms and using a GAMS license
 - [Tutorials and Examples](#) - Step-by-step guides including a number of examples
 - [GAMS Language and Environment](#) - Guide through components of GAMS Language and the environment for executing a GAMS model
- [Solver Manuals](#) - Manuals of solvers available in the distribution
- [Tools Manuals](#) - Manuals of tools available in the distribution
- [Application Programming Interfaces](#) - Manuals of Application Programming Interfaces
- [Glossary](#) - An alphabetical list of GAMS terms.
- [Bibliography](#)

1.1 Model Libraries

From the early stages of the development of GAMS we have collected models to be used in libraries of examples. Many of these are standard textbook examples and can be used in classes on problem formulation or to illustrate points about GAMS. Others are models that have been used in policy or sector analysis and are interesting for both the methods and the data they use. These model libraries are included with all GAMS systems and are also available online.

The following model libraries are available:

- **GAMS Model Library** - includes GAMS models representing interesting and sometimes classic problems, ranged from production and shipment by firms, investment planning, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and many more.

- **GAMS Test Library** - includes GAMS models developed for testing and quality control, both for the GAMS base module and the many solvers distributed with the GAMS system.
- **GAMS Data Library** - includes GAMS models demonstrating various utilities to interface GAMS with other tools and applications such as spreadsheets and database interface.
- **GAMS EMP Library** - includes GAMS Extended Mathematical Programming (EMP) models that illustrate and test the capabilities of GAMS/EMP.
- **GAMS API Library** - includes GAMS Models used as scripts to compile and execute application programs in various programming languages interfacing to GAMS.
- **FIN Library** - includes GAMS practical financial optimization models described in the book [Practical Financial Optimization: Decision Making for Financial Engineers](#) by Consiglio, Nielsen and Zenios,
- **NOA Library** - includes GAMS nonlinear optimization applications models based on the book [Nonlinear Optimization Applications Using the GAMS Technology](#) by Neculai Andrei.
- **PSOPT Library** - includes GAMS optimization models based on the book [Power System Optimization Modelling in GAMS](#) by Alireza Soroudi.

See [Accessing Model Libraries](#) on how to access a GAMS model from the model libraries.

For large parts of the documentation, references to models from the model libraries are enclosed in square parenthesis (for example, [TRANSPORT]).

1.2 Further Help

If you have a further question which is not answered by the documentation above, you can get further help from our [GAMS-FAQ](#) which contains materials collected from various support activities or post your question to [GAMS World Forum](#). You can also sign up to our [Newsletters](#) to get the latest information from GAMS. There is also [GAMS Lessons](#), a YouTube Video Channel providing you with some tutorials on how to use our system.

There are a number of [contributed documentations](#) that have been contributed by GAMS users as well as [presentations, books, posters, and advertisements](#) contributed by people working with GAMS. The McCarl GAMS User Guide are available in various formats ([PDF](#) and [HTML](#)) and can also be found in the GAMS distribution under mccarl/ subdirectory with an incremental installer ([ZIP](#)) available for download.

You can also visit our upcoming [courses and workshops](#) or contact one of [solution specialists](#) who have wide experience in GAMS modeling.

If you experience a problem using GAMS please contact our [Technical Support](#). If you have a confidential model that you cannot share as is, please read the [information on conversion of models](#) before submitting your models to our technical support.

Chapter 2

Preface

The GAMS documentation has changed considerably since it was first released in 1988: in format, in scope and content, and in how it is distributed and accessed. At the same time, it maintains many elements of the original style: part tutorial, part user's guide, and part reference manual. We describe here the evolution of the GAMS documentation and related topics.

Figure 2.1 Covers of GAMS User's Guide and Solver Manual

The first published GAMS documentation is the book *GAMS: A User's Guide* (aka the "red book") by Brooke, Kendrick, and Meeraus, published in 1988 by The Scientific Press. Copies were sold in bookstores and included a chapter on the model library (100 models at that time), a much-appreciated and well-used index, appendices describing the solvers available (MINOS and ZOOM), and a 5.25 inch floppy disk containing a student version of "PC-GAMS version 2.05". This was followed up in 1992 with *GAMS: A User's Guide, Release 2.25* (aka the "blue book") by a different publisher (Boyd & Fraser), a soft cover, and no floppy disk: by this time the software was available directly from GAMS. The final section of installation notes in the red book was replaced in the blue book by notes on the new features in GAMS 2.25, but the content was otherwise unchanged.

As the pace of development increased, it became clear that we needed a new documentation scheme, one that would allow us to update the document continuously as language features, models and model libraries, solvers, and tools/utilities were added to or updated in the system. Consequently, we converted the existing documentation to MS Word, expanded, updated, and edited it as appropriate, and sent it to the copy shop to be printed. This was a group effort spearheaded by Ramesh Raman, whose name was included as an author in the User's Guide first included (along with a CD) in shipments of our 18.0 release in Feb 1999. The solver manuals in this release were collected from various sources (with varying styles, content, and organization) and put into a separate binder. A further push was required to unify this solver documentation (using LaTeX) to use a common style and organization: this unified Solver Manual was included with the 21.0 release of May 2003. In addition to hard-copy, all of these documents were included as PDF in the GAMS system and freely available via the Web. Thus, the shift away from published documentation to manuals produced in-house went hand-in-hand with a shift from printed documents to viewing and searching PDF documents.

During this time Bruce McCarl had been regularly teaching GAMS courses: basic and advanced, targeting a general audience but with a distinct flavor of agricultural economics. As part of this he developed course material to use in his classes, and he was in a good position to notice that the GAMS User Guide was not keeping up with all the updates to the software. With some encouragement from GAMS, Bruce started the ambitious project of creating a new GAMS User's Guide, one that would be more complete, more to his taste with an increase in tutorial flavor, and designed to take full advantage of being a Web document: linked, cross-referenced, searchable, and indexed. The end result was the McCarl Guide that emerged as a PDF based on a Word document in 2002. This was redone in the more convenient CHM format with the 22.1 release of Mar 2006 and renamed as the *Expanded GAMS Guide (McCarl)* in release 22.3 of Nov 2006. We also kept the original GAMS User's Guide, by this time as PDF generated from LaTeX source. With its improved content, organization, and navigability, Bruce's new guide was a boon to all GAMS users, not just those taking his courses. We owe a debt of gratitude to Bruce for this and many other contributions.

The *Expanded GAMS Guide (McCarl)* was never intended to be printed and was not shipped as hard-copy with GAMS. In 2013, GAMS stopped making physical shipments altogether and moved to an online order-fulfillment system. For those who still wanted printed documentation, the documents were also made available via [Amazon's CreateSpace](#), but most users browsed the documents online or as part of an installed GAMS system, often via the GAMS IDE, so the need for printable documents was small and growing smaller.

Having two user's guides was counter-intuitive or confusing for some users, especially when the content for some topics was different, missing, or even contradictory. The additional effort required to maintain two documents became more noticeable, especially since the *Expanded User Guide (McCarl)* was implemented using a Windows-only product that did not lend itself to version control via SVN or git. When we documented our object-oriented APIs in Feb 2013, we used the opportunity to experiment with a doxygen-based authoring process that uses text files as source, is platform-independent, and produces output in multiple formats. The results were good, and in 2015 we hired a consultant, Martha Loewe, to research what it would take to convert all of the GAMS documentation to use the doxygen-based process and to set up a framework for this. We eventually committed fully to this process and produced a unified set of documentation as of release 24.9 in Aug 2017. This involved reorganizing things somewhat to better fit a linked document, merging the two user guides into one (while trying to maintain the best qualities of each), adding links throughout, and submitting everything to review and editing by internal subject matter experts so the content is accurate, updated, and complete. The end result is something we believe is an improvement over its predecessors, but it is also something we are committed to maintaining and improving. The current system allows and encourages immediate updates by the whole GAMS team and has helped foster a culture and attitude where this takes place.

2.1 Timeline for documentation released with GAMS software

Distribution	Month/Year	Change
18.0	Feb-99	IDE released plus IDE help (hlp), no other documentation
19.0	Jan-00	GAMS Users Guide (pdf from Word), installation notes, plus some solver chapters
19.1	Mar-00	Integration of documentation in the IDE
21.0	May-03	McCarl Guide (collection of linked pdf documents) on installation CD and web plus instructions how to integrate into GAMS system, IDE help format change hlp->chm, other tools document gdxutils.pdf, combined allsolvers.pdf plus individual solver chapters (with TOC document)
21.3	Jan-04	Added gdxutils.chm
21.4	Feb-04	Integrate the McCarl Guide
22.0	Aug-05	Added releasenotes.htm
22.1	Mar-06	McCarl Guide as chm, GAMS Users Guide (pdf from LaTeX)

Distribution	Month/Year	Change
22.3	Nov-06	McCarl Guide renamed to Expanded GAMS Guide (McCarl)
22.5	Jun-07	Tools documentation as chm and pdf
24.0	Feb-13	API documentation (.NET as chm, others as pdf)
24.1	Jul-13	.NET API tutorial as chm
24.2	Dec-13	Other API tutorials as pdf
24.3	Jul-14	API documentation as html
24.4	Dec-14	Solvers and many tools as html
24.5	Sep-15	GAMS Users Guide as chm, pdf, and html
24.8	Dec-16	Drop chm of GAMS Users Guide, html based unified documentation
24.9	Aug-17	Merged, revised, and reorganized GAMS User's Guide and McCarl Guide into new User's Guide
25.1	May-18	Documentation integration into studio

Chapter 3

Release Notes

3.1 Release Types

Major releases contain substantial changes to the GAMS system. The License Check date is set to the release date of the major release.

Minor releases are mainly issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. Additionally, they can provide a few new features that do not change existing behavior. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this minor release.

Maintenance releases do not provide any new features. They are issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this maintenance release.

3.2 Release History

- [38 Distribution](#) ([distribution start page](#))
 - [38.0.0 Beta release](#) (January 14, 2022)
- [37 Distribution](#) ([distribution start page](#))
 - [37.1.0 Major release](#) (November 11, 2021)
- [36 Distribution](#) ([distribution start page](#))
 - [36.1.0 Major release](#) (August 02, 2021)
 - [36.2.0 Minor release](#) (September 03, 2021)
- [35 Distribution](#) ([distribution start page](#))
 - [35.1.0 Major release](#) (April 29, 2021)
 - [35.2.0 Minor release](#) (June 02, 2021)
- [34 Distribution](#) ([distribution start page](#))
 - [34.1.0 Major release](#) (January 29, 2021)
 - [34.2.0 Minor release](#) (February 05, 2021)

- 34.3.0 Minor release (February 25, 2021)
 - 33 Distribution ([distribution start page](#))
 - 33.1.0 Major release (November 01, 2020)
 - 33.2.0 Minor release (December 01, 2020)
 - 32 Distribution ([distribution start page](#))
 - 32.1.0 Major release (July 31, 2020)
 - 32.2.0 Minor release (August 26, 2020)
 - 31 Distribution ([distribution start page](#))
 - 31.1.0 Major release (May 01, 2020)
 - 31.1.1 Maintenance release (May 16, 2020)
 - 31.2.0 Minor release (June 19, 2020)
 - 30 Distribution ([distribution start page](#))
 - 30.1.0 Major release (January 10, 2020)
 - 30.2.0 Minor release (February 07, 2020)
 - 30.3.0 Minor release (March 06, 2020)
 - 29 Distribution ([distribution start page](#))
 - 29.1.0 Major release (November 15, 2019)
 - 28 Distribution ([distribution start page](#))
 - 28.1.0 Major release (August 02, 2019)
 - 28.2.0 Minor release (August 19, 2019)
 - 27 Distribution ([distribution start page](#))
 - 27.1.0 Major release (April 24, 2019)
 - 27.2.0 Minor release (May 23, 2019)
 - 27.3.0 Minor release (July 04, 2019)
 - 26 Distribution ([distribution start page](#))
 - 26.1.0 Major release (February 02, 2019)
 - 25.1 Distribution ([distribution start page](#))
 - 25.1.1 Major release (May 19, 2018)
 - 25.1.2 Minor release (August 01, 2018)
 - 25.1.3 Minor release (October 30, 2018)
 - 25.0 Distribution
 - 25.0.1 Major release (January 17, 2018)
 - 25.0.2 Maintenance release (January 31, 2018)
 - 25.0.3 Minor release (March 21, 2018)
 - 24.9 Distribution
 - 24.9.1 Major release (August 30, 2017)
 - 24.9.2 Minor release (November 14, 2017)
 - 24.8 Distribution
 - 24.8.1 Major release (December 21, 2016)
-

- 24.8.2 Maintenance release (January 03, 2017)
 - 24.8.3 Minor release (January 28, 2017)
 - 24.8.4 Minor release (April 10, 2017)
 - 24.8.5 Maintenance release (May 10, 2017)
 - 24.7 Distribution
 - 24.7.1 Major release (March 14, 2016)
 - 24.7.2 Minor release (July 07, 2016)
 - 24.7.3 Maintenance release (July 11, 2016)
 - 24.7.4 Minor release (September 19, 2016)
 - 24.6 Distribution
 - 24.6.1 Major release (January 18, 2016)
 - 24.5 Distribution
 - 24.5.1 Major release (September 23, 2015)
 - 24.5.2 Maintenance release (September 29, 2015)
 - 24.5.3 Maintenance release (October 01, 2015)
 - 24.5.4 Maintenance release (October 15, 2015)
 - 24.5.5 Maintenance release (November 25, 2015)
 - 24.5.6 Maintenance release (November 27, 2015)
 - 24.4 Distribution
 - 24.4.1 Major release (December 20, 2014)
 - 24.4.2 Minor release (March 15, 2015)
 - 24.4.3 Maintenance release (April 02, 2015)
 - 24.4.4 Maintenance release (May 12, 2015)
 - 24.4.5 Maintenance release (May 26, 2015)
 - 24.4.6 Minor release (June 26, 2015)
 - 24.3 Distribution
 - 24.3.1 Major release (July 31, 2014)
 - 24.3.2 Minor release (August 29, 2014)
 - 24.3.3 Minor release (September 19, 2014)
 - 24.2 Distribution
 - 24.2.1 Major release (December 09, 2013)
 - 24.2.2 Maintenance release (March 04, 2014)
 - 24.2.3 Maintenance release (May 22, 2014)
 - 24.1 Distribution
 - 24.1.1 Major release (May 30, 2013)
 - 24.1.2 Maintenance release (June 16, 2013)
 - 24.1.3 Maintenance release (July 26, 2013)
 - 24.0 Distribution
 - 24.0.1 Major release (December 24, 2012)
 - 24.0.2 Maintenance release (February 14, 2013)
-

- 23.9 Distribution
 - 23.9.1 Major release (July 04, 2012)
 - 23.9.2 Maintenance release (August 29, 2012)
 - 23.9.3 Maintenance release (September 26, 2012)
 - 23.9.4 Maintenance release (October 20, 2012)
 - 23.9.5 Maintenance release (November 09, 2012)
 - 23.8 Distribution
 - 23.8.1 Major release (March 17, 2012)
 - 23.8.2 Maintenance release (April 05, 2012)
 - 23.7 Distribution
 - 23.7.1 Major release (July 14, 2011)
 - 23.7.2 Maintenance release (July 22, 2011)
 - 23.7.3 Maintenance release (August 23, 2011)
 - 23.6 Distribution
 - 23.6.2 Major release (December 13, 2010)
 - 23.6.3 Maintenance release (February 15, 2011)
 - 23.6.4 Maintenance release (April 01, 2011)
 - 23.6.5 Maintenance release (April 08, 2011)
 - 23.5 Distribution
 - 23.5.1 Major release (July 05, 2010)
 - 23.5.2 Maintenance release (August 18, 2010)
 - 23.4 Distribution
 - 23.4.1 Major release (May 21, 2010)
 - 23.4.3 Maintenance release (May 24, 2010)
 - 23.3 Distribution
 - 23.3.1 Major release (November 01, 2009)
 - 23.3.2 Maintenance release (November 18, 2009)
 - 23.3.3 Maintenance release (December 17, 2009)
 - 23.2 Distribution
 - 23.2.1 Minor release (August 14, 2009)
 - 23.1 Distribution
 - 23.1.1 Major release (July 13, 2009)
 - 23.1.2 Maintenance release (July 23, 2009)
 - 23.0 Distribution
 - 23.0.2 Major release (February 14, 2009)
 - 22.9 Distribution
 - 22.9.2 Major release (December 01, 2008)
 - 22.8 Distribution
 - 22.8.1 Major release (August 01, 2008)
-

- 22.7 Distribution
 - 22.7.1 Major release (May 01, 2008)
 - 22.7.2 Maintenance release (May 13, 2008)
- 22.6 Major release (December 24, 2007)
- 22.5 Major release (June 01, 2007)
- 22.4 Major release (February 12, 2007)
- 22.3 Major release (November 27, 2006)
- 22.2 Minor release (April 21, 2006)
- 22.1 Major release (March 15, 2006)
- 22.0 Major release (August 01, 2005)
- 21.7 Major release (April 01, 2005)
- 21.6 Minor release (January 26, 2005)
- 21.5 Minor release (November 11, 2004)
- 21.4 Major release (September 06, 2004)
- 21.3 Major release (January 19, 2004)
- 21.2 Maintenance release (September 03, 2003)
- 21.1 Maintenance release (June 02, 2003)
- 21.0 Major release (May 15, 2003)
- 20.7 Maintenance release (June 14, 2002)
- 20.6 Major release (May 25, 2002)
- 20.5 Maintenance release (January 28, 2002)
- 20.4 Maintenance release (January 21, 2002)
- 20.3 Major release (December 24, 2001)
- 20.2 Maintenance release (November 22, 2001)
- 20.1 Major release (October 31, 2001)

3.3 38 Distribution

3.3.1 38.0.0 Beta release (January 14, 2022)

3.3.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Albert Brouwer, Daniel Jungen, Scott McDonald, Tom Rutherford, Seyed Amin Sedgh, and Wenjin Zhou.

3.3.1.2 Platforms

- As [announced](#), dropped support for Mac OS X 10.14 (Mojave).
- Added support for Mac OS X 12 (Monterey).

3.3.1.3 GAMS System

3.3.1.3.1 GAMS

- Added new command line parameter [dumpOptGDX](#) to load the data needed in [dumpOpt files](#) from GDX instead of data statements.
- Added new command line parameter [ReferenceLineNo](#) to control the line numbers written to a [reference file](#).
- Extended the [Solve Summary](#) written with [asyncSolLst=1](#) to include information about controlling loop indices during job submission, name of the solver called, source line number of the solve statement, resource and iteration limit.
- Make handling of execution errors during model generation (e.g. division by zero in an equation) more consistent across different settings for the [solveLink](#) option. In the past, the error count was set to 0 automatically when returning from a solve with [solveLink=0](#) only (which is equivalent to setting [execError=0](#) after the solve statement). This is not done anymore.
- Write additional information about execution errors during model generation (e.g. division by zero error) to the lst file, e.g., the equation name and index causing the problem.
- Improve recognition of '/' as path delimiter on Windows.
- Pause automated time dependent log update while executing [embedded code](#) sections.
- Check for certain byte order marks (BOMs) in GAMS input files. Files with UTF8 BOM can be processed now, other BOMs generate a compilation error.
- Added support for (mixed-integer) quadratic models whose Q matrices contain more than $2^{31} = 2,147,483,648$ nonzeros in their upper triangle. At this time, only the solver links for CPLEX and ODHCPLEX are capable of handling such large model instances.
- Changed [system suffix](#) [isAlfaBeta](#) to [isAlphaBeta](#).
- Fixed a problem for EMP models with [holdFixed](#) model attribute.
- Fixed a problem where [IDCGenerateGDXInput](#), [IDCGenerateGDXOutput](#), [IDCGDXOutput](#) , and [IDCGenerateGDX](#) did not write a GDX file if the execution was stopped with [abort\[.noError\]](#).

3.3.1.3.2 Extended Mathematical Programming (EMP)

- Stochastic EMP: Changed the [stage](#) behavior so that it creates an explicit error when a stage gets assigned twice for the symbol. In the past, this caused erratic behavior.

3.3.1.3.3 Embedded Python Code Facility

- The Python version of GMSPython has been updated to 3.8.12.
-

3.3.1.4 Solvers

3.3.1.4.1 BARON

- New libraries 22.1.8.
 - new presolve implementation with novel presolve techniques for linear and nonlinear optimization problems improves performance for many problem classes
 - more classes of SOCPs are now recognized
 - new lift-and-project implementation that extends the previous RLT implementations to generic NLPs and MINLPs and leads to substantial reduction of duality gaps for difficult problems
 - improved tree management, including restarts of branch-and-bound search
 - improved branching routines for the identification of most important branching variables
 - dynamic LP algorithm selection strategy improves robustness for numerically difficult problems
 - improved control on the effect of floating point round-off errors
 - faster hashing routines
 - the embedded FilterSD algorithm is now off by default
 - better integration with GAMS NLP subsolvers
 - improvements to CBC and IPOPT interfaces
 - update the Xpress interface to work with FICO XPRESS 39
- Fixed reporting of proven irreducible infeasible sets ("IIS" instead of "(I)IS").

3.3.1.4.2 CONOPT

- New libraries 4.25
 - General improvements in the construction of the initial basis and in the startup of the optimization process, especially for very large models.
 - Many small improvements and corrections of errors found by users.

3.3.1.4.3 CONVERT

- The symbol We in `DumpGDX` is now stored sparse.
- Changed option default of `GDXHessian` and `GDXQuadratic` to 0.

3.3.1.4.4 COPT

- Added new parallel LP and MIP solver `COPT` 3.0.5 by Cardinal Operations (<https://www.shanshu.ai/copt>).
- For GAMS [demo and community licenses](#), [model size limitations](#) as for other solvers apply. For an unlimited GAMS/COPT or GAMS/COPT-Link license, contact sales@gams.com.

3.3.1.4.5 CPLEX

- Fix appending `userjobid` to `userincbcall`, `usergdxin`, and `usergdxnameinc` in BCH calls.
 - Fixed computing dual multiplier at cone top (QCP models).
-

3.3.1.4.6 DICOPT

- Fixed that non-default stage information was setup in sub-MIPs when `prioropt=0`.

3.3.1.4.7 KNITRO

- New libraries 13.0.
 - Introduces an updated, parallel, branch-and-bound solver for mixed-integer optimization. This updated solver is able to exploit parallelism and uses improved heuristics to solve mixed-integer problems much faster than before.
 - Offers new initial point strategies for non-convex quadratic programs (QPs) and quadratically constrained quadratic programs (QCQPs). These new initial point strategies improve the likelihood of finding the global solution, and can be used in conjunction with the Knitro multi-start procedure to search for global or better local solutions for non-convex QP and QCQP models.
 - Offers significant robustness and speed improvements on difficult nonlinear optimization problems.
 - Offers improved performance when using the SQP and MISQP algorithms on larger models.
 - Added options:
 - * `ncvx-qcqp-init`: Specifies the initialization strategy used for non-convex QPs and QCQPs.
 - * `mip_cutoff`: This value specifies the objective cutoff value for MIP.
 - * `mip_heuristic_lns`: Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics.
 - * `mip_liftproject`: Specifies rules for adding lift and project cuts.
 - * `mip_multistart`: Use to enable MIP multi-start at the branch-and-bound level.
 - * `mip_numthreads`: Specify the number of threads to use for MIP branch and bound.
 - Renamed options (old option names still available as synonyms but deprecated):
 - * `bar_pencons` to `bar_penaltycons`.
 - * `bar_penrule` to `bar_penaltyrule`.
 - * `mip_integral_gap_abs` to `mip_opt_gap_abs`.
 - * `mip_integral_gap_rel` to `mip_opt_gap_rel`.
 - * `par_msnumthreads` to `ms_numthreads`.
 - * `par_blasnumthreads` to `blas_numthreads`.
 - * `par_lsnumthreads` to `linsolver_numthreads`.
 - * `tuner_maxtimecpu` to `tuner_maxtime_cpu`.
 - * `tuner_maxtimereal` to `tuner_maxtime_real`.
 - Added option values:
 - * `blasoption`: 3.
 - * `mip_heuristic_diving`: bits 1 - 4.
 - Changed option defaults:
 - * `restarts`: -1 (auto).
 - * `mip_strong_candlim`: 128.

3.3.1.4.8 LocalSolver

- As [announced](#), dropped LocalSolver and LocalSolver70.
-

3.3.1.4.9 MOSEK

- New libraries 9.3.11.
- Added support for LPs and MIPs with more than 2^{31} entries in the coefficients matrix.

3.3.1.4.10 Ocuteract

- New libraries 4.0.0.
 - Reduced memory requirement and improved performance.

3.3.1.4.11 ODHCPLEX

- New libraries 6.0.8.
- Added support of solution pool export via [solnpool](#) and [solnpoolmerge](#).

3.3.1.4.12 SCIP Optimization Suite

- New libraries PaPILO 2.0 (406276c9).
 - Added dual postsolve functionality for LPs.
 - Immediate application of a presolvers reductions if run sequentially.
 - Improvements in performance and functionality of many presolvers.
 - For more details, see [37] and the [PaPILO CHANGELOG](#).
 - Updated TBB to version 2021.5.0.
 - New libraries SoPlex 6.0 (6b341763).
 - PaPILO can now be enabled as presolver by setting [int:simplifier](#) to the new value 2.
 - SoPlex can now be interrupted by Ctrl+C/SIGINT.
 - Changed default for option [int:simplifier](#) from 1 to new value 3. The value 1 now means "auto".
 - New option [real:simplifier_modifyrowfac](#).
 - For more details, see [37] and the [SoPlex CHANGELOG](#).
 - New libraries SCIP 8.0 (7f0f96909d).
 - Symmetry handling:
 - * New symmetry handling inequalities based on the Schreier Sims table, which are able to handle symmetries of arbitrary kinds of variables.
 - * The symmetry code can now heuristically search for orbitopes that do not completely handle a symmetry component and add certain Schreier Sims cuts to such components.
 - * In-tree restarts due to tree size estimation have been made compatible with orbital fixing.
 - * Improved performance of upgrades to packing/partitioning orbitopes, symresack cover separation, and propagation for orbisack and symresack.
 - * Symmetry handling has been extended to detect also symmetries between variables that also appear in nonlinear constraints.
 - Cutting planes:
 - * New separator [mixing](#) to generate mixing cuts.
 - * New separator [rlt](#) to compute cuts via the reformulation-linearization technique (RLT).
-

- * New separator [minor](#) to compute cuts from 2x2 minors of a violated semidefiniteness constraint that is implied by the extended formulation for bilinear products.
 - * New separator [interminor](#) to compute intersection cuts from 2x2 (not only principle) minors of a violated rank-one constraint that is implied by the extended formulation for bilinear products (currently disabled by default).
 - * Separator "aggregation" now uses the objective cutoff row as base row and separates lifted cover cuts based on newer lifting function of Letchford and Souli (2019).
 - * Separators "strongcg" and "gomory" now share the same computed basis.
- Primal Heuristics:
- * New construction heuristic [DPS](#) which additionally needs a user-provided decomposition and splits the problem into several sub-SCIPs according to this decomposition. The sub-SCIPs are solved and updated repeatedly until a feasible solution of the original problem is found.
 - * PADM can now reoptimize found solution with original objective function.
 - * The RENS neighborhood in the heuristic ALNS now fixes fractional variables if necessary for reaching its target fixing rate.
 - * Revised and improved heuristic subNLP, in particular choice of NLP iteration limit and starting condition and reuse of subSCIP.
- The handling of algebraic expressions and nonlinear constraints has been rewritten:
- * Support for trigonometric functions sine and cosine and for the entropy function has been added.
 - * Improved recognition of common subexpressions, in particular square and bilinear terms.
 - * All type of nonlinear constraints, including quadratic and second-order-cones, are now handled by the constraint handler for nonlinear constraints. The specialized constraint handlers have been removed. However, methods that work on a particular nonlinear structure are now implemented via [nonlinear handlers](#) (nlhdlr).
 - * Added nonlinear handler for quadratic, bilinear, convex, concave, and quotient expressions, second-order cone constraints, and perspective tightening for expressions in semi-continuous variables.
 - * As before, an extended formulation for nonlinear constraints is constructed. However, this formulation is now handled implicitly and used to construct the LP relaxation only, while the original formulation is used to check feasibility, propagate variable domains, etc. This difference should drastically improved the likelihood that a solution that satisfies the nonlinear constraints in the presolved problem is also feasible for the original problem.
 - * Products in nonlinear constraints are no longer disaggregated for the extended formulation.
 - * Improved analysis on which nonlinear variables in nonlinear constraints can be increased or decreased without harming feasibility by taking monotonicity into account.
 - * Improved linearization of (sums of) products of binary variables, e.g., clique information is now taken into account.
 - * When a variable appears in only one concave less-or-equal constraint, it will be fixed to one of its bounds in more cases now.
 - * New [branching rule for variables in nonlinear constraints](#) that scores candidates based on constraint violation, variable type, and pseudo-costs simultaneously. Variables that are added for the extended formulation of a nonlinear constraint are no longer branched on by default.
 - * New strategies to deal with weak estimators for nonlinear functions and small violations of nonlinear constraints.
 - * Improved under/overestimation of multidimensional vertex-polyhedral (e.g., multilinear or concave) functions by use of scaling and keeping the cut-generating LP around.
 - * Added tables to print statistics of nonlinear constraint handler, nonlinear handlers, and handlers for all supported functions.
- Revised and improved interfaces to Ipopt and CppAD, e.g.:
- * Optimization of taped expressions and sparse Hessian evaluation of CppAD are used now.
 - * Added table to print statistics on NLP solvers.
-

- The interfaces to Gurobi and Mosek are thread-safe now.
 - Parameters removed:
 - * `gams/resolvenlp`
 - * `constraints/abspower/*`, `constraints/bivariate/*`, `constraints/quadratic/*`, `constraints/soc/*`

 - * [table/cons_nonlinear/active](#), [table/cutsel/active](#), [table/exprhdlr/active](#), [table/nlhdlr/active](#), [table/nlhdlr_bilinear/active](#), [table/nlhdlr_quadratic/active](#), [table/nlpi/active](#)
 - * [timing/nlpieval](#)
- Parameters changed:
- * default of [constraints/nonlinear/maxpropounds](#) changed from 1 to 10
 - * default of [display/nexternbranchcands/active](#) changed from 2 to 1 also for nonlinear instances
 - * default of [display/nfrac/active](#) changed from 2 to 1 also if discrete variables are present
 - * default of [heuristics/dualval/priority](#) changed from 0 to -10
 - * default of [heuristics/lpface/priority](#) changed from -1104000 to -1104010
 - * default of [heuristics/mutation/priority](#) changed from -1103000 to -1103010
 - * default of [heuristics/nlpdiving/priority](#) changed from -1003000 to -1003010
 - * default of [heuristics/repair/priority](#) changed from 0 to -20
 - * default of [heuristics/simplerounding/priority](#) from 0 to -30
 - * default of [heuristics/subnlp/forbidfixings](#) from 1 to 0
 - * default of [heuristics/subnlp/itermin](#) changed from 300 to 20
 - * default of [SCIPheuristics_subnlp_priority](#) [heuristics/subnlp/priority](#) changed from -2000000 to -2000010
 - * default of [heuristics/trivialnegation/priority](#) changed from 40000 to 39990
 - * default of [heuristics/trustregion/priority](#) changed from -1102000 to -1102010
 - * default of [heuristics/trysol/priority](#) changed from -3000000 to -3000010
 - * default of [misc/usesymmetry](#) changed from 3 to 7 and range changed from $\{0, \dots, 3\}$ to $\{0, \dots, 7\}$
 - * default of [presolving/qpkktrf/maxrounds](#) changed from -1 to 0
 - * default of [propagating/obbt/onlynonconvexvars](#) changed from 0 to 1
 - * default of [propagating/symmetry/addsymresacks](#) changed from 1 to 0
 - * type of [propagating/symmetry/recomputerestart](#) changed from boolean to int with range $\{0, \dots, 2\}$
 - * default of [separating/strongcg/maxbounddist](#) changed from 1 to 0
 - * default of [separating/strongcg/priority](#) changed from -2000 to -100000
 - * replaced [separating/minortho](#) by [cutselection/hybrid/minortho](#), replaced [separating/minorthoroot](#) by [cutselection/hybrid/minorthoroot](#), replaced [separating/dircutoffdistfac](#) by [cutselection/hybrid/dircutoffdistweight](#), replaced [separating/efficacyfac](#) by [cutselection/hybrid/efficacyweight](#), replaced [separating/intsupportfac](#) by [cutselection/hybrid/intsupport](#), replaced [separating/objparalfac](#) by [cutselection/hybrid/objparalweight](#)
- For more details, see [37] and the [SCIP release notes](#).
- Added support for GAMS functions `sin`, `cos`, and `entropy` for GAMS/SCIP.
 - Since SCIP has dropped support for `min` and `max`, the GAMS/SCIP link reformulates GAMS functions `min` and `max` by use of `abs` now.
 - On Mac OS X, the use of PaPILO ([presolver/milp](#)) is currently disabled by default in SCIP due to software stability issues.
 - Removed the feature that ran Ipopt from a returned solution that is recognized by SCIP to be not feasible in the original (non-presolved) nonlinear problem in order to obtain a feasible solution.
-

3.3.1.4.13 SHOT

- New libraries 1.1 (e225a002).
 - Added parameter [Model.Reformulation.Quadratics.EigenValueDecomposition.Tolerance](#).

3.3.1.4.14 XPRESS

- New libraries 39.01.03.
 - Improved MIP performance:
 - * The Optimizer now uses an ML module to decide whether to use in-tree cutting. See [autoCutting](#).
 - * Improved separation of Mixed Integer Rounding (MIR) cuts.
 - * Improved cut activation and deactivation strategies.
 - * Improved application of strong branching during the tree search.
 - * More information carried through a MIP restart.
 - * The 'R' local search heuristic will now be called more frequently in the early phase of a MIP solve.
 - Improved crossover performance after a Barrier solve through automatic objective perturbation. See [barObjPerturb](#).
 - Improved Barrier performance for large problems on CPUs that support AVX2 (requires setting [cpuPlatform](#) to -2).
 - New options:
 - * [autoCutting](#): Automatically decide whether to generate cutting planes at local nodes in the tree.
 - * [barObjPerturb](#): Defines how the barrier perturbs the objective.
 - * [ioTimeout](#): Maximum number of seconds to wait for an I/O operation before it is cancelled.
 - * [maxStallTime](#): Maximum time in seconds that the Optimizer will continue to search for improving solution after finding a new incumbent.
 - * [preCliqueStrategy](#): Determines how much effort to spend on clique covers in presolve.
 - * [siftPresolveOps](#): Determines the presolve operations for solving the subproblems during the sifting algorithm.
 - Changed option default of [xslp_mipDefaultAlgorithm](#): 1.
- Added option [fixoptfile](#): name of option file which is read just before solving the fixed problem.
- Changed default value of option [mipAddCutoff](#) and [mipRelCutoff](#) to 0.
- Fixed unnecessary solve of fixed MIP (see [mipCleanup](#)) when solving a linear program as MIP.

3.3.1.5 Tools

3.3.1.5.1 BIB2GMS

- As [announced](#), dropped the tool `bib2gms`.

3.3.1.5.2 CSV2GDX

- Check for certain byte order marks (BOMs) in input files. Files with UTF8 BOM can be processed now, other BOMs generate an explicit error.
-

3.3.1.5.3 GAMS Studio

- New version 1.9.2.
 - Added Project Options editor.
 - Added possibility to create an empty project.
 - Adjusted loading from a model library to add files to active project working directory if "Open in existing project" is checked.
 - Stability improvements, bug fixes, and minor enhancements, e.g.:
 - * Expanded MIRO installation location on Mac OS X if AppBundle has been selected.
 - * Adjusted check if the MIRO data contract is available before the MIRO app is deployed.
 - * Changed mouse wheel behavior in tab bars:
 - **Mouse Wheel Up/Down**: moves active tab
 - **Ctrl + Mouse Wheel Up/Down**: changes active tab
 - * Added touch pad support for tab bars.
 - * Changed behavior of search in selection: the search selection is now only set once until the user resets it.
 - * Changed "Clear" button to remove search selection on first click when present.
 - * Fixed non-overridden recurrence of immediate options on command line parameters.
 - * Fixed jump behavior of search when using "This File" and navigating different files.
 - * Fixed Find Next broken for results across multiple files.
 - * Fixed crash on showing "Project Options" for a project without a runnable gms file.

3.3.1.5.4 GDXDIFF

- Reduce size of output GDX file in case of input files without differences.
- Added new option [ignoreOrder](#).

3.3.1.5.5 GDXMRW

- We mark GDXMRW as deprecated and may remove it in a future release. Please use [GAMS Transfer Matlab](#) instead. If you encounter issues with the transition to GAMS Transfer Matlab or if you have any feature requests for GAMS Transfer Matlab, do not hesitate to contact us through support.

3.3.1.5.6 HEXDUMP

- As [announced](#), dropped the tool `hexdump`.

3.3.1.6 APIs

3.3.1.6.1 C++ high-level API

- Removed conversion of mapped network drives to UNC paths.
 - Fixed addition of GAMS system directory to `PATH` on Windows.
-

3.3.1.6.2 GAMS Transfer Matlab

- New read-only `ConstContainer` (high reading performance).
- `Container` now supports to read from a `ConstContainer` in addition to a GDX file.
- New argument types in `Container::listVariables` and `Container::listEquations` to filter by variable or equation type, respectively.
- `Container::listSets` does not include aliases in the returned list anymore. However, it is still possible to include aliases in `Container::describeSets`.
- New argument `records` in `Container::read` to toggle reading records in addition to symbol meta data.

3.3.1.6.3 GAMS Transfer Python

- GAMS Transfer now works with Embedded Python Code.
- New read-only `Container` type called `ConstContainer` (high reading performance).
- New argument types for methods `listVariables()` and `listEquations()` to filter by variable or equation type, respectively.
- The method `listSets()` does not include aliases in the returned list anymore.
- The `Container.read()` argument `values` has been renamed to `records`.
- Fixed bug in `SpecialValues.isNegInf()` that did not properly detect scalar `-inf`.
- Fixed error handling when invalid records are set directly with `.records`.

3.3.1.6.4 GDX

- Internal adjustment to detection of special values when writing to GDX. The updated GDX behavior will allow better differentiation between distinct double-precision values that the user wants mapped to distinct special values. For example, `-0.0` is no longer confused with `+0.0`, and different IEEE NaN values can map to different GAMS special values.

3.3.1.6.5 GMO

- Added routines `gmoGetRowQNZOne64`, `gmoMaxQNZ64`, and `gmoObjQMatNZ64` to get element counts as 64-bit integer.
- Adjust routines `gmoGetRowQNZOne`, `gmoMaxQNZ`, and `gmoObjQMatNZ` to return -1 if the element count is too large for a 32-bit integer.

3.3.1.6.6 High-level APIs

- The `GAMSDatabase` GDX export method now writes *regular* instead of just *relaxed* domain information if available.
-

3.3.1.6.7 PAL

- Added function `palIsAlpha`. `palIsAlfa` has been deprecated.

3.3.1.6.8 Python

- Added support for Python 3.10.
- We plan to drop support for Python 3.6 in a future GAMS release.

3.3.1.7 Model Libraries

3.3.1.7.1 GAMS Test Library New models:

- `dumpopt2.gms` : Test `dumpOpt` with `dumpOptGDX`
- `encoding01.gms` : Test processing of source files with BOM

3.4 37 Distribution

3.4.1 37.1.0 Major release (November 11, 2021)

3.4.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Boyan Atanasov, Edna Johanna Molina Bacca, Abhijit Bora, Wolfgang Britz, Bruno Charlier, Hancheng Dai, Rob Davies, Ricardo M. Pinto de Lima, Bruce McCarl, Scott McDonald, Guillaume Nimal, Gwendal Nivanen, Zack Pecenak, Tom Rutherford, Nick Sahinidis, Shima Sasanpour, and Denys Yemshanov.

3.4.1.2 Platforms

- We will drop support for Mac OS X 10.14 (Mojave) with the next major release.
-

3.4.1.3 GAMS System

3.4.1.3.1 GAMS

- Added new intrinsic function [logit](#).
- Added new [conditional expression](#) `onState` to check the state of certain [dollar control options](#). An example can be seen [here](#).
- Added command line parameter and option [EpsToZero](#) as well as dollar control options [\\$onEpsToZero](#) and [\\$offEpsToZero](#) to allow writing EPS values as zero to GDX.
- Made command line parameters [holdFixedAsync](#), [sys15](#), [sys16](#), [sys17](#), [sys18](#), and [sys19](#) available in [option statements](#) as well.
- Avoid warnings if [\\$abort](#) or [\\$call.checkErrorLevel](#) are used within a [\\$ifThen ... \\$else](#) statement.
- Allow space in [limited domain](#) declaration like this: `Model transport / all, x (ij) /;`
- In the past, GAMS threw an execution error, when [execute.unload](#) failed because of an invalid file name given. Now, it tries to write to a file with a generic file name first (like it was always done with [put files](#) as well).
- Added a new command line parameter and option [maxGenericFiles](#) to specify the number of tries to write to a generic file as mentioned above.
- Extended the influence of [\\$offInclude](#) to suppress the [include file summary](#) and the creation of an [expanded include file](#) as well.
- Added support for (mixed-integer) linear models that generate more than $2^{31} = 2,147,483,648$ nonzeros. At this time, only the solver links for CPLEX, GUROBI, and XPRESS are capable of handling such large model instances. The number of rows and columns is still limited to 2^{31} .
- Removed a limitation for the model attribute [handle](#) that did not allow to set a value which is anything but a [Grid handle](#) (specifically, a [multi threading handle](#) was rejected before).
- Throw an explicit execution error, if a solver that comes without executable gets called with the [Grid Facility](#) (at the moment, this affects [DECIS](#) only).
- Fixed calling a solver with the [Grid Facility](#) that is not located in the GAMS system directory.
- Fixed alignment of [dmpSym](#) and [dmpUserSym](#) output in case of long symbol names.
- Fixed handling of paths with spaces in `gamsconfig.yaml` for items `scriptName` and `executableName` in section `solverConfig`.
- [\\$Call](#), [execute](#), and its variants allow now spaces in the path of the script/program to be called if properly quoted.
- Fixed a zero digit [display](#) bug, where 0 was shown as 0..
- Fixed wrong matrix error detections for discrete variables and right hand side of [external equations](#) in certain cases.
- Fixed that the GAMS execution system corrupted control or status information in the CPUs SSE registers on Linux when using [\\$IfE](#), [\\$IfThenE](#), and related.

3.4.1.3.2 Embedded Python Code Facility

- Print the Python script line number in case an exception is raised.
 - Register alias symbols in `gams.db`.
 - Provide domain information for symbols via `gams.db[sym].domains` and `gams.db[sym].domains_as_strings`.
 - Fix a problem in `pyEmbMI` for double bounded but not fixed variables.
 - The Python version of `GMSPython` has been updated to 3.8.11.
 - Removed package `schema` and its dependency `contextlib2` from `GMSPython`.
-

3.4.1.3.3 Extended Mathematical Programming (EMP)

- Added new stochastic EMP keyword [stageDefault](#) to change the default stage of symbols not assigned to a stage explicitly.
- Changed the `stage` behavior so that it does not count as a terminating error if it is used with a symbol missing in the model.

3.4.1.3.4 Windows Installer

- Associate `.gsp` (GAMS Studio project) files with GAMS Studio.

3.4.1.4 Solvers

3.4.1.4.1 ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2021.2.0 on Windows.

3.4.1.4.2 CONVERT

- Fix default behavior if reading option file fails.

3.4.1.4.3 CPLEX

- Fixed duplicate CPLEX output in GUSS cold starts with GUSS `logoption 2`.
- Fixed unwanted consideration of some GAMS command line options in tuning.
- Fixed possible ignorance of an interrupt signal (Ctrl+C).
- Disabling CPLEX solution pool on default (when [solnpool](#) and [solnpoolmerge](#) are not set).
- Fixed invocation of solution pool export in case of CPLEX termination code 104: solution limit reached.
- Fixed possible crash when using [mipstopexpr](#).

3.4.1.4.4 GUROBI

- New libraries 9.5.0.
 - Added norm constraints to general constraint type, see [genconstrtype](#).
 - New option [memlimit](#): Memory limit.
 - New option [worklimit](#): Work limit.
 - New option [lpwarmstart](#): Warm start usage in simplex.
 - New option [nlpheur](#): Controls the NLP heuristic for non-convex quadratic models.
 - New option [presos1encoding](#): Controls SOS1 reformulation.
 - New option [presos2encoding](#): Controls SOS2 reformulation.
 - New option [tunemetric](#): Metric to aggregate results into a single measure.
 - New option [tunetargetmipgap](#): A target gap to be reached.
 - New option [tunetargettime](#): A target runtime in seconds to be reached.
 - New option [liftprojectcuts](#): Lift-and-project cut generation.
 - Changed default option value of [TuneTrials](#): 0 (auto).
 - Changed default option value of [CrossoverBasis](#): -1 (auto). The option type changed from boolean to integer.
-

3.4.1.4.5 GUSS

- Fixed detection of update requests with symbols that are not present in the generated model.
- Fixed incorrect behavior of option `SolveEmpty` (not only empty but all scenarios were skipped after threshold reached).

3.4.1.4.6 KNITRO

- Added support for MCP model type.

3.4.1.4.7 Lindo/LindoGlobal

- New libraries 13.0.309.
- Added support for function `logit`.

3.4.1.4.8 LocalSolver

- New libraries 10.5 (20211014).

3.4.1.4.9 Mosek

- New libraries 9.3.7.

3.4.1.4.10 Ochteract

- Added new global MINLP solver `Ochteract` 3.5.0 (<https://ochteract.com/>).
- Ochteract can be used for model types QCP, RMIQCP, MIQCP, NLP, DNLP, RMINLP, and MINLP and is available for Linux and Windows systems.
- For GAMS [demo and community licenses](#), [model size limitations](#) similar to other global solvers apply. For an unlimited GAMS/Ochteract license, contact sales@gams.com.

3.4.1.4.11 SCIP

- New libraries 7.0 (b2afa5403b).

3.4.1.4.12 SHOT

- New libraries 1.1.0 (11fda1ec).
 - New option `Model.Reformulation.Quadratics.EigenValueDecomposition.Formulation`.
 - New option `Model.Reformulation.Quadratics.EigenValueDecomposition.Method`.
 - Renamed option `Model.Reformulation.Quadratics.UseEigenValueDecomposition` to `Model.Reformulation.Quadratics.EigenValueDecomposition.Use`.
 - Default value for option `Subsolver.Gurobi.NumericFocus` changed from 2 to 1.
-

3.4.1.4.13 SOPLEX

- New libraries 5.0 (ad7592b9).

3.4.1.4.14 XPRESS

- New libraries 38.01.05.

3.4.1.5 Tools

3.4.1.5.1 BIB2GMS

- We will remove the tool `bib2gms` in a future GAMS release.

3.4.1.5.2 FINDTHISGAMS

- Support for registry keys for `.gsp` (GAMS Studio project) file association has been added.

3.4.1.5.3 GAMS Studio

- New version 1.8.2.
 - New feature: Added tooltips to source code for [keywords](#) and [Dollar Control Options](#) (can be deactivated in the settings dialog).
 - Rework of the [Project Explorer](#):
 - * Changed naming from "group" to "project".
 - * Files now appear in folders relative to the working directory of the assigned project.
 - * Added import and export of projects.
 - * The projects context menu "Project options" allows to change the name and working directory of the project.
 - * Added individual working directories for each project.
 - * Added dialog to set the base directory on project import.
 - Highlight remotely executed log (NEOS or GAMS Engine).
 - Removed obsolete MIRO Hypercube mode.
 - Replace TAB characters by the proper amount of spaces when pasting text.
 - Set default TAB size to 8.
 - Allow to use GAMS Engine on a HTTP server when the local SSL is not present.
 - Skipped log duplicate in the NEOS log.
 - Added new search scope **Selection** which allows users to search inside a text selection.
 - Added zoom for `lxi` tree view when zooming in `lst` files.
 - Stability improvements and minor bug fixes, e.g.:
 - * Fixed NEOS and GAMS Engine being inactive due to an SSL detection issue.
 - * Fixed links to model in NEOS log.
 - * Fixed crash when editing long lines ending in an error mark.
 - * Fixed highlighting of wrong results in Search Result View.
 - * Fixed broken syntax highlighting of `execute_*`.
 - * Fixed completer not opening or staying open unwanted.
-

3.4.1.5.4 GDX2HAR/HAR2GDX

- We will remove the tools [gdx2har](#) and [har2gdx](#) in a future GAMS release. The tools can be accessed from the [CoPS web site](#).

3.4.1.5.5 HEXDUMP

- We will remove the tool `hexdump` in a future GAMS release. A similar functionality is available on Unix systems via the `od` utility with parameters `od -A x -t x1z -v`. On Windows `od` is distributed as part of the [POSIX](#) utilities.

3.4.1.5.6 SCENRED

- We will remove the tool [SCENRED](#) in a future GAMS release. The tool [SCENRED2](#) should be used instead.

3.4.1.6 APIs

3.4.1.6.1 C++ high-level API

- Fixed `GAMSOption::setOutput` parameter being ignored in `GAMSJob::run()`.

3.4.1.6.2 gams2numpy

- The binaries are now build with `numpy 1.20.3` instead of `numpy 1.19.5` for Python 3.7, 3.8, and 3.9.

3.4.1.6.3 GAMS Transfer

- New APIs [GAMS Transfer for Matlab](#) and [GAMS Transfer for Python](#) to exchange data between GAMS and Matlab and Python, respectively.

3.4.1.6.4 GMD

- Allow to add symbols via `gmdAddSymbol` and `gmdAddSymbolX` of type alias (`GMS_DT_ALIAS`).
 - Added function `gmdFindSymbolWithAlias` that provides the actual alias symbol rather than the aliased set in case the requested symbol is an alias.
 - Added function `gmdGetSymbolByNumber` that provides the symbol based on the `GMD_NUMBER` which includes the alias symbols.
 - Added information key `GMD_NRSYMBOLSWITHALIAS` for function `gmdInfo` to retrieve the number of symbols including alias symbols.
-

3.4.1.6.5 GMO

- Adjusted routine `gmoGetMatrixCol` to fail if called where quadratic structure is explicitly detected/handled (i.e. `useQ` is set). This routine was not intended to be used in this case.
- Added routines `gmoNZ64`, `gmoNLNZ64`, and `gmoLNZ64` to get non-zero counts as 64-bit integer.
- Fixed routine `gmoDirtySetRowFNLInstr`: it was not computing the number of stored NL instructions correctly.

3.4.1.6.6 PAL

- Added routines `palLicenseSolverCheckSizes64` and `palLicenseCheck64` for solvers that use 64-bit integers for non-zero counts.

3.4.1.6.7 Python high-level API

- Fixed a problem with property `domains` of a symbol in case the domain list consists of a `GamsSet` and string elements.

3.4.1.7 Model Libraries

3.4.1.7.1 GAMS Model Library

- MS Access and Excel files have been updated to the MS Office 2007 format, i.e., files with the `xls` extension were changed to `xlsx` or `xlsm` files, files with the `mdb` extension were changed to `accdb` files.
- The structured bibliographic information has been removed. As a consequence, the *Author* column in the table of models (documentation and Studio/IDE) has been removed as well as the *Reference* section for the individual model page (web). The bibliographic references remain part of the model source.

New Models:

- `rcpsp.gms` : **Resource-Constrained Project Scheduling Problem** (429)

3.4.1.7.2 GAMS Test Library New models:

- `asynfix02.gms` : Test asynchronous solves with `holdFixedAsync` setting
 - `genfile01.gms` : Test generic file names
 - `offinc01.gms` : Test dollar control option `$offInclude`
 - `embpy11.gms` : Test proper domain info in Embedded Code
 - `dco01.gms` : Test default state and switching state for dollar control options
 - `epstozero1.gms` : Test writing eps as zero to GDX
 - `fnlogit.gms` : Test correctness of logit intrinsic
 - `empsp01.gms` : Test EMPSP keyword `stageDefault`
 - `gurobi06.gms` : GUROBI test suite - general constraints norm
-

3.5 36 Distribution

3.5.1 36.1.0 Major release (August 02, 2021)

3.5.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Ricardo Manuel Pinto de Lima, Bruce McCarl, Scott McDonald, and Kirk A. Yost.

3.5.1.2 GAMS System

- The End User License Agreement ([eula.pdf](#) in the GAMS system directory) has been updated to version 08/2021.

3.5.1.2.1 GAMS

- Improved performance of model generation for certain equations where the index order of the equations caused an out of order index reference of variables like in this example:

```
ejk(j,k).. sum(i, x(i,j,k)) =e= 42;
```

Added new command line parameter [sys19](#) to deactivate this performance optimization.

- Added new function [platformCode](#) and new [compile time constants](#) to be used with it.
- Added information about available CPU sockets, cores, and threads to the log.
- Improve error message for invalid values of the [.scale](#) attribute.
- Allow to read [environment variables](#) and [command line parameters](#) at execution time in put context.
- Added [Put_Utility](#) commands [setEnv](#) and [dropEnv](#) to allow environment variable modification at execution time.
- Added Python function [gams.get_env](#) to [EmbeddedCode Python](#) to access modified environment variables after Python module [os](#) has been initialized.
- Fixed a problem causing an unexpected error when beginning execution time [embedded code](#) as first statement after starting from a [restart file](#).
- Fixed a potential warning using execution time [embedded code](#) after starting from a [restart file](#) which was created with [action=c](#).

3.5.1.2.2 Windows Installer

- Windows installer is now built with Inno Setup 6.
 - Command line parameter [/allUsers=yes|no](#) has been deprecated and will be removed in a future GAMS release. Use the new parameter [/installAllUsers=yes|no](#) instead.
 - New command line flags [/allUsers](#) and [/currentUser](#) can be used to explicitly control if the installation is performed in administrative or non-administrative installation mode.
-

3.5.1.2.3 GMSPython

- The Python version has been updated to 3.8.10.

3.5.1.3 Solvers

3.5.1.3.1 Bonmin

- We plan to drop Bonmin and BonminH with one of the next major releases.

3.5.1.3.2 CONVERT

- Added support for quadratic constraints in formats [CplexLP](#), [CplexMPS](#), and [FixedMPS](#).
- Added option [SkipNRows](#).
- Added option [QExtractAlg](#).
- Fixed writing `eps` for zero marginals of non-basic variables or equations in format [Gams](#).

3.5.1.3.3 CPLEX

- Added the following options:
 - [multobjoptfiles](#): List of option files used for individual solves within multi-objective optimization.
 - [usercut](#): User cut activation.
 - [usercutpool](#): Indicator to use user cuts.
 - [qextractalg](#): quadratic extraction algorithm in GAMS interface.
- Fixed handling of special values (incl. missing zero values) in [multimipstart](#).
- Fixed update of Jacobian elements within GUSS scenarios.
- Fixed setting [gubcovers](#) via [cuts](#).

3.5.1.3.4 GUROBI

- Added option [qextractalg](#): quadratic extraction algorithm in GAMS interface.

3.5.1.3.5 GUSS

- Added support of option [savepoint](#) for scenario solves.
-

3.5.1.3.6 Ipopt and IpoptH

- New libraries 3.14.1.

Attention

- Value `pardiso` of option `linear_solver` to choose Pardiso from Intel MKL has been **renamed to `pardisomkl`**. Renamed `pardiso_*` options to `pardisomkl_*`.
 - Added value `pardiso` for option `linear_solver` to choose to use Pardiso from the **Pardiso Solver Project**. This solver is **not included in the GAMS distribution**. A user needs to provide a Pardiso library. Added option `pardisolib` to specify name and path of Pardiso library. Added `pardiso_*` options.
 - Added option `hslib` to specify name and path of HSL library to be loaded at runtime (for users of GAMS/Ipopt or users that want to use HSL_MA77).
 - Changed default of `honor_original_bounds` to `no`. In addition, Ipopt now ensures that, in addition to option `bound_relax_factor`, variable bounds are relaxed by at most `constr_viol_tol`. The Ipopt log now shows the violation of variable bounds in the solution.
 - Fixed that marginals for fixed variables were not computed if `fixed_variable_treatment` is set to `make_parameter` (the default). Added value `make_parameter_nodual` for this option to disable calculation of marginals for fixed variables (which can cost an extra evaluation of the Jacobian).
 - Added options `max_wall_time`, `print_options_mode`, `print_advanced_options`, and `timing_statistics`.
 - Ipopt should now be threadsafe also when used with MUMPS as linear solver (a mutex ensures that only one thread executes MUMPS at a time).
 - For more information, including bugfixes, see the **Ipopt 3.14.0 release notes**.
- Changed default of `constr_viol_tol` to 1e-6.
 - **GAMS ResLim** now sets the default for Ipopt option `max_wall_time` instead of `max_cpu_time`.
 - If **GAMS ScaleOpt** is set, i.e., the model has been scaled manually, then the default of option `nlp_scaling_method` is set to `none`.
 - The interface has been extended to warmstart Ipopt if a modified model instance is solved, e.g., in the context of GUSS. For the warmstart, previously initialized Ipopt data structures are reused if possible and option `warm_start_init_point` is enabled, see also **Warmstarting IPOPT**.
 - Enabled `solvelink=6` capability for Ipopt and IpoptH.
 - Update of HSL routines (IpoptH only):
 - MA57 3.11.0.
 - HSL_MC68 3.3.1.
 - HSL_MA86 1.6.0.
 - HSL_MA97 2.6.0.
 - Update of MUMPS to version 5.4.0.
 - Changed default of `mumps_pivot_order` from 5 to 7.

3.5.1.3.7 JAMS

- Updated behavior and logging for models with `equ.var` matches in the model statement. If the trivial (aka empty or default) model transformation is specified in the EMP info file, nothing changes: the matches are used as before. In contrast, if a nontrivial or nonempty transformation is specified, the matches are ignored when creating the reformulated model and a message to this effect is sent to the log.

3.5.1.3.8 KNITRO

- New libraries 12.4.
 - Improved performance on mixed-integer nonlinear problems (MINLP).
 - Improved performance when using the limited-memory quasi-Newton Hessian approximation.
 - Added option [linsolver_maxitref](#): Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro.
 - Added option [bfgs_scaling](#): Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation.
 - Added option [bar_linsys_storage](#): Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps.
 - Added option [mip_cutting_plane](#): Specifies when to apply the cutting plane procedure.
 - Added option [mip_heuristic_diving](#): Specifies whether or not to enable the MIP diving heuristic.
 - Added option [mip_heuristic_feaspump](#): Specifies whether or not to enable the MIP feasibility pump heuristic.
 - Added option [mip_heuristic_mpec](#): Specifies whether or not to enable the MIP MPEC heuristic.
 - Added option [mip_heuristic_strategy](#): Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point.
 - Deprecated option [mip_heuristic](#): Use [mip_heuristic_strategy](#) instead.
- Added option [qextractalg](#): quadratic extraction algorithm in GAMS interface.

3.5.1.3.9 Lindo/LindoGlobal

- New libraries 13.0.291.

3.5.1.3.10 LocalSolver

- New libraries 10.5 (20210624).

3.5.1.3.11 MOSEK

- Added option [QEXTRACTALG](#).
- New libraries 9.2.47.

3.5.1.3.12 ODHCPLEX

- New libraries 6.0.4.

3.5.1.3.13 PATH

- New libraries 5.0.04 (maintenance release) include capability to further limit preprocessor output by specifying [output_preprocess_level](#) -1.
-

3.5.1.3.14 SCIP

- New libraries 7.0 (d012dac064).
- Updated Ipopt to Ipopt 3.14.1, see also [above](#).

3.5.1.3.15 SHOT

- New libraries 1.1 (c898dd84).
 - SHOT can now call itself to solve fixed NLP problems. Activated with new value 2 for option [Primal.FixedInteger.Solver](#). For nonconvex problems it is still recommended to use an external NLP solver.
Added also options [Subsolver.SHOT.ReuseHyperplanes.Fraction](#), [Subsolver.SHOT.ReuseHyperplanes.Use](#), [Subsolver.SHOT.UseFBBT](#).
 - Partition convex nonseparable quadratic functions as separate constraints using an eigenvalue decomposition-based reformulation. Activated with new option [Model.Reformulation.Quadratics.UseEigenV](#).
 - Support for performing an initial polyhedral approximation of the nonlinear feasible set before feasibility-based bound tightening. Activated with new option [Model.BoundTightening.InitialPOA.Use](#).
Added also options [Model.BoundTightening.InitialPOA.CutStrategy](#), [Model.BoundTightening.InitialPOA.Itera](#), [Model.BoundTightening.InitialPOA.StagnationIterationLimit](#), [Model.BoundTightening.InitialPOA.Constraint](#), [Model.BoundTightening.InitialPOA.ObjectiveConstraintTolerance](#), [Model.BoundTightening.InitialPOA.Objective](#), [Model.BoundTightening.InitialPOA.ObjectiveGapRelative](#), [Model.BoundTightening.InitialPOA.StagnationCo](#), [Model.BoundTightening.InitialPOA.TimeLimit](#).
 - Added support for semi-continuous and semi-integer variables.
 - Added support for special ordered sets.
 - Improved support for generating supporting hyperplanes for the entire nonlinear feasible set instead of the feasible sets for the individual constraint functions. Activated with new option [Dual.ESH.Rootsearch.UseMaxFunction](#).
 - Improved support for passing nonconvex quadratic functions directly to the MIP solver (if supported).
 - Added option [ModelingSystem.GAMS.QExtractAlg](#).
 - Added option [Output.GAMS.AlternateSolutionsFile](#).
 - Added option [Dual.HyperplaneCuts.SaveHyperplanePoints](#).
 - Added option [Dual.MIP.InfeasibilityRepair.Use](#).
 - Added option [Dual.ReductionCut.Use](#).
 - Changed default of option [Subsolver.Cbc.Scaling](#) from 0 to 4.
 - Changed default of option [Subsolver.Cplex.NumericalEmphasis](#) from 0 to 1.
 - Changed default of option [Subsolver.Gurobi.PoolSolution](#) from 1 to 10.
 - Changed default of option [Model.BoundTightening.FeasibilityBased.TimeLimit](#) from 5 to 2.
 - Changed default of option [Termination.DualStagnation.IterationLimit](#) from 50 to ∞ .
 - Changed meaning of values 1 and 2 for option [Model.Reformulation.Bilinear.IntegerFormulation](#).
 - Updated Ipopt to Ipopt 3.14.1, see also [above](#).
-

3.5.1.3.16 XPRESS

- New libraries 38.01.03.
 - Xpress Optimizer Release Notes:
 - * Improved MIP performance.
 - * It is now possible to activate a special heuristic solve mode for MIPs, which emphasizes finding new solutions.
 - * Improved sifting algorithm when used with Barrier.
 - * Improved numerical stability of the Barrier algorithm.
 - Xpress Nonlinear Release Notes:
 - * Significant MINLP performance improvements due to improved nonlinear presolver.
 - * Improved performance on instances with very large separable nonlinear expressions due to improved automatic differentiation.
 - * Multistart now uses the nonlinear primal integral for tie breaking.
 - Added options:
 - * `barPerturb`: In numerically challenging cases it is often advantageous to apply perturbations on the KKT system to improve its numerical properties.
 - * `barRefIter`: After terminating the barrier algorithm, further refinement steps can be performed.
 - * `clamping`: Allows for the adjustment of returned solution values such that they are always within bounds.
 - * `clamping_dual`: Adjust primal slack values to always be within constraint bounds.
 - * `clamping_primal`: Adjust primal solution to always be within primal bounds.
 - * `clamping_rdj`: Adjust reduced costs to always be within dual bounds implied by the primal solution.
 - * `clamping_slacks`: Adjust dual solution to always be within the dual bounds implied by the slacks.
 - * `genConsAbsTransformation`: Specifies the reformulation method for absolute value general constraints at the beginning of the search.
 - * `heurEmphasis`: Specifies an emphasis for the search w.r.t. primal heuristics and other procedures that affect the speed of convergence of the primal-dual gap.
 - * `inputTol`: Tolerance on input values elements.
 - * `mipComponents`: Determines whether disconnected components in a MIP should be solved as separate MIPs.
 - * `mipConcurrentNodes`: Sets the node limit for when a winning solve is selected when concurrent MIP solves are enabled.
 - * `mipConcurrentSolves`: Selects the number of concurrent solves to start for a MIP.
 - * `mipRestartFactor`: Fine tune initial conditions to trigger an in-tree restart.
 - * `mipRestartGapThreshold`: Initial gap threshold to delay in-tree restart.
 - * `netStallLimit`: Limit the number of degenerate pivots of the network simplex algorithm, before switching to either primal or dual simplex.
 - * `nodeProbingEffort`: Adjusts the overall level of node probing.
 - * `outputControls`: Toggles the printing of all control settings at the beginning of the search.
 - * `ppFactor`: Partial pricing candidate list sizing parameter.
 - * `preFolding`: Determines if a folding procedure should be used to aggregate continuous columns in an equitable partition.
 - * `siftPasses`: Determines how quickly we allow to grow the worker problems during the sifting algorithm.
 - * `siftSwitch`: Determines which algorithm to use for solving the subproblems during sifting.
 - * `xslp_presolveOps_noLinear`: Avoid performing linear reductions at the NLP level.
 - * `xslp_presolveOps_noSimplifier`: Avoid simplifying nonlinear expressions.
-

- Added option values:
 - * `deterministic`: 2.
 - * `mipRestart`: 2.
- Changed option defaults:
 - * `mipPresolve`: -257 to -1.
 - * `mipPresolve_symmetryReductions`: 0 to 1.
- Deprecated options:
 - * `heurStrategy`. Use `heurEmphasis` instead.
 - * `xslp_matrixTol`. Use `matrixTol` instead.
- Removed options:
 - * `treePresolve_keepBasis`.
 - * `treePresolve`.
 - * `treePresolveOps`.
 - * `xslp_analyze_autosavePool`.
 - * `xslp_analyze_recordLinearization`.
 - * `xslp_analyze_recordLinesearch`.
 - * `xslp_presolvePassLimit`.
 - * `xslp_timePrint`.
- Added option `algAfterNetwork`: Algorithm to be used for the clean up step after the network simplex solver.
- Added option `qextractalg`: quadratic extraction algorithm in GAMS interface.
- Removed options that were marked deprecated in GAMS 35.

3.5.1.4 Tools

3.5.1.4.1 Cholesky, Eigenvalue, Eigenvector, Invert

- We will remove the tools `cholesky`, `eigenvalue`, `eigenvector`, `invert` in a future GAMS release. Similar functionality has been added via `$libInclude linalg {cholesky,eigenvalue,eigenvector,invert}`. See the header of the file in `<sysdir>\inclib\linalg.gms` for details.

3.5.1.4.2 GAMS Studio

- New version 1.7.2.
 - Dropped support for Ubuntu 16.04 LTS and openSUSE Leap 15.2 because the updated AppImage now requires glibc 2.27. Dropped support for Debian 9.
 - New feature: Allow specifying location of User Model Libraries in Settings dialog.
 - Improved visual distinction between current and other groups in Project Explorer.
 - Added a warning message before printing large files.
 - Added a list of solvers for each model type to be selected in Extended Parameter Editor and Configuration Editor.
 - Added shortcut `Alt+I` (Mac OS X: `Option+I`) to fold blocks of dollar control options.
 - Added setting to automatically collapse dollar control option blocks when opening a file (default: off).
 - Changed shortcuts to show/hide Extended Parameter Editor
 - * Windows/Linux: From `Ctrl-Alt-3` to `Shift+Ctrl+3`.

- * Mac OS X: From `Shift-Command-3` to `Control-Option-3`.
- Improvements for syntax highlighter and code completer, e.g.:
 - * Added support for system attributes and compile-time constants.
 - * Added support of quoted elements in syntax highlighter.
 - * Disabled code completer for certain code blocks like `$onEmbeddedCode` or `$onPut`.
- Improvements for remote execution support, e.g.:
 - * Added support for GAMS Engine server with self-signed certificate (`https`).
 - * Added support for GAMS Engine server with `http` protocol.
 - * Added option to remember login credentials for GAMS Engine in Settings.
 - * Renamed "MIRO" Settings page to "Remote" to better reflect new content.
 - * Improved GAMS Engine dialog.
 - * Added file type `EFI` to send additional files to a GAMS Engine server.
- Stability improvements and minor bug fixes, e.g.:
 - * Fixed duplicate file entries in the Project Explorer when having two references with different case to a single file
 - * Fixed Studio title bar appearing outside of screen in some cases.
 - * Fixed wrong content of "File" tab in Reference File Viewer.
 - * Fixed missing check of some data locations for GAMS license file.
 - * Fixed `ESC` key not behaving like close button in Settings dialog.
 - * Fixed crash when reopening a closed log tab.
 - * Fixed that MIRO menu entries were not enabled when MIRO was automatically discovered.
 - * Fixed that theme could be broken in Settings dialog when using cancel button.

3.5.1.4.3 GDXRank, GDXRename

- We will remove the tools `gdxrank` and `gdxrename` in a future GAMS release. Similar functionality has been added via `$libInclude gdxservice {gdxrank,gdxservice}`. See the header of the file in `<sysdir>\includ\gdxservice.gms` for details.
- The `$libInclude rank` functionality now uses `$libInclude gdxservice gdxrank` to sort a one dimensional parameter instead of the `gdxrank` tool.

3.5.1.4.4 MCFilter

- We will remove the tool `mcfilter` in a future GAMS release. In case you depend on this tool, [this discussion at GAMS World Forum](#) gives an alternative.

3.5.1.4.5 MSAppAvail, Shellexecute, XLSTalk

- We will remove the tools `msappavail`, `shellexecute`, `xlstalk` in a future GAMS release. Similar functionality has been added via `$libInclude win32 {msappavail,shellexecute,xlstalk}`. See the header of the file in `<sysdir>\includ\win32.gms` for details.

3.5.1.5 APIs

- As [announced](#) we removed all Delphi variants but the `dcp` version (i.e. `gdxdcpdef.pas`) and all Fortran variants but the `f9` version (i.e. `gdxmf9def.f90`) of the low-level APIs.
-

3.5.1.5.1 CFG

- The function `cfgAlgAllowsModifyProblem` now reports correctly for all solvers if they provide the `xyzModifyProblem` functionality instead of a only for a fixed (and incorrect) list of solvers.

3.5.1.5.2 C++ high-level API

- Removed dependency on Qt. Now requiring C++17.
- Added support for Microsoft Visual Studio 2019.
- As [announced](#) we dropped support for Microsoft Visual Studio 2015.
- As [announced](#), the Clang compiled version of `libgamscpp.dylib` does not work on Mac OS X 10.14 or older anymore. It has been moved to the subfolder `apifiles/C++/lib/Clang/`. The new `libgamscpp.dylib` in `apifiles/C++/lib/` is compiled with GCC.

3.5.1.5.3 gams_engine

- Updated for GAMS Engine version 21.06.09 and now using OpenAPI Generator version 5.1.1.

3.5.1.5.4 gams2numpy

- New optional parameter `merge` in `gams2numpy.gmdFillSymbolStr` that allows duplicate records in the numpy array as well as writing to non-empty symbols.
- New optional parameter `relaxedType` in `gams2numpy.gmdFillSymbol(Str|Raw)`, and `gams2numpy.gdxWriteSymbol` that allows to automatically convert the columns of the numpy array into the required data types if possible.
- Fixed a bug that prevented error messages from being shown on Linux and further improved error handling.

3.5.1.5.5 GAMSX

- As [announced](#), we have dropped the GAMSX API with this release. The example `xp_example2` for various languages has been adjusted to call the GAMS executable instead of the `gamsxRunExecDLL` GAMS API function.

3.5.1.5.6 GEV

- The `gmoPtr` argument in function `gevGetCurrentSolver` is deprecated and not used anymore. It will be removed from this function in some future release. Moreover, the function should only be used in [solver link library](#) functions `xyzReadyAPI` or `xyzCallSolver`.
 - Add GEV option `SavePoint` to query the `savePoint` option.
-

3.5.1.5.7 GMO

- Added option `qExtractAlg` to control the technique used to extract quadratic structure from GAMS models. This structure extraction happens automatically for any QCP model type (e.g. QCP, MIQCP) and the current default choice `ThreePass` (= 1) is almost always the best one. But there are some cases where `DoubleForward` (= 2) performs much better.

3.5.1.5.8 Solverlink library interface

- The API of a [solver link library](#) has changed. This will only affect users that install additional solvers or build and maintain their own solver link libraries. The older version of the API is deprecated and will be removed in a future GAMS release. Moreover, COIN-OR project [GAMSlinks](#) provides a template to work with both new and old APIs.

3.5.1.6 Model Libraries

3.5.1.6.1 GAMS API Library

- Updated models `CPPex2`, `CSEX2`, `Cex2`, `Fex2`, `Jex1`, `Jex2`, `PBuildXPLevelAPI`, and `VBex2` to adjust for the removal of the GAMSX API.
- Updated model `Pgams_engine` to be compatible with the latest `gams_engine` API.

3.5.1.6.2 GAMS Data Library

- Many models have been adjusted to use the library include `win32` to compensate for the future drop of the utilities `msappavail` and `shellexecute`.
- Updated models `CHP`, `CHP2`, `Portfolio`, `Samurai`, `SpawnGAMSExcel`, `Sudoku`, and `transxls`. The corresponding Excel files have been changed from format `.xls` to `.xlsm`. Moreover, the VBA code has been adjusted to work without the dropped GAMSX API. The registry key to find the GAMS system directory has been updated.
- Model `Samurai2` has been dropped since it became a duplicate of model `Samurai` after the removal of the GAMSX API.
- Model `LeastSquares` has been updated to use `$libInclude linalg OLS` for solving the linear regression problem. The model also works now with more descriptive data set (diabetes data).

3.5.1.6.3 GAMS Test Library New models:

- `platform01.gms` : Test platform function
 - `qcp12.gms` : Test different GMO Q extraction algorithms
 - `asynfix01.gms` : Test asynchronous solves with `holdFixed`
 - `savep2.gms` : Test savepoint with async solves
 - `convert16.gms` : CONVERT test suite - Basic test of convert output for quadratic model
 - `embpy09.gms` : Test Embedded Code after restart
-

- scensol8.gms : Check if solver with modify problem use hotstart in GUSS
- gdxrename1.gms : Simple gdxrename test
- gdxrename2.gms : Tests some gdxrename stuff
- scensol9.gms : Test option savepoint in GUSS
- embpy10.gms : Test Embedded Code for Environment Variables
- etsuf01.gms : Test Execution Time Suffixes
- emp33.gms : JAMS: matches from model statement may be ignored

Models trilib01, trilib02, trilib03, parlib01, cpplib00:

- Removed jinja2 from associated source archive. It is now required to have the Python package jinja2 installed to run the ql.py script.

3.5.2 36.2.0 Minor release (September 03, 2021)

3.5.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Daniel Dias, Andreas Lundell, Bruce McCarl, and Tom Rutherford.

3.5.2.2 GAMS System

3.5.2.2.1 GAMS

- Added new command line parameter `holdFixedAsync` to allow the use of `holdFixed` for models solved `asynchronously`. Activating this option can lead to inconsistent solutions being reported.
- Fixed a potential crash introduced with GAMS 36.1.0 related to the `improved performance of model generation`.

3.5.2.3 Solvers

3.5.2.3.1 CONVERT

- Fixed MCP mapping for `DumpGDX`.

3.5.2.3.2 GAMSCHK

- Fix default solve behavior: if no GCK file is specified, no subsolver should be called as no solution is wanted.

3.5.2.3.3 GUSS

- Fixed options `OptfileInit` and `Optfile` being ignored.
- Added fallback to cold start in case of hot start failure.

3.5.2.3.4 IPOPT

- New libraries 3.14.3.
- Updated MUMPS to version 5.4.1.

3.5.2.3.5 MOSEK

- New libraries 9.3.4.
-

3.5.2.3.6 SHOT

- New libraries 1.1 (9a8893e7).

3.5.2.4 Tools

3.5.2.4.1 GAMS Studio

- New version 1.7.3 with various bug fixes, stability improvements, and minor enhancements, e.g.:
 - Allow to duplicate multiple lines at once.
 - Added navigation and selection by word using `ctrl+left/right` in LOG-Viewer.
 - Fixed highlighting issue when a symbol declaration ends with a space.
 - Fixed horizontal scroll in LST viewer when cursor is out of view.
 - Fixed that searching backwards in modified document was not working.
 - Fixed "Replace" ignoring case sensitivity option.

3.6 35 Distribution

3.6.1 35.1.0 Major release (April 29, 2021)

3.6.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Matthew Adams, Jürgen Apfelbeck, Wolfgang Britz, Yacine Gaoua, Carolin Kellenbrink, Masoud Javadi, Bruce McCarl, Scott McDonald, Will Raymond, Tom Rutherford, Sebastian Spieker, and Kirk A. Yost.

3.6.1.2 Platforms

- macOS 11 (on Intel CPUs) has been added to the list of supported Mac OS X versions.

3.6.1.3 GAMS System

3.6.1.3.1 GAMS

- Added new dollar control options `gdxLoad` and `gdxUnload` to load and unload symbols from and to GDY files in a single instruction at compile time.
 - Print an extra log line for echo dollar control options `$echo`, `$echoN`, and `$onEcho`, which write to an external file. When running GAMS from one of the [GAMS IDEs](#), this log line can be clicked to open the file created.
 - Extended the report generated by `dmpSym` and `dmpUserSym` to include another column reporting a memory estimate for each set, parameter, variable, and equation.
-

- Removed the columns DIM-OK, ACCESS, SPECVAL, EXTERN, TABLE, DOMAIN, and LAGLEAD from the report generated by `dmpUserSym`. This information is very technical and mostly of internal interest. These columns are still available with `dmpSym`.
- The status of [Multi-Threading](#) for [the Grid and Multi-Threading Solve Facility](#) has been changed from beta to released and fully supported.
- Fixed that the `stars` option was ignored for some messages in the output file.
- Fixed a problem that causes default records in the data statement or when loaded from GDX (see `$load`) being ignored with `implicit set definition`. So with

```
Set i;
Parameter p(i<) / i0 0, i1 1, i2 2 /;
```

only `i1` and `i2` made it into `i`. Now, `i0` is added as well.

- Fixed a problem, where `$onDotL` and `$onDotScale` were ignored in `put` statements.
- Fixed a problem, where `$onDelim` was applied incorrectly to `display` and `option` statements.
- Fixed a problem, where `$onSymXRef` and `$onUEIXRef` were ignored when there were too many references.
- Fixed and extended the behavior of `$eval`: If a GAMS function was hidden by a user defined symbol, `$eval` ignored the latter. This has been changed. Now, the GAMS function needs to be prefixed with `system.` to be accessed in this case. An example for this behavior is given [here](#).
- Fixed a potential problem when doing a filtered load of symbols with domain violations through `EmbeddedCode`.
- Fixed an unwanted compilation error that happened if `$onExternalInput` or `$onExternalOutput` were used on the same line and after `$if`.
- Fixed a problem where `dumpOpt` in combination with `$onVerbatim` skipped a leading substitution character in an `$ifThen` block.

3.6.1.4 Solvers

3.6.1.4.1 AlphaECP

- New version 2.11.01.
 - New options:
 - * `ECPtoltype`: AlphaECP termination criterion.
 - * `MIPoptcrlimtype`: Strategy to increase `MIPoptcrlim`.
 - * `MIPoptimaliter`: MIP is solved to optimality with this frequency.
 - * `TOLoptcr`: Relative termination tolerance for MINLP.
 - Minor bugfixes.
 - For more information, see the [release paper](#).

3.6.1.4.2 ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2021.2.0 on Linux and Mac OS X.

3.6.1.4.3 BARON

- The NLP solver selected with option `extNLPsSolver` is used in case `NLPSol` is set to -1 or 6 (and `AllowExternal` is 1). In the previous releases `Conopt` was used with `NLPSol` value -1.

3.6.1.4.4 BONMIN

- Fixed an issue where a problem with SOS constraints was rejected due to falsely detected negative variable bounds.

3.6.1.4.5 CONOPT

- New libraries for CONOPT3: 3.17K
 - Fixed perturbations of the Jacobian for external equations where 2nd order derivatives are not available.
- Fixed an issue resulting in insufficient CONOPT3 memory.
- Fixed an issue with multi-threading in CONOPT 4.

3.6.1.4.6 CPLEX

- New libraries 20.1.0.1.
- Added option `usercallparmfile`: Command-line parameter include file used in GAMS command-line calls triggered by BCH.
- Fixed incorrect reporting of infeasible solutions of the unrelaxed model in `feasopt` mode.
- Fixed incorrect variable matching for options `objnreltol` and `objnabstol`.
- Fixed parsing of individual objective functions for multiobjective optimization (any ordering of equation definitions is allowed now).

3.6.1.4.7 GAMSCHK

- Fix problem with handling of row/column patterns introduced in GAMS 34.3.

3.6.1.4.8 GUROBI

- New libraries 9.1.2.
 - Added possibility to write a single GDX file with the solution pool (see `solnpoolmerge`).
 - Added the following options:
 - `solnpoolmerge`: Enable merged solution pool GDX.
 - `solnpoolnumsym`: Number of variable symbols in merged solution pool GDX.
 - `solnpoolprefix`: Prefix for variable symbols in merged solution pool GDX.
 - `miptrace`: Filename of MIP trace file (formerly hidden and undocumented).
 - `miptracetime`: Node interval when a trace record is written (formerly hidden and undocumented).
 - `miptracetime`: Time interval when a trace record is written (formerly hidden and undocumented).
 - Fixed incorrectly processed (hidden) options `isvname` and `appname`.
-

3.6.1.4.9 GUSS/Scenario Solver

- Measure time internally rather than relying on solvers' reported `resUsd` to determine the overall running time.

3.6.1.4.10 KNITRO

- New GAMS/Knitro link using the KN interface.
 - Enabled the possibility to use `solvelink = 5` on Linux (other platforms were already enabled).
 - Added support of variable and equation scaling.
 - Added options:
 - `names`: Enable to pass variable and equation names to Knitro.
 - `blasoptionlib`: Specifies a dynamic library name that contains object code for BLAS/LAPACK functions.
 - `bndrange`: Specifies max limits on the magnitude of constraint and variable bounds.
 - `cg_pmem`: Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner.
 - `cg_precond`: Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms.
 - `cg_stoptol`: Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves.
 - `convex`: Declare the problem as convex by setting to 1 or non-convex by setting to 0.
 - `cpuplatform`: Specify the target instruction set architecture.
 - `initpenalty`: Specifies the initial penalty parameter used in the Knitro merit functions.
 - `linesearch`: Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate.
 - `newpoint`: Specifies additional action to take after every iteration in a solve of a continuous problem.
 - `presolve_level`: Set the level of presolve operations to enable through the Knitro presolver.
 - `presolve_initpt`: Control whether the Knitro presolver can shift a user-supplied initial point.
 - `presolve_passes`: Set a maximum limit on the number of passes through the Knitro presolve operations.
 - `presolveop_tighten`: Determine whether or not to enable the Knitro presolve operation to tighten variable bounds.
 - `restarts`: Specifies whether or not to enable automatic restarts in Knitro.
 - `restarts_maxit`: When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart.
 - `strat_warm_start`: Specifies whether or not to invoke a warm-start strategy.
 - `findiff_relstepsize`: Specifies the relative stepsize used for finite-difference gradients.
 - `findiff_terminate`: Specifies the termination criteria when using finite-difference gradients.
 - `infeastol_iters`: The optimization process will terminate if the relative change in the feasibility error is less than `infeastol` for `infeastol_iters` consecutive infeasible iterations.
 - `xtol_iters`: The optimization process will terminate if the relative change in all components of the solution point estimate is less than `xtol` for `xtol_iters`.
 - `bar_conic_enable`: Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm).
-

- `bar_initpi_mpec`: Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms.
 - `bar_linsys`: Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps.
 - `bar_maxcorrectors`: Specifies the maximum number of corrector steps allowed for primal-dual steps.
 - `bar_slackboundpush`: Specifies the amount by which the barrier slack variables are initially pushed inside the bounds.
 - `bar_switchobj`: Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase.
 - `act_lpfeastol`: Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms.
 - `act_lppenalty`: Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms.
 - `act_lppresolve`: Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms.
 - `act_parametric`: Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms.
 - `act_qppenalty`: Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm.
 - `mip_clique`: Specifies rules for adding clique cuts.
 - `mip_cutfactor`: This value specifies a limit on the number of cuts added to a node subproblem.
 - `mip_heuristic_terminate`: Specifies the condition for terminating the MIP heuristic.
 - `mip_intvar_strategy`: Specifies how to handle integer variables.
 - `mip_mir`: Specifies rules for adding mixed integer rounding cuts.
 - `mip_selectdir`: Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch and bound tree.
 - `mip_zerohalf`: Specifies rules for adding zero-half cuts.
 - `ma_outsub`: Enable writing algorithm output to files for the multi-algorithm (`algorithm=5`) procedure.
 - `ms_num_to_save`: Specifies the number of distinct feasible points to save in a file named `knitro_mspoints`.
 - `ms_outsub`: Enable writing algorithm output to files for the parallel multistart procedure.
 - `ms_savetol`: Specifies the tolerance for deciding if two feasible points are distinct.
 - `par_msumthreads`: Specify the number of threads to use for multistart (when `ms.enable = 1`).
 - `out_csvinfo`: Controls whether or not to generate a file `knitro_solve`.
 - `out_csvname`: Use to specify a custom csv filename when using `out_csvinfo`.
 - `out_hints`: Specifies whether to print diagnostic hints (e.g. about user option settings) after solving.
 - `outappend`: Specifies whether output should be started in a new file, or appended to existing files.
 - `outdir`: Specifies a single directory as the location to write all output files.
 - `outmode`: Specifies where to direct the output from Knitro.
 - `outname`: Use to specify a custom filename when output is written to a file using `outmode`.
- Added values to the following options:
 - `blasoption`: 2 (dynamic)
 - `bar_pencons`: -1 (auto), 3 (equalities)
 - `hessopt`: 7 (gauss_newton)
-

- `honorbnds`: -1 (auto)
- `ma_terminate`: 3
- `mip_knapsack`: 3 (all)
- `mip_outlevel`: 2 (iterstime), 3 (root)
- `mip_rootalg`: 4 (sqp), 5 (multi)
- `scale`: 2 (user_none), 3 (internal)
- Updated the following options to KNITRO defaults:
 - `fstopval`: maxdouble
 - `honorbnds`: -1 (auto)
 - `par_blasnumthreads`: 0
 - `par_lsnumthreads`: 0
 - `xtol`: 1e-12
 - `bar_pencons`: -1 (auto)
 - `bar_switchrule`: -1 (auto)
 - `mip_maxnodes`: 0
 - `mip_maxsolves`: 0
 - `mip_rounding`: -1 (auto)
- Deprecated options:
 - `bar_maxbacktrack`: Use `linsearch_maxtrials` instead.
 - `maxcgit`: Use `cg_maxit` instead.
 - `pivot`: Use `linsolver_pivottol` instead.
- Removed formerly deprecated options:
 - `maxcrossit`
 - `mu`
 - `feasible`
 - `feasmodetol`
 - `barrule`
- Removed unused option `reform`.
- Fixed an issue with options not being forwarded to Knitro.

3.6.1.4.11 Lindo/LindoGlobal

- New libraries 13.0.262:
 - LP Solver Improvements:
 - * With new enhancements made to the simplex solvers, the average performance on large instances where the number of variables is several times larger than the number of constraints has increased by several folds compared to the previous version.
 - * Improved performance on LP's when using multiple cores with concurrent execution of Primal, Dual, and Barrier.
 - MIP (Mixed Integer Program) Solver:
 - * Improved selection of defaults for cuts and heuristics.
 - Global Solver Improvements:
 - * Highly improved ability to recognize convexity of various composite functions, especially involving logarithms and sums, which can give a performance improvement of one order-of-magnitude in these cases.
 - * Performance improvement for convex-concave type functions.
 - * Enhanced capabilities for converting nonlinear functions to linear forms.
 - * Substantial performance improvement for non-convex quadratic models.
-

3.6.1.4.12 LocalSolver

- New libraries 10.0 (20210330).
- We plan to drop LocalSolver and LocalSolver70 by the end of 2021.

3.6.1.4.13 MOSEK

- New libraries 9.2.41.

3.6.1.4.14 MPSGE

- Increased the internal MAXFUN limit (from 5000 to 10000) on the number of components (inputs, outputs, taxes, etc.) in any MPSGE row.

3.6.1.4.15 ODHCPLEX

- New libraries 5.34.

3.6.1.4.16 SBB

- Added option [usercallparmfile](#): Command-line parameter include file used in GAMS command-line calls triggered by BCH.

3.6.1.4.17 SCIP

- New libraries 7.0 (c53330372e).

3.6.1.4.18 SNOPT

- New libraries 7.7.7 and new GAMS/SNOPT link.
 - Changed option value to SNOPT default for the following options:
 - [Linesearch Tolerance](#): 0.9
 - [LI Singularity Tolerance](#): 3.2e-11
 - Removed the following parameters:
 - Start Objective Check
 - Start Constraint Check
 - Stop Objective Check
 - Stop Constraint Check
 - Derivative Level
-

3.6.1.4.19 XPRESS

- Added support for choosing a different algorithm than primal simplex for solving the fixed MIP (see [mipCleanup](#)). The algorithm can be chosen with [defaultAlg](#) and [lpFlags](#).
 - Deprecated the following options:
 - [algorithm](#): Use [defaultAlg](#) or [lpFlags](#) instead.
 - [extraPresolve](#)
 - [lpThreads](#)
 - Added the following options:
 - [algAfterCrossover](#): Algorithm to be used for the final clean up step after the crossover.
 - [autoPerturb](#): Simplex: Indicates whether automatic perturbation is performed.
 - [autoScaling](#): Whether the Optimizer should automatically select between different scaling algorithms.
 - [backtrackTie](#): Branch and Bound: Specifies how to break ties when selecting the next node to work on when a full backtrack is performed.
 - [barCores](#): If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm.
 - [barFailIterLimit](#): Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm.
 - [barFreeScale](#): Defines how the barrier algorithm scales free variables.
 - [barGapTarget](#): Newton barrier: Target tolerance for the relative duality gap.
 - [barKernel](#): Newton barrier: Defines how centrality is weighted in the barrier algorithm.
 - [barObjScale](#): Defines how the barrier scales the objective.
 - [barOrderThreads](#): If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton barrier method.
 - [barPresolveOps](#): Controls the Newton barrier specific presolve operations.
 - [barRegularize](#): Determines how the barrier algorithm applies regularization on the KKT system.
 - [barRhsScale](#): Defines how the barrier scales the right hand side.
 - [branchChoice](#): Once a global entity has been selected for branching, this control determines which of the branches is solved first.
 - [branchDisj](#): Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search.
 - [branchStructural](#): Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search.
 - [cacheSize](#): Newton barrier: L2 or L3 (see notes) cache size in kB (kilobytes) of the CPU.
 - [choleskyAlg](#): Newton barrier: Type of Cholesky factorization used.
 - [choleskyTol](#): Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm.
 - [conflictCuts](#): Branch and Bound: Specifies how cautious or aggressive the optimizer should be when searching for and applying conflict cuts.
 - [coresPerCpu](#): Used to override the detected value of the number of cores on a CPU.
 - [cpuTime](#): How time should be measured when timings are reported in the log and when checking against time limits.
 - [crossoverAccuracyTol](#): Newton barrier: Determines how crossover adjusts the default relative pivot tolerance.
 - [crossoverIterLimit](#): Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates.
-

- **crossoverOps**: Newton barrier: Bit vector for adjusting the behavior of the crossover procedure.
 - **cutFactor**: Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during global search.
 - **cutSelect**: Bit vector providing detailed control of the cuts created for the root node of a global solve.
 - **dualGradient**: Simplex: Dual simplex pricing method.
 - **dualize**: Whether presolve should form the dual of the problem.
 - **dualizeOps**: Bit-vector control for adjusting the behavior when a problem is dualized.
 - **dualPerturb**: Factor by which the problem will be perturbed prior to optimization by dual simplex.
 - **dualStrategy**: Bit-vector control specifies the dual simplex strategy.
 - **elimFillin**: Amount of fill-in allowed when performing an elimination in presolve.
 - **elimTol**: Markowitz tolerance for the elimination phase of the presolve.
 - **feasibilityPump**: Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node.
 - **feasTolPerturb**: Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes.
 - **feasTolTarget**: Target feasibility tolerance for the solution refiner.
 - **forceParallelDual**: Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm.
 - **genConsDualReductions**: Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs.
 - **heurBeforeLp**: Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved.
 - **heurDiveIterLimit**: Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic.
 - **heurDiveRandomize**: Level of randomization to apply in the diving heuristic.
 - **heurDiveSoftRounding**: Enables a more cautious strategy for the diving heuristic.
 - **heurDiveSpeedUp**: Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed.
 - **heurDiveStrategy**: Branch and Bound: Chooses the strategy for the diving heuristic.
 - **heurForceSpecialObj**: Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer.
 - **heurFreq**: Branch and Bound: Frequency at which heuristics are used in the tree search.
 - **heurSearchEffort**: Adjusts the overall level of the local search heuristics.
 - **heurSearchFreq**: Branch and Bound: How often the local search heuristic should be run in the tree.
 - **heurSearchRootCutFreq**: How frequently to run the local search heuristic during root cutting.
 - **heurSearchRootSelect**: Bit vector control for selecting which local search heuristics to apply on the root node of a global solve.
 - **heurSearchTreeSelect**: Bit vector control for selecting which local search heuristics to apply during the tree search of a global solve.
 - **heurStrategy**: Branch and Bound: Heuristic strategy.
 - **historyCosts**: Branch and Bound: How to update the pseudo cost for a global entity when a strong branch or a regular branch is applied.
 - **indLinBigM**: Indicator constraints can be internally converted to regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value.
-

- **indPreLinBigM**: During presolve, indicator constraints can be internally replaced with regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value.
 - **llCache**: Newton barrier: L1 cache size in kB (kilo bytes) of the CPU.
 - **lpBest**: Number of infeasible global entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see **gomCuts**).
 - **lpIterLimit**: Number of iterations to perform in improving each lift-and-project cut.
 - **localChoice**: Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree.
 - **lpFlags**: Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem.
 - **lpFolding**: Simplex and barrier: Whether to fold an LP problem before solving it.
 - **lpLogDelay**: Time interval between two LP log lines.
 - **lpLogStyle**: Simplex: Style of the simplex log.
 - **lpRefineIterLimit**: Simplex iteration limit the solution refiner can spend.
 - **markowitzTol**: Markowitz tolerance used for the factorization of the basis matrix.
 - **maxCutTime**: Maximum amount of time allowed for generation of cutting planes and reoptimization.
 - **maxImpliedBound**: Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than **maxImpliedBound** will be applied to the problem.
 - **maxLocalBacktrack**: Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node.
 - **maxMemoryHard**: Sets the maximum amount of memory in megabytes the optimizer should allocate.
 - **maxMemorySoft**: When **resourceStrategy** is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate.
 - **maxMipTasks**: Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve.
 - **maxScaleFactor**: Determines the maximum scaling factor that can be applied during scaling.
 - **maxTime**: Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time.
 - **mipDualReductions**: Branch and Bound: Limits operations that can reduce the MIP solution space.
 - **mipFracReduce**: Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions.
 - **mipKappaFreq**: Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search.
 - **mipRampUp**: Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search.
 - **mipRefineIterLimit**: Defines an effort limit expressed as simplex iterations for the MIP solution refiner.
 - **mipRestart**: Branch and Bound: Controls strategy for in-tree restarts.
 - **mipToltarget**: Target **mipTol** value used by the automatic MIP solution refiner as defined by **refineOps**.
 - **miqcpAlg**: Determines which algorithm is to be used to solve mixed integer quadratically constrained and mixed integer second order cone problems.
 - **xslp_mipAlgorithm**: Bitmap describing the MISLP algorithms to be used.
 - **xslp_mipFixStepBounds**: Bitmap describing the step-bound fixing strategy during MISLP.
-

- `xslp_mipRelaxStepBounds`: Bitmap describing the step-bound relaxation strategy during MISLP.
 - `netCuts`: Determines the addition of multi-commodity network cuts to a problem.
 - `objScaleFactor`: Custom global objective scaling factor, expressed as a power of 2.
 - `optimalityTolTarget`: Target optimality tolerance for the solution refiner.
 - `outputLog`: Controls the level of output produced by the Optimizer during optimization.
 - `outputTol`: Zero tolerance on print values.
 - `preAnalyticCenter`: Determines whether analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs.
 - `preBasisRed`: Determines whether a lattice basis reduction algorithm should be attempted as part of presolve.
 - `preBndRedCone`: Determines whether second order cone constraints should be used for inferring bound reductions on variables when solving a MIP.
 - `preBndRedQuad`: Determines whether convex quadratic constraints should be used for inferring bound reductions on variables when solving a MIP.
 - `preCoefElim`: Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem.
 - `preComponents`: Determines whether small independent components should be detected and solved as individual subproblems during root node processing.
 - `preComponentsEffort`: Presolve: Adjusts the overall effort for the independent component presolver.
 - `preConeDecomp`: Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components.
 - `preConvertSeparable`: Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints.
 - `preDomCol`: Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem.
 - `preDomRow`: Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem.
 - `preDupRow`: Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem.
 - `preElimQuad`: Presolve: Allows for elimination of quadratic variables via doubleton rows.
 - `preImplications`: Presolve: Determines whether to use implication structures to remove redundant rows.
 - `preLinDep`: Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem.
 - `preObjCutDetect`: Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed.
 - `presolveMaxGrow`: Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem.
 - `presolveOps`: Specifies the operations which are performed during the presolve.
 - `presolvePasses`: Number of reduction rounds to be performed in presolve.
 - `primalPerturb`: Factor by which the problem will be perturbed prior to optimization by primal simplex.
 - `primalUnshift`: Determines whether primal is allowed to call dual to unshift.
 - `qcCuts`: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratically constrained or mixed integer second order conic problem with outer approximation.
-

- [qcRootAlg](#): Determines which algorithm is to be used to solve the root of a mixed integer quadratically constrained or mixed integer second order cone problem, when outer approximation is used.
- [qSimplexOps](#): Controls the behavior of the quadratic simplex solvers.
- [quadraticUnshift](#): Determines whether an extra solution purification step is called after a solution found by the quadratic simplex (either primal or dual).
- [randomSeed](#): Sets the initial seed to use for the pseudo-random number generator in the Optimizer.
- [refineOps](#): Specifies when the solution refiner should be executed to reduce solution infeasibilities.
- [relaxTreeMemoryLimit](#): When the memory used by the branch and bound search tree exceeds the target specified by the [treeMemoryLimit](#) control, the optimizer will try to reduce this by writing nodes to the global file.
- [repairIndefInitEq](#): Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible.
- [resourceStrategy](#): Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve.
- [rootPresolve](#): Determines if presolving should be performed on the problem after the global search has finished with root cutting and heuristics.
- [sbBest](#): Number of infeasible global entities to initialize pseudo costs on each node.
- [sbEffort](#): Adjusts the overall amount of effort when using strong branching to select an infeasible global entity to branch on.
- [sbEstimate](#): Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible global entity to branch on.
- [sbIterLimit](#): Number of dual iterations to perform in strong branching for each entity.
- [sifting](#): Determines whether to enable sifting algorithm with the dual simplex method.
- [xslp_algorithm](#): Bitmap describing the SLP algorithm(s) to be used.
- [xslp_analyze](#): Bitmap activating additional options supporting model / solution path analysis.
- [xslp_augmentation](#): Bitmap describing the SLP augmentation method(s) to be used.
- [xslp_barStartOps](#): Controls behaviour when the barrier is used to solve the linearizations.
- [xslp_convergenceOps](#): Bitmap describing which convergence tests should be carried out.
- [xslp_filter](#): Bitmap for controlling solution updates.
- [xslp_presolveOps](#): Bitmap indicating the SLP presolve actions to be taken.
- [xslp_zeroCriterion](#): Bitmap determining the behavior of the placeholder deletion procedure.
- [sosRefTol](#): Minimum relative gap between the ordering values of elements in a special ordered set.
- [treeCompression](#): When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the global file on disk.
- [treeCutSelect](#): Bit vector providing detailed control of the cuts created during the tree search of a global solve.
- [treeMemoryLimit](#): Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree.
- [treeMemorySavingTarget](#): When the memory used by the branch-and-bound search tree exceeds the limit specified by the [treeMemoryLimit](#) control, the optimizer will try to save memory by writing lower-rated sections of the tree to the global file.
- [treeQCCuts](#): Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratically constrained or mixed integer second order conic problem with outer approximation.

- Added options to conveniently set bits of XPRESS bitmap options:
-

- New bits of `refineOps`:
 - * `refineOps_lpOptimal`
 - * `refineOps_mipSolution`
 - * `refineOps_mipNodeLp`
 - * `refineOps_lpPresolve`
 - * `refineOps_iterativeRefiner`
 - * `refineOps_refinerPrecision`
 - * `refineOps_refinerUsePrimal`
 - * `refineOps_refinerUseDual`
 - * `refineOps_mipFixGlobals`
 - * `refineOps_mipFixGlobalsTarget`
 - New bits of `mipPresolve`:
 - * `mipPresolve_reducedCostFixing`
 - * `mipPresolve_logicPreprocessing`
 - * `mipPresolve_allowChangeBounds`
 - * `mipPresolve_dualReductions`
 - * `mipPresolve_globalCoefTightening`
 - * `mipPresolve_objBasedReductions`
 - * `mipPresolve_allowTreeRestart`
 - * `mipPresolve_symmetryReductions`
 - New bits of `presolveOps`:
 - * `presolveOps_singletonColRemoval`
 - * `presolveOps_singletonRowRemoval`
 - * `presolveOps_forcingRowRemoval`
 - * `presolveOps_dualReductions`
 - * `presolveOps_redundantRowRemoval`
 - * `presolveOps_duplicateColRemoval`
 - * `presolveOps_duplicateRowRemoval`
 - * `presolveOps_strongDualReductions`
 - * `presolveOps_variableEliminations`
 - * `presolveOps_noIpReductions`
 - * `presolveOps_noGlobalDomainChange`
 - * `presolveOps_noAdvIpReductions`
 - * `presolveOps_linDependRowRemoval`
 - * `presolveOps_noIntVarEliminations`
 - * `presolveOps_noIntVarAndSosDetect`
 - New bits of `scaling`:
 - * `scaling_rowScaling`
 - * `scaling_colScaling`
 - * `scaling_rowScalingAgain`
 - * `scaling_maximum`
 - * `scaling_curtisReid`
 - * `scaling_byMaxElemNotGeoMean`
 - * `scaling_bigM`
 - * `scaling_simplexObjScaling`
 - * `scaling_ignoreQuadRowPart`
 - * `scaling_beforePresolve`
 - * `scaling_noScalingRowsUp`
 - * `scaling_noScalingColsDown`
 - * `scaling_disableGlobalObjScaling`
-

- * [scaling_rhsScaling](#)
- * [scaling_noAggressiveQScaling](#)
- * [scaling_slackScaling](#)
- New bits of `lpFlags`:
 - * [lpFlags_dual](#)
 - * [lpFlags_primal](#)
 - * [lpFlags_barrier](#)
 - * [lpFlags_network](#)
- New bits of `cutSelect`:
 - * [cutSelect_clique](#)
 - * [cutSelect_mir](#)
 - * [cutSelect_cover](#)
 - * [cutSelect_mirRowAggregation](#)
 - * [cutSelect_flowpath](#)
 - * [cutSelect_implication](#)
 - * [cutSelect_liftAndProject](#)
 - * [cutSelect_disableCutRows](#)
 - * [cutSelect_gubCover](#)
 - * [cutSelect_zeroHalf](#)
 - * [cutSelect_indicator](#)
- New bits of `treeCutSelect`:
 - * [treeCutSelect_clique](#)
 - * [treeCutSelect_mir](#)
 - * [treeCutSelect_cover](#)
 - * [treeCutSelect_mirRowAggregation](#)
 - * [treeCutSelect_flowpath](#)
 - * [treeCutSelect_implication](#)
 - * [treeCutSelect_liftAndProject](#)
 - * [treeCutSelect_disableCutRows](#)
 - * [treeCutSelect_gubCover](#)
 - * [treeCutSelect_zeroHalf](#)
 - * [treeCutSelect_indicator](#)
- Renamed the following options to match the original XPRESS options names. Old option names currently serve as alias, but are deprecated and will be removed in an upcoming release:
 - `treePresolveKeepBasis` to `treePresolve_keepBasis`.
 - `slpKnitroOptFile` to `knitroOptFile`.
 - All XPRESS Nonlinear (SLP) options, e.g., `slpSolver` to `xslp_solver`.
- Fixed default values of single bit options for XPRESS bitmap options with negative default values.

3.6.1.5 Tools

3.6.1.5.1 GAMS Studio

- New version 1.6.1.
 - New feature: Static [Code Completion](#) which can be activated by pressing `Ctrl + Space`.
 - New feature: Allow to move multiple lines up and down using `Ctrl + Shift + Arrow`.
 - New feature: Allow to close view tabs using the middle mouse button.
-

- Added instant update of tab size in editor when changing corresponding setting.
- Added word under cursor as default search entry when no text selection is present.
- Allow to move block selections using the arrow keys.
- Added *.inc as common extension for GAMS files.
- Added user defined extensions for GAMS files.
- Added automatic reloading of files that appear in the GAMS log.
- Added setting for user defined extensions for files to be automatically reloaded.
- Added auto-reload button to file-changed dialog.
- Added Studio Documentation entry in Help menu.
- Added setting to change default open file behavior (new group or current group) and adjusted menu entry for alternative file opening behavior.
- Hotkey F1 jumps to the corresponding documentation entry for Project Explorer, Process Logs, GDX Diff Dialog, and Search Widget.
- Improved [GDX Viewer](#), e.g.:
 - * Added facility to access domains and filters in [Table View](#).
 - * Show original index position of domains in both list view and table view.
 - * Improved automatic column widths.
- Stability improvements and minor bug fixes, e.g.:
 - * Fixed crash when LST file is missing (e.g. because of setting `output=NUL`).
 - * Fixed "Reset View" not resetting splitter in the LST/LXI-Viewer.
 - * Fixed crash related to comment shortcut in solver option editor when pressing it multiple times.
 - * Fixed wrong sort order after resetting GDX Viewer.
 - * Fixed GAMS engine not appending `/api` to the URL on Mac OS X when clicking OK directly after editing the URL.
 - * Fixed `eo1Com` not working in some dollar control option lines (like `$include`).
 - * Fixed jump to next search result if the result is in a different file and the current one has no results.
 - * Fixed jump to search result occasionally not working.
 - * Fixed `Find Next/Prev` behavior for `.opt` files.

3.6.1.5.2 GDXDUMP

- Added a new line at the end of the file, which was missing if the option `noHeader` is set.

3.6.1.5.3 GDXMERGE

- Added command line option `strict`. When set to `true`, `gdxmerge` will terminate with an error in case input files cannot be found or the output file already exists.

3.6.1.5.4 GDXXRW

- Fixed a potential missing initialization if `incRC` is set for symbols with either `cDim` or `rDim` equal 0.
-

3.6.1.6 APIs

3.6.1.6.1 CFG

- With the next major release the last argument `opt: pointer` of function `cfgAlgReadyAPI` will be dropped.

3.6.1.6.2 DCT

- Functions `dctLoadWithHandle`, `dctSymDomIdx`, `dctDomNameCount`, and `dctDomName` have been deprecated and will be removed in the near future.

3.6.1.6.3 gams2numpy

- Improved error handling.
- New optional parameter `domains` for `gdxWriteSymbolStr` and `gdxWriteSymbolRaw` that can be used to specify the domains of the symbol. Parameter needs to be a list of strings.

3.6.1.6.4 GMO

- Updated to better handle cases where quadratic structure is explicitly detected (i.e. `useQ` is set) and some *but not all* of the nonlinear equations are quadratic. Several new functions have been added. In addition, some existing functions have been renamed - the new names are more descriptive and/or more consistent with new and existing function names. The old names are still available as deprecated synonyms - we expect to remove these synonyms in the near future and potentially without warning.
 - Updated API version to 20 - compatible with some older API versions.
 - New functions:
 - * `gmoObjLNZ`: Number of linear nonzeros in objective gradient.
 - * `gmoObjMLNZE`: Number of `GMOORDER_NL` nonzeros in objective gradient.
 - * `gmoObjQNZE`: Number of `GMOORDER_Q` nonzeros in objective gradient.
 - * `gmoObjCVecNZ`: Number of nonzeros in c vector of objective (-1 if Q information not used).
 - * `gmoObjConstEx`: Objective constant - this is independent of `useQ`.
 - * `gmoObjQConst`: Get constant in solvers quadratic objective.
 - * `gmoGetObjCVec`: Get c vector of quadratic objective.
 - * `gmoGetObjSparseEx`: Get information for gradient of objective function (sparse).
 - * `gmoGetRowStatEx`: Get Jacobian row nonzero counts: total and by `GMOORDER_XX`.
 - * `gmoGetRowCVecNZOne`: Number of nonzeros in c vector of row si (-1 if Q information not used).
 - * `gmoGetRhsOneEx`: Get individual equation RHS - independent of `useQ`.
 - * `gmoGetRowSparseEx`: Get info for one row of Jacobian (sparse).
 - * `gmoGetRowCVec`: Get c vector of the quadratic form for one row.
 - * `gmoGetRowQConst`: Get the constant of the quadratic form for one row.
 - * `gmoHessInclQRows`: if `useQ` is true, still include `GMOORDER_Q` rows in the Hessian.
 - Renamed functions:
 - * `gmoObjQNZ` → `gmoObjQMatNZ`: Number of nonzeros in lower triangle of Q matrix of objective (-1 if `useQ` is false).
 - * `gmoGetObjQ` → `gmoGetObjQMat`: Get lower triangle of Q matrix of objective.
 - * `gmoGetRowQ` → `gmoGetRowQMat`: Get lower triangle of Q matrix of one row.

3.6.1.6.5 High-Level APIs

- We might drop support for macOS 10.14 for the C++ API with the next major release.
- Fixed an issue with an updater symbol that tries to update a non-existing symbol in the model instance. This used to make the `solve` method of `GAMSModelInstance` fail, but now just increases the no-match count.
- Fixed `GAMSOptions.Output (.NET)`, `GAMSOptions.setOutput (Java)`, and `GamsOptions.output (Python)` parameter being ignored in `GAMSJob::Run()`.

3.6.1.6.6 Low-Level APIs

- For the next major releases, some clean-up of the distributed APIs is planned. In particular, it is planned to remove all Delphi variants but the `dcp` version (i.e. `gdxdcpdef.pas`) and all Fortran variants but the `f9` version (i.e. `gdxmf9def.f90`). Please contact us, if that causes any trouble for your operation.

3.6.1.6.7 PAL

- Added functions `palDataDirs` and `palConfigDirs` to retrieve [standard locations](#) searched by GAMS.

3.6.1.7 Model Libraries

3.6.1.7.1 GAMS Model Library

- `nurses.gms` : A Nurse Scheduling Problem (428)

3.6.1.7.2 GAMS Test Library New models:

- `gdxmerg3.gms` : Test strict mode
- `unload15.gms` : Test `$gdxUnload`
- `load13.gms` : Test `$gdxLoad`
- `conopt02.gms` : CONOPT test suite - multi-thread test
- `implset2.gms` : Test for Implicit Set Definition with default records
- `prevwork1.gms` : PreviousWork Test
- `decla3.gms` : Test correct loading after multi declaration of domain set
- `delim5.gms` : Limited scope for `$onDelim`
- `load14.gms` : Test loading of GDX file with bad UELs
- `eval08.gms` : Test `$eval` with hidden functions
- `embpy07.gms` : Test `no_match_limit` for model instance
- `embpy08.gms` : Test filtered load from Embedded Code

3.6.2 35.2.0 Minor release (June 02, 2021)

3.6.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Johannes Hedtrich, Bruce McCarl, Evangelos Panos, Thomas Rutherford, and Kirk A. Yost.

3.6.2.2 GAMS System

3.6.2.2.1 GAMS

- Allow to write [point files](#) with [asynchronous](#) solves as well.

- Moved the log line pointing to a [reference file](#) from the end of the compilation phase to the end of the run, to make it easier to recognize.
- Automatically deactivate `holdFixed` if a model is solved [asynchronously](#), since this could lead to inconsistent solutions otherwise. Note that this can make a square model non-square as in `cn01`. Also note, that this could require some adjustment to models which actually relied on the fact, that models solved like this did not update the solution for fixed variables. Such a change was done for the model `jacobi`.
- Fixed a problem where the file path specified with `$gdxIn` or `$gdxLoad` was ignored when `inputDir` was applied.
- Fixed a potentially broken work file written with [previousWork](#).
- Fixed the default for command line parameter `empty`. It should be `on` but was `off`.
- Fixed the dollar control options `$setComps`, `$setNames`, and `$splitOption`: They should generate [scoped](#) compile-time variable but generated [local](#) ones.
- Fixed potentially wrongly reported bounds for models solved with `solveLink=6`.
- Fixed missing info about objective variable with `solveLink = 3` and `asyncSolLst = 1`.

3.6.2.2.2 EMP

- Fixed handling of the empty UEL in the EMP info file

3.6.2.2.3 GMSPython

- Removed package `tqdm`.

3.6.2.3 Solvers

3.6.2.3.1 AlphaECP

- New library with some minor bug fixes.

3.6.2.3.2 CONVERT

- Fixed exporting of variable scale attribute in [DumpGDX](#) format.

3.6.2.3.3 CPLEX

- Fixed incorrect model status for feasible models after time out in multi-objective optimization.

3.6.2.3.4 KNITRO

- Fixed incorrect model status for KNITRO return code "All nodes have been explored. Integer feasible point found." (`KN_RC_MIP_EXH_FEAS`).
-

3.6.2.4 Tools

3.6.2.4.1 GAMS Studio

- New version 1.6.2. with various bug fixes, stability improvements and minor enhancements, e.g.:
 - Fixed issues with enumerated parameters in extended parameter editor.
 - Fixed issues with "set", "option", and "table" in code-completer.
 - Fixed code-completer opening in non-code files.
 - Fixed "Open in current group" not being used for "User Model Library" and "New file".

3.6.2.5 APIs

3.6.2.5.1 Python

- Fixed a bug in the GDX expert-level API that required `gdxSymbolGetDomain` to be called in a read context (e.g. after `gdxDataReadStrStart`).
- Fixed a bug in `gams2numpy` functions `gdxReadSymbolStr` and `gdxReadSymbolRaw` that altered the case of the `symName` argument.

3.6.2.5.2 DCT

- Fixed broken function `dctSymDomNames` for symbols that have the universe as part of their domain. This caused a crash in sensitivity analysis of CPLEX and Gurobi for models with such variable or equation symbols.

3.6.2.6 Model Libraries

3.6.2.6.1 GAMS Model Library

- Changed `jacobi.gms : Asynchronous Jacobi Methods` to work with the changed `holdFixed` behavior with asynchronous solves, mentioned [above](#).

3.7 34 Distribution

3.7.1 34.1.0 Major release (January 29, 2021)

3.7.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Wolfgang Britz, Michael Ferris, Erwin Kalvelagen, Antti Lehtila, Bruce McCarl, Scott McDonald, Cornelius Rüther, Shima Sasanpour, Kaushik Sinha, Elizabeth Wong, and Qi Yuan.

3.7.1.2 Platforms

- The minimal required GLIBC version of the distribution for GNU/Linux is now 2.17.
- Mac OS X 10.13 (High Sierra) is no longer supported.

3.7.1.3 GAMS System

3.7.1.3.1 GAMS

- Improved performance of *dense* operations with out-of-order index positions, as in the following code snippet, where the assignment to `d1` was significantly slower than the one to `d2` in the past:

```
d1(j,i) = sum(ij(i,j), exp(pij(i,j)));
d2(j,i) = sum(ij(i,j), abs(pij(i,j)));
```

- Added new debugging option `dmpUserSym`, to print all symbols defined by the user.
 - Added new variants `$showFiles`, `$showMacros`, and `$showVariables` of `$show` for shorter reports.
 - Print an extra log line for compile time GDY operations `$gdxIn` and `$gdxOut`. When running GAMS from one of the [GAMS IDEs](#), these log line can be clicked to open the file referenced.
 - Add anchors to the log that can be clicked when running GAMS from one of the [GAMS IDEs](#) for each mention of an input/include file.
 - Added extra info to the log in case of an unmatched `$ifThen` and its variants, that can be clicked when a GAMS IDE is used to jump to the initial dollar control option.
 - Added more details about the problem to the log in case of an error analyzing the solve statement.
 - Added new variants for the command line parameter `fileCase` which allow to use upper or lower case for referenced filenames only and not for the path to the files.
 - Fixed a bug where certain checks for errors in the model structure were skipped, if upper and lower bound of a variable are the same. While the selected solver would already have rejected the problem most likely, now GAMS generates an execution error also if lower and upper bounds are the same and
 - the bounds of discrete variables do not have integer values,
 - the lower and upper bounds of binary variables are not equal to 0 or 1, or,
 - the lower bounds of semiCont/semiInt variables are smaller than 0.
 - Altered the behavior of `execute.checkErrorLevel`, `put_utility exec.checkErrorLevel`, and `put_utility shell.checkErrorLevel` so the execution would stop right away also within a [Flow Control structure](#), like a `loop`, if an error is encountered. In the past, it would just stop after executing the flow control structure completely.
 - Changed the behavior for unloading symbols with `$unload`. In previous versions the writing of the symbols happened while the compiler processed the `$unload` instructions. With this version forward the writing of the symbols and data to GDY is delayed until the GDY file is about to be closed. This has several advantages, e.g. writing of aliases and full domain information, but it can result in different content of the GDY file in some corner cases. Please check for [details](#) in the documentation.
 - Avoid export of predefined symbols `diag` and `sameAs` to GDY. When all symbols should be exported, these are skipped. When they are tried to be exported explicitly, there will be a compilation error.
 - Allow to use `Put_Utility save` to write a [save file](#) of the current state of execution inside loops and other [flow control structures](#) as well.
 - Fixed a wrongly raised compilation error which could happen when an [implicit set definition](#) was used with a [table statement](#) without data.
 - Fixed a problem where `dumpOpt` in combination with `$onVerbatim` skipped parts of an `$ifThen` block.
-

3.7.1.3.2 GMSPython

- Added the packages `pyexcelerate`, `pyyaml`, `xlswriter`, and their dependencies.

3.7.1.4 Solvers

3.7.1.4.1 AMPL

- As [announced](#), dropped the meta-solver AMPL.

3.7.1.4.2 BARON

- New libraries 21.1.13.
 - Improved interface to IPOPT for local search.
 - Changed default for option `LPSol` to new value `-1`, which makes BARON use CPLEX for LP or MIP relaxations, if licensed, and CLP/CBC otherwise.
 - Further performance improvements and bugfixes.
- Added option `BarName` to specify name of file into which to write problem in BARON format.

3.7.1.4.3 BDMLP

- As [announced](#), dropped the solver BDMLP.

3.7.1.4.4 BENCH

- As [announced](#), dropped the tool BENCH.

3.7.1.4.5 CONOPT

- New library 4.22.
 - Some improvements for models with external equations.
-

3.7.1.4.6 CONVERT

- The two solver links `CONVERT` and `CONVERTD` were merged under the name `CONVERT`. Features that were formerly available in only one of the two solver links are now all usable with the new `CONVERT` link (except for the dropped features, see below). `CONVERTD` is an alias for `CONVERT` now.
 - JuMP format:
 - Added constraint names.
 - Using `@NLconstraint` and `@NLobjective` instead of `add_NL_constraint` and `set_NL_objective`, respectively.
 - Changed default of option `JuMP` to `jump.jl`.
 - Pyomo format:
 - Fix export of `SOS1` and `SOS2` variable types.
 - Changed default of option `Pyomo` to `pyomo.py`.
 - DumpGDX format (formerly Hessian or Jacobian):
 - The current behaviour of disabling variable and equation names or UELs when setting the option to `"NOVENAMES.gdx"` or `"NOUELS.gdx"` has no special effect anymore. Use `GDXNames` and `GDXUELS` instead.
 - New options:
 - `Width`
 - `DumpGDX` (replaces options `Hessian` and `Jacobian`)
 - `GDXNames` (instead of setting the former options `Hessian` or `Jacobian` to `"NOVENAMES.gdx"`)
 - `GDXUELS` (instead of setting the former options `Hessian` or `Jacobian` to `"NOUELS.gdx"`)
 - `GDXHessian` (enables hessian information for `DumpGDX`)
 - `GDXQuadratic` (enables quadratic information for `DumpGDX`)
 - Options `PermuteEqus` and `PermuteVars` are now available for all target languages.
 - Removed the following formats:
 - `AlphaECP`
 - `AmplNLC`
 - `Analyze`
 - `AnalyzeS`
 - `Baron` (GAMS/Baron link provides the option `BarName` to export this format)
 - `Lgo`
 - `LindoMPI` (GAMS/Lindo link provides the option `WRITEMPI` to export this format)
 - `LocalSolver` (GAMS/Localsolver link provides the option `writelsp` to export this format)
 - `LSPSol`
 - `Memo`
 - `Minopt`
 - `SFS`
 - `ViennaDag`
 - Removed the following experimental formats:
 - `AmplNLCG`
 - `CHull`
-

- CppAD
- Lago
- NLP2MCPE
- PDCO
- Qmaker (use [DumpGDX](#) with [GDXXquadratic](#) enabled instead)
- UnitBC
- The following formats are deprecated and may be removed in an upcoming release:
 - Hessian (use [DumpGDX](#) with [GDXHessian](#) enabled instead)
 - Jacobian (use [DumpGDX](#) instead)
- The following options don't have any effect anymore and will be removed in an upcoming release:
 - ConeReform
 - IntervalEvalDebug
 - Match
 - Terminate

3.7.1.4.7 CPLEX

- New libraries 20.1.0.
 - Conflict Analysis ([iis](#)) now supports SOS variables and indicator constraints.
 - Added options:
 - * [prereform](#): allows to set presolve reformulations
 - * [confictalg](#): algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model
 - * [nodecuts](#): allows to decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree
 - * [sos1reform](#): automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)
 - * [sos2reform](#): automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)
 - * Value 5 to [mipemphasis](#): finding high quality feasible solutions as early as possible
 - Deprecated options:
 - * [prelinear](#): Use [prereform](#) instead
 - Deprecated features (will be removed in a future CPLEX release):
 - * Remote Object functionality.
 - * Distributed parallel optimization of mixed integer programming models (MIP).
 - Fixed error messages for CPLEX error 5002 (CPXERR_Q_NOT_POS_DEF).
 - Fixed an error that caused a crash for special option file input.
 - Fixed an error that wrote additional quotes in GDX files of ranging and column generation information.
 - Fixed [miptrace](#) timing info.
-

3.7.1.4.8 Gurobi

- New libraries 9.1.1.
 - Added the following options:
 - `SolFiles`: location to store intermediate solution files
 - `DualReductions`: disables dual reductions in presolve
 - `ProjImpliedCuts`: projected implied bound cut generation
 - `PSDCuts`: PSD cut generation
 - `FeasRelaxBigM`: Big-M value for feasibility relaxations
 - Added possible option values for the following options:
 - `MinRelNodes`: -1 (automatic)
 - `NodeMethod`: -1 (automatic)
 - `PumpPasses`: -1 (automatic)
 - `StartNodeLimit`: -3 (shut off)
 - `ZeroObjNodes`: -1 (automatic)
 - `AggFill`: -1 (automatic)
 - `PreSparsify`: -1 (automatic)
 - `TuneResults`: -1 (best results)
 - `IISMethod`: 2 (ignores bound constraints)
 - `IISMethod`: 3 (IIS the LP relaxation)
 - `Method`: 5 (both primal and dual simplex)
 - Set option value to GUROBI default for the following options:
 - `scaleflag`: -1
 - `Cutoff`: maxdouble
 - `ImproveStartGap`: 0
 - `MinRelNodes`: -1
 - `NodeMethod`: -1
 - `PartitionPlace`: 15
 - `PumpPasses`: -1
 - `ZeroObjNodes`: -1
 - `AggFill`: -1
 - `PreSOS2BigM`: -1
 - `PreSparsify`: -1
 - `TuneResults`: -1
 - `TuneTrials`: 3
 - Removed the following options:
 - `premiqpmethod`
 - `workerport`
 - Options for how to access the Gurobi compute server, cluster manager, or Instant Cloud can all be **set through the Gurobi license file**. Therefore, the following link options have been removed:
 - `computeserver`
 - `csgroup`
-

- cspassword
 - csport
 - cspriority
 - csrouter
 - estimeoutfrac
 - estlsinsecure
 - icsecretkey
 - icpool
 - icpriority
 - instantcloud
- Fixed issue of missing logfile output for `logoption = 4`.
 - Fixed an error that wrote additional quotes in GDX files of ranging information.

3.7.1.4.9 Ipopt

- Updated MUMPS to version 5.3.5.

3.7.1.4.10 KESTREL

- The environment variable `NEOS_EMAIL` can now be used to provide an e-mail address when submitting a job to NEOS.
- Fixed unintentional reading from option file.

3.7.1.4.11 KNITRO

- New libraries 12.3.0.
 - Improvements in performance, memory usage, numerical stability, and overall stability.

3.7.1.4.12 LINGO

- As [announced](#), dropped the meta-solver LINGO.
-

3.7.1.4.13 LS

As [announced](#), dropped the tool LS.

One possibility to adapt existing GAMS code is to use the Python function `numpy.linalg.lstsq` via the GAMS embedded code facility.

For example, the GAMS code

```
Set i;
Parameter x(i), y(i);
Variables b0, b1, sse;
Equations sumsq, fit(i);
sumsq..  sse =n= 0;
fit(i).. y(i) =e= b0 + b1*x(i);
option lp = ls;
model leastsq /fit,sumsq/;
solve leastsq using lp minimizing sse;
```

to compute a linear regression for (x,y) can be replaced by

```
Set i;
Parameter x(i), y(i);
Scalars b0, b1, sse;
embeddedCode Python:
  import numpy as np
  x = np.array(gams.get('x', keyFormat=KeyFormat.SKIP))
  y = np.array(gams.get('y', keyFormat=KeyFormat.SKIP))
  A = np.vstack([np.ones(len(x)), x]).T
  res = np.linalg.lstsq(A, y, rcond=None)
  gams.set('b0', [res[0][0]])
  gams.set('b1', [res[0][1]])
  gams.set('sse', [res[1][0]])
endEmbeddedCode b0 b1 sse
```

For a more detailed example, see the new **LeastSquares.gms** model from the GAMS Data Library.

3.7.1.4.14 Mosek

- New libraries 9.2.35.

3.7.1.4.15 MPECDUMP

- As [announced](#), dropped the tool MPECDUMP.

3.7.1.4.16 NLPEC

- Set the (hidden) GAMS option `relPath` to 1 for the execution of the scalar GAMS model. This fixes a problem when running NLPEC under KESTREL on NEOS.

3.7.1.4.17 ODHCPLEX

- New libraries 5.31.
- Fixed missing output of final CPLEX solve for fixed model.
- Fixed possible values of option `odhpresolve` to 1 and 2.

3.7.1.4.18 PYOMO

- As [announced](#), dropped the meta-solver PYOMO.

3.7.1.4.19 SCIP

- New libraries 7.0 (9a11615b47).

3.7.1.4.20 SoPlex

- New libraries 5.0.2.

3.7.1.4.21 XPRESS

- Non-convex QCPs don't have to be solved as NLP anymore, but are solved by XPRESS Nonlinear if a XPRESS-NLP or XPRESS-MINLP license is used (XPRESS-MINLP for MIQCPs).
- Fixed an issue that prevented the use of XPRESS Knitro with a XPRESS link license.
- Fixed a bug that prevented to solve (MI)QCP models with an XPRESS-MIP license.

3.7.1.5 Tools

3.7.1.5.1 CSV2GDX

- Report the line/field records to the log that lead to UNDF conversion for trace level 1 or bigger.
-

3.7.1.5.2 GAMS Studio

- New version 1.5.2.
 - New feature: Allow to edit and store custom color themes in the settings dialog.
 - New feature: Allow to define custom sections in the code, that can be folded using `$onFold / $offFold`.
 - Improved MIRO deploy dialog.
 - Added e-mail field for NEOS submissions in NEOS dialog. This can also be initialized from environment variable `NEOS_EMAIL` (which can be set permanently in `gamsconfig.yaml`).
 - Changed "Autosave on Run" setting to save ALL modified files, not just files of the current group.
 - Changed default light theme comment color to grey for better distinction from declarations.
 - Disabled GAMS syntax highlighting between `$onPut/$offPut` and `$onEcho/$offEcho`.
 - Added "select entry" on clicking timestamp in log.
 - Pressing `Enter` in the LXI tree scrolls to the corresponding position in the LST view.
 - Adjusted list of files in Reference File Viewer to be sorted by order in which they have been used.
 - Stability improvements and minor bug fixes, e.g.:
 - * Fixed rare problem with undetected external file changes.
 - * Fixed broken include file links in combination with end of line comments.
 - * Fixed missing request for new search cache after switching file.
 - * Fixed rare crash related to LOG output.
 - * Fixed endlessly recurring message box for invalid GDX file.
 - * Fixed missing update of parameter history for a file assigned to more than one group.
 - * Fixed search results not being highlighted in `.log` files.
 - * Fixed search performance problem after reset search parameters.
 - * Fixed behavior of `ESC` key when current widget has a selection.
 - * Fixed syntax highlighting of `table` statements not detecting row headers.
 - * Fixed print dialog shortcut not working directly after Studio launch.

3.7.1.5.3 GDX2VEDA

- Increase the maximum length of symbol names in the Veda definition file from 31 to 63.

3.7.1.5.4 GDXDUMP

- When using the option `noData`, empty symbols were still written with a data statement. Now empty symbols are also loaded from GDX.

3.7.1.5.5 GDXMRW

- Switch from C to C++ as the compiler for these utilities.
 - An `unordered_map` container is now used to address a performance issue with `rgdx` and filtered reads.
-

3.7.1.6 APIs

3.7.1.6.1 C++

- We plan to drop support for Microsoft Visual Studio 2015 for the C++ API with the next major release.

3.7.1.6.2 Python

- Added support for Python 3.9.
- `gams2numpy`:
 - New functions `gdxGetUelList` and `gmdGetUelList` allow to retrieve the list of UELs.
 - `gdxReadSymbolRaw` and `gmdReadSymbolRaw` do not return the list of UELs anymore.
 - `gdxReadSymbolStr` and `gmdReadSymbolStr` have a new optional input parameter `uelList`.
 - Fixed a bug that prevented loading of required shared objects in certain cases.

3.7.1.6.3 Matlab

- New [GAMS Matlab API](#)
 - The API is distributed as package `GAMS` located in `apifiles/Matlab/api`.
 - Examples can be found in `apifiles/Matlab/examples`.

3.7.1.6.4 GMO

- Fixed the functions `gmoGetObjSparse`, `gmoGetRowSparse`, `gmoGetColSparse`, `gmoHessLoad`, `gmoHessLagStruct`, and `gmoHessLagVal`: they now work properly when `forceLinear` is set, e.g., when using `GUSS`.

3.7.1.7 Model Libraries

3.7.1.7.1 GAMS API Library

- Changed the following examples to use the MONO compiler `mcs` instead of `dmcs` on Unix:
 - `CSBenders.gms` : Test object oriented C# API using a (multi-threaded) Benders Decomposition Algorithm
 - `CSCalcInverse.gms` : Test expert level C# API to read and write indexed GDX
 - `CSCutstock.gms` : Test object oriented C# API using a cutting stock example
 - `CSEX1.gms` : Test expert level C# API to read and write GDX
 - `CSEX2.gms` : Test expert level C# API to read and write GDX, set options and execute GAMS
 - `CSWarehouse.gms` : Test object oriented C# API using a warehouse location problem
-

3.7.1.7.2 GAMS Data Library New models:

- **LeastSquares.gms** : Demonstrate the use of `numpy.linalg.lstsq` on the diabetes test problem using `linalg.ols` (141)

3.7.1.7.3 GAMS Test Library New models:

- **show01.gms** : Test `$show` feature
- **dmpsym01.gms** : Test `dmpSym` and `dmpUserSym` feature
- **ide01.gms** : Basic test for IDE mode
- **cplex08.gms** : CPLEX test suite - conflict analysis (841)
- **convert13.gms** : CONVERT test suite - apply dict to gams format (842)
- **convert14.gms** : CONVERT test suite - nonlinear expression reformulations (843)
- **convert15.gms** : CONVERT test suite - support of nonlinear functions (844)
- **unload12.gms** : Make sure that `sameAs` and `diag` cannot be exported to GDX (845)
- **unload13.gms** : Unload with relaxed and full domain (846)
- **unload14.gms** : Check that unload happens at GDX file closing time (847)
- **dumpopt1.gms** : Test `verbatim dumpOpt` (848)

Removed models:

- LS01 (394)
- LS02 (395)
- LS03 (397)
- LS04 (398)

3.7.2 34.2.0 Minor release (February 05, 2021)

3.7.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Bruce McCarl.

3.7.2.2 Solvers

3.7.2.2.1 CONOPT

- New libraries 4.23.
 - Improvements for models with external equations, models with very large objective terms, and models with variables that only appear in the objective function.
- Fix parallel function evaluation.

3.7.2.2.2 CONVERT

- Fix variable coefficients in JuMP format.

3.7.2.2.3 CPLEX

- Fixed issue of non-working option `userincbicall`.
-

3.7.2.2.4 GAMSCHK

- The output formatting for the BLOCKPIC and MATCHIT procedures was adjusted to better handle very small or large values.

3.7.3 34.3.0 Minor release (February 25, 2021)

3.7.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Luis Alberto Herrero Rozas, Robert Howlett, Erwin Kalvelagen, Antti Lehtila, Bruce McCarl, and Shima Sasanpour.

3.7.3.2 GAMS System

3.7.3.2.1 GAMS

- Fixed a problem with embedded Python code and directory names longer than 128 characters.
- Fixed embedded Python code exceptions not handled correctly in case the exception message is empty.
- Fixed a problem where `dumpOpt` in combination with `SonVerbatim` produced wrong dollar conditions in an `$ifThen` block.
- Fixed an abnormal termination issue that occurred on Windows with pathologically-structured large QP models and solvers that use QP structure explicitly.
- Fixed a potentially broken work file written with `previousWork`. There was a problem introduced with GAMS 34.1 for models written to the work file.
- Fixed wrong behavior of `break` in certain loops over a set with a single element.

3.7.3.3 Solvers

3.7.3.3.1 CONOPT

- New libraries 4.24:
 - The pre-processor has been updated so it will always return a solution.
- Fixed incorrect reference of row / column in error message.

3.7.3.3.2 CONVERT

- Fixed possibly incorrect sign of objective function in formats with explicit objective function (e.g., Ampl or JuMP).
 - Fixed missing objective constant in formats with explicit objective function (e.g., Ampl or JuMP).
 - Fixed possibly missing variable / equation in formats GAMS, DictMap and DumpGDX when converting multiple formats at a time.
 - Fixed possibly missing parenthesis when dealing with minus zero.
-

3.7.3.3.3 GAMSCHK

- An error in the POSTOPT procedure that could lead to a segmentation fault or undefined behavior was fixed.
- The output formatting in the BLOCKLIST procedure was improved.

3.7.3.3.4 MOSEK

- New libraries 9.2.38.

3.7.3.3.5 ODHCPLEX

- Fixed issue of possibly incorrect objective bound reported by GAMS.

3.7.3.3.6 OsiMosek

- Fixed reported dual bound ([ObjEst](#)) and model status if solved without having closed the optimality gap.

3.7.3.4 Tools

3.7.3.4.1 GAMS Studio

- New version 1.5.4. with various bug fixes, stability improvements and minor enhancements, e.g.:
 - Added support for ports in GAMS Engine URL.
 - Improved visibility of current word and parentheses highlighting.
 - Fixed wrong color initialization for dark theme.
 - Fixed unwanted cursor jump when searching listing files without results.
 - Fixed MIRO execution issue if model filenames contain spaces.
 - Fixed GDX file reloading while being rewritten.
 - Fixed file links in log not handling relative paths on Windows.

3.7.3.4.2 GDXDUMP

- With option [noData](#) the empty symbols are marked with an end of line comment `!!empty`.
- The dollar control options are written in a consistent camel-case style if the output is in GAMS syntax.

3.7.3.4.3 GDXXRW

- Fixed a crash which happened when the [rng](#) was defined multiple times for a [text](#) by accident.
-

3.7.3.5 APIs

3.7.3.6 Expert Level APIs

- When introducing `gdxStoreDomainSets` with [GAMS 33](#) the default was accidentally set to 0 (don't enable use of one dimensional sets as domain sets). This has been corrected with this version. Setting `gdxStoreDomainSets` to 0 is for *real* experts only, since it can cause inconsistent GDX files when used in combination with `gdxSymbolSetDomain`.

3.7.3.6.1 Matlab

- Fixed Java class attribute access to support Matlab versions down to 2017b.

3.8 33 Distribution

3.8.1 33.1.0 Major release (November 01, 2020)

3.8.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Pablo Cachinero, Michael Ferris, and Ben Huebner.

3.8.1.2 Platforms

- We plan to increase the minimal required GLIBC version of the distribution for GNU/Linux to 2.17 with the next major release.
- We plan to drop support for Mac OS X 10.13 (High Sierra) with the next major release.

3.8.1.3 GAMS System

3.8.1.3.1 GAMS

- Allow to set the [.stage attribute](#) for discrete variables as well. This can be useful for certain solvers like [SCIP](#).
 - The status of the [Embedded Code Facility](#) has been changed from beta to released and fully supported. The nature of embedded code (especially Python embedded code) prohibits a level of backward compatibility as we guarantee for *intrinsic* GAMS language features: The Python interpreter together with distributed packages are evolving. Moreover, the GAMS/Python communication (e.g. via `gams.get()/set()`) will be subject to necessary modifications.
 - Allow multi-line Python strings constructed with triple quotes (`'''` or `"""`) in [embedded Python code](#) without getting additional spaces from the internal extra indentation. For multiple lines of Python code that use the line continuation character `\`, extra indentation is not omitted.
 - Added new dollar control options [\\$on/offIDCPprotect](#) to control if symbols which are declared as [external input](#) can be changed at execution time.
-

- Quoted text in a [display statement](#) adds now an entry to the navigation pane of the [LST Viewer in GAMS Studio](#) as well.
- Print an extra log line when [execute_load](#) (or one of its variants) is executed. When running GAMS from one of the [GAMS IDEs](#), this log line can be clicked to open the file loaded. Also the log lines generated for [execute_unload\[idx\]](#) were adjusted for better distinction. So adding these lines to a model

```
execute_unload      't.gdx', f;
execute_unloadidx  't.gdx', f;
execute_load       't.gdx', f;
```

generates this log:

```
--- GDX File (execute_unload) C:\t m p\t.gdx
--- GDX File (execute_unloadidx) C:\t m p\t.gdx
--- GDX File (execute_load) C:\t m p\t.gdx
```

- Fixed a problem using [captureModelInstance](#) with [solveLink=5/6/7](#); if [captureModelInstance=1](#) and [solveLink=6/7](#), [solveLink](#) will be reset to 3/4 automatically.
- Fixed a problem with file names longer than 128 characters for option [IDCGenerateJSON](#).

3.8.1.3.2 GMSPython

- Added the packages [urllib3](#), [certifi](#), and their dependencies.

3.8.1.4 Solvers

3.8.1.4.1 AMPL, LINGO, MPECDUMP, PYOMO

- We plan to drop the meta-solvers AMPL, LINGO, MPECDUMP, and PYOMO with the next major release. [Convert](#) will continue to produce model instances in these formats with the exception of MPECDUMP.

3.8.1.4.2 ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2020.2 on Linux and Mac OS X.

3.8.1.4.3 BARON

- New libraries 20.10.16.
 - Performance improvements including faster automatic differentiation, improved probing, improved local search, and improvements in BARON's cutting plane routines.
 - Changed default of option [WantDual](#) to 1. That is, dual values are now provided by default for nonlinear problems, too.
 - CBC updated to 2.10.5.

3.8.1.4.4 BDMLP

- We plan to drop the LP/MIP solver BDMLP with the next major release. Other free alternatives like Cbc outperform BDMLP.
-

3.8.1.4.5 BENCH

- We plan to drop the meta-solver BENCH with the next major release. Scripting tools provide much better facilities to generate benchmarks.

3.8.1.4.6 CONOPT

- New library 4.21.
 - Added a warning if the unscaled residuals in a feasible model are large due to very large scale factors.
 - Updated the selection of definitional constraints and improved the numerical behavior.
 - Changed tolerances in the derivative debugger related to very large derivatives.
 - Logic for Definition constraints updated:
 - * Infeasibilities are handled with a forward push routine and a backward pull routine.
 - * The way dense fill-in is removed is updated and the runtime is improved.
 - Changed a tolerance in the Derivative debugger.
 - Fixed an error in one-dimensional search when there are large 2nd derivatives or discontinuous 1st derivatives. Tried to recover a point that did not exist.
 - Fixed an error with model **hda**: there was a conflict between monotonicity and a tolerance.
 - Fixed some occurrences of system errors 12371, 12372, 88120.
 - Fixed a problem with a very small pivot (non-default tolerance) that created an incorrect penalty constraint.
 - Fixed an error that could appear in models with very long constraints.

3.8.1.4.7 Convert and ConvertD

- Added support for semi-integer and semi-continuous variables and complementarity constraints to scalar JuMP output format.
- Added information about discrete variables to the GDX files created by options **Hessian** and **Jacobian** for **CONVERTD**.
- The **Hessian** and **Jacobian** option for **CONVERTD** report the **.stage** variable and equation attribute in the variable and equations records only. In the past, the **.prior** and **.scale** attributes were reported.
- Fixed an error with suppressed complementarity constraints in Pyomo output.
- Fixed handling of semicontinuous variables with lower bound equal upper bound when writing MPS files.

3.8.1.4.8 Couenne

- As [announced](#), the solver Couenne has been removed from the GAMS system. For the time being, libraries of GAMS/Couenne are available at the [COIN-OR GAMSlinks project](#). Note, that GAMS does not test or offer support for these libraries.
-

3.8.1.4.9 CPLEX

- The two solver links CPLEX and CPLEXD were merged under the name CPLEX. Features that were formerly available in only one of the two solver links are now all usable with the new CPLEX link. Those features include:
 - Formerly only CPLEX:
 - * SOS1 and SOS2 sets
 - * Branching priorities
 - * Indicator constraints
 - * Conflict refiner
 - * Ranging / sensitivity analysis
 - * Solution pool for mixed-integer (quadratic) problems
 - Formerly only CPLEXD:
 - * Better handling of quadratic constraints (e.g. providing duals)
 - * Hot start capability in [GUSS](#)
 - * Solving multiple instances of `GAMSModelInstance` in parallel using GAMS APIs
 - * `SolveLink=solveLink.AsyncThreads`
 - * Cplex remote object and distributed MIP
 - * Benders decomposition
 - New features:
 - Partial MIP starts: allow to only include variable levels to the MIP start that are integer (within the tolerance [tryint](#), see [mipstart](#))
 - Multiple MIP starts provided via GDX (see [multimipstart](#))
 - Lower / upper bound ranging / sensitivity analysis (see [bndrng](#))
 - Lazy constraints (see [userlazyconcall](#) or [.lazy](#))
 - Added MIP statistics (e.g. number of nodes, solve time, objective lower and upper bounds) to BCH call via GDX files [usergdxnameinc](#) and [usergdxname](#).
 - Added options:
 - Added option [multimipstart](#) for multiple MIP starts
 - Added option [conflictdisplay](#)
 - Added option [multobjtolmip](#): the default value changes the behavior of the multi-objective optimization for continuous models
 - Added option [bndrng](#): lower / upper bound ranging / sensitivity analysis
 - Added option [indicoptstrict](#): handle erroneous indicator constraints
 - Added option [userlazyconcall](#): adding lazy constraints using [BCH](#)
 - Added dot option [.lazy](#): select linear constraints as lazy constraints
 - Added option [mipstopexpr](#): custom MIP stopping criterion to terminate during branch-and-bound
 - Changed options:
 - Changed behaviour of [rngrestart](#): If the specified file extension is GDX, the ranging results will be exported as GDX instead of GMS.
 - Changed behaviour of [miptracetime](#) and [miptracetime](#): option has no effect and MIP trace is appended when the solver reports global progress
 - Changed behaviour of [quality](#): added entries regarding indicator constraints and MIP condition numbers
 - Changed default of [randomseed](#) from 0 to 201909284
-

- Changed default of [tuningtilim](#) from 10000 to 1e75
- Changed default of [tuningdettilim](#) from 1e7 to 1e75
- Changed default of [workmem](#) from 128 to 2048
- Changed name [rtlcuts](#) to [rlcuts](#)
- Added documentation for partial MIP starts to [mipstart](#)
- Updated documentation for multiobjective optimization about CPLEX's two different strategies for continuous and discrete models (see also [multobjtolmip](#)).
- Fixed an error in BCH user heuristics where a false objective function of the incumbent was reported to CPLEX (in former CPLEXD link).

3.8.1.4.10 GUROBI

- New libraries 9.1.0.
- New option [rngrestart](#): Export sensitivity information as GAMS readable format (GMS or GDX).
- New option [mipstopexpr](#): Custom MIP stopping criterion to terminate during branch-and-bound.
- New option [norelheurwork](#): controls NoRel heuristic.
- New option [norelheurtime](#): controls NoRel heuristic.
- New option [tuncleanup](#): Enables a tuning cleanup phase.
- New option [poolgapabs](#): Maximum absolute gap for stored solutions.
- New option [integralityfocus](#): Indicator for stricter enforcement of integrality constraints.
- New option value -1 for option [.lazy](#): Treat as a user cut.
- Removed option [norelheuristic](#). A finer control of Gurobi's NoRelHeuristic is done through the newly introduced options [norelheurwork](#) and [norelheurtime](#).

3.8.1.4.11 IPOPT

- Changed default of option [acceptable_iter](#) from 15 to 0. This disables a heuristic in Ipopt to stop early with a solution that doesn't satisfy the usual termination tolerances when progress is slow.

3.8.1.4.12 Kestrel

- Fixed a bug that prevented job submission on Linux and Mac OS X due to a missing certificate.

3.8.1.4.13 Lindo/LindoGlobal

- New libraries 12.0.210.
 - Added the facility to detect [irreducible infeasible and unbounded sets](#) (IIS and IUS) and some [options](#) to control this.
 - Added support for [functions](#) `div`, `log2`, `round`, and `trunc`.
-

3.8.1.4.14 LocalSolver

- New libraries 9.5 (20200923).

3.8.1.4.15 LS

- We plan to drop the least-square solver LS with the next major release. The Python method `numpy.linalg.lstsq` included in the GAMS distribution can be used within an embedded Python code section to efficiently minimize the sum of squared residuals.

3.8.1.4.16 MOSEK

- New libraries 9.2.28.

3.8.1.4.17 ODHCPLEX

- More features available in the GAMS link:
 - SOS1 and SOS2 sets
 - Branching priorities
 - Indicator constraints
 - Partial MIP starts: allow to only include variable levels to the MIP start that are integer (within the tolerance [tryint](#), see [mipstart](#)).
 - Multiple MIP starts provided via GDX (see [multimipstart](#))

3.8.1.4.18 SCIP

- New libraries 7.0 (5b13bda).
- The workaround to assign a non-continuous variable to a block for problem decomposition (use suffix `.prior` without `priorOpt=1`) is not necessary anymore (`.stage` is now available for non-continuous variables). If one runs a model that continues to use this workaround with this version of GAMS, all non-continuous variables will end up in block 1 independent of the `.prior` value.

3.8.1.4.19 SHOT

- Gurobi is now available as [solver for the MIP or MIQCP relaxation](#) on Mac OS X, too.
- Fixed return of final dual bound found by SHOT to GAMS (`objEst` attribute).

3.8.1.4.20 SolveEngine

- Dropped link to Satalia SolveEngine because Satalia retired SolveEngine Beta and a successor is not yet available.
-

3.8.1.4.21 SoPlex

- New libraries 5.0 (2afa64b6).

3.8.1.4.22 Xpress

- New libraries 8.10.1.
 - Removed option `mislpAlgorithmFinalSLP`.
 - Removed option `mislpAlgorithmNoFinalRounding`.
 - Added option `mislpCutStrategy`.
 - Added option `mipstopexpr`: Custom MIP stopping criterion to terminate during branch-and-bound.

3.8.1.5 Tools

3.8.1.5.1 GAMS IDE and GAMS Studio

- Fixed that Bonmin and Ipopt solver option files could not be created or edited via the options editor.

3.8.1.5.2 GAMS Studio

- New version 1.4.2.
 - New feature: Remote execution with **GAMS Engine**.
 - New feature: Allow to open `$(bat|lib)include` files by context menu, F2 shortcut, or holding `Ctrl` and click on the filename.
 - Renamed **About GAMS** dialog to **GAMS Licensing** dialog to make it more clear, that this allows to install a GAMS license.
 - Improved GAMS license detection during Studio start and in GAMS Licensing dialog; if the content of a license file is in the clipboard when starting Studio, a dialog to install the license is started.
 - Added support for comma separated list as file filter in search dialog.
 - Changed behavior of "Whole Words" search option: `$` is now considered a word boundary.
 - Reworked NEOS integration, e.g.:
 - * Allowing to kill submitted active jobs.
 - * Moved NEOS control options into dialog.
 - * Changed default parameter from `forceWork=1` to `previousWork=1`.
 - * Improved handling of network errors.
 - Minor bug fixes and improvements, e.g.:
 - * Added dialog for confidentiality and terms of use confirmation before submitting models to NEOS.
 - * Added Arrow Up/Down as shortcuts to jump to search results when **Results View** is focused.
 - * Added tooltips to options in search dialog.
 - * Syntax coloring improvements.
 - * Fixed file codec selection for the model assembly dialog.
 - * Fixed and enhanced reloading mechanism of the GDX Viewer.
 - * Fix to ensure that lowercase directory names are always used for MIRO directories, e.g. `data_mymodel` instead of `data_myModel`.
 - * Fixed empty history on welcome page when starting Studio with no tabs open.
 - * Fixed potential crash if files are modified in the background while a dialog is open.

3.8.1.5.3 MessageReceiverWindow

- Since GAMS does not support any 32bit platform anymore, this tool is compiled for x64 instead of Any CPU now.

3.8.1.5.4 MODEL2TEX

- Deprecated command line parameter `-e` has been removed.

3.8.1.6 APIs

3.8.1.6.1 .NET

- Since GAMS does not support any 32bit platform anymore, the .Net DLL is compiled for x64 instead of Any CPU now.

3.8.1.6.2 C++

- Adjusted compilation of examples to new handling of critical sections in [expert level APIs](#).
- Adjusted some examples since GAMS/CplexD is now a synonym for [GAMS/Cplex](#).

3.8.1.6.3 Python

- New experimental API `gams_magic` that enables the use of GAMS in [Jupyter](#) notebooks has been added. This release of `gams_magic` should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
- New API `gams_engine` that allows the creation of Python clients for [GAMS Engine](#) has been added.

3.8.1.7 Expert Level APIs

- The new files `gcmt.c` and `gcmt.h` are now required when compiling/linking C expert level API files (e.g. `gdxcc.c/h`) to protect critical sections in the interface for multi-threaded applications. On some platforms, this might also require linking against additional libraries, e.g. `libpthread` on Linux. Adding the define `GC_NO_MUTEX` when compiling the C expert level API files provides the old behavior.
- Added new call `gdxStoreDomainSets` to the GDX API to control the use of one-dimensional sets as domain sets. Disabling the storage of domain information for a one-dimensional set when writing to GDX saves memory but prevents the set from being used for domain checking.

3.8.1.8 Model Libraries

3.8.1.8.1 GAMS API Library New models:

- `Pgams_engine.gms` : Test `gams_engine` API (60)
 - `Pneos.gms` : Test submitting GAMS models to NEOS server (61)
-

3.8.1.8.2 GAMS Test Library New models:

- lindgl05.gms : Test new functions added to GAMS/Lindo(Global) (828)
- cplex04.gms : CPLEX test suite - free gams model test (829)
- cplex05.gms : CPLEX test suite - interactive (830)
- cplex06.gms : CPLEX test suite - multiobjective (831)
- cplex07.gms : CPLEX test suite - bch incumbent checker (832)
- sens01.gms : sensitivity / ranging test (833)
- mipstopexpr1.gms : mip stop expression test (834)
- attrib01.gms : Test attribute setting and preservation in Convert (835)
- gamsjupyter01.gms : Test GAMS Jupyter Notebooks (836)
- cmi01.gms : Test captureModelInstance option with all solveLink combinations (837)

3.8.2 33.2.0 Minor release (December 01, 2020)

3.8.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.8.2.2 GAMS System

3.8.2.2.1 GAMS

- Fixed some problems with [Implicit set definition](#):
 - When doing a filtered load from [GDX](#) or [embeddedCode](#), the defined set only gets the elements actually loaded but not the ones that were filtered out.
 - Merging to start of existing data (with [\\$onMulti](#)) does not lead to out-of-order data anymore.

3.8.2.3 Solvers

3.8.2.3.1 CPLEX

- Fixed issue where option [writemst](#) did not produce any output.

3.8.2.3.2 KNITRO

- Add workaround to avoid abnormal termination of Knitro 12.2 libraries on AMD processors.

3.8.2.4 Tools

3.8.2.4.1 GAMS Studio

- New version 1.4.5 with various bug fixes, stability improvements and minor enhancements, e.g.:
 - Added error output to system log if the given MIRO installation location is invalid.
 - Disabled run actions and MIRO menu when active group has no active executable file.
 - Fixed a problem with GAMS parameters being ignored in rare cases.
 - Fixed a potential crash when reloading a large `gms` file while the syntax highlighter was still processing that file.
 - Improved Search and Replace, e.g.:
 - * Improved performance of `Find Next/Previous`.
 - * Added possibility to interrupt `Find Next/Previous`.
 - * Fixed a problem which did not allow to jump to search results beyond the 50,000th match of the search term.
 - * Fixed handling of wrapped lines in search.
 - Improved MIRO and Engine dialogs, e.g.:
 - * Removed standalone MIRO assembly file dialog and added it to a new reworked MIRO deploy dialog instead.
 - * Fixed version comparison in GAMS Engine dialog.

3.9 32 Distribution

3.9.1 32.1.0 Major release (July 31, 2020)

3.9.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Youngdae Kim, Michaja Pehl, Thomas Rutherford, and Igor Sheleg.

3.9.1.2 Platforms

- Dropped support for Sparc Solaris and AIX systems.

3.9.1.3 GAMS System

3.9.1.3.1 GAMS

- New default values for some GAMS options:

	new default	old default
logOption	3	1
empty	on	off
errMsg	1	0
errorLog	2147483647	0
lstTitleLeftAligned	1	0
putPW	32767	255
pageContr	2	3
pageSize	0	58
pageWidth	32767	255
optCR	0.0001	0.1
intVarUp	0	1
resLim	1e10	1000
solveLink	2	0
iterLim	2147483647	2e9

In order to work with the default values active in GAMS 31, copy the file `gams31config.yaml` (part of the GAMS system directory) into the location searched by GAMS for configuration files (e.g. the GAMS system directory) with the name `gamsconfig.yaml`.

- Extended the impact of command line parameter `etLim`, so that it reduces `resLim` for models solved automatically if that is greater than `etLim - timeElapsed`.
- Added new option `zeroToEps` to allow reading zero values as EPS at execution time.
- Added new options `procTreeMemMonitor` and `procTreeMemTicks` to enable monitoring of a memory high-water mark for the GAMS process and all its children.
- Adjusted behavior of command line parameters `restart`, `restartNamed`, `save`, `saveObfuscate`, `xsave`, and `xsaveObfuscate`: If a file name is given including a file extension, this extension is kept. In the

past it was replaced by a default extension. Also, ? is not allowed in the file name when writing a save file anymore.

- Extended influence of command line parameter `inputDir`, so that it also extends the search path for GDx files loaded with `$gdxIn`.
- Extended the search space for files included via `$libInclude`, `extrinsic function libraries`, and `external equation libraries`: Now, the directories `inclib`, `extrinsic_functions`, and `external_equations`, resp., are checked in all `GAMS standard locations` before `[GAMS System Directory]/inclib`, `[GAMS System Directory]`, and `[GAMS Working Directory]`, respectively.
- Renamed the command line parameter `execErr` to `maxExecError` to be in sync with the related function `maxExecError`. The old name is still available as a synonym.
- Added command line parameter `previousWork` to instruct GAMS to write a workfile using the format of an older GAMS version. This is useful in particular with submission to the NEOS server.
- Adjusted the function values returned by the power functions (e.g. `x**y`). In some cases where `x` is very small and positive the derivatives may become unbounded but the function values are well-behaved and can still be computed precisely and without overflow.
- Fixed a problem on Linux when the `XGD_CONFIG_DIRS` or `XGD_DATA_DIRS` variables have more than 7 directory entries.

3.9.1.3.2 GMSPython

- Added the packages `pandas`, `numpy`, `openpyxl`, `schema`, `tqdm` and their dependencies.

3.9.1.3.3 Mac OS X Installer

- New way to install GAMS on Mac OS X using a PKG installer, see the [installation notes](#).

3.9.1.3.4 Windows Installer

- Added a checkbox for enabling/disabling the creation of a start menu entry to the `Select Start Menu Folder` Wizard page. The default state of the checkbox is inherited from previous installations.
- Command line argument `/noIcons` can be used in order to check the `Don't create a Start Menu folder` checkbox on the `Select Start Menu Folder` page.
- New command line argument `/desktopIcons=yes|no` (default:yes) can be used in order to turn on/off the creation of Desktop icons.
- The installer now writes all registry entries either to `HKEY_CURRENT_USER\Software\Classes` (current user) or `HKEY_LOCAL_MACHINE\Software\Classes` (all users).
- Show warning in case the system `GAMSDIR` environment variable is updated, but a user `GAMSDIR` environment variable exists and not vice versa.
- Always notify the operating system about changed environment variables.
- Changed the default installation location from `C:\GAMS\win64\XX.Y` to `C:\GAMS\XX` (e.g. `C:\GAMS\32`).
- Desktop shortcut names have been changed to `GAMS IDE 32` and `GAMS Studio 32`.
- Start menu entry reads `GAMS XX` (e.g. `GAMS 32`) instead of `GAMS XX.Y` (`win32/win64`).
- Fixed a bug that prevented file associations (`.gdx` and `.gms` files) from working properly in certain cases.

3.9.1.4 Solvers

3.9.1.4.1 Bonmin, CBC, Couenne, LocalSolver, Osi links, SHOT, SoPlex

- Fixed that a setting of GAMS option `iterlim` to 2000000000 (the previous default) was not passed on to the solver.

3.9.1.4.2 CONOPT

- Added Conopt4 to the [thread-safe solvers](#). It now can be used with `solveLink=6`.

3.9.1.4.3 CONVERT

- New output format: JuMP scalar model.

3.9.1.4.4 GUROBI

- Fixed a bug introduced with 31.1.0 and only partly fixed in 31.1.1 where the `GRB_LICENSE_FILE` environment variable was incorrectly dropped.

3.9.1.4.5 Ipopt

- Updated Mumps to 5.3.3.

3.9.1.4.6 KESTREL

- Kestrel interface source code has been ported from Python 2 to Python 3.
- Also on Windows, the source code of the link is now distributed instead of a binary.
- The GAMS distributed Python interpreter (`GMSPython`) is used for running the Kestrel client.

3.9.1.4.7 KNITRO

- New libraries 12.2.2.
 - Knitro 12 adds many improvements to the Knitro mixed-integer (MIP/MINLP) branch-and-cut solver. Several new cuts controlled by Knitro user options have been introduced including mixed-integer rounding cuts, zero-half cuts and clique cuts. In addition, improvements were made to the knapsack cuts implementation.
 - Knitro 12 offers several enhancements to the Knitro presolver. The presolver has been extended to allow multiple passes through the presolve operations. There are new presolve operations for variables in complementarity constraints and to tighten variable bounds.
 - Knitro 12 offers efficiency and storage/memory improvements in the callable library C API - the one used in the GAMS link!
 - Knitro 12.2 enables default parallelism when using multi-start or multi-algorithm features.
 - Knitro 12.2 offers several performance speed-ups:
 - * on very large models with the default (i.e. interior-point) algorithm: potentially dramatic
 - * when using the limited-memory BFGS Hessian option
 - * in the SQP algorithm
 - A number of minor bug fixes and performance improvements are included in this release: rare segmentation fault with knapsack cuts fixed, bug in convexity detection fixed, poor/slow choice of algorithm for LP sub-problems fixed, poor/slow presolve issue on MIP models fixed.

3.9.1.4.8 LocalSolver

- New libraries 9.5 (20200701).
- Setting `iterlim` to the maximal possible value (2147483647) will not change the default iteration limit of LocalSolver anymore, see also the documentation.

3.9.1.4.9 Mosek

- New libraries 9.2.14.

3.9.1.4.10 ODHCPLEX

- New libraries 5.2.2.
- New options `integerTol`, `subOrder`, `subPresolve`, `zeroTol`, `penPerturb`, and `threadZeroSync` have been added. The options `newCallback` and `variableClean` allow for more option values.
- New handling of solutions that are not quite integer but within the integer feasibility tolerance of CPLEX but become infeasible if one rounds the integer variables. ODHCPLEX used to reject such solutions (while in CPLEX (and other MIP solvers) such solutions are considered acceptable for the user).

3.9.1.4.11 SoPlex

- Setting `iterlim` to the maximal possible value (2147483647) will not change the iteration limit of SoPlex anymore, so that SoPlex will run without a limit.

3.9.1.4.12 XPRESS

- New libraries 8.8.5.
 - New solver: XPRESS SLP and XPRESS Knitro for nonlinear (mixed-integer) programming.
 - XPRESS SLP is a sequential linear programming (SLP) solver and XPRESS Knitro equals [Knitro](#), but the problem is passed through the XPRESS nonlinear presolve.
 - Both can solve convex MINLP to global optimality and act as a heuristic method for general nonconvex problems.
 - XPRESS SLP offers a multistart to run different configurations in parallel or to start with multiple initial guesses.
 - If both XPRESS SLP and XPRESS Knitro are licensed, XPRESS can choose the nonlinear solver automatically based on instance attributes.
 - For more information about the XPRESS SLP algorithm, see [FICO Xpress Optimization Help \(Nonlinear Reference Manual\)](#).
 - XPRESS SLP and XPRESS Knitro are available on all supported platforms.
 - XPRESS SLP requires a license for continuous nonlinear models or for mixed-integer nonlinear models.
 - XPRESS Knitro requires a GAMS/Knitro license in addition to the XPRESS license for (mixed-integer) nonlinear models.
-

3.9.1.5 Tools

3.9.1.5.1 CHK4UPD

- If the components of the checked license have different expiration dates, the validity of the license always refers to the base component now. In the past, the component with the oldest expiration date was used.

3.9.1.5.2 FINDTHISGAMS

- Support for registry key changes of the [Windows installer](#) has been added.
- New command line parameters `list`, `delete`, `write`, and `ide`. See the [documentation](#) for detailed information.

3.9.1.5.3 GAMS Studio

- New version 1.3.3.
 - New feature: [Code Folding](#)
 - * Shortcut `Alt+L` switches folding state of the current block.
 - * Shortcut `Alt+O` folds and `Shift+Alt+O` unfolds all foldable blocks.
 - * Code folding is possible for pairs of parentheses that span multiple lines or Dollar Control Options that come in pairs.
 - New feature: Remote execution on [NEOS Server for Optimization](#)
 - * Models can be executed remotely via the menu `GAMS -> Run NEOS` or the execute button located in the toolbar.
 - * Note: Usually it takes some time before the GAMS version at NEOS gets updated. During that time one might get an error because of an incompatible workfile version. This can be avoided by setting the command line parameter `previousWork` to 1.
 - New feature: [Navigation History](#)
 - * `Mouse button 4/5` or `Alt+Left/Right` on Windows/Linux and `Ctrl+[/]` on Mac OS X can now be used to jump back to a previous text cursor positions or forward again. This is helpful to quickly navigate between different locations in files that one is currently working with.
 - New feature: [Distraction Free Mode](#)
 - * Distraction Free Mode quickly turns off everything except for the editor window for better focus on modeling work. This is especially useful for small screens. When leaving Distraction Free Mode all Studio widgets will be put back where they were. To switch to and from Distraction Free Mode go to the Menu `> View > Distraction Free Mode`, or press `Ctrl+Alt+Enter` on Windows and Linux, or `Cmd+Option+Enter` on Mac OS X.
 - New feature: Print support for text files (`gms`, `txt`, `lst`, `dmp`, ...). This is accessible with the shortcut `Ctrl+P` or in the menu `File -> Print`.
 - Added automatic switch to first non-empty tab when searching the [Model Library Explorer](#). The old tab selection is restored if that tab contains results again.
 - Added header labels to copy actions in [GDX Viewer table view](#). Two additional entries that allow to copy without the labels are available via the context menu.
 - Added `dmp` extension to list of executable file types.
 - Added `Shift+Option+Up/Down` hotkey to start block-edit on Mac OS X.
 - Changed [terminal](#) to native Mac OS X Terminal on Mac OS X.
-

- Stability improvements and minor bug fixes, e.g.:
 - * Fixed syntax highlighter not recognizing "+" and "-" in "Model" statement.
 - * Fixed missing LXI pane for files containing more than one dot.
 - * Fixed group name for `gms` files containing more than one dot in the name.
 - * Fixed rare random crash when opening the MIRO Model Assembly File dialog.
 - * Fixed some icons not following selected theme.
 - * Fixed line wrapping behavior not following settings.
 - * Fixed that bookmarks in help view were not being saved permanently.
 - * Fixed crash on reading LXI files containing empty lines.
 - * Fixed some issues with the license file detection and info in the "About GAMS" dialog.
 - * Fixed missing reload if a opened GDX file gets recreated.

3.9.1.5.4 MODEL2TEX

- Source code of `model2tex` has been ported to Python 3 and does not support Python 2 anymore.
- Distribute source code instead of binary on Windows. `model2tex.exe` has been replaced by `model2tex.cmd`.
- The GAMS distributed Python interpreter (`GMSPython`) is used for executing `model2tex`.
- Command line parameter `-e` has been deprecated and will be removed in the future.

3.9.1.6 APIs

- Automatically finding a GAMS installation from the Windows registry has been changed according to the changes to the [Windows installer](#) (`[HKEY_CURRENT_USER|HKEY_LOCAL_MACHINE]\Software\Classes\gms.locat`).
- The performance of the Object-oriented APIs (in particular the class `GAMSDatabase`) has been improved.

3.9.1.6.1 .NET

- Change to `GAMSWorkspace.AddCheckpoint`: The `checkpointName` is now determined automatically as well when given as `string.Empty`, not only when set to `null` or being omitted.

3.9.1.6.2 Python

- As [announced](#), dropped support for Python 2. The Object-oriented API as well as the expert-level APIs can be used with Python 3.6, Python 3.7, and Python 3.8.
 - An experimental object oriented data interface called `gamstransfer` has been added. This interface is built on the expert-level Python APIs and simplifies the work of reading and writing GDX files. The underlying data structure is built on structured numpy arrays; this structure allows data to be easily converted directly to Pandas DataFrames (or other native Python data types). This release of `gamstransfer` should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
 - New experimental API `gams2numpy` for communicating data between GAMS and numpy arrays has been added. This release of `gams2numpy` should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
-

3.9.1.7 Model Libraries

3.9.1.7.1 GAMS Model Library New models:

- `scenmerge.gms` : Combining scenario results in a directory tree with `gdxmerge` (427)

3.9.1.7.2 GAMS Test Library New models:

- `zerotoeps1.gms` : Test data loading with `$onEps` and option `zeroToEps` (821)
- `idir01.gms` : Test including files from different locations (822)
- `mrw02.gms` : Test `MessageReceiverWindow.exe` from Python (823)
- `memmon1.gms` : Test `procTreeMemMonitor=1` behavior (824)
- `gams2numpy01.gms` : Test `gams2numpy` Python API string mode (826)
- `gams2numpy02.gms` : Test `gams2numpy` Python API raw mode (827)

3.9.1.7.3 GAMS API Library New models:

- `Pgamstransfer.gms` : Test `gamstransfer` API (58)
- `Pgams2numpy.gms` : Test `gams2numpy` API (59)

3.9.2 32.2.0 Minor release (August 26, 2020)

3.9.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Charles Chan, Ricardo Lima, Sandro Konrad Luh, Ami Reznik, Tom Rutherford, and Berk Uzundere.

3.9.2.2 GAMS System

3.9.2.2.1 GAMS

- Introduced new values 3 and 4 for option [savePoint](#) that allow to save the point file in the scratch directory.
- Fixed a bug which in rare cases caused GAMS to write files exceeding 80,000 characters per line (and thus the maximum line length GAMS can handle) when the command line parameter [dumpopt](#) was set.
- Fixed a bug in restart files that incorrectly stored the location of the GAMS configuration file ([gmscmpXX.txt](#)).
- Fixed a bug that is related to providing the GAMS configuration file ([gmscmpXX.txt](#)) explicitly via command line parameter [subSys](#).
- Fixed reporting of compilation errors in encrypted input files.
- Fixed the count of discrete variables in the [model statistics](#) in case any discrete variable was fixed.

3.9.2.2.2 Windows Installer

- Fixed a bug that prevented registry entries from being removed correctly during uninstallation.

3.9.2.3 Solvers

3.9.2.3.1 Gurobi

- New libraries 9.0.3.

3.9.2.3.2 Lindo/LindoGlobal

- New libraries 12.0.208.
 - Fixed a rare problem with stochastic problems.

3.9.2.3.3 Mosek

- New libraries 9.2.18.

3.9.2.3.4 SCIP

- New libraries 7.0 (80549b8905).
- PaPILO updated to 1.0 (d0e5444cd).

3.9.2.3.5 SoPlex

- New libraries 5.0 (3623dbc0).

3.9.2.4 Tools

3.9.2.4.1 GAMS Studio

- New version 1.3.4.
 - Minor bug fixes, e.g.:
 - * Show community license type in the solver matrix.
 - * Fixed missing tab browser button when Studio starts in maximized or full-screen mode.
 - * Fixed insertion of auto-closing characters in unwanted situations (e.g. beginning of a word).

3.9.2.4.2 GDX2VEDA

- Fixed a bug which in rare cases crashed the tool for large data sets on Windows.

3.9.2.5 Model Libraries

3.9.2.5.1 GAMS Test Library Updated models:

- `savep1.gms` : `execute_loadpoint`: `save point` - `clear` - `loadpoint` - `reoptimize` (65)
-

3.10 31 Distribution

3.10.1 31.1.0 Major release (May 01, 2020)

3.10.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Christoph Böhringer, Wolfgang Britz, Andreas Lundell, Scott McDonald, Victor Nechifor, Renger van Nieuwkoop, A. Omid, Christoph Palmeyer, Soumya Roy, Thomas Rutherford, Alireza Soroudi, Tim Varelmann, and Elizabeth Wong.

3.10.1.2 Platforms

- As [announced](#), dropped support for 32-bit MS Windows.

3.10.1.3 GAMS System

3.10.1.3.1 GAMS

- Extended the syntax of the [model statement](#) to allow to [restrict the domain of variables](#) used in the model at one spot.
- Added dollar control options [\\$on/offSuffixDLVars](#) and command line parameter [SuffixDLVars](#) to control whether it is allowed to use suffixes on [variables with limited domains](#) in a model.
- Added new command line parameters to initialize the state of certain [dollar control options](#): [Digit](#), [Empty](#), [EolCom](#), [Filtered](#), [InlineCom](#), [Listing](#).
- Extended the behavior of the command line parameter [checkErrorLevel](#), so that it also initializes the state of the dollar control option [\\$on/offCheckErrorLevel](#).
- Extended the behavior of the command line parameter [strictSingleton](#), so that it also initializes the state of the dollar control option [\\$on/offStrictSingleton](#).
- Added new command line parameters to set the default values for certain [put file attributes](#): [PutND](#), [PutNR](#), [PutPS](#), [PutPW](#).

- Removed the limit on the number of significant digits allowed in floating-point values in GAMS source.

Historically, GAMS has run on widely different platforms where even the floating-point arithmetic varied. To ensure the precision specified in the GAMS input didn't exceed what could be stored and computed with as GAMS ran, we limited the amount of precision (i.e. the number of digits used for numbers in the GAMS source) that could be specified. This limit could be relaxed by using the [\\$offDigit](#) control.

Modern computers all support IEEE double-precision arithmetic. It's a well-accepted and familiar standard, and the new behavior - to convert the decimal value in the GAMS source into the nearest double-precision value, regardless of the number of digits specified - is what is generally expected. There is a limit (currently 40) on the number of digits treated as significant: digits beyond this point are quietly treated as zero.

For "nice" values (i.e. those with fewer than 17 digits of precision and exponents of limited size, like 3.14159 or 2.5032e10) there is no difference in the old and new behavior. But for values specified with 17 or more digits of precision or having exponents of large size, the double-precision values can vary slightly between the old and new systems. The new values are the correct ones.

The new command line parameter [sys18](#) has been added in case any users require the old behavior.

- New options [encryptKey](#) and [decryptKey](#) to encrypt and decrypt source based on a key rather than a [target license](#). This allows developers to create [encrypted input files](#) that can be executed with any GAMS license and the right key.
- GAMS will search standard locations for the license file `gamslice.txt` including the GAMS system directory. The standard locations for your operating system are described in the [installation notes](#). You can also continue to use the [license](#) command line parameter to point to a specific license file.
- GAMS can now use a configuration file `gamsconfig.yaml` to specify default values for command line parameters and environment variables: see details in [GAMS Configuration in YAML Format](#). This can be used to implement user-specific default option settings that are shared between different GAMS versions. In the future, we also expect to use this capability to support the setting of options and defaults that support backward compatibility: this will become important as we change GAMS defaults in significant ways to modernize the user experience in the light of current computing environments and user expectations.
- Added [system suffixes](#) `%system.licenseFileName%`, `%system.userConfigDir%`, and `%system.userDataDir%`.
- Embedded Python Code Facility:
 - Embedded Python code can be used with [Python 3.6, 3.7, and 3.8](#). `GMSPython` is used for embedded code by default on the core platforms.
 - The GAMS command line parameter `pySetup` has been deprecated. The environment variable `GMSPYTHONLIB` that needs to point to the Python library (e.g. `python38.dll` on Windows) determines the Python installation to be used in [embedded Python code](#).
 - The `gams.set` method to write data back to GAMS has a new argument `mapKeys` that allows to pass a callable to remap the elements of the key.
- Removed GAMS return code 116 ("Could not find GMSPython").
- Fixed the `card` operator for scalar symbols, so that it always returns 1 when the symbol has data. In the past it might have been wrong for symbols that had no data in the declaration, but just from an assignment.
- Fixed issues where GAMS would crash on exceptionally large models (more than 268 million rows or columns) with certain non-default options selected.
- Fixed a problem which allowed multiple declarations of the same equation or variable when `$offMulti` was active.
- Fixed some 3-argument intrinsic functions whose third argument was optional (e.g. `ncpVUSin`) - these were not taking the default value for the third argument correctly into account when called with two arguments.
- Fixed a bug which caused wrong execution of `$onPut` and `embeddedCode` after [Programming Flow Controls](#) that were not terminated with a semicolon.
- Fixed a bug which caused variable and equation records fixed at 0 to be dumped incorrectly with `dumpOpt`.
- Fixed incomplete warning when writing a non-default status of `$on/offEmpty` to a save file.
- `execMode` did not prevent the execution of `scriptExit`. This has been fixed.

3.10.1.3.2 GMSPython

- GMSPython has been upgraded from Python 3.6 to Python 3.8 and comes without Python package installer `pip`.
 - Added the package `ply`.
-

3.10.1.3.3 Libinclude

- The libinclude file `rank.gms`, which is based on the `gdxrank` tool, got a complete overhaul. The temporary GDX files resides now in the scratch directory, so multiple GAMS models using `rank.gms` can coexist in the same working directory. Moreover, the percentile calculation works with sort values that may include `+inf/-inf`. Some checks have been added that result in execution errors in case the operation was not successful, e.g. if `gdxrank` failed to sort.
- Fixed a bug in `pyEmbMI.gms` that prevented string options from being set properly.

3.10.1.3.4 Documentation

- Improved the layout. The new layout provides a more responsive view on a smaller screen.

3.10.1.3.5 Windows Installer

- Default installation mode has been changed from `All Users` to `Current User`. This can be changed on the `Advanced Options` page or by providing `/allUsers=yes` when running the installer from a command prompt.
- The default application used for associating GAMS (`.gms`) and GDX (`.gdx`) files has been changed from the `GAMS IDE` to `GAMS Studio`.
- New command line argument `/allUsers=yes|no` (default:`no`) can be used in order to install for `All Users` instead of `Current User`.
- New command line argument `/noLicense=yes|no` (default:`no`) can be used in order to prevent any GAMS license from being written.
- New `GAMS License` page:
 - Allows to select a GAMS license to be used. The installer tries to find GAMS licenses in different locations and automatically selects a license to be used with the following precedence:
 - * Clipboard
 - * `C:\Users\username\Documents\GAMS`
 - * Previous GAMS installation found from the registry (User)
 - * Previous GAMS installation found from the registry (System)
 - A license file is written to `C:\Users\username\Documents\GAMS` when installing for `Current User` (default). Installing for `All Users` or checking `Write License to System Directory` will write the license to the system directory instead.

3.10.1.4 Solvers

3.10.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2020.0 on Windows.

3.10.1.4.2 BARON

- New libraries 20.4.14.
 - Improved local search strategies.
 - Increased effectiveness of cut pool manager.
 - Improved relaxations for MIQPs.
 - Added new `LP subsolver` based on HSL's LA04.
-

3.10.1.4.3 CBC

- GAMS/CBC did not use the default value for all parameters as documented and as used in the CBC standalone program. This has been fixed. To restore some of the previous behavior, the following parameter setting can be used:

```
nodeStrategy      hybrid
preprocess        off
cuts              off
cliqueCuts       off
flowCoverCuts    off
gomoryCuts       off
knapsackCuts     off
mirCuts          off
twoMirCuts       off
probingCuts      off
zeroHalfCuts     off
heuristics       0
feaspump         off
greedyHeuristic  off
roundingHeuristic off
```

3.10.1.4.4 CONOPT

- New libraries 3.13L.
 - Added new facilities to print the variables changed by the pre-processor. See options [prprec](#), [rtpprec](#), and [rtprel](#).
- New libraries 4.19.
 - Some errors related to the duals and basic/nonbasic flags for some definitional constraints and forcing constraints have been corrected.
 - The two tolerances `Tol_IFixed` and `Tol_DFfixed` for when a variables is fixed have been unified into a single tolerance, [Tol_Fixed](#).
 - The routine for detecting definitional constraints has been simplified and some options from previous versions are no longer used (`Flg_DC_Unique`, `Lim_DFVars`, and `Tol_Def_Ini`) and [Tol_Def_Mult](#) has a new default value.

3.10.1.4.5 CONVERT

- Added support for option [HeaderTimeStamp](#), which was added for `ConvertD` before, in `Convert`.

3.10.1.4.6 COUENNE

- We plan to drop Couenne with one of the next major releases.

3.10.1.4.7 CPLEX

- Fixed incorrect display of selection of [LPMethod](#) when rerunning without presolve for infeasible model.
 - Fixed incorrect selection of [LPMethod](#) when rerunning without presolve for infeasible model in `CplexD`.
-

3.10.1.4.8 GUROBI

- New libraries 9.0.2.
- If GAMS/Gurobi is licensed, the setting of the environment variable `GRB_LICENSE_FILE` is ignored. The setting of this environment variable interfered with the GAMS/Gurobi licensing.

3.10.1.4.9 IPOPT

- New libraries 3.13.2.
 - MA28 can no longer be loaded at run-time from a user-provided HSL library. Removed option 'ma28_pivtol'.
 - The default of option `ma77_order` has changed from 'amd' to 'metis'.
 - The default of option `ma97_print_level` has changed from 0 to -1.
 - The default of option `mumps_pivot_order` has been changed from 7 to 5 to work around a bug in MUMPS.
- Updated MUMPS to version 5.3.1. MUMPS has been build with OpenMP support enabled.
- Updated METIS (used by HSL codes and MUMPS) to version 5.1.0.

3.10.1.4.10 KESTREL

- Fixed a problem with the control file version that prevented Kestrel from being used in GAMS 30.

3.10.1.4.11 Lindo/LindoGlobal

- Increased the number of allowed nonlinear nonzeros in the global solver from 30 to 50 when operating under a demo license.

3.10.1.4.12 LocalSolver

- New libraries 9.5 (20200409).
 - Performance improvements on mixed-variable models like unit commitment or network design problems.
 - Performance improvements on routing and scheduling problems like CVRPTW or jobshop scheduling problems.
 - Better and faster lower bounds for nonlinear problems as well as for combinatorial problems like TSP.
- New parameter `verbosity`.
- Fixed handling of semi-integer variables.

3.10.1.4.13 MOSEK

- New libraries 9.2.4.
 - Avoid MOSEK error 1243 on general nonlinear models.
-

3.10.1.4.14 SCIP

- New libraries 7.0.0 (0bc4dc9c65).
 - The symmetry code has been completely restructured and modularity has been increased.
 - * It is now possible to use orbitopes (i.e., polyhedral symmetry handling techniques) and orbital fixing on the same instance.
 - * Branching decisions can now take symmetry information into account by filtering first variables from orbits (new parameter [branching/relpscost/filtercandssym](#)) and transferring pseudo cost information to variables in orbit (new parameter [branching/relpscost/transsympscost](#)).
 - * Improved performance of orbital fixing and orbitope propagation.
 - * Reduced memory usage of symmetry detection.
 - * Improved detection of packing/partitioning orbitopes.
 - * New possible value 3 for [misc/usesymmetry](#) and changed default from 2 to 3.
 - * Renamed parameter [propagating/orbitalfixing/enableafterrestart](#) to [propagating/symmetry/recompute](#) which decides whether to recompute symmetries after a restart or not.
 - * Changed default of [constraints/orbitope/propfreq](#) from 5 to 1.
 - * Changed default of [constraints/orbitope/sepafreq](#) from 5 to -1.
 - * Removed parameters [constraints/orbisack/checkalwaysfeas](#), [constraints/orbitope/checkalwaysfeas](#), [constraints/symresack/checkalwaysfeas](#).
 - * Removed parameters [presolving/symmetry/maxgenerators](#), [presolving/symmetry/checksymmetries](#), and [presolving/symmetry/displaynorbitvars](#) and added various new parameters in group [propagating/symmetry](#).
 - * Removed parameters [presolving/symbreak/consaddlp](#), [presolving/symbreak/addsymresacks](#), [presolving/symbreak/computeorbits](#), [presolving/symbreak/detectorbitopes](#), and [presolving/symbreak/addconsstiming](#).
 - * Removed parameters [propagating/orbitalfixing/symcomptiming](#), [propagating/orbitalfixing/performance](#) and [propagating/orbitalfixing/recomputerestart](#).
 - * New parameter [constraints/orbitope/usedynamicprop](#) to enable propagation of orbitope constraints by reordering the rows based on the branching strategy.
 - * New parameter [constraints/symresack/checkmonotonicity](#) to enable upgrade to packing/partitioning symresacks even if the underlying permutation is not monotone.
 - * New parameters [constraints/orbisack/forceconscopy](#), [constraints/orbitope/forceconscopy](#), and [constraints/symresack/forceconscopy](#).
 - Presolve:
 - * The presolve library **PaPILo** (Parallel Presolve for Integer and Linear Optimization) 1.0 has been integrated as [additional presolver](#) for mixed-integer linear programs.
 - * Expressions of form $|x|^p x$ in a nonlinear constraint are now sometimes recognized and handled by [abspower](#) constraints.
 - * Some more quadratic constraints are now recognized as second-order cone constraints.
 - * New presolver [dualsparsify](#) that tries to combine variables to cancel nonzero coefficients in the constraint matrix of a MIP.
 - * Improved performance of [tworowbnd](#) presolver. New parameters added. Changed default of [presolving/tworowbnd/priority](#) from -500000 to -2000.
 - * Extended presolver [dualinfer](#) by the ability to perform convex combinations of continuous variables to calculate better bounds for the dual variables. New parameters added.
 - * Huge clique tables are now avoided by restricting the number of nonzero entries relative to the number of nonzeros in the problem. New parameter [presolving/clqtablefac](#).
 - * New parameter [constraints/linear/extractcliques](#) to turn clique extraction off.
 - * Improved presolver "domcol" to not require a complete representation of all constraints in the matrix.
 - * Enabling aggressive presolving now activates all available presolving plugins, and decreases parameter [presolving/restartfac](#) correctly with respect to default.

- * New parameter `constraints/linear/maxdualmultaggrquot` and `constraints/linear/maxmultaggrquot` to limit the maximum coefficient dynamism of an equation on which multiaggregation is performed. Smaller values make multiaggregations numerically more stable.
 - * Changed default of `constraints/quadratic/empathy4and` from 0 to 2. This leads to stronger but larger reformulations for products of binary variables.
- Primal heuristics:
- * New Large Neighborhood Search heuristic "Trust region", available as both a [standalone heuristic](#) and a [neighborhood inside of Adaptive Large Neighborhood Search](#).
 - * New heuristic [Adaptive Diving](#), which registers all publicly available dive sets from other diving heuristics, learns online which divesets reach the best score, and executes them more frequently.
 - * New penalty alternating direction heuristic [PADM](#) that splits the problem into several sub-SCIPs according to a user-provided decomposition (see below). The sub-SCIPs are solved on an alternating basis until a feasible solution of the original problem is found.
 - * The [GINS heuristic](#) can make use of a user-provided decomposition (see below) by selecting a block of variables that maximizes the potential, and randomly selecting a start variable for the neighborhood and/or by selecting an interval of consecutive blocks as neighborhood, until fixing rate is reached. In this case, no variable is randomly selected. Several new parameters added for the use of a decomposition in [GINS](#).
 - * The LP face heuristic now wastes less time if it decides not to run.
 - * Improved performance of Adaptive Large Neighborhood Search heuristic on merely continuous problems.
 - * All primal heuristics that use sub-SCIPs are now disabled within the heuristics fast emphasis setting.
 - * Replaced parameter `heuristics/localbranching/useuct` by `heuristics/useuctsubscip`, which affects all LNS heuristics.
 - * New parameters `heuristics/shiftandpropagate/minfixingratelp` and `heuristics/locks/minfixingratelp` to stop the heuristics after propagating integer fixings if no sufficient fixing of the all variables (including continuous) could be achieved.
 - * Changed default value of `heuristics/coefdiving/freq` from 10 to -1.
 - * Changed default value of `heuristics/conflictdiving/freq` from -1 to 10.
 - * Changed default value of `heuristics/conflictdiving/lockweight` from 1.0 to 0.75.
 - * Changed default value of `heuristics/rins/nodesquot` from 0.1 to 0.3 (due to other code changes, this should not affect default behavior).
 - * New value 1 available for `heuristics/gins/potential` to allow computation based on local LP solution.
 - * The display column for memory usage ("mem") now shows the creator name for every new incumbent solution. The heuristic display characters now represents the type of the heuristic (diving, Large Neighborhood Search, propagation, etc.). Changed default of `display/width` from 139 to 143.
- Branching:
- * New rule [vanillafullstrong](#), mostly for scientific purpose.
 - * Improved branching point selection when branching on nonlinear variables. Instead of using exactly the LP solution, a point closer to the middle of the variables domain is chosen. Added parameters `branching/midpull` and `branching/midpullreldomtrig`.
 - * Many updates to parameters of [lookahead branching rule](#).
 - * New parameter `branching/relpscost/degeneracyaware` to switch degeneracy-aware hybrid branching, which adjusts weights of different scores in relpscost (hybrid) branching rule based on degeneracy information and skips strong branching for very high degeneracy rates.
- Separation:
- * Improvements in cut presolving and cgmp separator.
 - * New parameter `separating/cgmip/genprimalsols` that allows to generate initial primal solutions from Gomory cuts.
-

- * Changed default of `separating/rapidlearning/freq` from -1 to 5. Various new parameters for `rapidlearning`.
 - * Changed default of `separating/efficacyfac` from 1.0 to 0.6.
 - Approximations on the search tree completion and `estimates on the tree size` have been added.
 - * The approximate search tree completion is shown in a `new display column`.
 - * The tree size estimate is used to trigger a restart if, after a reasonable initialization, the estimated size of the remaining tree is large.
 - * New parameter group `branching/treemodel` to specify the tree model.
 - SCIP can now store user decompositions. A GAMS user can `specify one decomposition` via the `.stage` variable suffix. Statistics regarding the decomposition are printed to the log before presolving (if `display/statistics` is enabled) and after presolving. New parameter `decomposition/maxgraphedge`.
 - Extended the dual proof analysis for infeasible LPs to consider also locally valid rows (new parameter `conflict/uselocalrows`).
 - If a `reference value` is given, the primal-reference and reference-dual integrals are calculated automatically and printed within the SCIP statistics.
 - Emphasis settings for numerically challenging instances have been added. They increase numerical stability of (mostly) presolving operations such as (multi-)aggregations at the cost of performance.
 - Renamed parameters `misc/allowdualreds` and `misc/allowobjprop` to `misc/allowstrongdualreds` and `misc/allowweakdualreds`, respectively.
 - Replaced parameter `numerics/lpfeastol` by `numerics/lpfeastofactor` to specify which factor should be applied to the SCIP feasibility tolerance to initialize the primal feasibility tolerance of the LP solver.
 - New parameter `lp/minmarkowitz` to set the Markowitz stability threshold. High values sacrifice performance for stability.
 - Changed default of `propagating/redcost/useimplics` from TRUE to FALSE.
 - See also the `full release notes` and the `release paper`.
- Symmetry detection and handling is now available on Windows, too.
 - Updated Ipopt to 3.13, see `above`.
 - Removed value `soplex2` for option `lp/solver`. `soplex` is now the default if no CPLEX license is available.

3.10.1.4.15 SHOT

- New solver by Andreas Lundell (Åbo Akademi University, Finland) and Jan Kronqvist (Imperial College London, UK).
 - SHOT is a deterministic solver for mixed-integer nonlinear programming problems (MINLPs). It can solve convex and some nonconvex MINLP problems to global optimality. For other nonconvex problems, SHOT acts as a heuristic method, i.e., without providing guarantees of global optimality. For more information, see the `GAMS/SHOT solver manual`, the `SHOT website`, and the publications [169] [165].
 - SHOT 1.0.0 (527f1a11) is available for Linux, Mac OS X (≥ 10.13), and Windows. It can be used with a GAMS base system license.
-

3.10.1.4.16 SoPlex

- New libraries 5.0.0 (6535a3c8).
 - Improvements in memory management.
 - The number of violations is now shown in the log.
 - New options `bool:forcebasic`, `int:stattimer`, and `real:min_markowitz`. Replaced option `int:printcondition` by `int:printbasismetric`.
- GAMS/SoPlex is now available for `multithreaded solves`.

3.10.1.4.17 XPRESS

- New libraries v8.8.3 (aka Optimizer 35.01.04). It has been a longer-than-usual time since the previous library update, so the list of updates and improvements enhancing performance, stability, and correctness is extensive and not reproduced here. For details, visit and search the [FICO Community page](#).

3.10.1.5 Tools

3.10.1.5.1 GAMS IDE and GDXVIEWER

- As mentioned [above](#), we switched the default application to be associated with GAMS files on Windows from the GAMS IDE to [GAMS Studio](#) with this release. The classic GAMS IDE has been shipped with the GAMS system for the last 20 years and is still the workhorse for many GAMS programmers. However, it does not provide all the features we see in modern development environments. Both the GAMS IDE and GDXVIEWER rely on a rather old software stack, which is hard to maintain with current operating systems and will become even harder over time. So we plan to drop the GAMS IDE and GDXVIEWER with an upcoming major release.

3.10.1.5.2 GAMS Studio

- New version 1.1.0.
 - Stability improvements.
 - Introduced new settings format.
 - Attention
 - This required a reset of all settings. They are saved now in JSON format. As a consequence, Studio 1.0.0 cannot use settings that were written by Studio versions prior to 1.0.0 and vice versa.
 - Changed the default file encoding to UTF-8 for all platforms (this mostly affects Windows, there should be no change for other platforms).
 - Added option to change the default text encoding to `Edit -> Encoding -> Select encodings`.
 - Introduced Dark Theme for Windows and Linux as well (can be changed through `Settings -> Editor`).
 - Added editor for [GAMS Configuration](#) and menu entry for default GAMS Configuration file.
 - Added option to change display format of numerical values in GDX Viewer.
 - Changed location of default workspace and model library.

- Changed location where `gamslice.txt` is put when created using the "About GAMS" dialog to the new standard locations searched by GAMS (see [installation notes](#) for details).
- Improved shortcut layout:
 - * Reintroduced "Open Terminal" shortcut as `Ctrl+T`.
 - * Introduced shortcut for "Run MIRO base mode": `F8`.
 - * Introduced shortcut for "Run MIRO hypercube mode": `Shift + F8`.
 - * Introduced shortcut for "Run MIRO configuration mode": `Shift + F7`.
 - * Changed shortcut for focus "Project Explorer" to `Ctrl + 1`.
 - * Changed shortcut for focus "Editor" to `Ctrl + 2`.
 - * Changed shortcut for focus "Parameter Editor" to `Ctrl + 3`.
 - * Changed shortcut to extend and collapse "Parameter Editor" to `Ctrl + Alt + 3`
 - * Changed shortcut for focus "Tab Browser" to `Ctrl + 4`.
 - * Changed shortcut for focus "Process Log" to `Ctrl + 5`.
 - * Changed shortcut of duplicate line to `Ctrl+D`.
 - * Changed shortcut of "Toggle Comment" in "Parameter Editor" to `Ctrl + *`
 - * Changed shortcut of action "Go to matching parentheses" to: `Ctrl + B`
 - * Changed shortcut of action "Select to matching parentheses" to: `Ctrl + Shift + B`
 - * Fixed shortcut on Mac OS X: block edit mode is now `CMD+Shift+Arrow Key`.

3.10.1.5.3 GDXMERGE

- Fixed a problem when merging a GDX file with name `.gdx`.

3.10.1.5.4 GDXXRW

- Added new option `dSetText` to control the reading of explanatory text for set elements of [domain sets](#).

3.10.1.6 Object Oriented APIs

- Option `pySetup` has been removed from the class `GAMSOptions`.
- Removed GAMS return code 116 ("Could not find GMSPython") from the enumerate type representing the GAMS return code.
- Fixed a memory leak with `GAMSModelInstance.solve`.

3.10.1.6.1 C++

- As [announced](#), dropped support for Microsoft Visual Studio 2013.

3.10.1.6.2 Python

- GAMS Python API is now distributed in source code under the MIT open source license.
 - To access the GAMS API, the Python interpreter needs to find files in `<GAMS Systemdirectory>/apifiles/Python/` and `<GAMS Systemdirectory>/apifiles/Python/gams`, where `XY` corresponds to the Python version `X.Y`, e.g. `3.7`. The `GMSPython` installation is already set up to find all required files. The documentation section [Let Python find the GAMS Python files](#) gives details on how to use an external Python system with GAMS.
 - There is a different directory structure in `<GAMS Systemdirectory>/apifiles/Python`. The content of the `api` directory has been moved to different places:
 - `api_27` for the binary Python 2.7 API files,
 - `src` for the files required to build the expert-level API files from source,
 - `gams` for source files of the GAMS Python API plus a few extra Python source files for working with indexed EMP syntax, e.g. `emppython1`, and
 - `thirdparty` for the Python package `ply` for processing of indexed EMP syntax.
-

3.10.1.7 Expert Level APIs

- We plan to remove the GAMSX API with one of the next major releases.
- Added `palSetSystemName` to setup a generic auditline in PAL. Increased PAL API version to 3.

3.10.1.8 Model Libraries

3.10.1.8.1 GAMS API Library

- All Python examples have been reworked. Tests are performed also with the Python installation in GMSPython.
- New model `PBuildXPLLevelAPI.gms` : **Test building the expert-level APIs** (57).

3.10.1.8.2 GAMS Data Library New models:

- `rank01.gms` : **Rank a vector, and display the data in sorted order** (135)
- `rank02.gms` : **Generate percentiles for a random vector** (136)
- `rank03.gms` : **Use GDXRANK to report multisectoral Monte Carlo results** (137)
- `rank04.gms` : **Repeated computation of percentiles within a loop** (138)
- `rank05.gms` : **Percentile ranking of household expenditure data with heterogenous household size** (139)
- `GMSPythonCheck.gms` : **Consistency check for GMSPython** (140)

3.10.1.8.3 GAMS Model Library

- Updated model `encrypt.gms` : **Input file encryption demo** (318)
- New model: `waterld.gms` : **Design of a Water Distribution Network with Limited Domain of Variables** (426)

3.10.1.8.4 GAMS Test Library New models:

- `gdxxrw15.gms` : **GDXXRW - Testing option dSetText** (810)
 - `card03.gms` : **Test card operator for scalar symbols** (811)
 - `limdom01.gms` : **Test limited domains for variables in model** (812)
 - `limdom02.gms` : **Test performance of limited domains for variables in model** (813)
 - `limdom03.gms` : **Test the syntax of the model statement for limited domains for variables** (814)
 - `limdom04.gms` : **Advanced test for limited domains for variables in model** (815)
 - `fncpf3.gms` : **Test correctness of ncpf intrinsic** (816)
 - `fncpvupow2.gms` : **Test correctness of NCPVUpow intrinsic** (817)
 - `fncpvusin2.gms` : **Test correctness of NCPVUsin intrinsic** (818)
 - `loop10.gms` : **Test relaxed punctuation for control structures** (819)
 - `dirs01.gms` : **Test search and processing of gamslice.txt and gamsconfig.yaml in user space** (820)
-

3.10.1.8.5 PSOPT Model Library

- Updated model **MultiperiodDCOPF24bus** : Multi-period DC-OPF for IEEE 24-bus network considering wind and load shedding

3.10.1.9 Solver/Platform availability matrix

3.10.2 31.1.1 Maintenance release (May 16, 2020)

3.10.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jan Abrell, Michael Ferris, Nick Sahinidis, and Karlo Šepetanc.

3.10.2.2 GAMS System

3.10.2.2.1 GAMS

- Fixed a bug where loading an empty [universe](#) from a GDX file caused an error.
- Fixed a bug in `gamsinst` that is used by the IDE to display available solvers.
- GAMS continues to search directories for the license and configuration file even if the construction of some directory names fails due to the absence of some environment variables, e.g. `HOME`.

3.10.2.2.2 GAMS Data Exchange (GDX)

- Fixed a bug where domain violations in higher dimensions might have been undetected when writing symbols to GDX.

3.10.2.3 Solvers

3.10.2.3.1 GUROBI

- Fixed a bug introduced with 31.1.0 where the `GRB_LICENSE_FILE` environment variable was incorrectly dropped.

3.10.2.3.2 MOSEK

- New libraries 9.2.7.

3.10.2.4 Tools

3.10.2.4.1 GAMS Studio

- New version 1.1.1.
 - Added command line parameter editor warnings for missing values.
 - Fixed problem with command line parameters not being updated when changing group.
 - Fixed behavior of `Ctrl - End` shortcut in process log and `lst` file view.
 - Fixed settings export not working when file already exists.
 - Fixed numpad not working when running Studio from an AppImage on Linux.
 - Fixed `Shift+Arrow` Key not working when running Studio from an AppImage on Linux.
-

3.10.2.5 Object Oriented APIs

- Fixed a bug in the Python API when exporting options (`GAMSOptions.export()`) that contain `defines`.

3.10.2.6 Model Libraries

3.10.2.6.1 GAMS Test Library

- Updated model `dirs01.gms` : Test search and processing of `gamslice.txt` and `gamsconfig.yaml` in user space (820)

3.10.3 31.2.0 Minor release (June 19, 2020)

3.10.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Salvador Doménech Martínez, and Kaushik Sinha.

3.10.3.2 GAMS System

3.10.3.2.1 GAMS

- The demo/community license limit of indexed external in- and output symbols for the GAMS/MIRO connector has been increased from 5 to 10. There is no limit on *scalar* external in- and output symbols. Starting with this version, one dimensional singleton sets are also not limited.
- Extend the influence of the command line parameter `multiPass`, so that it also ignores errors about unknown dimension with empty data statements when set to 2.
- Added three new `put_utility` commands `incMsg`, `incLog`, and `incMsgLog` to include the content of a file into the log or listing file.
- Fixed a crash for CNS models which get solved *asynchronously* while `asyncSolLst` is set to 1.

3.10.3.3 Solvers

3.10.3.3.1 Gurobi

- Added option `dumpBCSol` to write incumbent solutions to GDX point files while Gurobi optimizes.

3.10.3.3.2 LocalSolver

- New libraries 9.5 (20200429).

3.10.3.3.3 Mosek

- New libraries 9.2.10.
-

3.10.3.3.4 SCIP

- New library 7.0 (01ae80d797).
- Fixed default setting for option `misc/usesymmetry` on Windows (was still set to 0, but should be 3).

3.10.3.3.5 SHOT

- New library 1.0.1.

3.10.3.4 Tools

3.10.3.4.1 GAMS Studio

- New version 1.1.2.
 - Performance improvements.
 - Stability improvements and minor bug fixes, e.g.,
 - * Fixed crash when reopening a tab of a file that was removed from Project Explorer.
 - * Fixed behavior of hotkeys to jump to beginning and end of line and page up/down.
 - * Fixed Goto dialog jumping to beginning of file when entering invalid values.
 - * Fixed shortcuts to focus Project Explorer and Editor not working when undocked.
 - * Fixed that sizes of dock-widgets were not stored in FullScreen or Maximized window.

3.10.3.5 Object Oriented APIs

3.10.3.5.1 .NET

- Fixed a problem with reading labels which contain non-ASCII characters through `GAMSSymbolRecord.Keys`.

3.10.3.6 Expert Level APIs

3.10.3.6.1 C#

- Fixed a problem with reading arrays of strings which contain non-ASCII characters through different APIs.

3.11 30 Distribution

3.11.1 30.1.0 Major release (January 10, 2020)

3.11.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Todd Munson, Suguru Otani, Nick Sahinidis, and Dimitri Tomanos.

3.11.1.2 Platforms

- As [announced](#), dropped support for Windows 7. The minimal required Windows version is now 8.1.
- Moved platform 32-bit MS Windows to [peripheral platforms](#). We will completely drop support for 32-bit MS Windows with GAMS 31 (which was [originally announced for GAMS 30](#)).

3.11.1.3 Licensing and Demo Limits

- The GAMS demo limits have been increased. GAMS will generate linear (LP, RMIP, MIP) models up to 2000 constraints and 2000 variables and up to 1000 constraints and 1000 variables for all other model types. No other limits apply (e.g. non-zeros or discrete variables). Some solvers (e.g., the global solvers ANTIGONE, BARON, and LindoGlobal) might enforce [additional restrictions](#).
- GAMS provides a free [community license](#) for users on request. This community license allows generating even larger models: up to 5000 constraint and variables for linear and 2500 constraints and variables for other model types. These free licenses are for demonstration and evaluation but not for commercial and production work, see the [GAMS End User License Agreement](#).
- Starting with this release, GAMS requires a valid license even for the free demo system. Free demo licenses (time-limited for 12 months) can be generated at the [download page](#). The free demo and community licenses require also a recent version (not older than 18 months) of GAMS to run. Please check the [license documentation](#) for details.
- GAMS Beta versions will stop working 90 days after their release. This is to prevent accidental use of beta software.

3.11.1.4 GAMS System

3.11.1.4.1 GAMS

- Added system suffix [MACAddress](#), which contains the MAC address of the first network adapter.
 - Allow to declare more than one parameter as [table](#) on a single line.
 - Added new dollar control options [\\$\[on\]\[off\]Filtered](#): These control how GAMS loads data from GDX with [\\$load](#), [\\$loadR](#), and [\\$loadM](#) as well as from [\\$offEmbeddedCode](#).
 - Added new dollar control options [\\$loadFiltered](#), [\\$loadFilteredM](#), and [\\$loadFilteredR](#) to load data from GDX in filtered mode explicitly.
 - Added new dollar control options [\\$\[on\]\[off\]ExternalInput](#) to load data implicitly from an external source and [\\$\[on\]\[off\]ExternalOutput](#) to save data implicitly to an external target.
 - Added new command line parameters [IDCGDXInput](#), [IDCGDXOutput](#), [IDCGenerateGDX](#), [IDCGenerateGDXInput](#), [IDCGenerateGDXOutput](#), [IDCGenerateJSON](#), and [IDCJSON](#).
 - Embedded Python Code:
 - Changed the optional boolean argument `domCheck` to an enumerated option `DomainCheckType` in the [gams.set](#) method in embedded code. *This might break existing code*. Even if the `domCheck` argument was not used, the default behavior at execution time changes. In previous versions the content was domain checked, now it is read filtered.
 - The argument `mergeType` was documented incorrectly. With type `MergeType.DEFAULT` (or no argument given) GAMS *merged* the content, in contrast to what the documentation said (here *replace* was mentioned).
 - Terminate with a proper error message if lines in the [EMP info file](#) exceed the maximum line length of 1020 characters.
 - Fixed a problem where the order of a semicolon and certain [dollar control options](#) changed the behavior of the compiler.
-

3.11.1.4.2 Installer

- In addition to `.gms` files, the Windows installer also associates `.gdx` files with either the GAMS IDE or GAMS Studio.

3.11.1.5 Solvers

3.11.1.5.1 BARON

- New libraries 19.12.7.
 - Performance improvements for large-scale and mixed-integer quadratic problems.
 - Improvements in interface to IPOPT.

3.11.1.5.2 CBC

- New libraries.

3.11.1.5.3 CONOPT

- New library 4.16 with bug fixes.
 - Improvement in the transition from Phase 0 to Phase 1 and in the one-dimensional search close to optimality.

3.11.1.5.4 CPLEX

- New libraries 12.10.0.0.
- New options `epLin` and `heuristicEffort`.

3.11.1.5.5 GUROBI

- New libraries 9.0.0.
 - Gurobi 9 comes with a new bilinear solver, which allows to solve non-convex quadratic programming problems. The new parameter `nonConvex` needs to be set.
 - New `general constraint` types have been added to model functions like `log`, `exp`, `sin`, `cos`, and `tan`. New options `funcPieces`, `funcPieceError`, `funcPieceRatio`, `funcPieceLength`, and `funcMaxVal` have been added to control the piece-wise-linear discretization. The `dot options` `doFuncPieces`, `doFuncPieceError`, `doFuncPieceRatio`, and `doFuncPieceLength` allow control on an individual constraint basis.
 - New parameters for new cutting planes: `BQPCuts`, `relaxLiftCuts`, and `RLTCuts`.
 - Fixed a problem when reporting the primal solution only.
 - Report the dual bound for continuous non-convex QP and QCP problems.
-

3.11.1.5.6 JAMS/LogMIP

- New option [userPFFile](#) to provide additional GAMS command line parameters for the GAMS run of the reformulated model.

3.11.1.5.7 LocalSolver

- New libraries 9.0 (20191219).

3.11.1.5.8 MOSEK

- New libraries 9.1.9.

3.11.1.5.9 ODHCPLEX

- New libraries 4.3.2 with bug fixes and performance improvements.

3.11.1.5.10 PATH

- New library 5.0.01 with bug fixes.
 - Fix seg fault when using the hidden option `output_hidden_options`.

3.11.1.5.11 SCIP

- New libraries 6.0 (90a56e0b).
 - Default for option `heuristics/rins/nodesquot` changed from 0.1 to 0.3.

3.11.1.6 Tools

3.11.1.6.1 GAMS Studio

- New version 0.14.1.
 - Stability improvements.
 - Added [GDX Diff dialog](#) to compare two GDX files. It can be opened by choosing `Tools > GDX Diff` from the menu or through the context menu off a GDX file in the [Project Explorer](#).
 - Allow to open OS specific terminal in current working directory (`Tools > Terminal`) or in working directory of a specific group (using the context menu in the Project Explorer)
 - * Note: This feature does not work on all Linux distributions, e.g., Ubuntu, yet.
 - Added basic integration of [GAMS MIRO](#) .
 - * Note: This requires a separate installation of the GAMS MIRO package.
 - Improved [GDX Viewer](#) layout to optimize used screen space.
 - Adjusted layout of [Reference File Viewer](#).
 - Added clear button to filter input field in GDX Viewer and Reference File Viewer.
-

3.11.1.7 Object Oriented APIs

3.11.1.7.1 C++

- We plan to drop support for Microsoft Visual Studio 2013 and maybe also 2015 with the next major release.

3.11.1.7.2 Python

- Added support for Python 3.8.
- As [announced](#), dropped support for Python 3.4.

3.11.1.8 Expert Level APIs

- Added support for Python 3.8.
- As [announced](#), dropped support for Python 3.4.

3.11.1.9 Model Libraries

3.11.1.9.1 GAMS Data Library New models:

- **pickstock.gms** : Stock selection problem with MIRO (133)
- **transport.gms** : Classical transportation problem with MIRO (134)

3.11.1.9.2 GAMS Test Library New models:

- **embpy05.gms** : Test merge/replace when loading data from embedded code (804)
 - **embpy06.gms** : Test domain check/filtered when loading data from embedded code (805)
 - **load12.gms** : Tests filtered load (806)
 - **idc01.gms** : Implicit Data Contract Test (807)
 - **gurobi05.gms** : GUROBI test suite - general constraints sin/cos (808)
 - **studio01.gms** : Test Studio Startup (809)
-

3.11.2 30.2.0 Minor release (February 07, 2020)

3.11.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Iswar Radhakrishnan, Simon Scolan, and Kirk Yost.

3.11.2.2 GAMS System

3.11.2.2.1 GAMS

- Fixed a problem when writing implicit data contract in JSON format ([IDCGenerateJSON](#)) with symbols that use a set more than once in its domain.
- Fixed a potential wrong domain violation error for symbols declared under [\\$onExternalInput](#).
- Fixed `gamsinst` and the IDE to give better messages in case a license file is absent.
- GAMS incorrectly removed indexed semi-integer and semi-continuous variables that have been fixed at a level other than zero with `holdFixed` set to 1. This has been fixed.
- GAMS also removes scalar semi-integer and semi-continuous variables now, when they have been fixed at zero with `holdFixed` set to 1.
- Fixed an issue where `protected` symbols could be changed using certain [option statements](#).
- Added new command line parameter `IDCProtect` to control assignment behavior of `external input` symbols at execution time: 0 allows assignment, 1 (default) protects external input symbols from being changed.
- Adjusted reading of GAMS command-line arguments on non-Windows platforms to allow for empty arguments and arguments with preceding and trailing blanks. Windows users will not be affected by this change, nor will users who do not use quotes to protect arguments. But these invocations will now work differently on Unix, and will give the same result as on Windows:

```

- gams main.gms --myPrefix "" user1 " four blanks here "
- $call gams subjob.gms --cityA Tokyo --cityB ""

```

3.11.2.3 Solvers

3.11.2.3.1 CONOPT

- New library 4.17 with bug fixes.
 - Fixed a problem where small infeasibilities were not correctly reported back to GAMS.

3.11.2.3.2 DICOPT

- Fixed a possible crash during exit when having used Ipopt as NLP solver.

3.11.2.3.3 GUROBI

- New libraries 9.0.1.
- Fixed a problem with [tuning](#) of lp/mps files. In contrast to the documentation, the tuning suite contained the model generated by GAMS when providing a list of models in lp/mps files to tune.
- Made value 3 available for Gurobi option [scaleFlag](#), available since Gurobi 7.5.

3.11.2.3.4 MOSEK

- New libraries 9.1.11.

3.11.2.3.5 PATH

- New library 5.0.02.
 - Fix to two preprocessor issues: wrong solutions were being returned.

3.11.2.4 Tools

3.11.2.4.1 GAMS Studio

- New version 0.14.3.
 - Stability improvements.
 - New icon design.
 - Added filter facility for value columns in [GDX Viewer](#).

3.11.3 30.3.0 Minor release (March 06, 2020)

3.11.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Andres J. Calderon, Antti Lehtila, Grégoire Pichenot, and Karlo Šepetanc.

3.11.3.2 GAMS System

3.11.3.2.1 GAMS

- Allow to create a [secure work file](#) on any platform for any target license platform.
- Fixed a bug which could have caused wrong domain violation errors with [\\$offEmbeddedCode](#).
- Symbols set in embedded Python code via the GAMS Python object oriented API (i.e. `gams.db[sym]`) were imported with `MergeType` "replace" and `DomainCheckType` "filtered". This has been adjusted to both `MergeType` and `DomainCheckType` set to "default".
- Fixed a problem which was introduced with [GAMS 30.1](#): The default for `$_on$offFiltered` should always be `$onFiltered`. This was not the case when [restarting](#) from an old work file.

3.11.3.3 Solvers

3.11.3.3.1 Antigone, Bonmin, Cbc, Couenne, Ipopt, SCIP

- The number of threads as specified by option [threads](#) was disregarded. This has been fixed.

3.11.3.3.2 CONOPT

- New library 4.18 with bug fixes.
- The degeneracy-breaking logic has been improved for numerically difficult models and the interaction between defined variables and initialized variables has been improved.

3.11.3.3.3 JAMS/LogMIP

- The maximum length of the directory name plus file name that GAMS can execute is 255. JAMS and LogMIP stopped working earlier. This has been fixed.

3.11.3.3.4 LocalSolver

- Added missing `lskeygen` tool for Linux system.

3.11.3.3.5 MOSEK

- New libraries 9.1.13.

3.11.3.4 Tools

3.11.3.4.1 GAMS Studio

- New version 0.14.4.
 - Stability improvements.
 - Introduced Dark Mode support for macOS.
-

3.12 29 Distribution

3.12.1 29.1.0 Major release (November 15, 2019)

3.12.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, David Bernal Neira, Erwin Kalvelagen, and Scolan Simon.

3.12.1.2 Platforms

- As [announced](#), dropped support for Mac OS X 10.12 (Sierra).
- After more than 20 years we plan to drop support for 32-bit MS Windows with the next major release. Some components, e.g., GAMS IDE and [gdxrw](#), will remain 32-bit executables in the 64-bit MS Windows GAMS distribution.
- We plan to drop support for MS Windows 7 with the next major release.

3.12.1.3 GAMS System

3.12.1.3.1 GAMS

- Extended the GAMS log to print out the [Double Dash Parameters](#) set in addition to the non-default [Command Line Parameters](#).
- Added dollar control option [\\$setDDLList.Cont](#) to allow to define a list of [double dash parameters](#) to be checked over multiple lines.
- Added new ways to execute external programs which implicitly check the [errorLevel](#) returned and raise a compilation or execution error if it is not zero, namely [\\$call.checkErrorLevel](#), [\\$hiddencall.checkErrorLevel](#), [execute.checkErrorLevel](#), [put_utility exec.checkErrorLevel](#) and [put_utility shell.checkErrorLevel](#). This behavior can also be triggered without using the [checkErrorLevel](#) suffix by setting [\\$onCheckErrorlevel](#) and [checkErrorLevel](#), respectively.
- Added command line option [captureModelInstance](#) to capture all model instances generated and solved by a solve statement during a GAMS run.
- Allow to declare a parameter as [table](#) without entering data.
- Added new [Dollar Control Options](#) [eval.Set](#), [evalGlobal.Set](#), and [evalLocal.Set](#) to define a compile-time variable based on the content of a GAMS [set](#).
- Removed limit of 10,000 columns in [table](#) declaration.
- Changed [trace record fields](#) of quadratic model types from historic to today's names (QP --> QCP, QMIP --> MIQCP, RQMIP --> RMIQCP).
- The [gams.exe](#) and [gamskeep.exe](#) programs on 64-bit Windows are now native 64-bit executables. Because of some technical requirements related to the Interrupt functionality, the IDE invokes GAMS via the new 32-bit program [gams32.exe](#).
- Fixed wrong return string for [%gams.action%](#).
- Fixed a problem with interval evaluation for [Extrinsic Functions](#).
- Fixed a problem with GAMS parameter [scriptExit](#) when running from the object-oriented APIs, GAMS Studio, or GAMS IDE.
- Fixed a problem with trace record field [ETSolve](#) which reported NA always.
- Fixed a problem with potentially wrong [explanatory text](#) when [implicit sets](#) are loaded using [\\$load](#).

3.12.1.3.2 Installer

- The DMG installer for Mac OS X has been reorganized and is now notarized, so that it should work on Mac OS X 10.15.
- The [selfextracting archive for Mac OS X](#) is now a 64-bit application.

3.12.1.4 Solvers

3.12.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2019.5 on Linux and Mac OS X.
- Updated Intel MKL libraries to version 2018.4 on Windows 64-bit again.

3.12.1.4.2 CBC

- New libraries.

3.12.1.4.3 CONOPT

- New library 4.15 with bug fixes.
- Option `DF_Method` has been replaced by the options `Tol_Def_Mult` and `Tol_Def_Ini`.

3.12.1.4.4 Convert

- Fixed a bug that caused a crash with option `nlp2mcp` selected.

3.12.1.4.5 DICOPT

- Fixed so called "integer cuts" when both binary and integer variables are present. DICOPT generated two integer cuts in this case, one that excluded the current values of binary variables and another one that excluded the current values of integer values. Now a single combined cut is generated, which allows that the values of the binary variables can repeat if the values of the integer values change and vice versa.
- Setting option `weight` to a value larger 10^{20} now disables the augmented penalty relaxation, that is, linearizations of nonlinear equations are added as hard constraints to the MIP relaxation instead of soft constraints.
- Enabling option `convex` now changes the default for option `weight` to `maxdouble`.

3.12.1.4.6 Examiner

- Added option `objvarAutoAdjust` to adjust objective variable to make objective equation feasible for models that allow objective reformulation.
-

3.12.1.4.7 Lindo/LindoGlobal

- New libraries 12.0.169.
- Added support for [function](#) `signPower`.

3.12.1.4.8 LocalSolver

- New libraries 9.0 (20191004) for Linux, Mac OS X, and 64-bit Windows.
 - Performance improvements on packing, routing, and scheduling problems as well as on nonlinear continuous problems.

3.12.1.4.9 LGO

- Fixed a bug in the computation of the best feasible solution - an uninitialized variable was used.

3.12.1.4.10 MOSEK

- New libraries 9.1.1.
- Correct rejection of problems with non-quadratic nonlinear objective function when constraints are linear.

3.12.1.4.11 SoPlex

- New libraries 4.0 (083219e0).

3.12.1.4.12 SCIP

- New libraries 6.0 (a15f6c41).

3.12.1.5 Tools

3.12.1.5.1 GAMS Studio

- New version 0.13.2
 - Stability and performance improvements.
 - Allow to adjust the numerical precision in the GDX Viewer.
 - Added dialog to create/update license file (pops up when a license is in the user's clipboard and "About GAMS" is opened).
 - Added full screen mode (shortcut on Windows and Linux: `ALT+Return`, shortcut on Mac OS X: `META+CMD+F`).
 - Added auto-resizing of columns when opening the Reference File Viewer.
 - Reworked process log to better handle long and fast output.
 - Improved behavior of F1 (Help) Key: Studio now opens widget specific help if available.
 - Renamed "Output View" to "Process Log".
 - Added a [tutorial](#) about the usage of GAMS Studio to the documentation.
 - As [announced](#), dropped Studio for 32-bit Windows.
-

3.12.1.6 Object Oriented APIs

3.12.1.6.1 Python

- Added support for Python 3.7 on Windows 64-bit, Linux, and Mac OS X.
- We plan to drop support for Python 3.4 with the next major release.
- Support for Python 2.7 officially stops January 1, 2020. We plan to drop support for Python 2.7 with some future release. If you rely heavily on the availability and support of the GAMS API for Python 2.7 please contact support@gams.com to discuss your options.

3.12.1.6.2 Java

- Increase the minimum version requirement of the Java Runtime Environment to Java SE 8.
- The remove operation **GAMSDatabaseIterator.remove** is no longer supported. The method now throws an instance of `java.lang.UnsupportedOperationException` and performs no other actions. (To remove all records of the current iterating symbol, use the method **GAMSSymbol.clear** instead.)
- Fixed the behavior of the remove operation **GAMSSymbolIterator.remove**. The method now removes all records of the last **GAMSSymbol** element returned by an instance of **GAMSSymbolIterator** and can be called only once per call to **GAMSSymbolIterator.next**. The behavior of an iterator is unspecified if the underlying collection is modified while iterating.

3.12.1.7 Expert Level APIs

- Added support for Python 3.7 on Windows 64-bit, Linux, and Mac OS X.
- We plan to drop support for Python 3.4 with the next major release.
- We plan to drop support for Python 2.7 with some future release.

3.12.1.8 Model Libraries

3.12.1.8.1 GAMS Model Library

- Added **inscribedsquare.gms : Inscribed Square Problem**.

3.12.1.8.2 GAMS Test Library

- Extrinsic function test models: Upgraded query-library generation code `ql.py` to Python 3. The default for property "description" has been changed to be an empty string.

3.12.1.9 Solver/Platform availability matrix

3.13 28 Distribution

3.13.1 28.1.0 Major release (August 02, 2019)

3.13.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Johan Löfberg, Hans Mittelmann, and José Luis Vilar Zanón.

3.13.1.2 Platforms

- We plan to drop support for Mac OS X 10.12 (Sierra) with the next GAMS major release.

3.13.1.3 GAMS System

3.13.1.3.1 GAMS

- Added new dollar control option `$scratchFileName`.
- Fixed a bug which caused a problem when `unloading` a multi-dimensional `Alias` at compile-time.

3.13.1.3.2 Documentation

- Improved ranking of results in `offline search` by minimizing the effect of the length of a document on the importance of a search term in that document.
- When searching the `index`, only relevant results are shown for subcategories as well.
- The `full-text search` now shows also results for a search in the `index`.

3.13.1.4 Solvers

3.13.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Downgraded Intel MKL libraries to version 2018.3 on Windows 64-bit.

3.13.1.4.2 ANTIGONE

- The `timelimit` is now applied to the wallclock time and wallclock time is reported in the log and back to GAMS.
-

3.13.1.4.3 BARON

- New libraries 19.7.13.
 - New relaxations and branching rules for nonconvex mixed-integer quadratic programs, leading to significant speedups for this class of problems.
 - Increased robustness in various range reduction routines.
 - Increased solvability of large-scale problems by BARON's cut generators.
 - Enhanced convexity recognition routines.
 - Updated to IPOPT 3.12.13 and CBC 2.10.1.
- Fixed passing constant equations to BARON.

3.13.1.4.4 CBC

- Revised [solver options](#).
 - Updated the documentation and possible values for many options, bringing them closer to the original Cbc option names and values.
 - The following options changed their type from boolean to string: [crossover](#), [cutoffConstraint](#), [combineSolutions](#), [Dins](#), [DivingRandom](#), [DivingCoefficient](#), [DivingFractional](#), [DivingGuided](#), [DivingLineSearch](#), [DivingPseudoCost](#), [DivingVectorLength](#), [feaspump](#), [naiveHeuristics](#), [pivotAndFix](#), [randomizedRounding](#), [Rens](#), [Rins](#), [roundingHeuristic](#), [proximitySearch](#), [presolve](#)
 - For options [dualPivot](#), [primalPivot](#), and [scaling](#) value "auto" has been renamed to "automatic".
 - For option [costStrategy](#), values "binaryfirst" and "binarylast" have been renamed to "01first" and "01last", respectively.
 - The following options have been added: [factorization](#), [denseThreshold](#), [smallFactorization](#), [sparseFactor](#), [biasLU](#), [psi](#), [substitution](#), [primalWeight](#), [autoScale](#), [bscale](#), [gamma](#), [KKT](#), [expensiveStrong](#), [OrbitalBranching](#), [infeasibilityWeight](#), [fixOnDj](#), [sosPrioritize](#), [cutLength](#), [lagomoryCuts](#), [latwomirCuts](#), [hOptions](#), [combine2Solutions](#), [diveSolves](#), [feaspump_artcost](#), [feaspump_fracbab](#), [feaspump_cutoff](#), [feaspump_increment](#), [dwHeuristic](#), [pivotAndComplement](#), [VndVariableNeighborhoodSearch](#)

3.13.1.4.5 CONOPT

- CONOPT3 accepts models with empty rows. The GAMS/CONOPT3 link sets the hidden option `LSAZRW` to true.

3.13.1.4.6 Convert

- Replaced the OSiL writer. The new writer [supports more GAMS intrinsic functions](#) and produces slightly smaller OSiL files with more compact expression trees.

3.13.1.4.7 IPOPT

- Fixed handling of Ipop't's feasible-point-found status.
-

3.13.1.4.8 LocalSolver

- Added option `logfreq`.

3.13.1.4.9 MOSEK

- New libraries 9.0.98.
 - Introduced the power and exponential cones, see also [Conic Programming](#).
 - As announced, the optimizer for general convex nonlinear problems has been removed. Thus, solving a NLP, DNLP, MINLP, or RMINLP for which a conic reformulation is not recognized will now result in a missing capability solver status with GAMS/Mosek.
 - Improved presolve for particular conic problems.
 - Tighten the stopping criteria when solving conic optimization problems: Changed default of [MSK_DPAR_INTPNT_CO_TOL_INFEAS](#) from 1e-10 to 1e-12, of [MSK_DPAR_INTPNT_CO_TOL_REL_GAP](#) from 1e-7 to 1e-8, and of [MSK_DPAR_INTPNT_QO_TOL_INFEAS](#) from 1e-10 to 1e-12. However, note that one can let Mosek relax feasibility and optimality tolerances if it cannot make sufficient progress, see [MSK_DPAR_INTPNT_CO_TOL_NEAR_REL](#) and [MSK_DPAR_INTPNT_QO_TOL_NEAR_REL](#).
 - Changed scaling of interior-point optimizer so better accuracy is obtained in some cases.
 - Introduced an outer approximation method for solving conic mixed integer optimization problems. This can be enabled with the parameter [MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION](#).
 - Much improved performance on recent AMD CPUs. For linear algebra, the BLIS library is employed when run on AMD CPUs.
 - Better performance on CPUs that support AVX-512 instructions.
 - Removed parameters: `MSK_DPAR_DATA_TOL_AIJ`, `MSK_DPAR_INTPNT_NL_*`, `MSK_DPAR_MIO_DISABLE_TERM_TIME`, `MSK_DPAR_MIO_NEAR_TOL_ABS_GAP`, `MSK_DPAR_MIO_NEAR_TOL_REL_GAP`, `MSK_IPAR_MIO_CONSTRUCT_SOL` and synonym "mipstart" (GAMS now always passes the starting point of a MIP to Mosek), `MSK_IPAR_OPF_MAX_TERMS_PER_LINE`, `MSK_IPAR_WRITE_DATA_FORMAT`
 - Further new parameters: [MSK_IPAR_PRESOLVE_MAX_NUM_PASS](#), [MSK_IPAR_PRESOLVE_MAX_NUM_P](#), [MSK_IPAR_SIM_SEED](#), [MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS](#), [MSK_IPAR_MIO_MAX_NUM_RO](#), [MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT](#), [MSK_IPAR_MIO_SEED](#), [MSK_IPAR_MIO_FEASPUMP_LEVEL](#), [MSK_IPAR_WRITE_COMPRESSION](#), [MSK_IPAR_OPF_WRITE_LL](#), [MSK_IPAR_PTF_WRITE_TRANSFORM](#)
 - Changed default of [MSK_DPAR_MIO_TOL_ABS_GAP](#) from 0 to value of GAMS option `OptCA` (was used for `MSK_DPAR_MIO_NEAR_TOL_ABS_GAP` before) and of [MSK_DPAR_MIO_TOL_REL_GAP](#) from 0 to value of GAMS option `OptCR` (was used for `MSK_DPAR_MIO_NEAR_TOL_REL_GAP` before).
- Fixed handling of Mosek certificates for primal and dual infeasibility, see [Infeasible/Unbounded Models](#).

3.13.1.4.10 SCIP

- New libraries 6.0 (f79421d).
-

3.13.1.5 Tools

3.13.1.5.1 GAMS Studio

- New version 0.12.3.
 - Stability and performance improvements.
 - Added GAMS [Solver Option Editor](#) to view and edit a solver-specific option file.
 - Renamed Option Editor to Parameter Editor to better distinguish solver options and GAMS parameters.
 - Added menu entry `GAMS -> Delete scratch directories` to delete all scratch directories in current working directory. A similar dialog will also be triggered if GAMS returns 110 ("Too many scratch directories").
 - Added file associations and icons for `.gms` and `.gdx` files on Mac OS X.
 - Changed shortcut to focus Main widget from `Ctrl+H` to `CTRL+E` (there was a collision on Mac OS X).
 - Improved keyboard navigation between files and widgets.
- We plan to drop Studio for 32 bit Windows with the next major release.

3.13.1.6 APIs

- As [announced](#), dropped support for Python 2.6.
- We plan to increase the minimum version requirement of the Java Runtime Environment to Java SE 8 with the next major release.

3.13.1.7 Model Libraries

3.13.1.7.1 GAMS Model Library

- Changed model sigma in `immun` to minimize standard-deviation instead of variance.
- Added missing nonnegativity requirement on variables in model `wall`.

3.13.1.8 Solver/Platform availability matrix

3.13.2 28.2.0 Minor release (August 19, 2019)

3.13.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Nayeem Chowdhury, Salvador Doménech Martínez, Michael Ferris, Antti Lehtila, Evangelos Panos, Jochen Urich, and Alexey Ziuzin.

3.13.2.2 GAMS System

3.13.2.2.1 GAMS

- Setting `$onMultiR` allows the redefinition of `macros` as well now.
- Fixed a problem finding the Python interpreter, that comes with GAMS, in certain cases.
- Fixed a bug in the model generation, which could have caused a crash or wrong results in some cases.

3.13.2.3 Solvers

3.13.2.3.1 CPLEXD

- Corrected reporting of solution for (MI)QCP problems when using `feasopt`.
- CplexD now reports the objective of the feasible relaxation in the solution summary when using `feasopt`.

3.13.2.4 Tools

3.13.2.4.1 GAMS Studio

- New version 0.12.4
 - Stability and performance improvements.
 - Improved robustness of glb file parser (see [User Libraries](#)).
 - Added "What's new" menu entry to show latest changes of Studio.

3.13.2.5 Object Oriented APIs

- Fixed a problem, where `GAMSDatabase.Export` triggered an exception because of domain violations, even if only relaxed domains were used.

3.13.2.5.1 Java

- Added new method `GAMSSymbolRecord.dispose` for on-demand release of external resources hold by non-java library.

3.14 27 Distribution

3.14.1 27.1.0 Major release (April 24, 2019)

3.14.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Arne Drud, Jan-Erik Justkowiak, Renger van Nieuwkoop, and Manuel Wetzel.

3.14.1.2 Platforms

- As [announced](#), support for Mac OS X 10.11 (El Capitan) has been dropped.
- As [announced](#), support for Windows Vista has been dropped.

3.14.1.3 GAMS System

3.14.1.3.1 GAMS

- Embedded Python Code:
 - Allow [Implicit Set Definition \(or: Domain Defining Symbol Declarations\)](#) now for symbols loaded from [embedded code](#) as well.
 - Changed the default behavior of `$offEmbeddedCode` and `endEmbeddedCode`: Previously, internal resources got freed and with the next start of an embedded Python code section, the Python environment had to be reinitialized. This is not the case anymore. Also, the interpreter stays "alive" now, which allows to access Python symbols defined in one embedded code block in a following block. The old behavior could still be activated by setting the new command line parameter `freeEmbeddedPython` to 1.
 - Changed the optional boolean argument `merge` to an enumerated option `mergeType` in the `gams.set` method in embedded code. *This might break existing code.* Even if the `merge` argument was not used, the default behavior at compile time changes. In previous versions the content of an already defined symbol was quietly replaced while GAMS now triggers a compilation error 194 `Symbol redefined`.
 - Fixed a bug in embedded code when setting `pySetup` to 0. Additional steps are required on Linux and Mac OS X to use an alternative Python installation. Details can be found in section [Porting to a Different Version of Python](#).
 - A `GAMSDatabase` created in embedded code via `gams.ws.add_database(source_database = gams.db)` had all the symbols but no data. This has been fixed.
 - `gams.db.export(file_name)` in embedded code resulted in an error for scalar symbols without data. This has been fixed.
 - Fixed a problem with `embeddedCode/continueEmbeddedCode` after an assignment that was not finished with a `;` like in this example:

```
Set i /1*3/;
Parameter xl(i);
xl(i) = uniform(0.5,1)
embeddedCode Python:
print(list(gams.get('xl')))
endEmbeddedCode
Display xl;
```

This leads to an error now. In the past, the assignment in line 3 was executed **after** the `embeddedCode` block leading to unexpected results.

- Extended the GAMS log to print out the non-default [Command Line Parameters](#).
- Improved performance of `execute_unload` when option `gdxUELS` is set to `full`.
- Improve performance of model generation when multi-dimensional variables are used, where the controlling set for dimension `n>1` is big, e.g.:

```
Set tiny /1*2/, huge /1*100000/ ;
Variable x(i,j); Equation e;
...
e.. sum((tiny,huge), x(tiny,huge)) =e= 42;
...
```

- Fixed a potential crash when more than 250 million [labels](#) are used in one model.
- Fixed a bug with [Implicit Set Definition](#): When used with [\\$onMulti](#) to merge data into a non-empty set, it could have happened that an element was added twice in some cases.
- Fixed a bug causing a broken dump file if [\\$onVerbatim](#) and [\\$ifThen](#) was used with [DumpOpt](#).

3.14.1.3.2 Documentation

- Added documentation for the [put_utility](#) keyword [assignText](#) (which has been in the system since 24.6).

3.14.1.3.3 GDX library

- Improve the behavior of GDX when handling large data sets (e.g. writing a set with 210 million elements, each having its own lengthy set text). Performance is better - less memory and less time are required. The limits on the amount of data that can be handled have been extended somewhat, and when these limits are reached this is handled more gracefully than previously - with a helpful message instead of a segmentation fault or erroneous results.
- Introduce consistent handling of the empty string vis-a-vis set text for UELs. *This is only relevant for user applications that use the low-level GDX API in an unsupported way.*
 - Previously the proper usage was to avoid adding the empty string to the list of set text strings. Applications that broke this rule would produce a GDX file with an abnormal internal structure. This structure may lead to jumbled set text.
 - With the updated GDX, it is not necessary to avoid adding an empty string to the set text list.
 - Applications holding to previous proper usage (i.e. those that avoid adding the empty string to the list of set text strings) will produce good GDX files regardless of GAMS version, and these files will behave as expected regardless of the GAMS version in which they are used.

3.14.1.4 Solvers

3.14.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2019.3 on Linux and Mac OS X and to 2018.4 on Windows 64-bit.

3.14.1.4.2 BARON

- New libraries 19.3.24.
 - Improved automatic differentiator that is up to two orders of magnitude faster for large-scale problems.
 - Improved data structures and cut pool manager to reduce memory footprint and time requirements for large-scale problems.
 - Improvements in various components, including parallel threads and BARON's IPOPT interface for Mac OS X.
 - New tree management algorithms.
 - Improved range reduction and probing algorithms.
 - Using Intel MKL for faster BLAS and LAPACK routines.
 - Ipopt now uses METIS for linear system partitioning.
 - New option [FirstLoc](#) to terminate BARON as soon as a local optimum is found.
 - New option [ClockType](#) to determine whether wall-clock or CPU time should be reported back to GAMS.
-

3.14.1.4.3 BDMLP and SBB

- The definition of SOS1 and SOS2 variables has changed. BDMLP and SBB used to *count* the number of elements in a set that are *off the lower bound*. BDMLP and SBB were the only two solvers in the GAMS solver portfolio with this definition. All other solvers counted elements that are *off zero*. The definition of SOS1 and SOS2 variables in BDMLP and SBB has been changed to the *off zero* definition to make their behavior more consistent with other GAMS solvers.

3.14.1.4.4 CBC

- New libraries 2.10.
 - Improved handling of SOS, starting point, and symmetries.
 - Improved performance of primal heuristics regarding the handling of implicit integer variables.
 - Mini-B&B is now disabled when solving with multiple threads.
 - Changed default value for [zero half cuts parameter](#) from `off` to `ifmove`.

3.14.1.4.5 CONOPT 4

- New library 4.11 with improvements in reliability and efficiency for large and difficult models.
- New option [Tol_Opt_LinF](#): Optimality tolerance when infeasible in Linear Feasibility Model.

3.14.1.4.6 CPLEX/CPLEXD

- New libraries 12.9.0.
 - New options: [CPLEXfolding](#), [CPLEXwriteprob](#) (CplexD only), [CPLEXwarninglimit](#).
 - New [hierarchical multi-objective optimization](#) (CplexD only): [CPLEXmultobj](#), [CPLEXmultobjmethod](#), [CPLEXobjnabstol](#), [CPLEXobjnreltol](#).
 - The symmetry breaking parameter [CPLEXsymmetry](#) now applies only to MIP models. Use the new [CPLEXfolding](#) parameter for LP models.

3.14.1.4.7 GUROBI

- New libraries 8.1.1.

3.14.1.4.8 JAMS

- Experimental indexed EMP syntax has been updated: It can now take all the equilibrium related keywords (`max`, `min`, `vi`, `qvi`, `dualvar`, `visol`, and `implicit`) and shared constraints and variables.

3.14.1.4.9 LocalSolver

- New libraries 8.5 (20190130).
 - Strong lower bounds based on nonlinear relaxation techniques coupled with innovative branch-and-bound heuristics.
-

3.14.1.4.10 Mosek

- New libraries 8.1.0.80.

3.14.1.4.11 ODHCPLEX

- New libraries 4.23.

3.14.1.4.12 OQNLP

- As [announced](#), OQNLP has been dropped.

3.14.1.5 Tools

3.14.1.5.1 CSDP

- See [ANTIGONE](#), [Bonmin](#), [Couenne](#), [Ipsopt](#), [SCIP](#).
- New library 6.2.0 on Mac OS X.

3.14.1.5.2 GAMS Studio

- New version 0.11.1.
 - Stability and performance improvements.
 - Introduced a [toolbar](#) to replace the "Execution and Option Parameter Editor".
 - Editor
 - * Improved the syntax highlighting.
 - * Allow to open huge read-only (lst) files without significant memory requirement.
 - * Added [bookmark](#) support.
 - * Added `Ctrl+Up`/`Ctrl+Down` as shortcut for line wise scrolling without moving the text cursor.
 - * Added `Ctrl+Home`/`Ctrl+End` as shortcut for page wise scrolling without moving the text cursor.
 - * Added warning pop-up when trying to open a >50 Mb file in edit mode.
 - Various
 - * Added `Ctrl+Alt+L` to extend/collapse the extended option editor
 - Forced light application theme on Mac OS X to circumvent problems using the Dark Mode of Mac OS X Mojave.

3.14.1.5.3 GDXDUMP

- New command line option `setText` to show the list of set text stored in a GDX file.
 - Option `symbols` now lists the cardinality of a symbol in the column `Records`.
-

3.14.1.5.4 GDXXRW

- Fixed exit behavior if there were some duplicate records found when reading a symbol but less than specified by `maxDupeErrors`: If there are no other errors the exit code is 0 now (it was 16 in the past)

3.14.1.5.5 GMSZIP/GMSUNZIP

- Replaced the 32bit binaries `gmszip` and `gmsunzip` by more recent 64bit versions on Mac OS X.

3.14.1.5.6 MPS2GMS

- Turn some errors that can be safely ignored when reading an MPS file into warnings.

3.14.1.6 Object Oriented APIs

3.14.1.6.1 Python

- Fixed a bug with default variable levels being 1.0 instead of 0.0.

3.14.1.7 Model Libraries

3.14.1.7.1 GAMS Data Library

- `GDX2ACCESSExample1.gms` : Dumping the Contents of `transport.gdx` (125)
- `GDX2ACCESSExample2.gms` : Writing Explanatory Text to Database (126)
- `GDX2ACCESSExample3.gms` : Dumping a large Table to Database (127)
- `GDX2ACCESSExample4.gms` : Special Value Mapping (128)
- `GDX2ACCESSExample5.gms` : Renaming Fields (129)

3.14.1.7.2 GAMS Test Library

- `sosmiqcp01.gms` : SOS1 and SOS2 behavior - MIQCP (794)
- `sosmip01.gms` : SOS1 and SOS2 behavior - MIP (795)
- `sosminlp01.gms` : SOS1 and SOS2 behavior - MINLP (796)

3.14.2 27.2.0 Minor release (May 23, 2019)

3.14.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Michael Burkhardt, and Karlo Šepetanc.

3.14.2.2 GAMS System

3.14.2.2.1 GAMS

- Fix problem with missing entries for scalar variables and equations in the index file for the [GAMS Output](#) in certain cases.

3.14.2.3 Solvers

3.14.2.3.1 CONOPT

- New library 3.17J.
- New library 4.12.

3.14.2.3.2 Lindo/LindoGlobal

- New libraries 12.0.157.

3.14.2.3.3 LOCALSOLVER

- New libraries 8.5 (20190430).

3.14.2.3.4 NLPEC

- Added new option [parmFile](#) to allow to point to additional options for the GAMS run of the scalar model produced by NLPEC.

3.14.2.3.5 ODHCplex

- New libraries 4.26.

3.14.2.3.6 OSIXPRESS

- Fixed use of standalone Xpress license.
-

3.14.2.4 Tools

3.14.2.4.1 GAMS Studio

- New version 0.11.2.
 - Stability and performance improvements.
 - GDX Viewer
 - * Added Drag and Drop feature in [GDX Table View](#)

3.14.2.5 Object Oriented APIs

3.14.2.5.1 Python

- Fixed a memory leak in the Python 3 version of the API.
- We plan to drop support for Python 2.6 with the next major release.

3.14.2.6 Expert Level APIs

- Fixed a memory leak in the Python 3 version of the APIs.
- We plan to drop support for Python 2.6 with the next major release.

3.14.3 27.3.0 Minor release (July 04, 2019)

3.14.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Erwin Kalvelagen, Wolfgang Kuehn, Bruce McCarl, and Michael Winkler.

3.14.3.2 GAMS System

- Fixed a bug that resulted in undercounting the number of physical and logical processors on Windows systems with more than 64 logical processors. GAMS/Base and many solvers use this count, e.g. when setting [threads](#) to 0 or -1.

3.14.3.2.1 GAMS

- Allow domain projection with [\\$load](#) also if the source symbol is a variable or equation.
 - Fixed the cause for an unwanted compilation error with `embeddedCode` in certain situations.
 - Unified behavior of the [profile](#) option: In the past, the `Profile Summary` was always written, when the profiling was activated from the command line, but was sometimes omitted when set as an option. Now, the summary gets always written. It does not matter anymore, where profiling was activated.
-

3.14.3.2.2 Documentation

- Added a [Preface](#) that reflects the history of the GAMS documentation. In particular it points out the importance of external contributors, in particular Bruce McCarl.

3.14.3.3 Solvers

3.14.3.3.1 BARON

- Fixed load of Xpress library on Linux.

3.14.3.3.2 CBC

- New libraries.

3.14.3.3.3 CONOPT

- New library 3.17K.
- Bug fix in library 4.12.

3.14.3.3.4 GAMSCHK

- Fixed error in postopt report. Previously, the report for the column occurring last in the listing file would be omitted, and all its entries would appear in the report for the preceding column.
- Fixed crash that occurred in some cases.
- The above problems occurred in GAMS 26 and previous. A fix was introduced with GAMS 27, but this fix went too far and introduced new problems. With this version, the fix to 27.1 is reverted and a more moderate fix is used instead.

3.14.3.3.5 LocalSolver

- Fixed missing solver log.

3.14.3.3.6 Mosek

- New libraries 8.1.0.81.
- Fixed ignoring option [solvefinal](#).

3.14.3.3.7 SCIP

- New libraries 6.0.2.
-

3.14.3.3.8 SoPlex

- New libraries 4.0.2.

3.14.3.4 Tools

3.14.3.4.1 GAMS Studio

- New version 0.11.5
 - Stability and performance improvements.
 - Added buttons to toolbar to show/hide Project Explorer, Output-, and Help widget.
 - Added shortcut **Ctrl+H** to focus Main widget.
 - Added shortcut **Ctrl+Shift+G** to focus Output widget.
 - Added shortcut **Esc** to close several widgets.
 - GDX Viewer:
 - * Columns in the data view are now resized to the minimum width necessary to see all the data automatically.
 - * Added shortcut to auto-resize all columns in the data view after the width was changed by hand (**Ctrl+R**).
 - Search:
 - * Added shortcut **Ctrl+Enter** for "Search All".
 - * Added ability to replace in more than one file at a time.
 - * Find Next/Previous now respects all search options and will jump to the next file if there are also matches.

3.14.3.5 Object Oriented APIs

3.14.3.5.1 Python

- Fixed a bug in `GamsJob.interrupt()` that caused an `OverflowError` on 64 bit platforms.

3.15 26 Distribution

3.15.1 26.1.0 Major release (February 02, 2019)

3.15.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Stefano Alva, Adam Christensen, Hanna Donau, Stephen Frank, Anastasis Giannousakis, Jan-Erik Justkowiak, David Laudy, Andreas Lundell, Thomas Maindl, Nils Mattus, Scott McDonald, Noah Rhodes, Tom Rutherford, and Anna Straubinger.

3.15.1.2 Versioning

From this release on, we use a new interpretation on the GAMS version number scheme $XX.Y.Z$. XX alone now indicates the GAMS distribution number (was $XX.Y$ before). Y is used to distinguish between beta, major, and minor releases of the XX distribution. Z is used to distinguish different maintenance releases. That is, we now use

- $XX.0.Z$ for beta versions,
- $XX.1.0$ for the major release of distribution XX ,
- $XX.Y.0$, $Y > 1$, for minor releases,
- $XX.Y.Z$, $Y \geq 1$, $Z > 0$, for maintenance releases.

See [Release Types](#) regarding the meaning or what constitutes a major, minor, or maintenance release. As before, we increase the required license date for major releases only.

Further, we changed the default installation directory of the GAMS system from using only the distribution number to also include the minor version number. Thus, as before, GAMS is now installed into directory names which contain the $XX.Y$ part of the GAMS version number.

3.15.1.3 Platforms

- We plan to drop support for Mac OS X 10.11 (El Capitan) with the next major release.
- We plan to drop support for Windows Vista with the next major release.
- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

3.15.1.4 GAMS System

3.15.1.4.1 GAMS

- Changed behavior of `$compress`, `$decompress`, and `$encrypt`: `source` and `target` cannot be identical anymore; this could have lead to unreliable behavior in the past.
- Extended the influence of `$onMulti`: This affects the `model statement` as well now.
- Added new dollar control option `$onMultiR`, which is similar to `$onMulti` but replaces existing data instead of merging into it.
- Added `put_utility` keyword `solver` to select a solver for a given or all possible model types by name at execution time.
- Extended the syntax to allow [Implicit Set Definition \(or: Domain Defining Symbol Declarations\)](#). Here is a small example showing how this can be used:

```
Set
  i 'canning plants'
  j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
      new-york  chicago  topeka
  seattle    2.5      1.7      1.8
  san-diego  2.5      1.8      1.4;

Display i,j;
```

And this is the result of the `Display` statement:

```
-----      10 SET i  canning plants

seattle   ,      san-diego

-----      10 SET j  markets

new-york,      chicago ,      topeka
```

- Updated the base module and components as necessary to allow for spaces in names of any files and directory used by GAMS, including the system directory, the working directory, the scratch directory, the process directory, and remove any checks warning about and preventing this. While the Windows system had already allowed spaces in previous versions, this change updates the other platforms to behave similarly.
- Changed the reading of command-line arguments on non-Windows platforms! This should only affect how arguments with spaces in them are passed on to GAMS. Previously, such arguments needed extra quoting or protection on non-Windows platforms. With this update, the extra protection is no longer needed: the same quoting of space-containing arguments can be used on all platforms. For example, with GAMS 25.1 and previous, two pairs of quotes were required on non-Windows platforms to protect spaces in an argument:

```
gams xx.gms --MY_GDX '"outer space"'
```

while now only one pair of quotes is needed on all platforms:

```
gams xx.gms --MY_GDX "outer space"
```

- Increased the number of [labels](#), which can be handled by GAMS from 200 million to ~ 2.1 billion and let GAMS terminate with the meaningful error message, if that limit is reached.
- Windows only: Fixed a bug which treated a path (e.g. to an input file or used as [inputDir](#)) as relative path, if it starts with `/`. Example: When running `cd C:\tmp && gams.exe /data/myModel.gms`, GAMS tried to load the file `C:\tmp\data\myModel.gms` in the past. Now, it loads `C:\data\myModel.gms`.
- Fixed some problems with option [asyncSolLst](#).
- Fixed a bug which could have caused GAMS to accept duplicate entries in a data statement, when they came in unsorted order.
- Fixed the dollar control option [\\$onUpper](#) (it did not do anything before).

3.15.1.4.2 GMSPython

- Updated `pip` to work with recent Mac OS X versions.

3.15.1.5 Solvers

3.15.1.5.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Fixed an MKL error when running any of these solvers after CPLEX with `solverlink=5` in the same GAMS run on Linux.
 - Updated Intel MKL libraries to version 2019.0 on Linux and to version 2018.3 on Windows 64-bit.
-

3.15.1.5.2 BARON

- New libraries 18.11.12 for 64-bit platforms.
 - New cutting planes for convex-transformable functions.
 - New cutting planes for polynomial optimization problems.
 - More robust treatment of cutting planes.
 - Improved optimality-based range reduction mechanisms.
 - CBC can now use multiple threads on Windows, too.
- We plan to drop BARON for Windows 32-bit with some future release.
- The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time.

3.15.1.5.3 Bonmin, CBC, Couenne, Ipopt

- New libraries.

3.15.1.5.4 CONOPT 4

- New library 4.09 with many reliability improvements and a fix for wrong non-opt markers.

3.15.1.5.5 CPLEX

- Ctrl-C (or Interrupt) was broken for GAMS/CplexD. This has been fixed.
- Improved performance of retrieving the solution for a QCP with many quadratic rows.

3.15.1.5.6 Gurobi

- The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time on Unix.
- Allow quadratic rows with =E= and let Gurobi deal with potential errors. Gurobi can sometimes substitute quadratic terms defined by =E= rows. The check of quadratic row to be either =L= or =G= in the GAMS/Gurobi link prevented this.

3.15.1.5.7 KESTREL

- Added support for [MPSGE](#) models.

3.15.1.5.8 Knitro

- New libraries 11.1.1 (11.0.1 for 32-bit Windows) containing several bug fixes and performance improvements, including:
 - improved performance on convex quadratic models,
 - improved generation of knapsack cuts, resulting in faster performance on some MINLP models,
 - improved performance when using the SQP algorithm,
 - new values for option [linsolver](#) to choose parallel factorization routines MA97 and MA86.
 - Artelys has announced that Knitro 11.0 was the last Knitro release to support 32-bit Windows. We will be dropping GAMS/Knitro for 32-bit Windows in the near future.
-

3.15.1.5.9 Lindo/LindoGlobal

- New libraries 12.0.90.
 - LP Solver Improvements:
 - * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 18% for the primal simplex and 15% for the dual simplex compared to the previous version.
 - * Improved performance on LP's when using multiple cores with concurrent execution of Primal, Dual, and Barrier.
 - Quadratic and Nonlinear Solver Improvements:
 - * Much faster handling of large quadratic matrices, e.g. 1000 x 1000.
 - Global Solver Improvements:
 - * Improved handling of discontinuous functions, e.g., MOD(x,k), ROUND(x).

3.15.1.5.10 LocalSolver

- New libraries 8.0 (20181106).
 - Performance improvements on routing & scheduling problems, especially Pickup & Delivery problems.
 - Learning algorithms inside LocalSolver, which allow to automatically and dynamically tune up the search process for each solved instance, were improved. This leads to improved performances, especially for short resolution times (minutes).

3.15.1.5.11 Mosek

- New libraries 8.1.0.72.

3.15.1.5.12 ODHCPLEX

- New libraries 4.09 for Linux with many reliability improvements.
- New libraries 4.13 for Windows 64-bit with many reliability improvements and addressing dynamic loading in concurrent threads and processes.
- Updated options: [DynamicSearch](#), [FirstFeas](#), and [Strategy](#)
- New options: [DecompDensity](#), [Divisor](#), [ODHFeasOpt](#), [MaxBacktrack](#), [NewCallback](#), [Recurse](#), [RecurseDecomp](#), [RecurseIterLim](#), [RecurseLog](#), [RecurseMinIterLim](#), [RecurseSolIterLim](#), [RelaxSOS2](#), and [ThreadLog](#).

3.15.1.5.13 OQNLP

- We plan to drop OQNLP with the next major release.
-

3.15.1.5.14 PATH

- New libraries 5.0.00.
 - Fixed crash in Lemke's method that could happen for models with extremely poor scaling.
 - New capability to use alternate basis-handling packages via dynamic loading of shared libraries. Two alternate packages are currently supported:
 - * BLU-LUSOL: Block LU updating using the LUSOL routines. The shared library required for this is included in the distribution.
 - * UMFPACK: Tim Davis' multifrontal LU factorization package. The shared library required for this is **not** included in the GAMS distribution, but can be downloaded from the [SuiteSparse](#) site. N.B.: We have verified UMFPACK on Linux, Mac OS X, and Windows using UMFPACK v5.7.7 from SuiteSparse 5.3.0.

3.15.1.5.15 SCIP

- New libraries 6.0.1.
 - Primal Heuristics
 - * new diving heuristic [farkasdiving](#) that dives into the direction of the pseudosolution and tries to construct Farkas-proofs
 - * new diving heuristic [conflictdiving](#) that considers locks from conflict constraints
 - * performance improvements for Adaptive Large Neighborhood Search
 - changed default of parameter [heuristics/alns/adjustminimprove](#) from 1 to 0
 - changed default of parameter [heuristics/alns/alpha](#) from 0.2 to 0.0016
 - new parameter [heuristics/alns/adjusttargetnodes](#)
 - changed default of parameter [heuristics/alns/eps](#) from 0.5 to 0.468584
 - changed default of parameter [heuristics/alns/gamma](#) from 0.2 to 0.0704146
 - changed default of parameter [heuristics/alns/minimprovehigh](#) from 0.1 to 0.01
 - changed default of parameter [heuristics/alns/minimprovelow](#) from 0.0001 to 0.01
 - removed parameter [heuristics/alns/stallnodefactor](#)
 - changed default of parameter [heuristics/alns/startminimprove](#) from 0.05 to 0.01
 - changed default of parameter [heuristics/alns/targetnodefactor](#) from 1.5 to 1.05
 - new parameter [heuristics/alns/unfixtol](#)
 - changed default of parameter [heuristics/alns/crossover/minfixingrate](#) from 0.4 to 0.3
 - changed default of parameter [heuristics/alns/dins/maxfixingrate](#) from 0.5 to 0.9
 - changed default of parameter [heuristics/alns/dins/minfixingrate](#) from 0.1 to 0.3
 - changed default of parameter [heuristics/alns/localbranching/minfixingrate](#) from 0 to 0.3
 - changed default of parameter [heuristics/alns/mutation/minfixingrate](#) from 0.4 to 0.3
 - changed default of parameter [heuristics/alns/proximity/minfixingrate](#) from 0 to 0.3
 - changed default of parameter [heuristics/alns/rens/maxfixingrate](#) from 0.7 to 0.9
 - changed default of parameter [heuristics/alns/rins/maxfixingrate](#) from 0.6 to 0.9
 - changed default of parameter [heuristics/alns/rins/minfixingrate](#) from 0.2 to 0.3
 - changed default of parameter [heuristics/alns/zeroobjective/minfixingrate](#) from 0 to 0.3
 - New branching rule [lookahead](#) that evaluates potential child and grandchild nodes to determine a branching decision
 - LP Solver Interface
 - * [lp/checkstability](#) is now properly implemented for use with SoPlex
 - * new parameter [lp/alwaysgetduals](#)

- * new parameter [lp/checkfarkas](#)
- Separation (cutting planes)
 - * cuts generated from certain quadratic constraints with convex feasible region are now global
 - * new parameter `separating/dircutoffdistfac`
 - * new parameter `separating/efficacyfac`
 - * removed parameter `separating/maxincrounds`
 - * new parameter [separating/zerohalf/dircutoffdistweight](#)
 - * new parameter [separating/zerohalf/efficacyweight](#)
 - * changed default of parameter `separating/zerohalf/goodscore` from 0.9 to 1
 - * new parameter [separating/zerohalf/goodmaxparall](#)
 - * new parameter [separating/zerohalf/initseed](#)
 - * new parameter [separating/zerohalf/maxparall](#)
 - * new parameter [separating/zerohalf/objparalweight](#)
- Symmetry Handling
 - * restructured timing of symmetry computation to allow to add symmetry handling components within presolving
 - * changed default of parameter [constraints/symresack/ppsymresack](#) from 0 to 1
 - * new parameter `presolving/symbreak/addconsstiming`
 - * changed default of parameter `presolving/symbreak/detectororbitopes` from 1 to 0
 - * removed parameter "presolving/symmetry/computepresolved"
 - * new parameter `propagating/orbitalfixing/enabledafterrestarts`
 - * new parameter `propagating/orbitalfixing/performpresolving`
 - * changed default of parameter `propagating/orbitalfixing/presolpriority` from 0 to -1000000
 - * changed default of parameter `propagating/orbitalfixing/presoltiming` from 28 to 16
 - * new parameter `propagating/orbitalfixing/symcomptiming`
- improved bound tightening for some quadratic equations
- new parameter [display/relevantstats](#)
- new parameter [misc/scaleobj](#)
- removed `implfree` presolver
- See also the [full release notes](#) and the [release paper](#).

3.15.1.5.16 SELKIE The [SELKIE solver](#) - new to GAMS with this release - is an EMP solver that implements decomposition methods for multi-agent equilibrium and related models.

3.15.1.5.17 SoPlex

- New libraries 4.0.1.
 - new simplifier step to perform variable aggregation for equations with two variables
 - new parameter [bool:ensureray](#) to re-solve the original problem in case of infeasibility/unboundedness to get a valid proof/ray
 - See also the [full release notes](#) and the [release paper](#).
-

3.15.1.5.18 Xpress

- New libraries 33.01.10.
 - local symmetry re-detection in MIP tree search
 - improved branching for highly symmetric MIPs
 - new or improved cuts, degeneracy handling, crossover, preprocessing
 - FICO does not release patches for all platforms with each patch release, so some platforms lag behind the most-used ones.

3.15.1.6 Tools

3.15.1.6.1 CSDP

- See [ANTIGONE](#), [Bonmin](#), [Couenne](#), [Iopt](#), [SCIP](#).

3.15.1.6.2 CSV2GDX

- Extended recognition of [special values](#):
 - N/A is recognized as NA,
 - TRUE is recognized as 1,
 - FALSE, NONE and NULL are recognized as 0.
- Added new option [text](#) to specify the column to get explanatory text from when reading a set.
- Changed handling of bad UELs: Reading a bad UEL (e.g. a UEL exceeding the maximum length) causes an error now. The old behavior can be enabled again using the new option [acceptBadUels](#).

3.15.1.6.3 GAMS Studio

- New version 0.10.3
 - Stability and performance improvements.
 - Added a new section [Comparing GAMS Studio and GAMSIDE](#) to the documentation.
 - Added a [Reference File Viewer](#) to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS models and is created using the [reference](#) parameter when running the model.
 - Added a [Tab Browser](#) to list and search through all open files. It is accessible with a button next to the main tab bar or via the shortcut `Ctrl+K`.
 - [GDX Viewer](#) :
 - * Added a first, basic version of a [Table View](#) : The new button "Table View" switches the view to a table based representation. The button is only enabled for multidimensional symbols and puts the last dimension into the header of the table. Drag and drop of items is not yet supported but will be in the future.
 - * Added option to hide specific value columns for variables and equations.
 - * Added support for the use of different encodings using the "Edit->Encoding" menu. The default encoding for a GDX file generated in Studio by running a GMS file with automatic GDX creation (F10) is the one used by the GMS file.
 - Editor
-

- * Added smart typing: Automatic insertion of closing character for brackets and quotes.
- * Added ability to select text and press either a opening bracket or quote to surround text with these symbols.
- * Improved backspace behavior, if auto indentation is active.
- Output Widget
 - * Added info, warning, and error messages to GAMS Studio system log.
 - * GAMS log files are now written to disk (can be disabled in settings).
 - * Added "clear log" context menu entry.
- Project Explorer
 - * Studio automatically adds all files specified through GAMS parameters (.gdx, .ref, .lst) to the Project Explorer.
 - * Allow to rename Project Explorer groups.
 - * Groups are closed if they are empty.
 - * If a group is closed the associated GAMS process will be stopped.
 - * Added drag and drop of files between groups.
 - * Added shortcut to focus Project Explorer (**Ctrl+J**) and allow to navigate using arrow keys to select a file.
 - * Added "Select all", "Expand all" and "Collapse all" to the context menu.
 - * Added shortcut to select all files (**Ctrl+A**).
- Various
 - * Added context menu for tabs (offering different close actions).
 - * Added animation for groups with running GAMS processes.
 - * Studio comes to foreground when double clicking a Studio-associated file.
 - * The "About GAMS" dialog contains many important information like used GAMS version, system directory, or license information. It features a "Copy System Information" button which copies all of these information to easily attach them to a support request. The dialog has a second tab which gives an overview about solvers, their license status, and what kinds of capabilities they have.
 - * "File -> New..." dialog starts with a default for a new file name.
 - * "File -> Open..." (or drag'n'drop) of one file now focuses that file if it is already present in the Project Explorer.
 - * New entry "File -> Open... in new group" to force creation of new group (even if the is already present in the Project Explorer).
 - * "File -> Open..." (or drag'n'drop) of multiple files puts all files opened at once into a single group instead of individuals.
 - * Added shortcut to focus command line parameter edit field (**Ctrl+L**).
 - * Added **Ctrl+F** as close shortcut for search dialog.
 - * Changed shortcut to open Settings dialog to **F7**.

Note

This version of GAMS Studio does not support the Dark Mode of MacOS Mojave. Please disable this mode to use GAMS Studio.

3.15.1.6.4 GDXDUMP

- New options for writing out special values: `NAOut`, `UndfOut`, `PInfOut`, `MInfOut`, and `ZeroOut`.
 - Fixed broken generated GAMS code, if `Ue1Table` option was used, but there were no UELs.
 - Lower and upper bounds of equations are dumped always now (even if their values are the default). This fixes a potential problem, that the equation type is unknown for the generated GAMS code.
 - When writing CSV files the element text of set elements could not be written. Now with enabled option `CSVSetText` the element text of a set element is written as the last column in the CSV file.
-

3.15.1.6.5 GDXXRW

- Fixed a bug which could have caused a crash when reading merged cells from Excel using the GDXXRW options `useRC` and `cMerge=1`.

3.15.1.6.6 MODEL2TEX

- The new script `model2tex.sh` sets the required dependencies for the `model2tex` tool on Linux and Mac OS X. Using this script is the recommended way for using `model2tex`. Calling the Python script directly is not recommended anymore since the used Python interpreter would need to be configured manually. `model2tex.sh` uses the Python interpreter that comes with the GAMS distribution.

3.15.1.7 Object Oriented APIs

3.15.1.7.1 Python

- The `setup.py` script now installs the `idx` expert-level API.

3.15.1.8 Model Libraries

3.15.1.8.1 GAMS Data Library New models added:

- `csv2gdx2.gms` : CSV2GDX Example 2 - Reading CSV Files with CSV2GDX (111)
 - `csv2gdx3.gms` : CSV2GDX Example 3 - Reading Semicolon separated Data (112)
 - `csv2gdx4.gms` : CSV2GDX Example 4 - Dealing with missing Labels and Duplicates (113)
 - `csv2gdx5.gms` : CSV2GDX Example 5 - Reading more than one Parameter from a single Input File (114)
 - `csv2gdx6.gms` : CSV2GDX Example 6 - Reading economic Data from the World Bank Data Catalog (115)
 - `csv2gdx7.gms` : CSV2GDX Example 7 - Reading special Values with CSV2GDX (116)
 - `csv2gdx8.gms` : CSV2GDX Example 8 - Reading an compressed encrypted Input File (117)
 - `csv2gdx9.gms` : CSV2GDX Example 9 - Reading Options from an external File (118)
 - `GDXXRWExample17.gms` : Reading several Scalars from Spreadsheet (119)
 - `GDXXRWExample18.gms` : Reading Sets from Spreadsheet (120)
 - `GDXXRWExample19.gms` : Writing Parameter to Spreadsheet including Zero Values (121)
 - `GDXXRWExample20.gms` : Reading empty Cells with `colMerge` and reading merged Excel Ranges with `cMerge` (122)
 - `GDXXRWExample21.gms` : Skipping empty Rows or Columns and Ignoring Rows or Columns (123)
 - `GDXDUMPExample1.gms` : GDXDUMP - Adding double Quotes to an user defined Header when writing to CSV (124)
-

3.15.1.8.2 GAMS EMP Library New model added:

- **emppython1.gms** : Three Simple EMP Models with Indexed EMP Syntax and Python Parser (104)

3.15.1.8.3 GAMS Test Library New models added:

- **csv2gdx7.gms** : CSV2GDX - Checking the Error Messages for incorrect Parameter Input (752)
 - **csv2gdx8.gms** : CSV2GDX - Testing the valueDim Option (753)
 - **csv2gdx9.gms** : CSV2GDX - Testing the Field Separator Tab (754)
 - **csv2gdx10.gms** : CSV2GDX - Testing the Field Separator Semicolon (755)
 - **csv2gdx11.gms** : CSV2GDX - Testing the Field Separator Comma (756)
 - **selkie01.gms** : SELKIE test suite (757)
 - **selkie02.gms** : SELKIE test suite (758)
 - **selkie03.gms** : SELKIE test suite (759)
 - **selkie04.gms** : SELKIE test suite (760)
 - **selkie05.gms** : SELKIE test suite (761)
 - **selkie06.gms** : SELKIE test suite (762)
 - **selkie07.gms** : SELKIE test suite (763)
 - **selkie08.gms** : SELKIE test suite (764)
 - **selkie09.gms** : SELKIE test suite (765)
 - **selkie10.gms** : SELKIE test suite (766)
 - **selkie11.gms** : SELKIE test suite (767)
 - **selkie12.gms** : SELKIE test suite: sub-diagonalization (768)
 - **selkie13.gms** : SELKIE test suite: dualvar (769)
 - **selkie14.gms** : SELKIE test suite: isolated implicit variable (770)
 - **selkie15.gms** : SELKIE test suite: proximal perturbation (771)
 - **selkie16.gms** : SELKIE test suite: obj variable setting (772)
 - **selkie17.gms** : SELKIE test suite: obj variable setting (773)
 - **selkie18.gms** : SELKIE test suite: obj variable not free (774)
 - **selkie19.gms** : SELKIE test suite: equation marginal values (775)
 - **put12.gms** : Testing put_utility solver (776)
 - **gdxxrw8.gms** : GDXXRW - Testing the Option intAsText (777)
 - **gdxxrw9.gms** : GDXXRW - Testing the Option checkDate (778)
 - **gdxxrw10.gms** : GDXXRW - Testing cMerge when reading Sets with the values Option (779)
 - **gdxxrw11.gms** : GDXXRW - Reading and writing special Values (780)
-

- **gdxxrw12.gms** : GDXXRW - Testing the skipEmpty and cMerge Option (781)
- **gdxxrw13.gms** : GDXXRW - Testing the values Option when reading or writing Set Elements (782)
- **gdxxrw14.gms** : GDXXRW - Testing different Excel Range Specifications (783)
- **gdxdump2.gms** : GDXDUMP - Testing the dumping Functionality on several GDX Files (784)
- **gdxdump3.gms** : GDXDUMP - Dumping special Values of a Parameter from GDX (785)
- **gdxdump4.gms** : GDXDUMP - Dumping special Values of Variable-Subfields from GDX (786)
- **onmulti8.gms** : Test for \$onMultiR (787)
- **implset1.gms** : Test for Implicit Set Definition (788)
- **emppy1.gms** : Test an equilibrium model using emp python (789)
- **emppy2.gms** : Formulate the simplevi.gms example using emp python (790)
- **emppy3.gms** : Test a combination of optimization and vi agents using emp python (791)
- **miqcp04.gms** : Test behavior for integer infeasible model (792)
- **duplic01.gms** : Detecting duplicate entries in unsorted data (793)

3.16 25.1 Distribution

3.16.1 25.1.1 Major release (May 19, 2018)

3.16.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Eden Huang, Katja Buhrkal Jensen, Jan-Erik Justkowiak, Erwin Kalvelagen, Marko Loparic, Bruce McCarl, Scott McDonald, Edmund Moshhammer, Andres Ramos, Tom Rutherford, Wilfredo Sifuentes, and Tapio Westerlund.

3.16.1.2 Platforms

- On Windows, some solvers in the GAMS distribution as well as [GAMS Studio](#) have dependencies on certain MS Visual C++ runtime libraries. Most of them are included in the GAMS distribution or are present on most Windows systems. However, we are aware that in rare cases, some libraries are missing. In such situations, we advise to run the appropriate installer for these libraries:
 - On a 32-bit GAMS version, execute `[GAMS system]\apifiles\C++\lib\vs2013\vc redistrib_x86.exe`, followed by `[GAMS system]\apifiles\C++\lib\vs2015\vc redistrib_x86.exe`.
 - On a 64-bit GAMS version, execute `[GAMS system]\apifiles\C++\lib\vs2017\vc redistrib_x64.exe`.

3.16.1.3 GAMS System

3.16.1.3.1 GAMS

- New conditional expressions to be used in [conditional compilation](#), namely `gdxDimension`, `gdxEquType`, `gdxParType`, `gdxSetType`, `gdxSymExist`, `gdxVarType`, and `uelExist`. Details about these can be found [here](#).
- New command line option `LstTitleLeftAligned`: Write title of LST file left aligned.
- New command line option `ShowOSMemory`: Show the memory usage reported by the operating system (either resident set size or virtual set size) instead of the internal counting.
- GAMS throws now a compilation error if an unexpected suffix at a symbol is encountered in an [option statement involving identifiers](#). In the past such suffixes were ignored, which could have given the impression that they were actually doing something. So, all the `.dim1` suffixes in the following example will create an error now:

```
Set i(*)
    j(*)
    ij(*,*) / i1.j1, i1.j2, i2.j1, i2.j2 /;

Option i < ij.dim1;
Option i <= ij.dim1;

Set      k      / k1*k6 /;
Parameter ii(*) / i1 4, i2 5, i3 6 /
    iii(k,*);

Option iii > ii.dim1;
Option shuffle = ii.dim1;
```

- The details of the expansion of [multi-line macros](#) were changed with this release. In the past, trailing white space in the macro definition was always removed. Now, in multi-line macros, the white space before the continuation character `\` is preserved. This example demonstrates the difference:

```
$macro xAndY(x,y) x and \
                    y
scalar x /1/;
if(xAndY(1,x), display 'true');
```

In the past, this caused a compilation error, since the macro was expanded to `if(1 andy, display 'true');` ("and" and "y" were concatenated to "andy"). Now that the white space after "and" is preserved, this does not cause a problem anymore.

- The statement `Alias (k,k);` for an unknown symbol `k` causes a compilation error now.
 - In rare cases, embedded code recognized indented Python code incorrectly. This has been fixed.
 - New property `gams.debug` for controlling debug information of the Object-oriented API in embedded code sections.
 - Fixed a problem related to SSL support in `GMSPython` that prevented certain tools (e.g. `pip`) from working on Linux and Mac OS X.
 - Models of type `MCP` can now be solved with modifiable parameters in the `GUSS` framework and as OO-API `GAMSModelInstance`.
-

3.16.1.4 Solvers

3.16.1.4.1 BARON

- New libraries 18.5.8.
 - Updated to Ipopt 3.12.8 and CBC 2.9.9.
 - Replaced Ipopt's linear solver MUMPS by MA57 from [HSL](#), a collection of Fortran codes for large-scale scientific computation. Thus, when using IPOPT as NLP solver, BARON may now be more robust and a little faster, especially for problems without integer variables.
 - New bounds reduction strategies based on optimality conditions can reduce the size of the branch-and-bound tree.
 - Rewrote core memory management routines for speed increase and memory reduction.
 - On some problems, BARON currently provides incorrect marginal values. This problem will be fixed in the near future.
- The use of Ipopt in BARON on MacOS X is no longer disabled by default.
- There will be no future updates of BARON for Windows 32-bit.

3.16.1.4.2 Bonmin(H), CBC, Couenne

- Wall-clock time is now always used to apply a timelimit to Branch-and-Bound. The `nww` option `clocktype` can be used to switch back to CPU time.

3.16.1.4.3 CONOPT

- New libraries 4.05 for CONOPT 4.
 - Improvements for multi-threading.
- New libraries for CONOPT 3.
- Fixed problems with redundancy in preprocessor and an issue related to system error 2024.

3.16.1.4.4 ConvertD

- Added options [PermuteVars](#) and [PermuteEqus](#) to permute the declaration of variables and equations, respectively, in scalar GAMS output.
- Tweaked printing of variable bounds and activity levels in scalar GAMS output.
- Fixed handling of infinite upper bounds for integer variables in scalar GAMS output: A line that sets GAMS option [intvarup](#) to 0 is now added to the output.

3.16.1.4.5 Couenne

- New libraries.
-

3.16.1.4.6 DICOPT

- Improvements to Feasibility Pump:
 - Fixed handling of nonlinear objective function when maximizing.
 - Fixed update of cutoff decrement after a solution with objective value very close to zero has been found.
 - Fixed translation of NLP projection problem optimal value to norm of associated projection. Changed default for option `fp_projzerotol` from 1e-6 to 1e-4.
 - Added creation of cuts derived from solution of NLP projection problem. Use option `fp_projcuts` to disable.
 - Added option `fp_integercuts` to disable integer cuts or enable them for mixed-binary problems only. The latter is the new default.
 - Added option `fp_mipgap` to specify an optimality tolerance (relative gap limit) for the MIP projection problem.
 - The `stall limit` is now only applied after a first solution has been found. Changed default for option `fp_iterlimit` to 20.

3.16.1.4.7 GUROBI

- New libraries 8.0.
 - As announced for [GAMS 24.9](#), Gurobi 8 is no longer supported for Windows 32-bit. We continue to ship Gurobi 7.5 for this platform.
- New partition heuristic based on user annotation via the new `dot option .partition` and enabled with new option `PartitionPlace`.
- Completely new interface to Gurobi's Remote Services (i.e. compute server, distributed algorithm, and instant cloud). For details see [Compute Server](#) and the following sections.

3.16.1.4.8 JAMS

- Added capability to handle [QVI](#) models.
- The options controlling the reformulation strategy for shared variables in multi-agent EMP models have changed: see [ImplVarModel](#) for details.

3.16.1.4.9 LocalSolver

- New libraries 7.5 (20180405).
- To use LocalSolver 7.5, a machine-specific LocalSolver license is now required on Linux, too. See the solver manual on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing `LOCALSOLVER70` instead of `LOCALSOLVER` as solver.

3.16.1.4.10 Mosek

- New libraries 8.1.0.53.
-

3.16.1.4.11 ODHCPLEX

- A new solver [GAMS/ODHCPLEX](#) from Optimization Direct Inc. has been added to the GAMS solver portfolio.
- The solver implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models and uses IBM CPLEX as its underlying solver engine.
- The heuristics decomposition method works in an automatic fashion or can be guided by user specified selections.
- Users will need a GAMS/CPLEX or GAMS/Cplex link license for this solver to work. Commercial users will also need a GAMS/ODHCPLEX license.
- Currently, the solver is available for Windows 64-bit only.

3.16.1.4.12 SCIP

- New libraries 5.0 (09c736f).
 - changed default for parameter `constraints/quadratic/gaugecuts` from 1 to 0
 - changed default for parameter `heuristics/completesol/freq` from 1 to 0
 - changed default for parameter `separating/cmip/freq` from -1 to 10
 - changed default for parameter `separating/cmip/freq` from 1 to 0
 - changed default for parameter `separating/flowcover/freq` from -1 to 10
 - changed default for parameter `separating/flowcover/freq` from 1 to 0

3.16.1.4.13 Xpress

- New libraries 32.01.10 containing several minor bug fixes and performance improvements.

3.16.1.5 Tools

3.16.1.5.1 GAMS Studio

- This release contains the first preview version of [GAMS Studio](#) - a completely new integrated development environment for GAMS. GAMS Studio is still in a very early stage of development, but we believe it is already mature enough to be a productive tool. GAMS Studio is available for Linux, Mac OS X, and Windows only.
 - GAMS Studio combines many (but not all) features of the classic GAMS IDE with some new elements:
 - a code editor to write GAMS models (including basic syntax coloring, block edit mode, etc.),
 - execution of GAMS models,
 - an output panel that presents the progressing GAMS log,
 - a listing viewer (including a tree view to navigate through the file) to inspect the listing file,
 - an interactive option editor to set GAMS parameters,
 - a GDX viewer that shows the table of content and data of GDX files and offers useful details like sorting and filtering of data,
-

- a project explorer helps to manage different projects in one session, and
- an integrated help system to make it easier to find additional information, e.g., by pressing F1 while the cursor is on a GAMS keyword in the code editor.
- We encourage our users to weigh in, help prioritize GAMS Studio's future development directions, or provide any other feedback. If you find problems, miss features, or have comments, please send a note to studio@gams.com.
- It is also possible to contribute directly or build on top of GAMS Studio, since the source code is available on GitHub (<https://github.com/GAMS-dev/studio>) under the GNU GPL license (see <https://github.com/GAMS-dev/studio>).
- We plan to provide updates for GAMS Studio frequently in the near future, also separate from new releases of the GAMS distribution. To facilitate the update process, Studio includes an interactive check (requiring an Internet connection) for the availability of newer versions. This "Check for Update" button can be found below the menu "Help".
- A short overview about GAMS Studio can be found in the YouTube channel [GAMS Lessons](#).

Note

- - New options to define the association for GAMS files (`.gms`) have been added to the installer for GAMS on Windows. For now, the GAMS IDE is still the default choice, but this may change for future releases.
 - On Linux, Studio is installed in the form of an AppImage as part of the GAMS system directory.
 - On Mac OS X, Studio is part of the DMG installer only. It is installed as an additional application in the `Applications` directory next to the GAMS Terminal application and is available through the Launchpad. GAMS files (`.gms`) are associated with GAMS Studio.

Attention

- - In rare cases, GAMS Studio crashes when the `Open` or `Save` dialog gets opened. This is mostly related to third party software, e.g. older versions of "Dell Backup and Recovery". It is recommend to update, switch off or uninstall the software.
 - We are aware of some performance issues at this stage of development. So while things work well, for example, with the models from our model libraries, you might experience some delay when working with huge files, e.g., while searching or when the log is processed for very long output.

3.16.1.5.2 XLSDump

- Sometimes, Excel Spreadsheets contain links to pictures, which cannot be found. This situation caused an error in XLSDump in previous versions. Now, such an error is ignored.

3.16.1.6 Object Oriented APIs

- New implementation of `GAMSJob.Interrupt()` on Linux and Mac OS X that removes dependency to the command line tool `pstree`.

3.16.1.6.1 C++

- Added support for Microsoft Visual Studio 2015 on Windows 32-bit.
-

3.16.1.6.2 Java

- Changed the naming scheme of a temporary working directory to be created from `yyyyMMdd_HHmss` to the prefixed `gams_` (defined by `GAMSGlobals.workingDirectoryPrefix`), in case no working directory has been specified.
- Fixed the behavior when a `GAMSDatabase` is added with a name that already exists. A `GAMSException` will be raised now (see `GAMSWorkspace.addDatabase(String databaseName)` and `GAMSWorkspace.addDatabaseFromGDX(String.gdxFileName, String databaseName)`).
- Calls on `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` are no longer available, because calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommended to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See `GAMSDatabase.dispose`, `GAMSModelInstance.dispose`, and `GAMSOptions.dispose`.

3.16.1.7 Expert Level APIs

- All Java native interfaces to [expert-level APIs](#) are now included in `[Path/To/GAMS]/apifiles/Java/api/GAMSJava`

3.16.1.7.1 GMO

- The constant `MAXEVALTHREADS` (i.e. the number of parallel threads supported for function and derivative evaluations in the solver interface library `GMO`) has been increased from 16 to 64. This effectively increases the same limit in the `CONOPT4` solver.

3.16.1.8 Model Libraries

3.16.1.8.1 PSOPTLIB - Power System Optimization Modelling in GAMS

- This new library by Alireza Soroudi has been added to the GAMS system. This is a collection of the models based on the book [Power System Optimization Modelling in GAMS](#) by Alireza Soroudi. The library contains a selection of 32 models from various areas of power system optimization expressed in GAMS. Book and library describe how the General Algebraic Modeling System (GAMS) can be used to solve various power system operation and planning optimization problems. The book is the first of its kind to provide readers with a comprehensive reference that includes the solution codes for basic/advanced power system optimization problems in GAMS, a computationally efficient tool for analyzing optimization problems in power and energy systems. The book covers theoretical background as well as the application examples and test case studies. It is a suitable reference for dedicated and general audiences including power system professionals as well as researchers and developers from the energy sector and electrical power engineering community and will be helpful to undergraduate and graduate students.
- You can retrieve the individual models through the IDE and Studio model library browser, via the command line utility `psoptlib` or through calls in the Object Oriented APIs.

3.16.1.8.2 GAMS EMP Library

- `simpleqvi1.gms` : Simple Quasi-Variational Inequality (101)
 - `simpleqvi2.gms` : Simple Quasi-Variational Inequality (102)
 - `simpequil3.gms` : Simple Generalized Nash Equilibrium Problem (103)
-

3.16.1.8.3 GAMS Model Library

- `guss2dim.gms` : Two dimensional scenario GUSS Example (423)
- `obstacle.gms` : An Obstacle Problem (424)
- `csched`: Added two more formulations for a related problem. Contributed by Tapio Westerlund.

3.16.2 25.1.2 Minor release (August 01, 2018)

3.16.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Shaoyan Guo, Eden Huang, David Laudy, Evangelos Panos, Wilfredo Sifuentes and Larissa de Vries.

3.16.2.2 Platforms

- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

3.16.2.3 GAMS System

3.16.2.3.1 GAMS

- Fixed a bug which caused an unexpected error when using the + operator in a [model statement](#) with the following symbol being a model itself, like this:

```
variable x;
equation e1, e2;
e1.. x =L= 5;
e2.. x =G= 3;
model m2 /e2/;
model m /e1+m2/;
solve m min x use lp;
```

3.16.2.4 Solvers

3.16.2.4.1 BARON

- Fixed translation of branching priority values when specified in BARON options file and GAMS option [PriorOpt](#) not enabled.
 - Specifying `maxdouble` as branching priority in a BARON options file now behaves as if specifying `inf` as branching priority in a GAMS model.
-

3.16.2.4.2 BONMIN

- The default for option `number_cpx_threads` is now initialized according to the value of the GAMS option `threads`.

3.16.2.4.3 CONOPT

- New libraries 3.17I for CONOPT 3.
- New libraries 4.06 for CONOPT 4.

3.16.2.4.4 GUSS

- Models with variable parameters and model attribute `holdFixed=1` could not be solved with 25.1.1. In this release the `holdFixed` option is automatically turned off.

3.16.2.4.5 Ipopt

- New libraries.
 - Fixed problems in handling of time limit (`reslim`).

3.16.2.4.6 LocalSolver

- New libraries 7.5 (20180601).

3.16.2.4.7 ODHCplex

- New libraries 3.4.3.
- ODHCplex is now available for Linux, too.

3.16.2.4.8 SoPlex

- New libraries 3.1 (b0e0048).

3.16.2.4.9 SCIP

- New libraries 5.0 (1d9c207).

3.16.2.5 Tools

3.16.2.5.1 MODEL2TEX

- Backslashes in the explanatory text of symbols are replaced automatically with `\textbackslash`.
-

3.16.2.5.2 GAMS Studio

- New version 0.9.2
 - Stability improvements
 - Allow only one instance of Studio to run at the same time (when file association for Studio is active, a double click on a gms file will open that file in a running Studio instance and does not open a new Studio)
 - Added startup parameter `--gams-dir` to specify a non-default GAMS system folder to be used
 - Added shortcuts for **Interrupt** and **Stop** (**F12** and **Shift+F12**)
 - Restructured the **File** -> **Encoding** menu
 - About dialog: added button to copy product information to clipboard
 - GDX Viewer: added facility to search for symbols
 - Option Editor: allow to use F1 to open help
 - Project Explorer:
 - * "Add Existing Files" allows to add multiple files at once
 - * Added context menu entry to open the log for a group-node
 - Note
 - When migrating from an older version of GAMS Studio, one might have an empty project explorer and no recent files listed. This is expected behavior because of a bug fix within the GAMS Studio settings file.

3.16.2.6 Object Oriented APIs

3.16.2.6.1 Python

- Fixed a bug that prevented the `setup.py` file to be called with parameter `-noCheck` for turning off the version check.
- The `setup.py` script can be used from an arbitrary location. It is not required anymore to switch to the files location before installing.

3.16.3 25.1.3 Minor release (October 30, 2018)

3.16.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.16.3.2 GAMS System

3.16.3.2.1 GAMS

- Fixed a bug which caused the `sysIdent` property not being set correctly after a solve statement.
 - Fixed a bug which could have caused a problem with `execute_load` being called after `endEmbeddedCode` in a loop.
-

3.16.3.3 Solvers

3.16.3.3.1 ANTIGONE

- If interrupting ANTIGONE (using Ctrl+C, for example), the final [trydual NLP solve](#) does no longer stop immediately in the first iteration.

3.16.3.3.2 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.4 on Mac OS X.

3.16.3.3.3 CONVERTD

- When using options `Jacobian` or `Hessian`, new symbols `iobj`, `objConst`, and `objJacVal` are written to the GDX file. If the model can be reformulated with a true objection function, the symbol `iobj` contains the label of the objective defining equation, while the symbols `objConst` and `objJacVal` contain the objective constant and the coefficient of the objective variable. If the model cannot be reformulated with a true objective, `iobj` will be empty and `objConst` and `objJacVal` will be 0.

3.16.3.3.4 GUROBI

- New libraries 8.1.0.
- Option [GUROBIprelinearize](#) allows the value of 2 (Force Linearization and get compact relaxation).

3.16.3.3.5 JAMS

- Added some experimental indexed EMP syntax. See example model `emppython1.gms : Three Simple EMP Models with Indexed EMP Syntax and Python Parser`.

3.16.3.3.6 Lindo/LindoGlobal

- New libraries 11.0.338.

3.16.3.3.7 MOSEK

- New libraries 8.1.0.64.

3.16.3.4 Tools

3.16.3.4.1 CSDP

- See [ANTIGONE](#), [Bonmin](#), [Couenne](#), [Ipopt](#), [SCIP](#).
-

3.16.3.5 Object Oriented APIs

3.16.3.5.1 Python

- The `UpdateAction Primal` and `Dual` in a `GamsModifier` were not recognized and triggered an exception. This has been fixed.

3.16.3.6 Model Libraries

3.16.3.6.1 GAMS EMP Library

- `emppython1.gms` : Three Simple EMP Models with Indexed EMP Syntax and Python Parser (104)

3.17 25.0 Distribution

3.17.1 25.0.1 Major release (January 17, 2018)

3.17.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Jeff Dischler, Michael Ferris, Dhruv Gupta, Erwin Kalvelagen, Florian Landis, Andre Lemelin, Erfan Mohagheghi, Anthony Paul, and Nathan Sudermann-Merx.

3.17.1.2 Platforms

- Due to the discontinuation of Cplex on Windows 32bit (with Cplex 12.7 in 2016) we are faced with potentially phasing out/dropping solvers depending on Cplex on Windows 32bit with the next major release. The most likely candidate for this is ANTIGONE. These solvers will still be available for 64-bit Windows and other supported platforms. Other solver vendors (e.g. Gurobi and FICO-Xpress) have also announced the discontinuation of their product on the Windows 32bit platform. If you rely heavily on the availability and support of the Windows 32bit platform please contact support@gams.com to discuss your options.
 - As [announced](#), dropped support for x86-64 Solaris.
 - As [announced](#), increased the minimal required MacOS X version to 10.11.
 - As [announced](#), increased the minimal required GLIBC version on Linux to 2.12.
-

3.17.1.3 GAMS System

3.17.1.3.1 GAMS

- Extended the `$offEmbeddedCode` facility to allow the use of a "projection operator":
`$offEmbeddedCode {symbol[<[=]embSymbol[.dimX]]}`
 More information can be found [here](#).
- Added support for the Object-oriented GAMS Python API in the Embedded Code Facility for Python. The method `gams.set()` accepts instances of type `GamsParameter`, `GamsSet`, etc. as data. Instances of `GamsWorkspace` and `GamsDatabase` can be retrieved using the properties `gams.ws` and `gams.db`. The property `gams.wsWorkingDir` can be used to specify the working directory of the created `GamsWorkspace`.
- Added `$libinclude pyEmbMI` to conveniently work with Python OO-API `GamsModelInstance` from embedded code. See **embmiex1.gms : Simple Embedded Code ModelInstance example**.
- Fixed a problem in embedded code when reading an empty scalar symbol.
- Fixed a problem when solving a model with `solveLink` 5, 6, or 7 with communicating scales without `scaleOpt` active.
- The EPS value in the Embedded Code Facility for Python has been changed to 4.94066E-324. This is the same value that is used for EPS in the Object-oriented Python API.
- New `Put_Utility save`: Writes a `save file` of the current state of execution.
- Improvement for the `Put_Utility Statement`: It is no longer required to define a `file` and activate it, just to use a `put_utility`.
- New command line option `fileStemApFromEnv`: Append a string read from an environment variable to the `fileStem`.
- Change to command line option `fileStem`: Create an immediate error when the value contains a `"\"` or `"/"` character to avoid problems later on.
- Fixed a bug with `execute.unload`, which could have caused a `set` to be exported mistakenly as `alias` to a different `set`, if symbol renaming was used.
- Fixed a bug which prevented to open more than 65,000 `put files`.
- Solves with `scaleOpt=1` using GUSS or instantiations of OO-API `GAMSModelInstances` resulted in some circumstances in the report of scaled solutions or other erroneous behavior. Hence GAMS will now reset the `modelName.scaleOpt` attribute to NA before such a solve or `GAMSModelInstance` generation. As a consequence, models solved via GUSS or as a `GAMSModelInstance` in the OO-APIs will not be `scaled by GAMS`.
- Solving MCP models with `scaleOpt=1` using the solvers AMPL or PYOMO creates an execution error now. In the past this lead to wrong results potentially.

3.17.1.4 Solvers

3.17.1.4.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.0 for Linux and Mac OS X and to version 2018.1 on Windows 64-bit.

3.17.1.4.2 CBC

- New libraries.
-

3.17.1.4.3 CONOPT

- New libraries 3.17G (Conopt3).
- New libraries 4.04 (Conopt4).
 - Fixed a system error 65666.

3.17.1.4.4 Couenne

- New libraries.
 - Bugfixes and tuning for fixed point bound tightening.
- If Couenne does not find a feasible solution, but the initial point is feasible, then the initial point is now reported back to GAMS.

3.17.1.4.5 CONVERT

- If the filename provided for the `Jacobian` or `Hessian` option contains the string `novenames` `ConvertD` will not export the original equation and variable names as set text to elements of sets `i` and `j`. Having the original equation and variable names can make the GDX file significantly larger and slow to write and read.
- Fixed a problem when trying to write scaled MCP models.

3.17.1.4.6 CPLEX

- New libraries 12.8.0.
- New parameters
 - `SubMIPScale`: Parameter to scale the problem matrix when CPLEX solves a subMIP during MIP optimization
 - `SubMIPStartAlg`: Starting algorithm for subMIP of a MIP
 - `SubMIPSubAlg`: Algorithm for subproblems of a subMIP of a MIP
 - `DynamicRows`: Switch for dynamic management of rows
 - `Sifting`: Switch for sifting from simplex optimization
- In `CplexD` allow the `BendersPartition` to be set via the `.stage variable suffix` together with option `BendersPartitionInStage`.

3.17.1.4.7 Gurobi

- Fixed a problem for model with SOS variables but no constraints.

3.17.1.4.8 KESTREL

- New options `neos_username` and `neos_user_password` can be used in the option file in order to submit authenticated jobs using a NEOS user account.
-

3.17.1.4.9 LocalSolver

- New libraries 7.5 (20171117) for Mac OS X and Windows.
 - Preprocessing entirely rewritten: size reduction by a factor up to 10 on some huge instances.
 - Combinatorial models based on booleans and integers: performance improvement and increased ability to prove optimality.
 - Continuous linear and nonlinear models: performance improvement through the integration of state-of-the-art algorithms.
- Note, that to use LocalSolver 7.5, a machine-specific LocalSolver license is now required. See the solver manual on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing LOCALSOLVER70 instead of LOCALSOLVER as solver.

3.17.1.4.10 Mosek

- New libraries 8.1.0.34.

3.17.1.4.11 SBB

- Fixed a bug introduced in 24.8 that prevents the [infeasSeq](#) option to work.

3.17.1.4.12 SCIP

- New libraries 5.0 (2b35b18).
 - SCIP can now automatically detect and exploit symmetries in MIPs (Linux and Mac OS X only)
 - * added parameter [misc/usesymmetry](#) to determine which symmetry handling should be used
 - * added parameter groups [presolving/symmetry](#), [presolving/symbreak](#), [constraints/symresack](#), [constraints/orbisack](#), [constraints/orbitope](#)
 - Presolving
 - * new presolver [sparsify](#) that tries to cancel nonzero coefficients in linear constraints by adding multiples of linear equalities
 - * disabled reformulation of products of a binary variable with a linear term that does not solely involve binary variables
 - added parameter [constraints/quadratic/binreformbinaryonly](#) to disable reformulation of products of binary and non-binary variables
 - * revised disaggregation of quadratic constraints: the number of created constraints can now be controlled and the disaggregated constraints are scaled in order to increase numerical accuracy
 - replaced [constraints/quadratic/disaggregate](#) by [constraints/quadratic/maxdisaggrsize](#) to bound the total number of created constraints when disaggregating a quadratic constraint
 - added parameter [constraints/quadratic/disaggrmergemethod](#) to change the strategy of how to merge independent blocks of quadratic constraints
 - Primal Heuristics
 - * new primal heuristic [ALNS](#) that orchestrates eight different LNS heuristics adaptively using algorithms for the multi-armed bandit problem
-

- * new primal heuristic [MPEC](#) that solves a MPEC reformulation of a mixed-binary nonlinear problem by regularized NLP reformulations
 - * improved the clique and variable bound pre-root heuristics, which are now often able to fix many more variables
 - removed parameters `heuristics/cliue/{multiplier,initseed}`
 - replaced parameter `heuristics/{cliue,vbounds}/minfixingrate` by [heuristics/cliue/minintfixingrate](#), [heuristics/vbounds/minintfixingrate](#), [heuristics/cliue/minmipfixingrate](#), and [heuristics/vbounds/minmipfixingrate](#), which check the fixing rate before LP solving and after sub-MIP presolve
 - added parameters [heuristics/cliue/maxbacktracks](#) and [heuristics/vbounds/maxbacktracks](#) to limit the number of backtracks in the fix-and-propagate phase
 - added parameters [heuristics/cliue/uselockfixings](#) and [heuristics/vbounds/uselockfixings](#) to enable fixing of additional variables based on variable locks
 - added parameters [heuristics/vbounds/feasvariant](#) and [heuristics/vbounds/tightenvariant](#) to specify the fixing variants used by the vbounds heuristic
 - changed default for parameters [heuristics/cliue/freq](#) and [heuristics/vbounds/freq](#) from -1 to 0
 - changed default for parameter [heuristics/cliue/priority](#) from -1000500 to 5000
 - changed default for parameter [heuristics/vbounds/priority](#) from -1100600 to 2501
 - * added parameters [heuristics/completesol/beforepresol](#), [heuristics/completesol/maxlpiter](#), and [heuristics/completesol/maxcontvars](#)
 - * changed default for parameter [heuristics/indicator/oneopt](#) from 1 to 0
 - * changed default for parameter [heuristics/locks/minfixingrate](#) from 0.25 to 0.65
 - * changed default for parameter [heuristics/locks/priority](#) from 2000 to 3000
 - Separation (cutting planes)
 - * utilizing linear inequalities (computed in the OBBT propagator) to compute stronger linearizations for bilinear terms
 - added parameters `constraints/quadratic/usebilineqbranch`, `constraints/quadratic/minscore` and `constraints/quadratic/bilineqmaxseparounds`
 - added parameter `constraints/quadratic/mincurvcollectbilinterms` to change the minimal curvature of constraints to be considered when returning bilinear terms to other plugins
 - added parameters [propagating/obbt/itlimitfactorbilin](#), [propagating/obbt/minnonconvexity](#), and [propagating/obbt/createbilineqs](#)
 - * improved cut post-processing (apply coefficient tightening, enforce maximal dynamism), selection, and management
 - added parameters [separating/maxlocalbounddist](#), [separating/maxcoefratio](#), and [separating/intsupportfac](#)
 - removed parameter `separating/orthofac`
 - changed default for parameter [separating/cutagelimit](#) from 100 to 80
 - changed default for parameter [separating/minefficacy](#) from 0.05 to 0.0001
 - changed default for parameter [separating/minefficacyroot](#) from 0.001 to 0.0001
 - changed defaults for parameters [separating/minortho](#) and [separating/minorthoroot](#) from 0.5 to 0.9
 - changed default for parameter [separating/objparalfac](#) from 0.0001 to 0.1
 - changed default for parameter [separating/poolfreq](#) from 0 to 10
 - * MIP cutting planes are now separated within the tree search, too
 - parameter [separating/maxstallrounds](#) only applies to nodes in the tree (not the root node, anymore); use the new parameter [separating/maxstallroundsroot](#) for the root node
 - added parameters `separating/*/expbackoff` to all separators, which increases the frequency exponentially over the depth in the tree
 - added parameter `separating/maxincrounds`
-

- changed default for parameter [separating/maxstallrounds](#) from 5 to 1
 - changed default for parameter [separating/maxrounds](#) from 5 to -1
 - changed default for parameter [separating/maxroundsrootsubrun](#) from 1 to -1
 - changed default for parameter [separating/gomory/delayedcuts](#) from 1 to 0
 - changed default for parameter [separating/gomory/freq](#) from 0 to 10
 - changed default for parameter [separating/gomory/maxbounddist](#) from 0 to 1
 - changed default for parameter [separating/impliedbounds/freq](#) from 0 to 10
 - changed default for parameter [separating/impliedbounds/maxbounddist](#) from 0 to 1
 - changed default for parameter [separating/strongcg/freq](#) from 0 to 10
 - changed default for parameter [separating/strongcg/maxbounddist](#) from 0 to 1
 - changed default for parameter [separating/strongcg/maxsepacuts](#) from 50 to 20
 - changed default for parameter [separating/zerohalf/freq](#) from -1 to 4
 - changed default for parameter [separating/zerohalf/maxbounddist](#) from 0 to 1
 - * new implementation of zerohalf separator
 - added parameters [separating/zerohalf/badscore](#), [separating/zerohalf/densityoffset](#), [separating/zerohalf/goodscore](#), [separating/zerohalf/maxcutcands](#), [separating/zerohalf/maxrowdensity](#), [separating/zerohalf/maxslack](#), [separating/zerohalf/maxslackroot](#), and [separating/zerohalf/minviol](#)
 - removed parameters [separating/zerohalf/delayedcuts](#), [separating/zerohalf/ignoreprevzcuts](#), [separating/zerohalf/maxcutsfound](#), [separating/zerohalf/maxcutsfoundroot](#), [separating/zerohalf/maxdepth](#), [separating/zerohalf/maxncalls](#), [separating/zerohalf/maxtestdelta](#), [separating/zerohalf/onlyorigrows](#), [separating/zerohalf/relaxcontvars](#), [separating/zerohalf/scalefraccoeffs](#), [separating/zerohalf/trynegscaling](#), [separating/zerohalf/usezhcutpool](#), [separating/zerohalf/preprocessing/*](#), and [separating/zerohalf/separating/*](#)
 - changed default for parameter [separating/zerohalf/maxroundsroot](#) from 10 to 20
 - changed default for parameter [separating/zerohalf/maxsepacuts](#) from 50 to 20
 - changed default for parameter [separating/zerohalf/maxsepacutsroot](#) from 500 to 100
 - * faster implementation of CMIR cut generation heuristic
 - moved many parameters for flowcover and cmir separators to new parameter group [separating/aggregation](#)
 - changed default for parameters [separating/cmir/freq](#) and [separating/flowcover/freq](#) from 0 to -1
 - changed default for parameters [separating/cmir/maxbounddist](#) and [separating/flowcover/maxbounddist](#) from 0 to 1
 - changed default for parameter [separating/cmir/priority](#) from -3000 to -100000
 - changed default for parameter [separating/flowcover/priority](#) from -4000 to -100000
 - * additional parameter changes
 - removed parameter [separating/feastofac](#)
 - removed parameter [separating/cgmip/allowlocal](#)
 - removed parameters [separating/{gomory,strongcg}/maxweightrange](#)
 - changed default for parameter [separating/gomory/makeintegral](#) from 1 to 0
 - changed default for parameter [separating/gomory/maxrank](#) from 3 to -1
 - changed default for parameter [separating/gomory/sidetypebasis](#) from 0 to 1
 - added parameter [constraints/indicator/maxsepanonviolated](#) to stop separation after separation of non violated cuts
 - removed parameters [constraints/{abspower,bivariate,quadratic,nonlinear}/mincutefficacysepa](#), [constraints/{abspower,bivariate,quadratic,nonlinear}/mincutefficacyenfocac](#), and [constraints/soc/minefficacy](#)
 - Propagation
 - * use disjoint set to reduce peak memory usage and time to compute clique table connectedness information
 - * added analysis of the clique table which identifies possible aggregations via the search for strongly connected components and may detect infeasible assignments on the way
-

- added parameter [propagating/vbounds/minnewcliques](#) to specify the minimum number of new cliques to trigger another clique table analysis
 - added parameters [propagating/vbounds/maxcliquesmedium](#) and [propagating/vbounds/maxcliquesexha](#) to limit the number of cliques relative to the number of binary variable for performing clique table analysis
 - changed default for parameter [propagating/vbounds/presolpriority](#) from 0 to -90000
 - changed default for parameter [propagating/vbounds/presoltiming](#) from 28 to 24
 - * extended conflict analysis by analyzing dual solutions of boundexceeding LPs and improved dual ray analysis
 - removed parameters [conflict/usemir](#) and [conflict/prefermir](#)
 - added parameter [conflict/sepaaltproofs](#)
 - added parameter [conflict/prefinproof](#) to determine whether to prefer infeasibility proof to boundexceeding proof
 - changed default for parameter [conflict/useboundlp](#) to 'b'
 - changed default for parameter [conflict/maxvarsfac](#) from 0.1 to 0.15
 - changed default for parameter [conflict/maxvarsfac](#) from 30 to 0
 - LP Relaxation
 - * use LP solution polishing during probing and diving mode to activate it during many primal heuristics; remains disabled during strong branching and OBBT
 - only effective if using SoPlex as [LP solver](#)
 - added value 3 for parameter [lp/solutionpolishing](#) to enable LP polishing only during probing and diving mode
 - * added parameter [lp/refactorinterval](#) to change the refactorization interval of the LP solver
 - removed parameters [constraints/{abspower,bivariate,nonlinear,quadratic,soc}/scaling](#)
 - added parameter [groups table/*](#) to control statistic output
 - See also the [full release notes](#), the [changelog](#), and the [release paper](#).
- Fixed a problem when solving a model with [solveLink](#) 6 or 7 with [scaleOpt](#) active.

3.17.1.4.13 SolveEngine

- The GAMS time limit ([reslim](#)) is now passed to SolveEngine. Added solver option [hardtimelimit](#) to specify a time limit that is enforced on the GAMS side.

3.17.1.4.14 SoPlex

- New libraries 3.1.0 (876e6e8).
 - New scaling method that combines geometric and equilibrium scaling. Use new value 6 for option [int:scaler](#) to activate this.
 - See also the [release paper](#).

3.17.1.4.15 Xpress

- New libraries 32.01.05.

3.17.1.5 Tools

3.17.1.5.1 CDSP

- See [ANTIGONE](#), [Bonmin](#), [Couenne](#), [Ipopt](#), [SCIP](#).
-

3.17.1.5.2 GDXXRW

- Sometimes, Excel is not ready (e.g. because some data needs to be refreshed, when a worksheet is opened), when a read request is sent by GDXXRW. This could cause an exception. With this release we changed the behavior of GDXXRW to wait a second and resend the request in this case. This basically mimics the behavior of setting `RWait` to 1000 in case of the mentioned exception.

3.17.1.6 Object Oriented APIs

3.17.1.6.1 C++

- Changed the compiler from GCC to Clang on Mac OS X.
- Added support for Microsoft Visual Studio 2015 and Microsoft Visual Studio 2017 on Windows 64-bit.
- API binaries have been moved to `apifiles/C++/lib`. On Windows, there are further subdirectories for different compiler versions.
- Update of Visual Studio solutions for the examples on Windows. Three different solutions reflecting the supported versions of Microsoft Visual Studio are available (e.g. `examples-vs2013.sln`, `examples-vs2015.sln`, `examples-vs2017.sln`).
- The GAMS C++ API tutorial has been reworked. Information about building the C++ API examples via `cmake`, `qmake`, and Microsoft Visual Studio has been added.
- New example `TransportGDX` that shows how to import and export GDX files. A description has been added to the tutorial.

3.17.1.6.2 .NET

- Changes for `GAMSSymbol` and `GAMSSymbolRecord`: Both classes got the `IEquatable<T>` Interface. As a result the behavior of the `Equals` function as well as the `==` and `!=` operators were modified. For both classes `Equals` and `==` returns now true, if the internal data reference is the same. Here is an example:

```
GAMSVariable x1 = db.GetVariable("x");
GAMSVariable x2 = db.GetVariable("x");
if(x1 == x2)
    Console.WriteLine("x1 == x2");
else
    Console.WriteLine("x1 != x2");
if (x1.Equals(x2))
    Console.WriteLine("x1 equals x2");
else
    Console.WriteLine("x1 does not equal x2");
```

In previous versions we got this output:

```
x1 != x2
x1 does not equal x2
```

Now we get:

```
x1 == x2
x1 equals x2
```

- New example `TransportGDX` that shows how to import and export GDX files.

3.17.1.6.3 Java

- The minimum version requirement of the Java Runtime Environment for using the GAMS Java API is now Java SE 7.
- New `TransportGDX` example to demonstrate how to import and export GDX files.
- Removed method `GAMSSymbol1.compact`, deprecated since [24.8.1 \(December 2016\)](#).
- Changed equivalence behavior of `GAMSSymbol` and `GAMSSymbolRecord` objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
 - Two symbols are equivalent if and only if they have the same internal reference.
 - Two symbol records are equivalent if and only if they have the same internal reference.

The behavior of operator `==` remains unchanged. The following example illustrates the new equivalence behavior:

```
GAMSVariable x1 = db.getVariable("x");
GAMSVariable x2 = db.getVariable("x");
GAMSVariable x3 = x1;
assertTrue(x1.equals(x2)); // true, previously false
assertFalse(x1 == x2); // false, previously false
assertTrue(x1.equals(x3)); // true, previously true
assertTrue(x1 == x3); // true, previously true
```

3.17.1.6.4 Python

- Added implementation of `__eq__()` and `__ne__()` to classes `_GamsSymbol` and `_GamsSymbolRecord` and its derived classes. As a result the behavior of the operators `==` and `!=` has changed. `==` now returns `True`, if the internal data reference is the same. The behavior of `is` remains unchanged. The following example illustrates the change:

```
x1 = db["x"]
x2 = db["x"]
print(x1 == x2) # now: True, before: False
print(x1 is x2) # now: False, before: False
```
- New example `transport_gdx.py` that shows how to import and export GDX files. A description has been added to the tutorial.

3.17.1.7 Expert Level APIs

- As [announced](#), the expert-level C++ API files were removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in the last major release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.
- The expert-level Java API files now ensure the load of jni libraries in the similar order as those employed by the Object Oriented Java API: first load from `java.library.path`, if neither specified nor found then from the directory where the API classes are located.

3.17.1.7.1 GDX

- Do not allow empty filename as argument for `gdxOpenAppend`, `gdxOpenRead`, `gdxOpenWrite`, and `gdxOpenWriteEx`. This will create an error right away now.
-

3.17.1.8 Model Libraries

3.17.1.8.1 GAMS Model Library

- **embmiex1.gms** : Simple Embedded Code ModelInstance example (417)
- **spbenders1.gms** : Stochastic Benders - Sequential GAMS Loop (418)
- **spbenders2.gms** : Stochastic Benders - Async Subsolve GAMS Loop (419)
- **spbenders3.gms** : Stochastic Benders - Sequential GamsModelInstance (420)
- **spbenders4.gms** : Stochastic Benders - Parallel MPI (421)
- **spbenders5.gms** : Stochastic Benders - Parallel MPI with GAMSModelInstance (422)
- Most models in the GAMS Model library have been refurbished to reflect a common syntax style and features introduced since the model was added.
- **prime**: Make use of the **break** statement for a little nicer and faster formulation.

3.17.1.8.2 GAMS Test Library

- **scensol7.gms** : Test GUSS Option ReportLastScen (737)
- **emp27.gms** : Test LOGMIP/EMP on x.fx=0 handling (738)
- **embpy03.gms** : Test projection operator when loading data from embedded code (739)
- **qcp11.gms** : Test dual solution of SOCP (740)
- **put11.gms** : Put_Utility without file handle (741)

3.17.2 25.0.2 Maintenance release (January 31, 2018)

3.17.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Tom Rutherford.

3.17.2.2 GAMS System

3.17.2.2.1 GAMS

- Bugfix: `$offEmbeddedCode` does not ignore `$onUNDF` anymore.
- Bugfix: Special values (NA, EPS, INF, ...) are correctly communicated from embedded code back to GAMS.
- Bugfix: Took care about a problem, which caused an unexpected execution error for certain uses of `Put.Utility`.
- Fixed a bug in GMSPython on Mac OS X which prevented the Python interpreter from working. This problem occurred with the DMG installer only.

3.17.2.3 Solvers

3.17.2.3.1 ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- On Linux, removed the MKL libraries that were optimized to certain x86 instruction sets (AVX, etc.) as this resulted in errors when running ANTIGONE or SCIP, probably due to library conflicts.

3.17.2.3.2 CPLEX

- Option [Tuning](#) can be repeated in a GAMS/Cplex option file to provide a larger number of model instances for tuning. Before this change the number was restricted by the maximum line length of an option line (256 characters).

3.17.2.3.3 LocalSolver

- New libraries 7.5 (20180119) for Mac OS X and Windows.

3.17.2.4 Tools

3.17.2.4.1 CSDP

- See [ANTIGONE](#), [Bonmin](#), [Couenne](#), [Ipopt](#), [SCIP](#).

3.17.2.4.2 CSV2GDX

- Bugfix: Reading sets (no Value or Values option) with the option AutoRow works again.

3.17.3 25.0.3 Minor release (March 21, 2018)

3.17.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Dominik Bongartz, Wolfgang Britz, Erwin Kalvelagen, Maria Kannavou, Hans Mittelmann, Christoph Pahlmeyer, Gilles Scouvar, and Hermann Westerholt.

3.17.3.2 GAMS System

3.17.3.2.1 GAMS

- Bugfix for [Put_Utility](#): If a `put_utility` statement was used as the first statement to mark a `file` as active (so no statement like `put fx;` was used before) and following `put` or `put_utility` statements did not mention this `file` explicitly, then the `file` association got lost.
 - Bugfix: Avoid a crash when one of the following [attributes](#) was used on an empty [Singleton Set](#): `.len`, `.uel`, `.val` (an execution error is generated instead now)
 - Bugfix for command line option [fileStemApFromEnv](#): In the past, if the input file was defined including a file extension, the value of this option was extended to the extension and not to the file stem as intended. This is fixed now.
 - Bugfix for [\\$if exist File](#) on Windows: In the past, if a file was specified as `<Drive>:/<File>`, e.g., `C:/t.txt` (note the forward slash `/` after the colon `!`), this always returned false, even if the file exists. That has been fixed now.
-

3.17.3.3 Solvers

3.17.3.3.1 BARON

- Fixed use of [.EquClass](#) option.

3.17.3.3.2 BONMIN(H), CBC, Couenne

- Branch-and-bound now checks wallclock-time, if running with multiple threads.

3.17.3.3.3 CONOPT4

- New libraries 4.05.
 - Improved the selection of post-triangular variables when there are multiple candidates.

3.17.3.3.4 CPLEX

- Bugfix: If the Cplex conflict refiner (triggered by option [iis](#)) could not identify a conflict the behavior was erratic. This has been fixed.
- Bugfix: Value 6 for option [MIPStart](#) was documented but got rejected. This has been fixed.

3.17.3.3.5 DICOPT

- Fixed setup of NLP projection problem in feasibility pump.
- Fixed stopping criterion when using [stop](#) on crossover: DICOPT was stopping as soon as the relative gap between the objective value of the best known solution and the bound provided by the MIP relaxation was below 0.001, thus might have declared suboptimal solutions as optimal. With this release, DICOPT will use the value of GAMS option [optcr](#) as optimality tolerance. Note, that the default for this option is 0.1 (!).

3.17.3.3.6 Ipopt(H)

- New libraries.

3.17.3.3.7 MOSEK

- No update, but be aware that [Mosek announced](#) to drop the convex nonlinear optimizer in their next major release (Mosek 9). Thus, in a future GAMS release, GAMS/Mosek will not accept models with model types NLP or DNLP anymore. Note, that linear or quadratic problems (LP, MIP, (MI)QCP) are not affected.
-

3.17.3.3.8 SCIP

- New libraries 5.0.1 (227c4c7).
 - New option `presolving/symmetry/displaynorbitvars`.

3.17.3.3.9 SoPlex

- New libraries 3.1.1 (ab921a5).

3.17.3.4 Tools

3.17.3.4.1 MODEL2TEX

- Added support for singleton sets.
- Fixed a dependency bug on Mac OS X which prevented `model2tex` from working.
- Fixed a bug regarding SOS variables.
- Fixed a bug regarding domain jumps.
- Added support for Python 3 on Linux and Mac OS X.

3.18 24.9 Distribution

3.18.1 24.9.1 Major release (August 30, 2017)

3.18.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jan Abrell, Etienne Ayotte-Sauvé, Wolfgang Britz, Florian Habermacher, Florian Häberlein, Maximilian Held, Ignacio Herrero, Hanspeter Höschle, Erwin Kalvelagen, Toni Lastusilta, John Ross, Tom Rutherford, and Linus Schrage.

3.18.1.2 Platforms

- The set of supported platforms has not changed, but we've divided it into the *core* platforms (Windows 32-bit, Windows 64-bit, Linux, and Mac OS X) and the *peripheral* platforms (AIX, x86-64 Solaris, and Sparc64 Solaris). See [Supported Platforms](#) for more details. Please note, however, that we are *not* changing the content or behavior of GAMS based on this division: GAMS models will continue to work in the same cross-platform way for both core and peripheral platforms.
 - We will drop support for x86-64 Solaris with GAMS 25.0.
 - We may increase the minimal required GLIBC version on Linux to 2.12 with GAMS 25.0.
 - We may increase the minimal required MacOS X version to 10.11 with GAMS 25.0.
-

3.18.1.3 GAMS System

3.18.1.3.1 GAMS

- New feature, the [Embedded Code Facility](#): This extends the connectivity of GAMS to other programming languages. It allows the use of Python code during compile and execution time. GAMS symbols are shared with the external code, so no communication via disk is necessary. The embedded code feature is available on Linux, MacOS X, and Windows. For these platforms, a Python 3.6 installation is included with the GAMS distribution. If the user wants to work with a different Python 3.6, installed separately, for models with embedded code the new command line option `pySetup` needs to be set to 0.

Note

This feature is currently in beta status. Any feedback to support@gams.com is appreciated.

- New command line option `procDirPath`: Specifies the directory where the process directory should be created.
 - New compile time constants to set the model attribute `solPrint`:
 - 0 = `%solPrint.Off%`
 - 1 = `%solPrint.On%`
 - 2 = `%solPrint.Silent%`
 - New compile time constants to set the model attribute `solveOpt`:
 - 0 = `%solveOpt.Replace%`
 - 1 = `%solveOpt.Merge%`
 - 2 = `%solveOpt.Clear%`
 - Allow new string synonyms to set the integer values of the following command line options:
 - `solPrint`: `Off` (=0); `On` (=1); `Silent` (=2)
 - `sysOut`: `Off` (=0); `On` (=1);
 - Fixed a bug where the following dollar control options did not get written to the dump file when the command line parameter `dumpOpt` was used. Sometimes this caused an error in the generated file.
 - `$_on|off]DotScale`
 - `$_on|off]Embedded`
 - `$_on|off]Expand`
 - `$_on|off]Local`
 - `$_on|off]Macro`
 - `$_on|off]Margin`
 - `$_on|off]Order`
 - `$_on|off]StrictSingleton`
 - `$_on|off]UNDF`
 - Fixed an error which caused the loss of equation information when using the [Grid facility](#) in certain cases. This could have caused problems when a hot start should be performed.
 - A parameter error is now created if the key of a 'double dash' GAMS parameter exceeds 63 characters (in the past, the key was truncated silently in this case).
 - Fixed a crash which happened if the `.t1` suffix was used on an empty Singleton Set in a put statement.
 - Fixed a bug which could have caused a crash if nested loops were used in a particular combination.
 - Fixed a bug with `$onPut ... $offPut` in a `for` and `repeat` structure: When `$onPut` was the first statement inside one of these programming flow control features, it was executed just once and not repeatedly.
-

3.18.1.3.2 Special Functions

- Several of the more exotic GAMS intrinsic functions (aka "special functions") were re-implemented to address some bug reports and to pass a more rigorous set of tests. The updated functions include the [loggamma](#), [gamma](#), [logbeta](#), [beta](#), and [binomial](#) functions. In general, the updated functions offer improved precision and a more consistent behavior in exceptional cases (e.g. overflows, singularities, and domain violations) compared to the previous versions. In addition, the gamma and beta functions are now classified as smooth (NLP) instead of nonsmooth (DNLP) and the domains of the beta and binomial functions have been changed.

3.18.1.3.3 Documentation

- The contents of GAMS User's Guide and the McCarl (Expanded) User's Guide have been merged, revised, and reorganized as [User's Guide](#) as well as [A GAMS Tutorial by Richard E. Rosenthal](#). Also other parts of the documentation has been reorganized and are now more closely integrated.
- The McCarl GAMS User Guide (CHM and PDF) can now be found in the `mccarl/` subdirectory in the distribution.
- The PDFs containing the solver manuals and the GAMS User's Guide have been replaced by a single [PDF](#) containing large parts of the current documentation. However, the main format for the documentation is [HTML](#).

3.18.1.4 Solvers

3.18.1.4.1 BARON

- New libraries 17.8.7.
 - New range reduction techniques and relaxations for quadratic constraints.
 - New heuristics for finding feasible solutions of integer programs.
 - Improvements in interfaces to local NLP solvers, including the use of second-order derivatives.
 - FilterSQP added to the list of local solvers. New option [AllowFilterSQP](#) and added new possible value 14 for option [NLPSol](#).
 - Bugfixes.

3.18.1.4.2 CBC

- New libraries.
 - Fixed some problems with the handling of SOS type 2 in presolve.
- Added option [dumpsolutionsmerged](#) to write all found alternate solutions into a single GDX file.

3.18.1.4.3 Conopt

- New libraries 3.17E and 4.03.
 - Fixed a serious error in Conopt4 for exactly threads=8. Moreover, improved multi-threading performance.
 - Major revisions to Conopt4 for reliability and performance.
 - The option [Rtzn](#) is now user settable for Conopt3.
-

3.18.1.4.4 CONVERT

- The GAMS equation and variable scale values (suffix `.scale`) will be communicated to CONVERT independent of the `ScaleOpt` model attribute.

3.18.1.4.5 CPLEX

- Added option `workerAlgorithm` to select the method for optimizing Benders subproblems.
- Added option `writeAnnotation` to create Cplex annotation file.
- The header of `MIP/solve trace` files contains now the option number and the name of the model.

3.18.1.4.6 DECIS

- DecisC, DecisM, and the EMP-SP solver Decis are now available for MacOS X.

3.18.1.4.7 GAMSCHK

- The procedures that generate output in the listing file are summarized at the end of the GAMSCHK execution. If you use the IDE, these summary lines are clickable and locate the cursor to the corresponding subsection in the IDE. Moreover, the procedures are also entered in the listing file index after the Solution Report.
- The lower bound for options `LevelFilt` and `MargFilt` has been reset from 1 to -5.

3.18.1.4.8 GUROBI

- New libraries 7.5.1.
 - Fewer constraint violations in MIQP solutions: Gurobi has tightened the internal tolerances for MIQP models to reduce the number of cases where the solution exhibits small constraint violations.
- New parameter `startNodeLimit` provides additional control over how much is performed to complete a partial MIP start.
- Gurobi 7.5 will be the last Gurobi release that supports 32-bit Windows. You should plan to migrate your applications to 64-bit Windows in the future.
- The header of `MIP/solve trace` files contain now the active option number and the name of the model.

3.18.1.4.9 GUSS/Scenario Solver

- Fixed a problem when initializing variables bounds to 0 (`updateType=0`) that have scenario update parameters for lower and upper bounds.
-

3.18.1.4.10 Lindo/LindoGlobal

- New libraries 11.0
 - LP Solver Improvements:
 - * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 20% for the primal simplex and 15% for the dual simplex compared to the previous version.
 - MIP Solver Improvements:
 - * New symmetry detection capabilities to reduce overall branch-bound effort. This may dramatically reduce the time needed to prove optimality on some models with integer variables.
 - * Perspective and soft-clique cuts effective on difficult MIQP and models with assignment constraints.
 - Global Solver Improvements:
 - * Improved stability and robustness through several enhancements to quadratic recognition and range reduction.
 - Nonlinear Solver Improvements:
 - * New major release of the nonlinear solver.
 - * Improved preprocessor.
 - * Use of interval function and derivative computations.
 - * Advanced scaling leading to improved solution quality.

3.18.1.4.11 LocalSolver

- New libraries 7.0 (20170728).
 - Reinforcement of mixed-integer linear programming (LP & MIP) techniques for combinatorial optimization.
 - Reinforcement of nonlinear programming techniques (NLP) for numerical optimization.

3.18.1.4.12 MINOS

- New libraries 5.6 (dated July 2016).
 - Improved handling of singularities and empty cols in pivoting code.
 - Further bug fixes and improvements.
- Fix improper handling of scaled CNS models.
- Fix handling of logging frequency.
- [QUADMINOS](#), the quadruple-precision version of MINOS, has been available in previous releases (since 24.4). This release includes the library model [\[DQQ\]](#), an example of how to use MINOS and QUADMINOS together to compute greatly improved solutions at moderate cost.

3.18.1.4.13 MOSEK

- New libraries 8.1.0.23.
 - Performance of the presolve has been improved slightly.
 - Multi-thread performance of the conic optimizer has been improved for certain large models.
 - Changed scaling for quadratic and quadratically constraint optimization problems.
 - Bugfixes.
-

3.18.1.4.14 MPSGE

- The MPSGE `$sysInclude mpsgeset` allows now for an optional argument `-mt=0` or `1` after the model name. The default value for the argument `mt` can be controlled via the `double dash` option `--MPSGEMT=0` or `1`. If the `mt` option is set to `1` the `MODEL.GEN` file is created in the GAMS scratch directory. Hence the `$include` before the solve needs to read `$include "%gams.scrdir%MODEL.GEN"`. This allows to run multiple MPSGE jobs with the same model in the same working directory. The default of this option is `0`. The model `hansmge` demonstrates the use.

3.18.1.4.15 SBB

- The header of `MIP/solve trace` files contains now the option number and the name of the model.

3.18.1.4.16 SCIP

- New libraries 4.0 (9d3c1b1).
 - Improved conflict analysis through central conflict pool and dual ray analysis for primal infeasible LPs.
 - New solution polishing to improve integrality of LP solutions when using SoPlex as LP solver.
 - Added adaptive solving behavior of SCIP based on `solving phases` and heuristic transitions.
 - Revised pseudo random number generation and introduced `central random seed` for all plugins.
 - Randomized tie-breaking in different parts of the code to reduce performance variability.
 - New primal heuristics `GINs`, `LP face`, `Complete Sol`, `Locks`, `Repair`, and `Multistart`.
 - The 1-opt heuristic is now iterated as long as new incumbents are found.
 - Improved tuning of heuristic timings.
 - Reduced memory usage of primal heuristics that use problem copies.
 - New presolving steps that disaggregate SOC constraints, `reformulate QP's by adding KKT conditions`, and treat variables appearing only in a single quadratic constraint with proper square coefficients.
 - New separators for `gauge cuts`, `convex projection cuts`, and `perspective cuts for indicator constraints`.
 - Improved knapsack approximation algorithms, greedy knapsack solution for the flow cover separation, clique partitioning, and clique separation.
 - New propagator for `OBBT on convex NLP relaxation`.
 - Tuned propagation methods of several constraint handlers and propagation timings.
 - Improved and extended stuffing for `linear constraints`.
 - Changed handling of coupling constraints for `indicator constraints`.
 - See also the `full release notes`, the `changelog`, and the `release paper`.
 - Changed parameters:
 - * `presolving/components/*` moved to `constraints/components/*`
 - * `conflict/depthscorefac` renamed to `conflict/graph/depthscorefac`
 - * `misc/permutationseed` renamed to `randomization/permutationseed`
 - * `misc/permuteconss` renamed to `randomization/permuteconss`
 - * `misc/permutevars` renamed to `randomization/permutevars`
 - * `branching/random/seed`: default changed from `0` to `41`
 - * `constraints/indicator/sepacouplingcuts`: default changed from `0` to `1`
 - * `constraints/SOS1/perfimplanalysis`: default changed from `1` to `0`
 - * `heuristics/ofins/freq`: default changed from `-1` to `0`

- * `heuristics/reoptsols/freq`: default changed from -1 to 0
 - * `heuristics/trivialnegation/freq`: default changed from -1 to 0
 - * `heuristics/cliique/initseed`: default changed from 0 to 61
 - * `lp/solver`: default changed from `soplex` to `soplex2`, if CPLEX is not licensed
 - * `presolving/abortfac`: default changed from 0.001 to 0.0008
 - * `separating/cliique/cliquedensity`: default changed from 0.05 to 0
 - * `conflict/usesb`: default changed from 0 to 1
- Added option `gams/dumpsolutionsmerged` to write all found alternate solutions into a single GDX file.
 - Changed default for `timing/clocktype` to wallclock time.
 - Initial variable levels can now be passed as partial solution to SCIP. To control the various possibilities, the type of option `gams/mipstart` has changed from bool to integer. See also subsection [Starting point](#) in the GAMS/SCIP solver manual.

3.18.1.4.17 SolveEngine

- New solver SolveEngine to solve LP and MIP problems remotely via the Satalia SolveEngine. The SolveEngine aggregates different solution algorithms for optimization problems and automatically selects an algorithm that seems to suite best for a given model instance.
- GAMS/SolveEngine comes free of charge with any licensed GAMS system. Users must have an API key for the Satalia SolveEngine to submit jobs.

3.18.1.4.18 SoPlex

- New libraries 3.0 (c32c55a).
 - Added a new [scaling implementation](#) Least squares (Curtis-Reid scaling).
 - Added [persistent scaling](#) to keep scaled LP for multiple reoptimizations.
 - Added an experimental version of a decomposition based approach to avoid degeneracy in the dual simplex method. This feature is activated by setting the parameter `bool:decompositiondualsimplex` to true, which sets the basis representation to 'row' and the algorithm to 'dual'.
 - New parameter `bool:computedegen` to enable computation of the degeneracy of the basis in each iteration.
 - New parameter `int:printcondition` to enable printing the condition number of the basis during solve.
 - Automatically use the row representation for problems with more than 20% more constraints than variables.
 - Changed default for parameter `int:factor_update_max` from 200 to new value 0.
 - See also the [full release notes](#) and the [release paper](#).
 - Changed default `type of timer` to wallclock time.
-

3.18.1.4.19 XPRESS

- New libraries: Optimizer 31.01.09 (aka XPRESS 8.3). There are many improvements and additions:
 - The parallel MIP code has been completely rewritten to improve performance and scalability.
 - * Reduced overhead for small, easy MIPs.
 - * Reduced the memory usage for very large MIPs, especially those that are significantly reduced during the initial preprocessing.
 - * Heuristics can now be run in parallel with cutting in deterministic mode. Previously, heuristics would only be run in parallel after cutting.
 - * Improved implementation of zero-half cutting.
 - * Aggregated Mixed Integer Rounding cuts have been improved for network-type problems.
 - New presolve reductions, strengthenings and reformulations for convex quadratic problems.
 - Improved performance and numerical stability of crossover.
 - Code support for AVX2 in the barrier solver: use option [cpuPlatform](#) to select the target instruction set.
 - Crossover after a barrier solve is now multi-threaded: see option [crossoverThreads](#) for details.
- The header of [MIP/solve trace](#) files contains now the option number and the name of the model.

3.18.1.5 Tools

3.18.1.5.1 CSV2GDX

- New option `ValueDim`: Indicate if an extra dimension for values is added even if there is just one value column. This is ignored, if there is no value column.

3.18.1.5.2 GDXDUMP

- Fixed a problem with writing a scalar variable or equation in CSV format with all fields.

3.18.1.5.3 GDXMERGE

- Improved feedback about problems when processing input files.

3.18.1.6 Object Oriented APIs

- Fixed a bug regarding `SymbolUpdateType.Zero` that prevented records from being updated in `GAMSModelInstance.Solve()`.

3.18.1.6.1 C++

- This release contains a beta version of the object-oriented C++ API that can be used to control GAMS from within C++11 and later. It allows the seamless integration of GAMS into C++ applications by providing appropriate classes for the interaction with GAMS. The `GAMSDatabase` class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the `GAMSJob` class and by using the `GAMSModelInstance` class a sequence of closely related model instances can be solved in an efficient way.
 - The API is available in the distributions for Linux, MacOS X, and Windows.
 - Furthermore, the C++ API is published under MIT license and is hosted at the [GAMS GitHub](#) organization.
 - To use this API please check the [GAMS API documentation](#).
-

3.18.1.6.2 .NET

- New functions `GAMSWorkspace.AddJobFromApiLib`, `GAMSWorkspace.AddJobFromNoaLib` to create `GAMSJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library.

3.18.1.6.3 Python

- New functions `GamsWorkspace.add_job_from_apilib`, `GamsWorkspace.add_job_from_noalib` to create `GamsJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library.
- Added a version check for the `setup.py` scripts to avoid unintentional installation of wrong versions.

3.18.1.7 Expert Level APIs

- With GAMS 25.0, the expert-level C++ API files will be removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in this release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.

3.18.1.7.1 GAMS Modeling Object

- Changed the function `gmoGetModelTypeTxt`: Added argument for model type number instead of using the model type of the stored model.

3.18.1.8 Model Libraries

3.18.1.8.1 GAMS Data Library

- `embeddedSort.gms` : Sorting of numerical data using the embedded code facility (108)
- `embeddedSplit.gms` : Splitting of labels using the embedded code facility (109)
- `embeddedMultiInstance.gms` : Handling multiple instances of the embedded code facility at once (110)

3.18.1.8.2 GAMS Model Library

- `dqq.gms` : Warm-starting quad-precision MINOS (414)
 - `cbenders.gms` : Cplex Benders for a Simple Facility Location Problem (415)
 - `robustlp.gms` : Robust linear programming as an SOCP (416)
-

3.18.1.8.3 GAMS Test Library

- mpsge14.gms : MPSGE sync test: .GEN/integer1/nsolves (713)
- fnsincosintrv.gms : Test sin/cos func/grad interval evals (714)
- procdir1.gms : Test correct behavior of procDir, scrDir and procDirPath (715)
- empbp06.gms : Bilevel model with phantom vars owned by leader (716)
- fnslexp.gms : Test correctness of slexp intrinsic (717)
- fnslexp2.gms : Test correctness of slexp intrinsic (718)
- fnsqexp.gms : Test correctness of sqexp intrinsic (719)
- fnsqexp2.gms : Test correctness of sqexp intrinsic (720)
- fnsllog10.gms : Test correctness of sllog10 intrinsic (721)
- fnsllog102.gms : Test correctness of sllog10 intrinsic (722)
- fnsqlog10.gms : Test correctness of sqlog10 intrinsic (723)
- fnsqlog102.gms : Test correctness of sqlog10 intrinsic (724)
- fnslrec.gms : Test correctness of slrec intrinsic (725)
- fnslrec2.gms : Test correctness of slrec intrinsic (726)
- fnsqrec.gms : Test correctness of sqrec intrinsic (727)
- fnsqrec2.gms : Test correctness of sqrec intrinsic (728)
- fnloggamma.gms : Test correctness of loggamma intrinsic (729)
- fnbinomial.gms : Test correctness of binomial intrinsic (730)
- breakcont2.gms : Advanced test for break and continue statements (731)
- fnlogbeta.gms : Test correctness of logbeta intrinsic (732)
- fnbeta.gms : Test correctness of beta intrinsic (733)
- ssuffix.gms : List of all System Suffixes (734)
- embpy01.gms : Test for embedded code facility (735)
- embpy02.gms : Test for embedded code facility (736)

3.18.2 24.9.2 Minor release (November 14, 2017)

3.18.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Paul Buckland, William N. Caballero, Xin Fang, Christophe Gouel, Fabricio Porrás-Ortiz, Shigeru Tsubakitani, and Haoshui Yu.

3.18.2.2 GAMS System

3.18.2.2.1 GAMS

- Added prefixing of PYTHONPATH with the site-packages directory of the GAMS Python 3.6 installation in GMSPython.
- Added support for Python sets in the Embedded Python Code method `gams.set()`.
- Speed up detection/extraction of quadratic terms for QCP models.
- Do not allow the use of [Embedded Code](#) if `execMode` is set to 2 or higher.

3.18.2.2.2 Installer

- Removed the execution of a Python script during the Windows installation process that patches the path of certain Python programs in `GMSPython\Scripts`.

3.18.2.3 Solvers

3.18.2.3.1 BARON

- New libraries 17.10.16.
- Due to a problem with the Ipopt interface in BARON on Mac OS X, the use of Ipopt in BARON is currently disabled on Mac OS X.
- GAMS can now pass a term like `(negativeConstant)**negativeIntegerVariable` to BARON.

Note

By default, GAMS correctly [rejects such a formulation](#), though. To work around this, `MaxExecError` needs to be set to a positive number and the option `sys12` needs to be set to 1. Here is an example, how this could be used:

```
scalar a /-2/;
integer variable x;
x.lo = -3;
x.up = 3;

variable z;
equation e;

e.. z =e=a**x;

model m /e/;
x.l=1;
MaxExecError = 10;
option sys12 = 1;
solve m min z use minlp;
```

3.18.2.3.2 CPLEX

- Removed any limits on the number of [Threads](#) in a GAMS/CPLEX option file. Previously, the maximum for option [Threads](#) was 128.

3.18.2.3.3 CONOPT

- New libraries 3.17F.
 - Fixed an infinite loop when using option [LMMXSF](#).

3.18.2.3.4 CONVERT

- Fix for variables with negative lower and infinite upper bound in LINGO output. The LINGO output has been changed to always use the @Bnd keyword to write variable bounds.

3.18.2.3.5 GUROBI

- New libraries 7.5.2.

3.18.2.3.6 GUSS/Scenario Solver

- Added the GUSS option `ReportLastScen`. If this is set to 1 the solution of the last scenario will be reported back to GAMS rather than solution of the base case. This is particularly useful when GUSS is used to implement a homotopy approach where the shock to a parameter is sliced in several small shocks and hence the last scenario represents the solution to the shocked system.

3.18.2.3.7 Lindo/LindoGlobal

- New libraries 11.0.300.

3.18.2.3.8 LogMIP

- Fixed improper handling of variables fixed at zero that occurred if they were used in nonlinear equations in a disjunction reformulated via the convex hull.

3.18.2.3.9 Mosek

- New libraries 8.1.0.31.
- Fixed dual solution for conic quadratic problems.

3.18.2.3.10 SCIP

- New libraries 4.0 (#22b4564).

3.18.2.3.11 SoPlex

- New libraries 3.0 (#3bfa247).
-

3.18.2.4 Object Oriented APIs

3.18.2.4.1 C++

- Added a try/catch block around the code that uses the classes from the GAMS C++ OO-API in all examples. Without this, the exceptions thrown by the methods of the GAMS classes will not be reported and *harmless* exceptions, like a compilation or execution error in the GAMSJob.run method result in application crashes.

3.18.2.4.2 Python

- Fixed a bug in the setup script that prevented files from being installed in the correct location in certain cases.

3.19 24.8 Distribution

3.19.1 24.8.1 Major release (December 21, 2016)

3.19.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Etienne Ayotte-Sauvé, Wolfgang Britz, Göran Bylund, Wietse Dol, Gregory Dourbois, Katja Jensen, Josef Kallrath, Toni Lastusilta, Renger van Nieuwkoop, and Tom Rutherford.

3.19.1.2 Platforms

- On Linux, the minimal required GLIBC version is now 2.7.
- On MacOS X, for some solvers (ANTIGONE, BARON, CPLEX, COIN-OR, SOPLEX, SCIP) the minimal required Mac OS X version is now 10.10. We will drop support for older Mac OS X versions for the complete GAMS system with the next major release.
- A generic license (with platform code GEN) is now limited to the platforms Windows, Linux, and Mac OS X. If you have a generic license and need a license for one of the other platforms (e.g. AIX), please contact sales or support to receive an additional license file for that platform free of charge.

3.19.1.3 GAMS System

3.19.1.3.1 GAMS

- The statements **Break** and **Continue** were added to allow more control over the execution of control structures (loop/while/repeat/for):
 - **Break [n] ;**: Terminate the n inner most control structures (n is optional, if it is omitted, it is set to 1).
 - **Continue ;**: Jump to the end of the inner most control structure.
-

- Extend the report summary of the solution report to print the number of variables and equations where the level was projected to one of the bounds (compare model attribute `tolProj`), if that number is greater than 0.
- The model attribute `tolProj` to project levels to bounds is no longer ignored when the GAMS Grid Facility (`SolveLink = 3` or `4`) is used.
- New command line option `fileStem`: Sets the file stem for output files which use the input file name as stem by default, see `fileStem` for more details.
- New option `MCPRHoldfx` (can be set using the [option statement](#), a [command line parameter](#), or [model attribute](#)):
 - Prints list of rows that are perpendicular to variables removed due to the holdfixed setting if set to 1.
- New option `AsyncSolLst` (can be set using the [option statement](#), or a [command line parameter](#)):
 - If set to 1, GAMS prints a solution listing to the `lst` file also when an asynchronous solve (see [The Grid and Multi-Threading Solve Facility](#)) is used.
 - The default value is 0.
- New variant for the `SolveLink` option and model attribute: 7 (compile time constant `%solveLink.Threads Simulate%`) - The problem is passed to the solver in core without use of temporary files, GAMS waits for the solver to come back but uses same submission process as 6 (see [Multi-threading Submission Testing](#))
- New function `numCores` (available at both compile and execution time): Returns the number of logical cores in the system.
- Allow [macro](#) expansion in the domain list of a symbol declaration.
- New dollar control `splitOption` that splits a string representing a option/value pair into option name and option value.
- Fixed a problem with the optional `maxWait` parameter of the function `readyCollect`.
- Fixed potential error in file created by `dumpOpt`, if there were symbols loaded from GDX.
- Fixed an error which could lead to wrong results when assigning to a symbol while the symbol's alias was used on the right hand side of the assignment.
- Fixed an error which could lead to a crash if a [phantom set element](#) was used to control an assignment inside a loop.
- Fixed a problem with unscaling solutions for MCP models that resulted in incorrect dual values for scaled MCPs. For an example, compare the new test library model `mcp11` when run with 24.8 and with something previous.

3.19.1.3.2 Documentation

- The offline documentation now provides [search](#) and [keyword](#) indexing functionalities in addition to navigating the documentation.
 - The Microsoft Compiled HTML help file `gams.chm` is no longer available.
 - The table of contents for browsing the GAMS model libraries is now available offline in HTML format.
-

3.19.1.4 Solvers

3.19.1.4.1 BARON

- New libraries 16.12.7.

3.19.1.4.2 CPLEX

- New libraries 12.7.0.0.
- Support for the platform MS Windows 32 bit, Solaris i86pc, and Solaris SPARC 64bit has been dropped by IBM for Cplex 12.7. The GAMS system for these platforms contains Cplex 12.6.3.
- Cplex 12.7 implements [Benders Algorithm](#). This is available in CplexD only.
- The [IIS](#) option triggers now the conflict refiner. The IIS function in Cplex 12.7 has been replaced by the conflict refiner. The [IIS](#) option now also works on infeasible models with model status `Infeasible No Solution` as well as on problems with discrete variables.
- New parameters
 - [BendersFeasCutTol](#): Tolerance for whether a feasibility cut has been violated in Benders decomposition
 - [BendersOptCutTol](#): Tolerance for optimality cuts in Benders decomposition
 - [BendersStrategy](#): Benders decomposition algorithm as a strategy
 - [DataCheck](#): Data consistency checking and modeling assistance
 - [RLTCuts](#): Reformulation Linearization Technique (RLT) cuts
- Modified parameters:
 - [MipStart](#): A value of 6 accepts the (partial) MipStart without any checks

3.19.1.4.3 CONOPT

- This distribution includes the first official release of the [CONOPT4](#) solver. The chapter in the solver manual has an interesting subsection on [when you should use CONOPT4](#) for all existing CONOPT users.
- The current solver alias CONOPT still points to the [CONOPT3](#) solver. This might change in the next, or next but one major release. We invite you to share your experience with this new version of CONOPT via support (support@gams.com) with us.

3.19.1.4.4 ConvertD

- Write proper scale and prior information for equations and variables with option `Jacobian`.

3.19.1.4.5 DICOPT

- An implementation of a Feasibility Pump primal heuristic (for convex MINLP) has been added to DICOPT. This heuristic can be run before the actual DICOPT algorithm. Outer approximation cuts from the MIP subproblem of the Feasibility Pump are transferred to initialize the MIP outer approximation of the main DICOPT algorithm. Option [feasumpump](#) can be used to enable the Feasibility Pump and [various other options](#) are available to tune the feasibility pump.
 - Option [convex](#) has been added to indicate the presence of convex MINLP. If this option is set, the defaults for various other options are modified.
-

3.19.1.4.6 GUROBI

- New libraries 7.0.1.
- Explore alternative solutions via the [Solution Pool](#).
- New parameters
 - [BestObjStop](#): Objective value to stop optimization
 - [BestBdStop](#): Objective bound to stop optimization
 - [InfProofCuts](#): Infeasibility proof cut generation
 - [StrongCGCuts](#): Strong-CG cut generation
 - [DegenMoves](#): Degenerate simplex moves
 - [TuneCriterion](#): Tuning criterion
 - [SolNPool](#): Activate export of alternative solution
 - [PoolSolutions](#), [PoolSearchMode](#), and [PoolGap](#) to control generation of alternative solutions
- Gurobi 7 supports general constraints. With the help of the dot-option [.GenConstrType](#) the user can classify a constraint to be of type `Max`, `Min`, `Abs`, `And`, and `Or`.
- Gurobi 7 supports [indicator constraints](#).
- Gurobi 7 supports multi objective hierarchical optimization. Details can be found in the GAMS/Gurobi manual, in subsection [Multiple Objectives](#).

3.19.1.4.7 JAMS

- New option [ZipDebug=xxx.zip](#) to specify that, in the event of abnormal termination or behavior, a zip file of debugging info be created.
- New reformulation options to handle shared or duplicated equations and variables in equilibrium models.

3.19.1.4.8 Knitro

- New libraries 10.2.0.
 - Significant speed and robustness improvements when using BFGS ([hessopt=2](#)) or L-BFGS ([hessopt=6](#)) Hessian approximations with the default Knitro interior-point method.
 - General performance improvement on mixed-integer models.
 - Minor bug fixes.
 - New mixed-integer SQP (MISQP) algorithm for nonlinear mixed-integer models ([mip_method=3](#)). This new algorithm is intended for small, potentially non-convex models with possibly expensive function evaluations. It can be used even when integer variables are not relaxable (i.e. functions can only be evaluated with integer variables at integer points) by setting [mip_relaxable=0](#), and can be used with parallel multistart.
 - New option [mip_nodealg](#) to control algorithm used at B&B nodes: overrides the generic [algorithm](#) option.
 - The [Knitro Tuner](#) is now available from the GAMS/Knitro link.
-

3.19.1.4.9 Lindo/LindoGlobal

- New libraries 10.0.131.
 - LP Solver Improvements:
 - * With new enhancements made to the simplex solvers, the average performance on large instances has increased by 35% for the primal simplex and by 20% for the dual simplex compared to the previous version.
 - MIP Solver Improvements:
 - * New heuristic algorithms help to find significantly better solutions for many models with knapsack constraints and block structures.
 - * New MIP preprocessing level devoted to tightening variable bounds for some nonlinear models.
 - Stochastic Solver Improvements:
 - * Improved cut management for Nested Benders Decomposition Method leading to speed improvements over 60% for large linear multistage SP instances.
 - * Better handling of multistage SP models which do not have full-recourse.
 - Global Solver Improvements:
 - * Incorporates bound tightening process to the linearization procedure and improve solvability of linearized model.

3.19.1.4.10 LocalSolver

- New libraries 6.5 (20160729).
 - For near-linear (discrete or continuous) problems, new moves have been introduced based on linear programming and mixed-integer linear programming techniques. These moves allow to intensify the search on near-linear models by exploring optimally larger neighborhoods.
- Added possibility for "Hierarchical Optimization of Multiple Objective Functions".
- Removed option `origlog`. GAMS/LocalSolver will now always print the original LocalSolver log.
- Fixed level values of aggregated variables in solution.

3.19.1.4.11 Mosek

- New libraries 8.0.0.48 ([Mosek release notes](#))
 - Presolve performance has been improved.
 - The eliminator in the presolve has been reimplemented, is usually faster, and requires much less memory.
 - Presolve has been improved on conic quadratic problems.
 - The numerical stability of conic optimizer has been improved significantly, particularly for semidefinite optimization problems.
 - The scaling routine for the conic optimizer is more aggressive.
 - Quadratic and quadratically constrained problems are now internally converted to conic form and are solved using the conic optimizer. Nevertheless full primal and dual information to the original problems is available.
 - A dualizer for conic quadratic problems is now available. By default it dualize the problems before optimizing if deemed worthwhile. The dualization is transparent to the user and can be turned off.
-

-
- The conic optimizer linear algebra is now parallelized using Cilk Plus and scales better when the number of threads is increased for large problems. Moreover, for smallish problems using too many threads does not hurt performance.
 - The computational efficiency graph partitioning based ordering method in the interior-point optimizer has been improved.
 - It is now possible to force the interior-point optimizer to run in the calling thread.
 - Only one mixed integer optimizer is available now, which corresponds to the mixed integer conic optimizer that was introduced with version 7.
 - The primal network simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.
 - The primal-dual simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.
 - The concurrent optimizer has been removed. It is suggested to use the interior-point optimizer instead.
 - The following GAMS/Mosek options have been removed:
 - * MSK_IPAR_ANA_SOL_BASIS
 - * MSK_IPAR_ANA_SOL_PRINT_VIOLATED
 - * MSK_IPAR_CONCURRENT_NUM_OPTIMIZERS
 - * MSK_IPAR_CONCURRENT_PRIORITY_DUAL_SIMPLEX
 - * MSK_IPAR_CONCURRENT_PRIORITY_FREE_SIMPLEX
 - * MSK_IPAR_CONCURRENT_PRIORITY_INTPNT
 - * MSK_IPAR_CONCURRENT_PRIORITY_PRIMAL_SIMPLEX
 - * MSK_DPAR_FEASREPAIR_TOL
 - * MSK_IPAR_FEASREPAIR_OPTIMIZE
 - * MSK_IPAR_INTPNT_FACTOR_DEBUG_LVL
 - * MSK_IPAR_INTPNT_FACTOR_METHOD
 - * MSK_IPAR_LOG_CONCURRENT
 - * MSK_IPAR_LOG_NONCONVEX
 - * MSK_IPAR_LOG_PARAM
 - * MSK_IPAR_LOG_SENSITIVITY
 - * MSK_IPAR_LOG_SENSITIVITY_OPT
 - * MSK_IPAR_MAX_NUM_WARNINGS
 - * MSK_IPAR_MIO_CONT_SOL
 - * MSK_IPAR_MIO_CUT_CG
 - * MSK_IPAR_MIO_CUT_LEVEL_ROOT
 - * MSK_IPAR_MIO_CUT_LEVEL_TREE
 - * MSK_IPAR_MIO_FEASPUMP_LEVEL
 - * MSK_DPAR_MIO_HEURISTIC_TIME
 - * MSK_IPAR_MIO_HOTSTART
 - * MSK_IPAR_MIO_KEEP_BASIS
 - * MSK_IPAR_MIO_LOCAL_BRANCH_NUMBER
 - * MSK_DPAR_MIO_MAX_TIME_APRX_OPT
 - * MSK_IPAR_MIO_PRESOLVE_AGGREGATE
 - * MSK_IPAR_MIO_PRESOLVE_PROBING
 - * MSK_IPAR_MIO_PRESOLVE_USE
 - * MSK_DPAR_MIO_REL_ADD_CUT_LIMITED
 - * MSK_IPAR_MIO_STRONG_BRANCH
 - * MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS
 - * MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS
 - * MSK_DPAR_MIO_TOL_REL_RELAX_INT
-

- * MSK_DPAR_MIO_TOL_X
 - * MSK_IPAR_MIO_USE_MULTITHREADED_OPTIMIZER
 - * MSK_IPAR_NONCONVEX_MAX_ITERATIONS
 - * MSK_DPAR_NONCONVEX_TOL_FEAS
 - * MSK_DPAR_NONCONVEX_TOL_OPT
 - * MSK_IPAR_PRESOLVE_ELIM_FILL (use [MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL](#) instead)
 - * MSK_IPAR_PRESOLVE_ELIMINATOR_USE
 - * MSK_IPAR_PRIMAL_REPAIR_OPTIMIZER
 - * MSK_IPAR_QO_SEPARABLE_REFORMULATION
 - * MSK_IPAR_WARNING_LEVEL
 - * MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_CONIC_ITEMS (use [MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_CONIC_ITEMS](#) instead)
 - * MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_NL_ITEMS (use [MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_NL_ITEMS](#) instead)
 - * MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_PSD_ITEMS (use [MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_PSD_ITEMS](#) instead)
- The following GAMS/Mosek options have been added:
- * [MSK_DPAR_DATA_SYM_MAT_TOL](#): Absolute zero tolerance for elements in symmetric matrices.
 - * [MSK_DPAR_DATA_SYM_MAT_TOL_HUGE](#): An element in a symmetric matrix which is larger than this value in absolute size causes an error.
 - * [MSK_DPAR_DATA_SYM_MAT_TOL_LARGE](#): An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.
 - * [MSK_DPAR_INTPNT_QO_TOL_DFEAS](#): Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
 - * [MSK_DPAR_INTPNT_QO_TOL_INFEAS](#): Controls when the conic interior-point optimizer declares the model primal or dual infeasible.
 - * [MSK_DPAR_INTPNT_QO_TOL_MU_RED](#): Relative complementarity gap feasibility tolerance used when interior-point optimizer is applied to a quadratic optimization problem.
 - * [MSK_DPAR_INTPNT_QO_TOL_NEAR_REL](#): Termination tolerance multiplier that is used if no accurate solution can be found.
 - * [MSK_DPAR_INTPNT_QO_TOL_PFEAS](#): Primal feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
 - * [MSK_DPAR_INTPNT_QO_TOL_REL_GAP](#): Relative gap termination tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
 - * [MSK_IPAR_INTPNT_MULTI_THREAD](#): Controls whether the interior-point optimizers can employ multiple threads if available.
 - * [MSK_IPAR_MIO_CUT_CLIQUE](#): Controls whether clique cuts should be generated.
 - * [MSK_IPAR_MIO_CUT_GMI](#): Controls whether GMI cuts should be generated.
 - * [MSK_IPAR_MIO_CUT_IMPLIED_BOUND](#): Controls whether implied bound cuts should be generated.
 - * [MSK_IPAR_MIO_CUT_KNAPSACK_COVER](#): Controls whether knapsack cover cuts should be generated.
 - * [MSK_IPAR_MIO_CUT_SELECTION_LEVEL](#): Controls how aggressively generated cuts are selected to be included in the relaxation.
 - * [MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE](#): Enables or disables perspective reformulation in presolve.
 - * [MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL](#): Controls whether presolve can be repeated at root node.
 - * [MSK_IPAR_MIO_VB_DETECTION_LEVEL](#): Controls how much effort is put into detecting variable bounds.
 - * [MSK_IPAR_OPF_WRITE_HEADER](#): Write a text header with date and MOSEK version in an OPF file.
-

- * [MSK_IPAR_OPF_WRITE_HINTS](#): Write a hint subsection with problem dimensions in the beginning of an OPF file.
 - * [MSK_IPAR_OPF_WRITE_PROBLEM](#): Write objective, constraints, bounds etc.
 - * [MSK_IPAR_OPF_WRITE_SOL_BAS](#): Whether to include basic solution in OPF files.
 - * [MSK_IPAR_OPF_WRITE_SOL_ITG](#): Whether to include integer solution in OPF files.
 - * [MSK_IPAR_OPF_WRITE_SOL_ITR](#): Whether to include interior solution in OPF files.
 - * [MSK_IPAR_OPF_WRITE_SOLUTIONS](#): Enable inclusion of solutions in the OPF files.
 - * [MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL](#): Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve.
 - * [MSK_DPAR_SEMIDEFINITE_TOL_APPROX](#): Tolerance to define a matrix to be positive semidefinite.
 - * [MSK_IPAR_WRITE_DATA_PARAM](#): If this option is turned on the parameter settings are written to the data file as parameters.
 - * [MSK_IPAR_WRITE_LP_FULL_OBJ](#): Write all variables, including the ones with 0-coefficients, in the objective.
 - * [MSK_IPAR_WRITE_MPS_FORMAT](#): Controls in which format the MPS is written.
 - * [MSK_IPAR_WRITE_TASK_INC_SOL](#): Controls whether the solutions are stored in the task file too.
 - * [MSK_SPAR_WRITE_LP_GEN_VAR_NAME](#): Sometimes when an LP file is written additional variables must be inserted.
- For the following options, the default value has changed:
- * [MSK_DPAR_MIO_TOL_FEAS](#) from 1e-7 to 1e-6
 - * [MSK_IPAR_LOG_MIO_FREQ](#) from 1000 to 10
 - * [MSK_IPAR_WRITE_PRECISION](#) from 8 to 15
- Fixed selection of optimizer for "fixed solve" of a mixed-integer conic problem.

3.19.1.4.12 Pyomo

- Fixed compatibility issues with different versions of Pyomo.

3.19.1.4.13 SCIP

- New libraries 3.2 (#0d4fc08).
- Changed the default LP solver to SoPlex also for the case where a CPLEX license is available, due to problems when using CPLEX 12.7.0.0 as LP solver in SCIP.

3.19.1.4.14 SoPlex

- The GAMS/SoPlex interface has been rewritten and does not use the OsiSpx layer anymore. The solver OSISOPLEX is now an alias for the solver [SoPlex](#).
 - SoPlex parameter files can now be used.
 - SoPlex can now be warmstarted when only the model instance data changes (e.g., via GUSS).
 - New libraries 2.2 (df190de).
-

3.19.1.5 Tools

3.19.1.5.1 CSV2GDX

- Improved error reporting.

3.19.1.5.2 GDXDUMP

- New command line option `CSVAllFields` to get all fields (level, marginal, lower, upper, and scale) when writing a variable or equation symbol in CSV format.

3.19.1.5.3 MODEL2TEX

- Increased the page width of the txt file generated by the GAMS command line option `docfile` to 32767 (max. value).
- Changed the default encoding to `latin` and added a new command line parameter that allows to change the encoding (`-e=ENCODING`)
- Changed the default format of the symbol tables.
- The JSON style file contains a new property called `columnSetting` that allows to adjust the columns.
- Avoid some unnecessary parentheses in sum and product operators.
- Minor change in the equations subsection that removes several warnings.
- Several minor bug fixes.

3.19.1.5.4 GDXXRW

- Fixed a problem when writing a symbol with option `merge` or `clear` to a range with `CDim=0` or `RDim=0`.

3.19.1.5.5 GMSZIP/GMSUNZIP

- New versions of **Info-ZIP's** tools `zip` (version 3.1c02) and `unzip` (version 6.00). The executable names have been prefixed with "gms" for clear identification.

3.19.1.6 Object Oriented APIs

- New option `GAMSOptions.ErrorLog`: Maximal number of error message lines written to the log for each error.

3.19.1.6.1 .NET

- New examples that demonstrate the use of the API in a graphical environment: `TransportGUI`, `CutstockGUI`, `FarmGUI`.
 - Distribute compiled GUI examples in directory `<GAMSDir>\apifiles\GUIexamples` on Windows.
 - `GAMSWorkspace.AddJobFromFile`: Throw an exception if a given file does not exist.
-

3.19.1.6.2 Python

- The option `GamsOptions._errorlog` has been renamed to `GamsOptions.errorlog` in order to indicate it as public.

3.19.1.7 Model Libraries

3.19.1.7.1 GAMS API Library

- `PInterrupt.gms` : Test GamsJob interrupt mechanism in object oriented Python API (54)
- `CSInterrupt.gms` : Test GamsJob interrupt mechanism in object oriented .Net API (55)

3.19.1.7.2 GAMS Model Library

- `asyncloop.gms` : Transportation Problem with async loop body execution (411)
- `trnsindic.gms` : Fixed Charge Transportation Problem with Indicator Constraints (412)
- `timesteps.gms` : Accessing previous (or next) time steps in an equation fast (413)
- Modified models:
 - Make use of the new `break` statement to formulate the following models a little nicer: `tsp1`, `tsp4`, `cutstock`, `awktsp`, `sddp`, `sipres`, `allbases`, `qfilter`
 - `tgridmix`: The of logic of submission and collection has been reworked so that the scenario sets do not have to be one dimensional and ordered (contributed by Tom Rutherford).
 - `asyncjobs`: The logic for putting out the log line in time intervals was flawed and has been corrected.

3.19.1.7.3 GAMS Test Library

- `emp17.gms` : Simple test of one optimizing agent (693)
 - `breakcont1.gms` : Test break and continue statements (694)
 - `lindgl04.gms` : Test non-convex quadartic program with Lindo(Global) (695)
 - `mcp11.gms` : Test marginals for a scaled MCP problem (696)
 - `csv2gdx1.gms` : Test csv2gdx on input containing spaces (697)
 - `gdxrw7.gms` : Test merge and clear option for special data layout (698)
 - `scale02.gms` : Test that an MCP with scales is rejected when appropriate (699)
 - `emp18.gms` : Test JAMS/EMP on implicit variable handling (700)
 - `emp19.gms` : Test JAMS/EMP on implicit variable handling (701)
 - `emp20.gms` : Test JAMS/EMP on implicit variable handling (702)
 - `emp21.gms` : Test JAMS/EMP on implicit variable handling (703)
 - `emp22.gms` : Test JAMS/EMP on implicit variable handling (704)
-

- `emp23.gms` : Test JAMS/EMP on implicit variable handling (705)
- `emp24.gms` : Test JAMS/EMP on implicit variable handling (706)
- `emp25.gms` : Test JAMS/EMP on implicit variable handling (707)
- `emp26.gms` : Test JAMS/EMP on implicit variable handling (708)
- `gurobi02.gms` : GUROBI test suite - general constraints max,min,abs (709)
- `gurobi03.gms` : GUROBI test suite - general constraints and,or (710)
- `slx01.gms` : run tests for different solvelink values (711)
- `gurobi04.gms` : GUROBI test suite - multi objective (712)

3.19.2 24.8.2 Maintenance release (January 03, 2017)

3.19.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Evangelos Panos.

3.19.2.2 GAMS System

3.19.2.2.1 GAMS

- Change for command line parameter `MultiPass`: If it is set to 2, als errors from `$gdxIn` are ignored now
- Fixed a bug which caused wrong results in some assignments which use symbols that were used out-of-order in previous assignments.

3.19.2.3 Solvers

3.19.2.3.1 SCIP

- Added a workaround that allows for using CPLEX 12.7.0.0 as LP solver in SCIP again. For the moment, the default is still to use SoPlex.

3.19.3 24.8.3 Minor release (January 28, 2017)

3.19.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Mohammad R. Hesamzadeh, and Katja Jensen.

3.19.3.2 GAMS System

3.19.3.2.1 GAMS

- Fixed potentially wrong values for model attribute `etSolver` for cases where the command line option `solveLink` was set to 1, 2 or 5.
-

3.19.3.3 Solvers

3.19.3.3.1 BARON

- New libraries 17.1.2.
 - More robust links with COIN-OR solvers and a better link with FICO Xpress.
 - Some new RLT cuts are included in relaxations.

3.19.3.3.2 DE

- Create a capability error if DE is called to solve a model of type EMP without stochastic information.

3.19.3.3.3 DECIS

- Create a capability error if DECIS is called to solve a model of type EMP without stochastic information.

3.19.3.3.4 Examiner2

- Fix behavior when the subsolver returns a model status like `19 Infeasible - No Solution`. The model status can be passed unchanged back to GAMS in such a case.

3.19.3.3.5 Kestrel

- Adjusted the default URL to https using port 3333.
- Fixed a bug that prevented to specify the protocol in the `neos_server` parameter in an option file. The complete format of the parameter is now `protocol://host:port`.

3.19.3.3.6 LINDO

- Create a capability error if LINDO is called to solve a model of type EMP without stochastic information.

3.19.3.3.7 MOSEK

- New libraries 8.0.0.53.

3.19.3.3.8 SCIP

- Changed the default LP solver back to CPLEX, if available (see also [24.8.1](#) and [24.8.2](#) release notes).
-

3.19.3.4 Tools

3.19.3.4.1 GDXDUMP

- Fixed wrong output in case of nested quotes in symbol text.

3.19.3.5 Model Libraries

3.19.3.5.1 GAMS Model Library

- **linearne**: Minor fix to model formulation (contributed by Mohammad R. Hesamzadeh).

3.19.4 24.8.4 Minor release (April 10, 2017)

3.19.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Ivan Leung, Tara Rengarajan, and Sajjad Shafiei.

3.19.4.2 GAMS System

3.19.4.2.1 GAMS

- Fixed an issue which caused unnecessary memory consumption if many indexed symbols with explicit labels were used.

3.19.4.3 Solvers

3.19.4.3.1 BARON

- New libraries 17.4.1.
 - Bug fixes and an enhanced convexity detector.

3.19.4.3.2 CPLEX

- New libraries 12.7.1.0.
 - Note that with this update the log generated by Cplex changed in a way that the Cplex options set (either by the user or by GAMS defaults) are displayed. This is intentional and no sign of a problem. So one could see something like this in the log when running GAMS/Cplex:

```
CPXPARAM_Simplex_Limits_Iterations      2000000000
CPXPARAM_TimeLimit                      1000
CPXPARAM_Threads                         1
```

3.19.4.3.3 DICOPT

- Fixed serious bug in feasibility pump implementation.

3.19.4.3.4 Examiner, Examiner2

- The list of checks to perform for solved models was set incorrectly when the trace option was used.

3.19.4.3.5 GUROBI

- New libraries Gurobi 7.0.2.
- Added options [MultiObjMethod](#) and [MultiObjPre](#).
- Fixed a problem that lead to wrong error messages when setting the [ObjNAbsTol](#) and [ObjNRelTol](#) parameters.
- Fixed a problem that reported back the wrong alternative solution.

3.19.4.3.6 JAMS

- Fix problem with bilevel models having variables owned by the leader but not appearing in the leader objective or constraints.

3.19.4.3.7 Lindo/LindoGlobal

- New libraries 10.0.179.

3.19.4.3.8 MOSEK

- New libraries 8.0.0.60.

3.19.4.3.9 NLPEC

- Fix problem handling empty constraints (e.g. $f \dots \text{eps} * x =G= 0$) that appear in MPEC models. Note that such models can easily be produced by JAMS/EMP.

3.19.4.4 Object Oriented APIs

3.19.4.4.1 Python

- Added support for Python 3.6.
 - Fixed a bug in `GamsJob.run()` that prevented the underlying GAMS model from terminating, if executables spawned by GAMS generate log output that is not captured.
-

3.19.5 24.8.5 Maintenance release (May 10, 2017)

3.19.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Ana Carolina, Gary Goldstein, Erwin Kalvelagen, Amit Kanudia, Toni Lastusilta, Antti Lehtila, Bruce McCarl, and Hans Kristian Ringkjøb.

3.19.5.2 Platforms

- The AIX system is now build on AIX 7.1.

3.19.5.3 GAMS System

3.19.5.3.1 GAMS

- Fixed a bug which could cause a crash in particular assignments involving singleton sets or explicit labels. This was introduced with GAMS 24.8.4.
- Fixed problems with the `break` statement:
 - There was a potential crash if `break` was used in a "sparse loop", e.g., `loop(j$x(j), ...)`.
 - If `break` was used in a loop with more than one index, e.g., `loop((i,j), ...)`, that loop was treated as multiple loops for the `break` statement, one for each index. Now it is treated as just one loop as intended.
 - Fixed a problem where a loop was not correctly recognized as a loop if it runs over just one fixed element, e.g., `loop(i('i2'), ...)`.

3.19.5.4 Solvers

3.19.5.4.1 BARON

- Initialize BARON option `Threads` with value of GAMS option `Threads`, if the latter is at least 1.

3.19.5.4.2 CBC

- New libraries.
 - Fixed a bug in presolve that caused problems with fixed discrete variables.

3.19.5.4.3 GUROBI

- Suboptimal solutions were not reported back to GAMS. This has been fixed.

3.19.5.4.4 Lindo/LindoGlobal

- New libraries 10.0.182.
-

3.19.5.4.5 MOSEK

- New libraries 8.0.0.69.

3.20 24.7 Distribution

3.20.1 24.7.1 Major release (March 14, 2016)

3.20.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Alex Dowling, Johannes Hedtrich, Austin Milt, and Salvador Pineda.

3.20.1.2 GAMS System

3.20.1.2.1 GAMS

- Be more strict when the syntax `$LOAD par=var.L` is used: This creates an error now, if `par` is not a parameter (if `par` was a variable before, the complete variable `var` was loaded as if the suffix was omitted)
- GAMS Grid Facility (`SolveLink = 3` or `4`)
 - Fixed a bug for the model attribute `objval`: This could have been wrong when the objective variable was scaled.
 - Fixed a bug for the marginals: These could have been wrong when the objective variable was scaled.
- Solving in parallel threads (`SolveLink = 6`)
 - Allow to solve scaled models (model attribute `scaleOpt` is set to 1) as well (this generated an execution error before).

3.20.1.3 Solvers

3.20.1.3.1 BARON

- New libraries 16.3.4.
 - Faster LP interfaces.
 - Additional checks on solution reliability of LP and NLP subsolvers.
 - New automatic differentiation routines.
 - Improved handling of memory-intensive problems.
 - Enhanced presolving for continuous and integer programs.
 - New primal heuristic for integer programs.
 - New facilities for solving constraint (non)linear systems (CNS).
-

3.20.1.3.2 CBC

- New libraries.

3.20.1.3.3 ConvertD

- The GDX file created with option `Jacobian` contains now a set ANI that indicates the non-linear Jacobian elements.

3.20.1.3.4 CPLEX

- For an unbounded model Cplex did not mark the unbounded variables correctly. This has been fixed.

3.20.1.3.5 GUROBI

- Gurobi Optimization, Inc. has decided to end the current arrangement that allows us to offer GAMS/Gurobi integrated licenses. GAMS will continue to offer the latest version of Gurobi but users will need to get a Gurobi license from Gurobi Optimization, Inc. plus a GAMS/Gurobi link license from GAMS or use the free OsiGurobi link. This includes evaluation and demo licenses. For existing GAMS/Gurobi customers the following transition arrangements have been negotiated. The GAMS/Gurobi integrated license will continue to work as long as the license stays under maintenance. Academic GAMS/Gurobi customers will not be able to renew maintenance on their GAMS/Gurobi integrated license, their license will be changed into a GAMS/Gurobi link license. Academic users can get free Gurobi licenses from www.gurobi.com. In the past, academic GAMS/Gurobi link or GAMS/OsiGurobi licenses did not require a Gurobi license installed. This has changed with this release
- New libraries 6.5.1
- The option `PreSOS1BigM` and `PreSOS2BigM` were incorrectly classified as integer options. They have been reclassified as real option.

3.20.1.3.6 IPOPTH

- Fixed a memory access issue in the linear solver HSL MA86 in case of very large models.

3.20.1.3.7 LocalSolver

- New libraries 6.0 (20160308).

3.20.1.3.8 MOSEK

- New libraries 7.1.0.49.
-

3.20.1.3.9 SBB

- Fixed a problem with option `UserHeurCall`. This option required that all discrete variables were declared first in the model. This is not necessary anymore.

3.20.1.3.10 SCIP

- New libraries 3.2 (#f69c505).
 - The timing mask for parameters `constraints/.../presoltiming`, `presolving/.../timing`, and `propagating/.../presoltiming` changed from 2/4/8 for fast/medium/exhaustive to 4/8/16.
 - Parameter `constraints/SOS1/updateconflpresol` has been renamed to `constraints/SOS1/perfimplanalysis`.
 - [Detailed Changelog](#).

3.20.1.3.11 SOPLEX

- New libraries 2.2 (#12d3858).

3.20.1.4 Tools

3.20.1.4.1 GAMS IDE

- Fixed a bug which caused an error when opening the FINLIB (Practical Financial Optimization Models).

3.20.1.4.2 MODEL2TEX

- Fixed a bug regarding negative variables.
- Fixed a bug regarding subscripts of symbol names with underscores.
- Fixed a bug that prevented alternative names from being replaced in Ord constructs.
- New parameter `-o` (`-OUTPUT`) that allows to specify an alternative output file.
- Use UTF8 encoding.
- The columns of the symbol table have a fixed (equal) width.
- The original name of a symbol that is changed using the JSON style file is displayed in the symbol table.
- The JSON style file is alphabetically sorted by keys.

3.20.1.5 Object Oriented APIs

- Fixed a bug with the property `GAMSOptions.Defines` (.NET), `GAMSOptions.defines` (Java), and `GamsOptions.defines` (Python): When too many entries were added, all of them were ignored.
-

3.20.1.5.1 Python

- Fixed a memory leak in GamsDatabase.

3.20.1.6 Model Libraries

3.20.1.6.1 GAMS Test Library

- `scale01.gms` : Test results of scaled model (692)

3.20.2 24.7.2 Minor release (July 07, 2016)

3.20.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Peter Alexander, Daniel Balistrieri, Paul Buckland, Denis Hess, Eden Huang, Josef Kallrath, Sherman Robinson, Tom Rutherford, Jihh-Shyang Shih, and Loic Ventre.

3.20.2.2 Platforms

- With the next major release, the minimal glibc version requirement for the GAMS distribution on Linux will be increased to 2.7.

3.20.2.3 GAMS System

3.20.2.3.1 GAMS

- Improved the performance for assignments from one large symbol to itself inside a loop, when only one element gets changed, e.g.:

```
loop((j,cty,yrs,sim), ...; par(j,cty,'Total',yrs,sim) = sum(lnd, par(j,cty,lnd,yrs,sim));)
```
- Fixed a performance issue which caused very long model generation time for large scalar models.

3.20.2.4 Solvers

3.20.2.4.1 BARON

- New libraries 16.5.16.
 - Added option `WantDual` to indicate whether BARON should make a final call to an NLP solver to try to compute duals if an inexpensive method of calculating them failed.
- `CompIIS` option did not print IIS into listing file. This has been fixed.

3.20.2.4.2 CBC

- New libraries.
-

3.20.2.4.3 CPLEX

- New libraries 12.6.3.0.2.
- A memory leak in Cplex has been fixed that showed up in combination with the OO-API GAMSModelInstance class.
- Fixed a problem with CplexD option [FreeGamsModel](#).
- Fixed a problem with MipStart in combination with SemiInt or SemiCont variables with lower bound 0.

3.20.2.4.4 GUROBI

- New libraries 6.5.2.

3.20.2.4.5 JAMS

- Fix handling of objectives in optimizing agents of equilibrium systems in cases where the objective coefficient was not 1 or -1, and in the equation level returned for the objective row(s).

3.20.2.4.6 LocalSolver

- New libraries 6.0 (20160625).

3.20.2.4.7 Mosek

- New libraries 7.1.0.52.

3.20.2.4.8 OsiMosek

- Fixed handling of gap tolerances and node limit of MIP solves.

3.20.2.4.9 SBB

- Fixed a problem with models that have domain violations in the root NLP.
- Clearly identify text written to the listing file as output from the root solver.

3.20.2.4.10 SCIP

- New libraries 3.2 (#e99d344).

3.20.2.4.11 SoPlex

- New libraries 2.2 (#3c5e86f).
-

3.20.2.4.12 PATH

- Fixed a problem with bogus report of empty rows/cols when benchmarking a model, i.e. solving with iterlim=0.

3.20.2.4.13 XPRESS

- Maintenance update of Optimizer libraries for Windows, Linux, and Mac to 28.01.14.
- Several minor bug fixes that affect correctness and performance in some uncommon cases.

3.20.2.5 Tools

- Increase maximum available memory for GDXVIEWER, MDB2GMS, SQL2GMS, XLS2GMS, GDX2HAR, and HAR2GDX to 3GB.

3.20.2.5.1 CSV2GDX

- Fixed a problem with labels with trailing blanks. Labels with trailing blanks potentially resulted in a broken GDX file.
- Introduced the symbolic constant `LastCol` for the [Values](#) parameter.
- Report duplicate keys.

3.20.2.5.2 GDXXRW

- Fixed a problem with unnecessary memory consumption when writing with option clear or merge.
- Symbols and text were not written in sequence as instructed. This has been fixed.
- Added command line parameter `ReCalc` that by default prevents frequent recalculations in Excel while writing to the spreadsheet.

3.20.2.6 Object Oriented APIs

- Fixed a bug which did not clear a pending Ctrl-C event, so that it might have been applied to a following `GAMSModelinstance.Solve` by accident.
- Fixed a problem, that caused a crash instead of a `GAMSException` in some rare cases.

3.20.2.6.1 Python

- Fixed a minor bug regarding the names of `GamsJob` listing files.

3.20.2.7 Model Libraries

- Some URLs in various models have been updated.
-

3.20.3 24.7.3 Maintenance release (July 11, 2016)

3.20.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Josef Kallrath, and Toni Lastusilta.

3.20.3.2 Tools

3.20.3.2.1 CSV2GDX

- Fixed a bug which caused an error when reading sets from a csv file.

3.20.3.2.2 MODEL2TEX

- Fixed a bug regarding wrongly generated equations in the generated LaTeX file.

3.20.4 24.7.4 Minor release (September 19, 2016)

3.20.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Manuel Alvarez, Felix Färber, Ricardo Manuel Pinto de Lima, and Tara Rengarajan.

3.20.4.2 GAMS System

3.20.4.2.1 GAMS

- Fixed a problem when using extrinsic function libraries using API version 1.
- Extend possible range of `n` in `fact(n)` at compile time. It was limited to 20 in the past. Now it can be up to 166 (as in assignments at execution time).

3.20.4.2.2 Installer

- New default group name (`GAMS xx.x (xx bit)`) for the start menu on Windows 10.

3.20.4.3 Solvers

3.20.4.3.1 BARON

- New libraries 16.8.24.
 - Small performance improvements and robustification of LP solver interfaces and bugfixes.
 - The starting point is now utilized before invoking projection and other initialization strategies.
 - The option `DeltaTerm` is now recognized again.
-

3.20.4.3.2 Couenne

- New libraries.

3.20.4.3.3 CPLEXD

- The option `MipStart` accepts now values other than 0 and 1. The value describes the effort level Cplex uses to determine a MipStart from the starting variable levels. The value 2 is interesting because it just checks for feasibility of the MipStart. In this case the level of all variables, not only the discrete ones, are passed on to Cplex.

3.20.4.3.4 DE

- DE crashed if multiple joint variables were present in one stage. This has been fixed.

3.20.4.3.5 Lindo/LindoGlobal

- New libraries 9.0.293.

3.20.4.3.6 Mosek

- New libraries 7.1.0.55.

3.20.4.3.7 SCIP

- New libraries 3.1 (#6b9196f).

3.20.4.3.8 SoPlex

- New libraries 2.2 (#074950a).

3.20.4.4 Tools

3.20.4.4.1 CSV2GDX

- Fixed a bug which lead to a rejection of unquoted labels with spaces. This bug was introduced in 24.7.2.

3.20.4.4.2 GDXXRW

- Fixed a bug which caused an error message when reading a sheet with a non-empty range that contained no data.
-

3.20.4.5 Object Oriented APIs

- `GAMSModelInstance.Instantiate`: Skip creation of GDX file, which was unreachable from within the APIs anyway.

3.20.4.5.1 Python

- Added support for Python 3.4 on Mac OS X.
- Fixed a problems with Exceptions in `GamsWorkspace`.

3.21 24.6 Distribution

3.21.1 24.6.1 Major release (January 18, 2016)

3.21.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Etienne Ayotte-Sauvé, Michael Ferris, Per Ivar Helgesen, Erwin Kalvelagen, Martha Loewe, Geoff Moore, and Renger van Nieuwkoop.

3.21.1.2 Platforms

- The minimal supported Mac OS X version has been increased to 10.9 (Mavericks). COIN-OR solvers, Gurobi, SCIP, and SoPlex now require a system with at least Mac OS X 10.9. The GAMS base system, tools, and other solvers are still working on Mac OS X 10.7 and 10.8, but may stop working in a future release without extra announcement.
- The installer for Wine on Linux has been dropped.

3.21.1.3 GAMS System

3.21.1.3.1 GAMS

- Increased controlled set nesting limit from 120 to 300.
 - New option `SHUFFLE`.
 - New option for command line parameter `MultiPass`:
 - 0: standard compilation
 - 1: check-out compilation
 - 2: as 1 and in addition skip `$call` and ignore errors because of missing files with `$include (NEW)`
 - Allow to load variable and equation attributes into a parameter at compile time, e.g. `$LOAD par=var.L` (par being a parameter and var a variable)
-

- Solving in parallel threads (beta feature)

A new variant for the `SolveLink` option and model attribute has been added. If `SolveLink` is set to 6 (compile time constant `%solveLink.Async Threads%`), GAMS does not wait for the solver to return and does not collect the result when a solve statement is executed. Instead, the model is generated and then passed to the solver in a separate thread while GAMS continues the execution. This way, multiple models can be solved in parallel and the results can be collected later.

This is similar to the `Grid Facility` (`SolveLink = %solveLink.Async Grid%=3`) with the difference, that the solver does not operate in its own process space but in a separate thread, which allows efficient in-memory communication between GAMS and the solver (like it is done with `SolveLink = %solveLink.Load Library%=5`). After the solve statement, one can store a handle of the model instance (using the model attribute `mymodel.handle`) and use the same `functions` that are used for the `Grid Facility` to collect the solution and deal with the model instance: `HandleCollect(handle)`, `HandleStatus(handle)`, and `HandleDelete(handle)`.

The new function `ReadyCollect(handleParameter [, maxWait])` can be used to wait until a model is ready to be collected. It can be used for both `SolveLink = %solveLink.Async Threads%` and `SolveLink = %solveLink.Async Grid%`. The arguments and return codes are:

- Arguments
 - * `handleParameter`: parameter holding handles of model instances to wait for
 - * `maxWait`: maximum time to wait (+INF if omitted)
- Return Codes
 - * 0: (one of) the requested job(s) is ready
 - * 1: no active job to wait for
 - * 2: no handle provided
 - * 3: invalid handle
 - * 4: user specified time-out when using a `SolveLink = %solveLink.Async Threads%` handle
 - * 5: user specified time-out when using a `SolveLink = %solveLink.Async Grid%` handle
 - * 8: unknown error (should not happen)

The new option `threadsAsync` (available on the command line and with the option statement) sets the maximum number of threads that should be used for the asynchronous solves. If a negative number is set, this specifies how many of the available processors on the host machine should not be used. The default setting is -1.

Currently, the following solvers can be used with `SolveLink = %solveLink.Async Threads%`:

- CONOPT
- CPLEXD
- GUROBI
- MOSEK
- OSICPLEX
- OSIGUROBI
- SCIP

If another solver is selected, `SolveLink = %solveLink.Async Grid%` will be used instead (which is noted in the log).

An example of how this new feature can be used, can be seen in the GAMS Model Library model `tgridmix`.

3.21.1.3.2 Stochastic Programming with EMP

- Fixed a bug which caused wrong expected values for parametric distribution using the `RandVar` keyword.

3.21.1.4 Solvers

3.21.1.4.1 ANTIGONE

- New libraries.

3.21.1.4.2 BARON

- The handling of branching priorities in a GAMS/BARON options file has changed. Priorities should now always be given in [the GAMS convention](#).

3.21.1.4.3 Convert

- GAMS branching priorities are now converted to BARON branching priorities when writing a BARON input file.

3.21.1.4.4 CPLEX

- New libraries 12.6.3.
- Cplex and CplexD now report the deterministic time spend (in `ticks` not in seconds) in the [model attribute](#) `ETA1g`.
- IBM's Cplex cloud offering "DOcloud" can be accessed via the [Kestrel solver](#).

3.21.1.4.5 DICOPT

- New option [usexinit](#) instructs DICOPT to start the NLP sub-solves from the user supplied input point.

3.21.1.4.6 GUROBI

- New libraries 6.5.
- New option [PreMIQCPForm](#) that determines the format of the presolved version of an MIQCP model.
- New option `WorkerPort` specifies a non-default port number for the distributed worker machines.
- New option [VarHint](#). The variable hints communicated through [level](#) and [tryint](#) will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree.
- GAMS/Gurobi supports solving models in the [Gurobi Instant Cloud](#).
- Fixed a problem with option [IIS](#) for models with SOS variables.

3.21.1.4.7 IPOPT

- MKL Pardiso is now available as [linear solver](#) on Mac OS X, too.
-

3.21.1.4.8 KESTREL

- The Kestrel client provides experimental access to [IBM's DOcloud](#) offering.

3.21.1.4.9 PATH

- Minor fix for zero tolerance in the basis reset routine of the Lemke method.

3.21.1.4.10 Sulum

- Sulum will be dropped from the distribution with GAMS 24.8.

3.21.1.4.11 XPRESS

- Updated Optimizer libraries for Windows and Linux: 28.01.05 → 28.01.10.
- Several minor bug fixes that affect correctness and performance in some corner cases.

3.21.1.5 Tools

3.21.1.5.1 ASK

- New feature [SelectDirectory](#).

3.21.1.5.2 GAMS IDE

- Sorting by symbol name is no longer case sensitive.
- GDX viewer can now show numbers with full precision.
- The option editor no longer shows the dot options.
- Fixed a bug where the cursor was not shown after double-clicking on a red line.

3.21.1.5.3 GDX2SQLITE

- New version 0.7.
 - Added option [varchar](#) to export character columns as `VARCHAR(255)` instead of `TEXT`.
 - Better names of columns when option [small](#) is used.
 - Adding timing info.

3.21.1.5.4 GDXMERGE

- Protect against very large symbols causing memory errors.
 - Added option [EXCLUDE](#) to exclude symbols from being merged.
-

3.21.1.5.5 GDXXRW

- An empty range is no longer an error.

3.21.1.5.6 SQL2GMS

- In the old version double quotes were removed when reading a command file. In this version we keep double quotes to be able to escape SQL names (table names, column names). E.g. we now can handle non-standard names by double quoting them in a query. Depending on the database you can do:

```
q=select "Some COLUMN" from "This Table"
```

Note that some databases (such as SQL Server) use [] for this goal.

In the special case where you write:

```
q="select c from t"
```

the surrounding double quotes are removed before passing the query on to the database.

3.21.1.5.7 MODEL2TEX

- If an identifier is changed using the specifications in the JSON style file, underscores are no longer changed from "_" to "_". This makes it possible to use subscripts when replacing an identifier.

3.21.1.6 Object Oriented APIs

3.21.1.6.1 Java

- Fixed a bug in `GAMSModelInstance.copyModelInstance` method when duplicating scratch directory.

3.21.1.6.2 Python

- New example `transport8a.py`.

3.21.1.7 Model Libraries

3.21.1.7.1 GAMS EMP Library

- **nbcontindep**: use sampling for continuous distributions if another solver than Lindo is selected
 - **nbcontjoint**: use sampling for continuous distributions if another solver than Lindo is selected
 - **nbsimple**: use discrete distribution
-

3.21.1.7.2 GAMS Test Library

- `shuffle1.gms` : Test for option `shuffle` (690)
- `sl601.gms` : Check correct behavior when using `solveLink=6` (691)

3.22 24.5 Distribution

3.22.1 24.5.1 Major release (September 23, 2015)

3.22.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Guillaume Erbs, Michael Ferris, Mahbube Habibian, Josef Kallrath, Jean Mercenier, Stan Peter, Ingmar Schlecht, and Mark Thissen.

3.22.1.2 Platforms

- Support for Windows XP has been dropped completely with this release (as announced).

3.22.1.3 GAMS System

3.22.1.3.1 GAMS

- New model attributes
 - `maxInfes`: Maximum of infeasibilities
 - `meanInfes`: Arithmetic mean of infeasibilities
 - New option `solver`. This simplifies the selection of the (default) solver for multiple model types.
 - The command line option `solver=abc` initializes the default solver for the model types `abc` is capable of to `abc`. This initialization is done before the default solvers of individual model types are set via command line options. So a command line with `lp=conopt solver=bdmlp` will first set BDMLP as the default solver for model types LP, RMIP, and MIP (these are the model types BDMLP can handle) and then reset Conopt as the default solver for LP. The order of these parameters on the command line has no impact (i.e. `lp=conopt solver=bdmlp` behaves identically to `solver=bdmlp lp=conopt`). If multiple occurrences of option `solver` appear, the last one sets the option as it is with other options, including LP, MIP, ...
 - The solver for multiple model types can be set via the `Option solver=abc;` in the GAMS model source code. This sets the solver for model types `abc` can handle to `abc`. With the `option solver=abc;` the order among other solver setting options is significant. For example, `option lp=conopt, solver=bdmlp;` will first set the solver for LP to Conopt and in the next step to BDMLP because BDMLP is capable of handling model type LP. Setting `solver` twice can also make sense: `option solver=conopt, solver=cbc;` will result into setting the solver for model types CNS, DNLP, NLP, QCP, RMIQCP, and RMINLP to Conopt and the solver for model types LP, RMIP, and MIP to CBC.
 - When using `$LOADDC` the reporting of domain errors has been improved.
 - This release features several improvements of the execution system. The following lists some (extreme) examples:
-

- Improved performance when indices of accessed symbol are in "wrong" order, e.g.:

```
$if not set size $set size 10000
set v / v1*v%size% /
e / e1*e%size% /;
alias(v,w);
set evw(e,v,w) /#e:#v:#w/
    vw(v,w);
vw(v,w) = sum(e, evw(e,v,w));
```

The final assignment can be done in less than 1% of the time required by GAMS 24.4.

- Improved performance when assigning to non-empty symbols when the assignment is driven by their domain, e.g.:

```
$if not set size $set size 5000
set i / i1*i%size% /; alias (i,j);
parameter a(i,j), b(i,j);
a(i,j)$uniform(0,1)<0.95 = 1;
b(i,j) = not a(i,j);
a(i,j) = b(i,j);
```

The final assignment can be done in just ~5% of the time required by GAMS 24.4.

- Improved performance when executing certain combinations of mappings, e.g.:

```
$if not set size1 $set size1 8000
$if not set size2 $set size2 24
set hi / 1*%size1% /
    ti / 1*%size2% /
    h / h1*h%size1% /
    t / t1*t%size2% /
    hmapx(h,hi) / #h:#hi /
    tmapx(t,ti) / #t:#ti /;
parameter xi(hi,ti), x1(h,t);
xi(hi,ti) = uniform(0,1);
x1(h,t) = sum((hmapx(h,hi),tmapx(t,ti)), xi(hi,ti));
```

The final assignment can be done in just ~2% of the time required by GAMS 24.4.

- Improved performance when "searching" a lot in a large symbol, e.g.:

```
$if not set size1 $set size1 50
$if not set size2 $set size2 200000
$if not set size3 $set size3 150000
set f /f1*f%size1%/
    j /j1*j%size2%/
    l /l1*l%size3%/
    flmap(f,l);
flmap(f,l)=uniform(0,1)<0.25;
parameter jlpar(j,l) /#j:#l 10/
    fjpar(f,j);
fjpar(f,j) = sum(l$flmap(f,l), jlpar(j,l));
```

The final assignment can be done in just ~1% of the time required by GAMS 24.4.

3.22.1.3.2 Documentation

- The complete GAMS technical documentation (release and installation notes, user's guides, solver and tools manuals, API reference manuals) is now available in HTML format with a unified table of contents. The documentation is available in the following forms:
 - The [online GAMS documentation](#) provides search and keyword indexing functionalities in addition to navigating the GAMS documentation.

– The offline documentation allows access without a network connection:

- * The main navigation page can be found at [GAMS system directory]/docs/index.html (not linked from the GAMS IDE).
 - * For Windows, additionally a Microsoft Compiled HTML Help file is available at [GAMS system directory]/docs/gams.chm and linked from the GAMS IDE Menu: Help -> GAMS Documentation.
- The following documents are still available in PDF format: GAMS User's guide, McCarl Expanded GAMS User's guide, all solver manuals, and GAMS GDX API.

3.22.1.3.3 Installer

- New way to install GAMS on Mac OS X using a DMG file.

3.22.1.4 Solvers

3.22.1.4.1 ANTIGONE

- Added option `conopt_optfile` to set name of options file to be used for CONOPT calls in ANTIGONE.

3.22.1.4.2 BARON

- Now also available for Mac OS X.
- New libraries 15.9.22.
- New NLP solver for local search: FilterSD.
- Options:
 - New option `Threads`: Number of cores used for solution of MIP subproblems.
 - New option `IISOrder`: Order in which constraints are considered in the search for an IIS.
 - Options `ConTol` and `IntTol` removed. Tolerances are now set by `AbsConFeasTol`, `RelConFeasTol`, `AbsIntFeasTol`, and `RelIntFeasTol`.
 - Options `MultMSize`, `MultRel`, `NLPDoLin`, `MipGap`, `MipNodes`, `MipRel`, `NoutIterMip`, `BilRel`, `Cvxbt`, `CvxInitOA`, `CvxRel`, `MipCuts`, and `RLTRel`: Algorithmic features that have been parameterized are now handle in an automatic way.
- The time limit is enforced based on CPU time for single-threaded jobs and based on wall-clock time for multi-threaded jobs.
- Simplified the screen output (eliminated some details and simplified time to a real number in seconds).
- Updated CBC to 2.9.5.
- Updated Ipopt to 3.12.3.

3.22.1.4.3 CBC

- New libraries 2.9.
 - Introduced specialized branching methods for dealing with "big Ms".
 - Introduction of conflict cuts (off by default, enable with option `conflictcuts`).
 - Introduced new methods for dealing with symmetry.
-

3.22.1.4.4 Conopt

- New libraries 3.17A.
 - Corrected problem with options [Ls2ndi](#) and [Lmusdf](#).
 - Systems errors related to very tight memory (984) and the inversion routine (2027) have been removed.
 - Three new options have been added to allow the modeler to see the order of the pre-triangular and post-triangular part of the model and the definitional equations:
 - * [PRPRET](#): Flag for printing the pre-triangular part of the model.
 - * [PRDEF](#): Flag for printing the defined variables and their defining constraints.
 - * [PRPOST](#): Flag for printing the post-triangular part of the model.

3.22.1.4.5 Couenne

- New libraries 0.5 (major update).
- Better handling of function `signpower(x,k)` for positive integer $k \leq 10$.
- The default values for the following options have changed:
 - `cont_var_priority` from 2000 to 99.
 - `int_var_priority` from 1000 to 98.
 - `feas_pump_milpmethod` from -1 to 0.
 - `feas_pump_poolcomp` from 0 to 4.
 - `output_level` from 0 to 4.

3.22.1.4.6 CPLEX

- New option [FreeGamsModel](#). This option preserves memory by dumping the GAMS model instance representation temporarily to disk. This option is available in CplexD only.

3.22.1.4.7 GUROBI

- New libraries 6.0.5 (technical release).
- New option [FreeGamsModel](#). This option preserves memory by dumping the GAMS model instance representation temporarily to disk.

3.22.1.4.8 GUSS/ScenarioSolver

- The set of GUSS model attributes (`Set ma "GUSS Model Attributes" / System.GUSSModelAttributes /;`) has changed:
 - The attribute `NumNOpt` has been removed.
 - The attributes `MaxInfes` and `MeanInfes` have been added.

3.22.1.4.9 IPOPT

- New libraries 3.12 (minor changes).
-

3.22.1.4.10 JAMS

- [SubSolver](#) option fixed: it was sometimes ignored.

3.22.1.4.11 Kestrel

- The option file can be omitted. In this case, the Kestrel call is done with default settings.

3.22.1.4.12 Lindo/LindoGlobal

- Dropped Lindo/LindoGlobal libraries for Intel Solaris as announced previously.
- New libraries 9.0.225.

3.22.1.4.13 LocalSolver

- New libraries 5.5.
 - Improved accuracy and performance on numerical or mixed-variable optimization problems.

3.22.1.4.14 MINOS

- Adjusted default upper bound on the superbasics limit from 500 to 5000 and consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 5000 superbasics, limit the Hessian dimension to 5000 even though the superbasic limit is larger.

3.22.1.4.15 MOSEK

- New libraries 7.1.0.33.
 - The GAMS option [iterlim](#) now sets the iteration limit for both simplex and interior point algorithms.
 - More MOSEK options are now available in GAMS/Mosek:
 - [MSK_IPAR_MIO_CUT_CG](#): Controls whether CG (Chvatal-Gomory) cuts should be generated.
 - [MSK_IPAR_MIO_CUT_CMIR](#): Controls whether mixed integer rounding cuts should be generated.
 - [MSK_IPAR_MIO_PROBING_LEVEL](#): Controls the amount of probing employed by the mixed-integer optimizer in presolve.
 - [MSK_IPAR_MIO_RINS_MAX_NODES](#): Controls the maximum number of nodes allowed in each call to the RINS heuristic.
 - [MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS](#): Maximum value of fractional part of right hand side to generate CMIR and CG cuts for.
 - [MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS](#): Minimum value of fractional part of right hand side to generate CMIR and CG cuts for.
 - [MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT](#): If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.
-

3.22.1.4.16 OS

- Now a hidden solver. Will be dropped from the distribution at some time (without further notice).

3.22.1.4.17 PATH

- New libraries 4.07.03.
- Adjusted to use wall-clock time on all platforms.
- Time limit checked more frequently, e.g. at each pivot.
- The presolve has been extended to find more reductions.
- Minor bug fixes.

3.22.1.4.18 SCIP

- New libraries 3.2 #c9c4375 (major update):
 - New presolvers "tworowbnd", "dualagg", "implfree", "redvub", and "stuffing", and improved presolve for ranged- and equality-type linear constraints.
 - Presolving levels FAST, MEDIUM, and EXHAUSTIVE are now used to better coordinate the various presolvers.
 - Generalized upgrade from (SOC-representable) quadratic constraints to SOC constraints.
 - New primal heuristics "distribution diving", "indicator", and "bound", improved clique and variable bound heuristics, and adjusted diving heuristics to solve fewer LPs.
 - New branching rules "distribution", "multaggr", and a new rule for SOS1 constraints.
 - New reliability notions and improved treatment of nonlinearities in hybrid reliability pseudo cost branching.
 - New separator "eccuts" for generating edge-concave cuts for quadratic constraints and improved separation for convex quadratic constraints.
 - Decreased total memory usage by using more buffer data structures.
 - Improved propagation and separation for SOS of type 1 by using information from a conflict graph.
 - See also the [full release notes](#), the [change log](#), and the [technical report](#).
 - The following options were removed or replaced:
 - `constraints/.../delaypresol` and `constraints/.../timingmask` replaced by `constraints/.../presoltime` and `constraints/.../proptiming`.
 - `presolving/domcol/singcolstuffing` replaced by `presolving/stuffing/...`
 - `presolving/.../delay` replaced by `presolving/.../timing`.
 - `propagating/.../presoldelay` replaced by `propagating/.../presoltime`.
 - `propagating/obbt/maxlookahead` removed.
 - For the following options, the default value changed:
 - `constraints/SOS1/sepafreq` from 0 to 10.
 - `"heuristics/clique/minfixingrate"` from 0.5 to 0.25.
 - `"heuristics/vbounds/minfixingrate"` from 0.5 to 0.25.
 - `heuristics/actconsdiving/maxdiveavgquotnosol` from 0 to 1.
-

- [heuristics/actconsvdiving/maxdiveubquotnosol](#) from 0.1 to 1.
- [heuristics/dins/nwaitingnodes](#) from 0 to 200.
- [lp/rowrepswitch](#) from -1 to 1.2.
- [presolving/abortfac](#) from 0.0001 to 0.001.
- [presolving/restartfac](#) from 0.05 to 0.025.
- [presolving/immrestartfac](#) from 0.2 to 0.1.
- [presolving/dualinfer/priority](#) from 20010000 to -200.
- [propagating/obbt/itlimitfactor](#) from 5 to 10.

3.22.1.4.19 SoPlex

- New libraries 2.2.0 (major update).

3.22.1.4.20 SULUM

- New libraries 4.3.892.
 - Several bug fixes in both the MIP solver and the LP solver.
 - Improved numeric stability, degeneracy handling, and perturbation scheme in LP optimizer.
 - Added a new combined pricing scheme to the dual simplex optimizer.
 - Improved presolve and restart in MIP optimizer.

3.22.1.4.21 XPRESS

- New libraries for XPRESS v7.9: Optimizer 28.01.05.
 - Significantly improved linear algebra routines for the simplex solvers improving efficiency of a wide range of problems.
 - Improvement heuristics called more often.
 - The MIP log now provides information which heuristic finds a solution.
 - Improved linear dependency checker for large problems.
 - Improved scaling, including scaling of big-M type rows and of the Curtis-Reid scaling option.
 - Improved inference-learning from infeasible subproblem during the MIP search.
 - Improved presolver for quadratic instances.
 - Improved handling of Special Ordered Sets.
 - Improved propagation of conflict cuts.

3.22.1.5 Tools

3.22.1.5.1 GAMS IDE

- In the model library browser the IDE may provide hints about the content of the column when hovering over the headers.
 - Option to specify file extensions for files that will be reloaded without a confirmation dialog.
-

3.22.1.5.2 GDXDIFF

- When renaming the temporary file to `gdxdiff.gdx` fails, issue a `ViewClose` command in case the file is open in the GAMSIDE and try to rename again.
- If no difference was found, issue a message in the log indicating this.
- Add a set with two elements with explanatory text of the two files compared.

3.22.1.5.3 GDXMERGE

- When a filename cannot be used as a UEL, use a generated name instead.

3.22.1.5.4 GDXXRW

- New options `IgnoreRows` and `IgnoreColumns` to ignore a set of rows or columns for a symbol. Rows can be specified as `IgnoreRows=1,4:5` and columns `IgnoreColumns=A,D:F` or `IgnoreColumns=1,4:6`.

3.22.1.5.5 MODEL2TEX

- The beta version of this tool allows the automatic generation of LaTeX code that documents a given GAMS model.

3.22.1.5.6 MPSGE

- The documentation of MPSGE has moved again. It can now be found in the User's Guide.

3.22.1.6 Object Oriented APIs

- New examples `SpecialValues` and `Clad` (Java: `specialvalues/SpecialValues.java`, `clad/Clad.java`; Python: `special_values.py`, `clad.py`).
- New functions to retrieve models from the GAMS API Library and the Nonlinear Optimization Applications Library:
 - .NET: `GAMSWorkspace.ApiLib` and `GAMSWorkspace.NoaLib`.
 - Java: `GAMSWorkspace.addJobFromApiLib` and `GAMSWorkspace.addJobFromNoaLib`.
 - Python: `GamsWorkspace.apilib` and `GamsWorkspace.noalib`.

3.22.1.6.1 Python

- Added support for Python 3.4 (Windows and Linux only). The examples have been changed to be compatible with all supported Python versions.
-

3.22.1.7 Model Libraries

3.22.1.7.1 NOALIB - Nonlinear Optimization Applications Using the GAMS Technology

- This new library by Neculai Andrei has been added to the GAMS system. This is a collection of the models based on the book [Nonlinear Optimization Applications Using the GAMS Technology](#) by Neculai Andrei. The library contains a wide spectrum of nonlinear optimization applications expressed in GAMS. The book and library emphasize the local solutions of the large-scale, complex, continuous nonlinear optimization applications, and the abundant examples in GAMS are highlighted by those involving ODEs, PDEs, and optimal control. The collection of these examples will be useful for software developers and testers.
- You can retrieve the individual models through the IDE model library browser or via the command line utility `noalib`.

3.22.1.7.2 GAMS API Library

- `CSSpecialValues.gms` : Test handling of Special Values in object oriented C# API (47)
- `PSpecialValues.gms` : Test handling of Special Values in object oriented Python API (48)
- `JSpecialValues.gms` : Test handling of Special Values in object oriented Java API (49)
- `CSNUnit.gms` : Compiles and runs NUnit tests for object oriented C# API (50)
- `CSClad.gms` : Test changing solver options while running using the interrupt method (51)
- `PClad.gms` : Test changing solver options while running using the interrupt method (52)
- `JClad.gms` : Test changing solver options while running using the interrupt method (53)

3.22.1.7.3 GAMS Data Library

- `invert1`: Pass `gams.sysdir%` to R script to make linkage between GAMS and R explicit.
- `gdxmrw_tr3`: Canonical form LP created in Matlab and solved via `gams()` Mex-function.
- `gdxmrw_tr4`: Better example of `gams()` usage.
- `gdxmrw_tr5`: Better example of `gams()` usage.

3.22.1.7.4 GAMS EMP Library

- `transecs`: Fix formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.
 - `farmnbd.gms` : **The Farmer's Problem - Stochastic with NBD** (100)
-

3.22.1.7.5 GAMS Model Library

- In the IDE the GAMS Model Library browser has now a **Lic** column indicating the license requirement of a model. The letters **D** and **G** indicate that the model does not require a license. Models with **G** can even be solved by a global solver without a license (the demo limit for global solvers is 10 variables and 10 equations). A letter **L** indicates that a license is required.
 - **tgridmix**: Fix the logic for sleeping. Only do that if no more jobs to be scheduled or all cores are busy.

3.22.1.7.6 GAMS Test Library

- **asynntrp**: Make this model work under Unix that have the **pstree** utility available.
- **call6.gms** : Call GAMS in a folder containing a % (674)
- **cmexrc01.gms** : Trigger unexpected cmexRC error (675)
- **rs02.gms** : Solving Three-dimensional Noughts and Crosses using Cplex and Gurobi distributed MIP (676)
- **single04.gms** : Check handling of singleton sets assigned and referenced in a loop (677)
- **model2tex1.gms** : Test that model2tex produces a tex file (678)
- **exmcp6.gms** : External Equation - Example MCP 6 (679)
- **scensol6.gms** : Test execute_loadhandle for GUSS/GRID (680)
- **idxperm1.gms** : Check correct behavior when permuting indices in model generation (684)
- **idxperm2.gms** : Check correct behavior when permuting indices in loop etc (685)

3.22.2 24.5.2 Maintenance release (September 29, 2015)

3.22.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Kevin Doran and Renger van Nieuwkoop.

3.22.2.2 GAMS System

3.22.2.2.1 GAMS

- Fixed a bug which caused a crash for certain assignments, in particular it had to be an assignment to a symbol that was also referenced on the RHS, with permuted indices and we actually set some of the records to zero which were non-zero before.

3.22.2.3 Object Oriented APIs

3.22.2.3.1 .NET

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. (This is for Mono only.)
-

3.22.2.3.2 Python

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. The property `GamsWorkspace.system_directory` now always returns the canonical path with all symbolic links resolved.

3.22.2.4 Model Libraries

3.22.2.4.1 GAMS Test Library

- `idxperm3.gms` : Check correct behavior when permuting indices of symbol used on LHS and RHS (686)

3.22.3 24.5.3 Maintenance release (October 01, 2015)

3.22.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz.

3.22.3.2 GAMS System

3.22.3.2.1 GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments

3.22.4 24.5.4 Maintenance release (October 15, 2015)

3.22.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Per Ivar Helgesen and Jan Imhof.

3.22.4.2 GAMS System

3.22.4.2.1 GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments, in particular it had to be an assignment using the same controlling set more than once in one symbol, e.g. `p(i,j,i)`.
- Fixed a bug when handling suffixes (e.g. `.val`) of Singleton Sets in Equations.

3.22.4.3 Object Oriented APIs

3.22.4.3.1 .NET

- Fixed a bug with the property `GAMSOptions.IDir`.
-

3.22.4.4 Model Libraries

3.22.4.4.1 GAMS Test Library

- `single05.gms` : Check correctness of set attributes for singleton sets (687)
- `idxperm4.gms` : Check correct behavior when permuting indices of symbol using same controlling set multiple times (688)

3.22.5 24.5.5 Maintenance release (November 25, 2015)

3.22.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Albrecht, Stefan Kemnitz, Martha Loewe, Thomas Maindl, Bruce McCarl, and Andres Ramos.

3.22.5.2 GAMS System

3.22.5.2.1 GAMS

- GAMS now always reports the upper bound that is sent to the solver in the column listing and solution report. Hence, with `IntVarUp=1` GAMS prints the value of 100 for integer and semiint variables that are at default bound value `+INF`.
- Fixed a bug which could cause a crash when referencing attributes of equations (e.g. marginals) after a model was solved with a non-default `solveLink` setting and there was no solution returned.

3.22.5.2.2 Stochastic Programming with EMP

- Fixed a bug which caused wrong sample sizes if the `sample` keyword was used more than once and with different sample sizes.

3.22.5.3 Solvers

3.22.5.3.1 Cbc

- New libraries.

3.22.5.3.2 CplexD

- Fixed a problem with the `computeserver` option. The value for the `computeserver` option is limited to 255 characters. In order to specify a longer list of workers, one can now use multiple lines with the `computeserver` option.
-

3.22.5.3.3 Ipopt

- New libraries.

3.22.5.3.4 LocalSolver

- New libraries 5.5 (20151028).

3.22.5.3.5 Mosek

- New libraries 7.1.0.41.

3.22.5.3.6 SCIP

- New libraries 3.2 (#e9a5ca7).
 - Removed options `constraints/SOS1/bipbranch`, `constraints/SOS1/neighborbranch`, and `constraints/SOS1/sos1branch`.

3.22.5.3.7 SoPlex

- New libraries 2.2 (#f17b9e7).

3.22.5.4 Tools

3.22.5.4.1 put_toexcel, put_tohtml

- Fixed a problem with `put_toexcel` and `put_tohtml`.

3.22.6 24.5.6 Maintenance release (November 27, 2015)

3.22.6.1 Solvers

3.22.6.1.1 COUENNE

- New libraries.

3.22.6.1.2 IPOPT, BONMIN, SCIP

- Fixed issue that Ipopt and Bonmin always read `ipopt.opt`, despite of the `optfile` setting in GAMS.
-

3.23 24.4 Distribution

3.23.1 24.4.1 Major release (December 20, 2014)

3.23.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Jeff Linderth, and Erkka Rinne.

3.23.1.2 GAMS System

3.23.1.2.1 GAMS

- Fixed a bug causing a potential crash when solving an EMP model having an open file handle without an external file name at the same time.
- The `execMode` setting is not ignored by `put_utility` anymore.
- Added `gbin/md5sum.exe` to Windows distribution. This utility allows users to verify the file integrity of newly downloaded GAMS installation files.
- The `gbin_new` directory will be removed with the next distribution.

3.23.1.2.2 Installer

- Windows installer removes the GAMS entry in the current user hive of the registry, if GAMS is installed for all users. Previously, the hive for the current user remained unchanged in this situation.

3.23.1.2.3 Extrinsic Function libraries

- The new extrinsic function library `parcclib` was added to the system. This library demonstrates how to access the GAMS parameter file and use it's information through the GAMS Option Object. Further information can be found in the GAMS User's Guide, Appendix J.
 - Allow up to 20 arguments (used to be 10).
 - Support for extrinsic function libraries that do not provide gradient and/or Hessian values. GAMS uses finite differences (same method as for `.gradn` and `.hessn`) to approximate the derivatives, even inside a solver. The example function library `trilib` now implements function `Sine` without any derivatives and leaves their calculation to GAMS.
 - New GAMS options have been introduced to parameterize the numerical derivative calculations. While these are most important for extrinsic functions, they also apply to the `.gradn/.hessn` calculations of intrinsic functions.
 - `FDDelta`: step size in the numeric gradient and Hessian calculation. For single argument functions, GAMS evaluates the function at $f(x-d)$ and $f(x+d)$ for the numerical gradient. If function values are used for the numerical Hessian, GAMS evaluates at $f(x-2d)$, $f(x)$, and $f(x+2d)$. For multi argument functions, the same is done for the components of the input argument vector. The default for `FDDelta` is $1e-5$. This option can be set from the command line, in an option statement, and as a model attribute.
 - **Note:** In previous releases it was possible to set the step size for `.gradn/.hessn` using the option `Real1`. This does not work anymore.
-

- **FDopt**: The option value packs two option in the different digits: ij . The i digit indicates if scaling of the step size (**FDDelta**) by the value of the input argument should be turned off. If $i=0$ (scaling on) the following step size is used: $\max(1, |x|) * \text{FDDelta}$. The j digit is mostly for testing, but has one setting that might be relevant when the extrinsic function provides gradient but no Hessian values. The numerical derivatives routine in this case uses the gradient calculation from the extrinsic function to approximate the Hessian. If the gradient is expensive to calculate compared to a function evaluation, it could be beneficial to use multiple function values to approximate the Hessian. In this case set the j digit to 1. Here are all possible values for this option:
 - * 0: All derivatives analytically if available, for numerical Hessian use gradient values, scale delta
 - * 1: All derivatives analytically if available, for numerical Hessian use function values, scale delta
 - * 2: Gradient analytically, force Hessian numerically using gradient values, scale delta (testing only)
 - * 3: Gradient analytically, force Hessian numerically using function values, scale delta (testing only)
 - * 4: Force gradient and Hessian numerically, scale delta (testing only)
 - * 10: Same as 0, but no scale of delta
 - * 11: Same as 1, but no scale of delta
 - * 12: Same as 2, but no scale of delta (testing only)
 - * 13: Same as 3, but no scale of delta (testing only)
 - * 14: Same as 4, but no scale of delta (testing only)
- **Note**: In previous releases it was possible to deactivate the scaling for `.gradn/.hessn` using the option `Integer1`. This does not work anymore.
- Renamed and better documented the `EXTRFUNC_ERROR` enum to `EXTRFUNC_EVALERROR` in the C header `extrfunc.h`. The old values are deprecated and will be removed in a future release.

3.23.1.2.4 Documentation

- The manuals of all solver and several tools are now available in HTML format. A PDF that contains all solver manuals is still available (<docs/solvers/allsolvers.pdf>).

3.23.1.3 Solvers

3.23.1.3.1 AlphaECP

- Alpha-ECP v2.10.06.
 - Added support for solver trace file, i.e. new option `solvetrace`.

3.23.1.3.2 ANTIGONE, GloMIQO

- Now also available for Mac OS X.

3.23.1.3.3 BARON

- New libraries 14.4.0.
 - Added reliability branching for integer variables.
 - Bug fixes in CBC interface and IIS module.
 - Improved performance of problem reading and reformulation.
 - Updated Ipopt to version 3.11.9.
-

3.23.1.3.4 BENCH

- Removed option `cumulative`. This option makes no sense anymore since all solvers are spawned asynchronously and all get the same limits.

3.23.1.3.5 CBC

- Fixed a race-condition in log output when using multiple threads.
- New libraries.

3.23.1.3.6 Couenne

- New libraries.

3.23.1.3.7 CONOPT

- New libraries 3.16D.
 - Tolerance adjustments that make sense if NaN appears in intermediate calculations.

3.23.1.3.8 CPLEX

- Don't rerun primal simplex in cases where there is already an infeasibility status.
- New libraries 12.6.1.
- New parameters:
 - `qtolin` controls the linearization of the quadratic terms in the objective function of a QP or MIQP model
 - `localimplied` controls the generation of locally valid implied bound cuts

3.23.1.3.9 DICOPT

- Added support for `=N=` rows.

3.23.1.3.10 GUROBI

- New libraries 6.0.0.
 - Fixed problem in tuning. Previous version did not write out link options in the tuned option file.
 - Gurobi 6.0 supports a distributed MIP algorithm (option `DistributedMIPJobs`). This requires the Gurobi Compute Server to be licensed.
 - Explicit lazy constraint: Users can use the "dot" option `.lazy` to mark constraints as lazy. Possible values are 0, 1, 2, and 3. See option `.lazy` for details.
 - Option `ConcurrentMIPJobs` has been renamed to `ConcurrentJobs`. The distributed concurrent optimizer now also handles LP models.
 - Option `ScaleFlag` allows now value 2 which enables aggressive scaling.
 - New parameters:
 - `DistributedMIPJobs` controls the number of workers of the distributed MIP algorithm
 - `.lazy` marks constraints as lazy constraints
 - `LazyConstraints` controls the use of lazy constraints
-

3.23.1.3.11 Knitro

- New libraries 9.1.0.
 - Overall speed and robustness improvements on NLP and MINLP models.
 - New algorithm choice introduced: active-set SQP.
 - Optional barrier solution refinement procedure: option `bar_refinement` = NO/yes.
 - Deterministic parallel multi-start: option `ms_deterministic` = no/YES.
- Dropped Knitro for Solaris on Intel CPUs (as announced).

3.23.1.3.12 LocalSolver

- Added the hybrid mathematical programming solver `LocalSolver` 5.0 (Beta) from Innovation 24 to the GAMS solvers portfolio.
- LocalSolver can be applied to large-scale, mixed-variable, non-convex optimization problems (GAMS model types MIP, (MI)QCP, (MI/D)NLP). It combines local search techniques, constraint propagation and inference techniques, linear and mixed-integer programming techniques, and nonlinear programming techniques in a unique hybrid neighborhood search approach to find high-quality feasible solutions. Hence, LocalSolver offers an alternative for problems where conventional branch-and-bound and/or outer-approximation based solution methods do not provide satisfactory results.
- It is suggested to set the GAMS options for iteration or timelimit (`iterlim`, `reslim`) appropriately to limit the effort that LocalSolver spends on the problem.

3.23.1.3.13 Lindo/LindoGlobal

- We will drop Lindo/LindoGlobal libraries for Intel Solaris with the next major release (24.5).
- New libraries 9.0.142 for Linux, Mac OS X, and Windows:
 - Support for semi-continuous variables.
 - Simplex LP algorithm implementation has been improved for speed and robustness. The performance improvements compared to previous version are 90% for primal simplex and 45% for the dual simplex.
 - Knapsack related cuts improvements. Significantly faster solve times on models with certain knapsack-like constraints.
 - Improved default node selection rules improves performance on most MIPs.
 - New branching variable rule options: maximum coefficients and neighborhood branching. Can reduce number of branches on certain MIPs.
 - Perspective reformulation capability gives improved performance on quadratic portfolio models with semi-continuous variables, e.g. min-buy quantities.
 - Improved default settings for NLPs gives 5% average speed improvement.
 - New preprocessing for LP/MIP significantly reduces coefficient density of certain dense matrices.

3.23.1.3.14 Mosek

- New libraries 7.1.0.12.
 - Improved performance of the mixed-integer conic optimizer.
-

3.23.1.3.15 MSNLP/OQNLP

- These solvers now use Conopt as their default solver if Conopt is licensed. Otherwise they will use lsgrg as before.

3.23.1.3.16 OS

- We plan to drop the OS solver with GAMS 24.5. The capability of convert to write OSiL files will be kept.

3.23.1.3.17 SCIP

- New libraries 3.1 #020d055.

3.23.1.3.18 SoPlex

- New libraries 2.0 #d67b17b.

3.23.1.3.19 Sulum

- New libraries 4.0.665.
 - Improvements in presolve, leading to more reductions.
 - General improvements in obtaining a feasible solution faster, especially with focus on the root node to obtain a good bound. Rewrite and improvements of feasibility pump, objective diving.
 - The simplex algorithm is now exchanging more information with the branch and cut method. Improvement of SINS heuristic (finding a better basis after the node solve).
 - Added a MIP root restart feature based on reductions.
 - Cutting planes generation was both improved and extended.
 - Changed default for option `mipmaxrestarts` from 5 to 1.

3.23.1.3.20 XPRESS

- New libraries for XPRESS v7.8: Optimizer 27.01.02.
 - Automatic solution refinement for LP and MIP models.
 - Improved deterministic concurrent LP.

3.23.1.4 Tools

3.23.1.4.1 GAMSIDE

- Added option to suppress trailing zeroes in GDX viewer.
 - Improved ability to open files from the Windows Shell.
 - Cutoff for number of lines to be syntax colored or not.
 - When saving a file, the Undo buffer is no longer cleared.
-

3.23.1.4.2 GDXDUMP

- Text quoted with a single quote did not have a separator when writing `SymbolAsSet`.
- Added option `SymbolAsSetDI`.
- Avoid string overflow when quoting text.
- Added more types for sets and equations.

3.23.1.4.3 GDXXRW

- Added option `values=All` which is the new default when `CDim=0` or `RDim=0`.

3.23.1.4.4 GDXVIEWER

- Added ACCDB format as an output option for MSAccess.

3.23.1.4.5 GDX2SQLite, Scenred, Scenred2

- These tools are now also available for AIX.
- Moved documentation of Scenred and Scenred2 from docs/solvers to docs/tools.

3.23.1.4.6 IDECMDS

- Allow a pattern to be specified to close files.

3.23.1.4.7 MPS2GMS

- The `mips2gms` tool now produces proper generic GAMS source for models with quadratic terms.
- Bug fix for MPS files written by Cplex that contain SOS constraints.

3.23.1.4.8 MPSGE

- Moved manual to "docs/tools".

3.23.1.5 Expert Level APIs

- There are new API files for the "Indexed GDX" (IDX) library in `<GAMS Dir>\apifiles\<Language>\api:`
 - The indexed GDX library can be used to read and write indexed GDX files.
 - Each symbol in such a GDX file must be a parameter.
 - Each parameter must have a domain consisting of a UELs which forms an integer sequence starting at 1.
 - This way the data is provided in a format convenient to store in arrays in the target language.
 - In GAMS such a file can be read using `$LoadIDX` during compilation.
 - In GAMS such a file can be written using `execute_unloadIDX` during execution.
 - The new example `<GAMS Dir>\apifiles\CSharp\xp_CalcInverseIDX` makes use of this API, this example is also used in the APILib model `CSCalcInverse`.
-

3.23.1.5.1 Python

- Fixed a bug regarding lists of strings in Python 3 (e.g. `gdxDataWriteStr()`).

3.23.1.6 Object Oriented APIs

- We changed the handling of GAMS Aliases in the object oriented APIs:
 - If we ask for the number of GAMSsymbols in a GAMSDatabase, the Aliases will be excluded.
 - If we iterate over all GAMSsymbols in a GAMSDatabase, Aliases will be skipped.
 - If we ask explicitly for an Alias in a GAMSDatabase (`GAMSDatabase.GetSet("a")` with `a` being an Alias) we will get a reference to the GAMSset referenced by the Alias, not the Alias itself.
 - Note: Aliases can appear in a GAMSDatabase only, if it was initialized by a GDX file containing an Alias.
 - The new examples `Alias` demonstrate this new behavior for the different OO API languages.

3.23.1.6.1 Python

- Fixed a bug in `GamsDatabase.merge_record` that prevented the function from creating a record if none was found.

3.23.1.7 Model Libraries

3.23.1.7.1 GAMS API Library This is a new collection of GAMS models. It can be accessed in the GAMS IDE at `Model Libraries -> GAMS API Library` or through the command line tool `apilib`. The models in this collection can be used as scripts to compile and execute the example applications using the GAMS object oriented APIs as well as the expert level APIs, which can be found in `<GAMS Dir>/apifiles`.

- `apiutil.gms` : Generates the API Model Library files (01)
 - `testapi.gms` : API Quality Assurance Test (02)
 - `Cex1.gms` : Test expert level C API to read and write GDX (03)
 - `CSEX1.gms` : Test expert level C# API to read and write GDX (04)
 - `CPPex1.gms` : Test expert level C API to read and write GDX in C++ (05)
 - `DCex1.gms` : Test expert level Delphi (function) API to read and write GDX (06)
 - `DOex1.gms` : Test expert level Delphi (object) API to read and write GDX (07)
 - `DPex1.gms` : Test expert level Delphi (pure) API to read and write GDX (08)
 - `Fex1.gms` : Test expert level Fortran API to read and write GDX (09)
 - `Jex1.gms` : Test expert level Java API to read and write GDX (10)
 - `Pex1.gms` : Test expert level Python API to read and write GDX (11)
 - `VBex1.gms` : Test expert level VB.Net API to read and write GDX (12)
 - `Cex2.gms` : Test expert level C API to read and write GDX, set options and execute GAMS (13)
-

- CSEX2.gms : Test expert level C# API to read and write GDX, set options and execute GAMS (14)
 - CPPex2.gms : Test expert level C API to read and write GDX, set options, and execute GAMS in C++ (15)
 - DOex2.gms : Test expert level Delphi (object) API to read and write GDX, set options and execute GAMS (16)
 - Fex2.gms : Test expert level Fortran API to read and write GDX, set options and execute GAMS (17)
 - Jex2.gms : Test expert level Java API to read and write GDX, set options and execute GAMS (18)
 - Pex2.gms : Test expert level Python API to read and write GDX, set options and execute GAMS (19)
 - VBex2.gms : Test expert level VB.Net API to read and write GDX, set options and execute GAMS (20)
 - CStrseq.gms : Test object oriented C# API running a sequence of examples based on a transport model (21)
 - CPPtrseq.gms : Test object oriented C++ API running a sequence of examples based on a transport model (22)
 - Jtrseq.gms : Test object oriented Java API running a sequence of examples based on a transport model (23)
 - Ptrseq.gms : Test object oriented Python API running a sequence of examples based on a transport model (24)
 - VBtrseq.gms : Test object oriented VB.Net API running a sequence of examples based on a transport model (25)
 - CSBenders.gms : Test object oriented C# API using a (multi-threaded) Benders Decomposition Algorithm (26)
 - JBenders.gms : Test object oriented Java API using a (multi-threaded) Benders Decomposition Algorithm (27)
 - PBenders.gms : Test object oriented Python API using a (multi-threaded) Benders Decomposition Algorithm (28)
 - CSCutstock.gms : Test object oriented C# API using a cutting stock example (29)
 - JCutstock.gms : Test object oriented Java API using a cutting stock example (30)
 - PCutstock.gms : Test object oriented Python API using a cutting stock example (31)
 - CSDomainChecking.gms : Test object oriented C# API for domain checks (32)
 - JDomainCheck.gms : Test object oriented Java API for domain checks (33)
 - PDomainChecking.gms : Test object oriented Python API for domain checks (34)
 - JInterrupt.gms : Test object oriented Java API for interrupting running GAMS jobs (35)
 - CSTsp.gms : Test object oriented C# API using a Traveling Salesman Problem (36)
 - JTsp.gms : Test object oriented Java API using a Traveling Salesman Problem (37)
 - PTsp.gms : Test object oriented Python API using a Traveling Salesman Problem (38)
 - CSWarehouse.gms : Test object oriented C# API using a warehouse location problem (39)
-

- **JWarehouse.gms** : Test object oriented Java API using a warehouse location problem (40)
- **PWarehouse.gms** : Test object oriented Python API using a warehouse location problem (41)
- **CSAlias.gms** : Test handling of Aliases in object oriented C# API (42)
- **JAlias.gms** : Test handling of Aliases in object oriented Java API (43)
- **PAlias.gms** : Test handling of Aliases in object oriented Python API (44)
- **apihtm.gms** : Generates HTM apilib library files (45)
- **CSCalcInverse.gms** : Test expert level C# API to read and write indexed GDX (46)

3.23.1.7.2 GAMS Data Library

- Note: Opening an Excel file (.xls) in protected view may work improperly due to [Microsoft issue 2745652](#). Fix: Enable editing of the Excel file and reopen the file.
- **gdxmrw_qp1_starter.gms** : Portfolio Analysis with Matlab and GAMS (91)
- **gdxmrw_qp2_starter.gms** : Portfolio Analysis with Matlab and GAMS (92)
- **gdxmrw_tr1.gms** : Transport LP with non-indexed GDX data interface (93)
- **gdxmrw_tr2.gms** : Transport LP with indexed GDX data interface (94)
- **gdxmrw_qp3.gms** : QP solver M-file using GAMS and GDXMRW (95)
- **gdxrw_autoopen.gms** : Tests that gdxrw calls the auto_open macro facility (96)
- **gdxmrw_qp4.gms** : Calling GAMS model from Matlab (97)
- **gdxmrw_intro01_init.gms** : Introduction to data transfer between Matlab and GAMS (98)
- **gdxmrw_intro02_init.gms** : Introduction to calling GAMS from Matlab (99)
- **gdxmrw_irgdx01_init.gms** : Reading data from a indexed GDX file with IRGDX (100)
- **gdxmrw_iwgdx01_init.gms** : Writing data into a indexed GDX file with IWGDX (101)
- **gdxmrw_rgdx01_init.gms** : Reading data from a GDX file into a structure with RGDX (102)
- **gdxmrw_wgdx01_init.gms** : Writing structured data into a GDX file with WGDX (103)
- **gdxmrw_ext01_init.gms** : Extended use of GDXMRW (104)

3.23.1.7.3 GAMS Model Library

- Modified models
 - **tsp1** and **tsp4** now use Singleton Sets
 - **flowchan** had incorrect boundary conditions
 - **licememo**: give a full solver/model type matrix independent of the actual license
 - **partssupply.gms** : **Parts Supply Problem** (404) (contains ps2.f.s .. ps5.s.mn, which are still available, as submodels)
 - **qfilter.gms** : **Audio filter design using quad-precision MINOS** (405)
 - **derivst.gms** : **How to test derivatives of functions** (406)
 - **carseq.gms** : **Car Sequencing** (407)
 - **pmedian.gms** : **P-Median problem** (408)
 - **sgolfer.gms** : **Social Golfer Problem** (409)
-

3.23.1.7.4 GAMS Test Library

- Modified Models
 - **trilib01**, **trilib02**, and **trilib03**: Compare numeric gradient and Hessian values in the models. Function **Sine** in the library does not provide derivatives anymore. Lower the tolerances for acceptance due to numerical derivatives of function **Sine**
- **indic04.gms** : Test of indicator constraints with explicit labels (663)
- **parlib01.gms** : Test extrinsic functions in **parclib** (667)
- **convert10.gms** : **CONVERT** test suite - check interval evaluator in **Convert** (668)
- **convert11.gms** : **CONVERT** test suite - check interval evaluator in **Convert** (669)
- **convert12.gms** : **CONVERT** test suite - check interval evaluator in **Convert** (670)
- **lazy01.gms** : Test lazy constraints (671)
- **mps2gms1.gms** : Test **mps2gms** (672)
- **execmode01.gms** : Test **execmode** behavior (673)

3.23.2 24.4.2 Minor release (March 15, 2015)

3.23.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Sergey Kuznetsov, Ricardo M. De Lima, and Corey Noone.

3.23.2.2 GAMS System

3.23.2.2.1 GAMS

- Fixed potential problem when running on Windows in a `workDir` containing a `%`.
- Fixed problem with EMP solves with `solvelink=Solvelink.AsyncGrid%`.
- Fixed problem with GUSS/Grid when using `execute_loadhandle` instead of `handlecollect`.

3.23.2.3 Solvers

3.23.2.3.1 ANTIGONE

- New libraries.

3.23.2.3.2 CONOPT

- Introduced new boolean option **PreTri2Log** that send message from Conopt's pre-triangular analyzer that go to the listing file also to the GAMS log. The option requires the generation of the model dictionary, so `mymodel.DictFile=1`; has to be added before the **Solve** statement.
-

3.23.2.3.3 CONVERT

- Convert and ConvertD: Fix for writing scalar MCP models that contained fixed variables removed by `holdfixed=1`.
- ConvertD: Add support for external equations in scalar GAMS models.
- ConvertD: Propagate EPS to scalar GAMS models.

3.23.2.3.4 Couenne

- New libraries.

3.23.2.3.5 Examiner2

- Support added for custom trace files.

3.23.2.3.6 GUROBI

- New libraries 6.0.2.

3.23.2.3.7 Lindo/LindoGlobal

- New libraries 9.0.157 for Linux, Mac OS X, and Windows.

3.23.2.3.8 LocalSolver

- New libraries 5.0 (20150119).

3.23.2.3.9 Mosek

- New libraries 7.1.0.24.

3.23.2.3.10 SCIP

- New libraries 3.1 #67d713c.
- Fixed overwriting of solvetrace file by final NLP resolving.

3.23.2.3.11 SoPlex

- New libraries 2.0 #8381aa4.
-

3.23.2.4 Tools

3.23.2.4.1 GDXMRW

- `gdxInfo`: fix output of domains in symbol declaration
- `gdxInfo`: handle aliases properly

3.23.2.5 Object Oriented APIs

- Fixed overwriting of the default value for the `integer1` option when running with `GAMSModelInstance`, which lead to unexpected solver behavior.
- Fixed potential problem with `GAMSModelInstance` used with BARON.

3.23.2.5.1 .NET

- New property `GAMSSymbol.DomainsAsStrings`: Domains of Symbol, each element is a string, if the domain is an alias in GAMS, this call will return the name of the Alias, not the name of the aliased Set.

3.23.2.5.2 Java

- Changed naming scheme of GDX output scratch file to sequence number.

3.23.2.5.3 Python

- Fixed a bug in the constructor of all subclasses of `_GamsSymbol` that occurred when the explanatory text was omitted.
- New property `_GamsSymbol.domains_as_strings`: Domains of Symbol, each element is a string. If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.

3.23.2.6 Expert Level APIs

3.23.2.6.1 GMO

- Fixes to `gmoGetRowJacInfoOne` and `gmoGetColJacInfoOne`: In case of an empty row/column, now return -1 in `colidx/rowidx` if index base is 0.

3.23.2.7 Model Libraries

3.23.2.7.1 GAMS Model Library

- `dyncge.gms` : A Recursive-Dynamic Standard CGE Model (410)
-

3.23.3 24.4.3 Maintenance release (April 02, 2015)

3.23.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Guillaume Erbs and Emiliano Traversi.

3.23.3.2 Solvers

3.23.3.2.1 Examiner2

- Fixed incapability to continue on a trace file that already has trace records in it.

3.23.3.2.2 LocalSolver

- Corrected computation of values for free variables that appeared (linearly) in one equation only.

3.23.3.3 Tools

3.23.3.3.1 GDXXRW

- In 24.4.2 we quietly introduced a new way to determine the content of a sheet. This resulted in a bug for empty sheets and sheets that have been saved with an active filter. This has been fixed.

3.23.4 24.4.4 Maintenance release (May 12, 2015)

3.23.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Thomas Counsell, Michael Ferris, Jean Mercenier, and Loïc Ventre.

3.23.4.2 Solvers

3.23.4.2.1 Gurobi

- New libraries 6.0.4.
- The new libraries do not work on Windows XP anymore. As the library for COIN-OR solvers, SCIP, and SoPlex link to the Gurobi library, these solvers also do not work on Windows XP anymore.

3.23.4.2.2 Ipopt

- New libraries for Linux and Mac OS X.
 - Fixed an issue in the MA97 interface that lead to convergence problems.

3.23.4.2.3 Minos

- Consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 500 superbasics, limit the Hessian dimension to 500 even though the superbasic limit is larger.

3.23.4.2.4 Mosek

- New libraries 7.1.0.30.

3.23.4.2.5 Xpress

- New libraries Optimizer 27.01.08 (was 27.01.02 before).

3.23.4.3 Tools

3.23.4.3.1 GDXDUMP

- Fixed a problem when writing a scalar or scalar variable/equation in format CSV.

3.23.4.4 Object Oriented APIs

- Fixed a potential problem with `GAMSModelinstance` and certain OS culture settings.

3.23.4.5 Model Libraries

3.23.4.5.1 GAMS EMP Library

- **transecs**: Fixed formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.

3.23.5 24.4.5 Maintenance release (May 26, 2015)

3.23.5.1 Solvers

3.23.5.1.1 COIN-OR solvers, SCIP, SoPlex

- On Windows 32bit, OsiGurobi was split off into a separate library, so that other COIN-OR solvers (e.g., Bonmin, Cbc, Couenne, Ipopt) and SCIP and SoPlex do not require the Gurobi 6.0.4 library anymore. Thus, for this release, only Gurobi and OsiGurobi do not run on Windows XP anymore (see [24.4.4 notes on Gurobi](#)).
-

3.23.6 24.4.6 Minor release (June 26, 2015)

3.23.6.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Rich Roberts, and Jens Schulz.

3.23.6.2 Solvers

3.23.6.2.1 CONOPT

- New libraries 3.16F.
- New option LMUSDF for handling definitional equations.
- New option RVFILL for memory allocation when memory is tight.
- Changed a sorting procedure in the preprocessor. Models with some very dense rows and many pre-triangular variables can experience a significant speedup for the preprocessor.

3.23.6.2.2 CPLEX

- New libraries 12.6.2.0.
- Option changes:
 - The popular option value -1 for `BarCrossAlg` to turn off the crossover after a run with barrier has been deprecated. The new way to turn off crossover is to set the new option `SolutionType` to 2.
 - The option `SolutionTarget` has been renamed to `OptimalityTarget`.
 - The option `CutsFactor` has a new default (-1).
- New options:
 - `BQPCuts`: Boolean Quadric Polytope cuts for solving nonconvex QP or MIQP to global optimality.
 - `CPUMask`: Switch and mask to bind threads to processors. Binding threads to processors/cores helps to reduce variability in running time when using multiple threads.
 - `SolutionType`: Type of solution (basic or non basic) for an LP or QP. Set this option to 2 to prevent crossover after barrier.

3.23.6.2.3 MOSEK

- New libraries 7.1.0.31.

3.23.6.3 Tools

3.23.6.3.1 GAMSIDE

- Added `.ref` for reference file to the files open dialog.
 - Left arrow in the first character position now moves to the end of the previous line.
-

3.23.6.3.2 GDXXRW

- Restore the old behavior when reading a set with `Values=Strings`; all elements will be included, not only the ones with a string.
 - Option `Values=String` and `All` are now deprecated and results in a warning; replaced with `Dense`.
 - New options `Values=Dense` or `Sparse`.

3.23.6.3.3 XLSTalk

- Allow for up to 9 parameters for macro call.

3.24 24.3 Distribution

3.24.1 24.3.1 Major release (July 31, 2014)

3.24.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Bond, Sebastian Bothor, Jared Erickson, Michael Ferris, Josef Kallrath, Bastian Niebel, Matt Preston, and Tom Rutherford.

3.24.1.2 Platforms

- The Linux 32bit and Solaris 32bit distributions have been dropped (as announced).
- Support for Windows XP may be dropped with some future GAMS version. As several of our solver vendors have already dropped support for Windows XP, some components of a GAMS system may cease to work under Windows XP in the future. If you notice that a 64bit GAMS system is not working on your Windows XP 64bit machine, please let us know.

3.24.1.3 GAMS System

3.24.1.3.1 GAMS

- Introduced new keyword `Singleton Set`: A `Singleton Set` in GAMS is a special `Set` that has at most one element (zero elements are allowed as well). `Singleton Sets` can be especially useful in assignment statements since they don't need to be controlled by a controlling index nor an indexed operator, e.g.:

```
Set          s          / s1*s3 /;
Singleton Set single(s) / s2   /;
Parameter p(s);
Scalar      x;

p(s) = ord(s);
x = p(single);
```

NOTE: Assigning membership to `Singleton Sets` is different than to usual sets. Since `Singleton Sets` can never have more than one element, any assignment to a `Singleton Set` first clears or empties the set, so no explicit clear is necessary. This is illustrated in the following example:

```
Set          i      Static Set          / a, b, c /
            ii(i) Dynamic Set          /   b   /;
Singleton Set si(i) Dynamic Singleton Set /   b   /;

ii('c') = yes;
si('c') = yes;

Display ii, si;
```

Here is the output from the `display` statement in the listing file:

```
----      8 SET ii  Dynamic Set
b,      c

----      8 SET si  Dynamic Singleton Set
c
```

More information can be found in the GAMS Users Guide.

- The behavior of assignments to `Singleton Sets` can be influenced by the new option `strictSingleton` [0/1]: This option affects the behavior of a membership assignment to a `Singleton Set`. With `strictSingleton = 0` GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With `strictSingleton = 1` (default), such an assignment raises an error. This option be set via an option statement and via a command line option.
- Similarly, data statements for `Singleton Sets` can be influenced by the new dollar control options `$onStrictSingleton/$offStrictSingleton`: With `$offStrictSingleton` GAMS does not complain about a data statement for a `Singleton Set` that has more than one element but takes the first one. With `$onStrictSingleton` (default), such an assignment raises an error.
- Introduced so-called obfuscated save files, which are save files where symbol and UEL names have been obfuscated. The new options `saveobfuscate` (`so`) and `xsaveobfuscate` (`xso`) can be used to generate uncompressed and compressed, respectively, obfuscated save files. Additionally, a new option `restartNamed` (`rn`) has been added which can be used to bring back the original names when restarting from an obfuscated save file. The intended use is the following.
 - Compile (only) a GAMS model into a named and an obfuscated save file:

```
$call gams trnsport a=c s=0named saveobfuscate=0anon
```
 - Move the obfuscated save file to a non-secure machine and execute it there:

```
$echo * Empty > empty.gms
$call gams empty r=0anon s=1anon
```
 - Bring the new (still obfuscated) save file with the results back to the safe machine and do a continued compilation with reporting and export. The continued compilation restarts from the obfuscated save file with all the results, etc., but gets a second save file with proper names through option `restartNamed`:

```
$echo execute_unload 'supply', supply.m; > unload.gms
$call gams unload r=1anon restartNamed=0named
```

In this execution, everything is taken from the obfuscated restart file, except for the symbol and UEL names and the listing file title and subtitle, which are taken from the file specified via `restartNamed`.

- Allow to load the universe of labels from a GDX file into a set at run-time:

```
execute_load 'someFile', someSet=*
```

Note, that only labels known to the GAMS program will be loaded.

- Fixed a bug that caused wrong results when evaluating `prod` (or `smin/smax`) over an empty set inside `sum` like in the following example:

```
sets r          / 1      /
     s          / 1, 2  /
     rs(r,s)   / 1.1    /
     subrs(r,s) / 1.2   /;
scalar z1;
z1 = sum(rs, prod(subrs(rs), 2));
display z1;
```

- Fixed a bug in calling error logging routine for extrinsic functions from within solvers.

3.24.1.3.2 Function libraries

- The extrinsic function library `cppcplib` has been expanded to include functions for the PDF and CDF of the trivariate normal distribution. Additionally, documentation for `cppcplib` has been added to Appendix J of the GAMS User's Guide and the relevant testlib models `cpplib00` thru `cpplib05` have been added or updated.

3.24.1.4 Solvers

3.24.1.4.1 ANTIGONE, Bonmin, Cbc, Couenne, SCIP, Sulum

- Solvetrace files now include the GAMS input name (usually GAMS model name with `.gms` extension stripped) in the header line.

3.24.1.4.2 BARON

- New libraries 14.0.2
 - Significant advances in the handling of integer programs. In addition to several classes of integer cutting planes, calls to MIP solvers and hybrid LP/MIP/NLP relaxations for MINLPs have been added.
 - Complete rewrite of the interfaces to LP solvers.
 - Improvements in probing routines.
 - More robust checks for the validity of the solution of LP/NLP subsolvers.
 - Introduced interfaces to COIN-OR/OSI and CBC 2.8.9.
 - Increased numerical robustness for numerically challenging problems.
 - New range reduction techniques.
 - Systematic treatment of infeasible problems. With the `CompIIS` option, which by default is 0, the computation of an Irreducible Inconsistent Set (IIS) can be requested. Five different algorithms are available, with corresponding values of `CompIIS` equal to 1, ..., 5. Algorithm 1 is a fast heuristic, while algorithms 2 through 5 are more time consuming exact algorithms. If an IIS is found, it is reported in the GAMS listing file. BARON does not consider bounds on binary variables to be part of the IIS. For general integers, the option `IISint` can be used to signal that general integers should be considered as potential members of the IIS, i.e., integrality constraints are questioned.
- Fixed handling of BARON termination status when activating `DeltaTerm` option.

3.24.1.4.3 BONMIN

- Dropped MIP capability (use CBC instead).

3.24.1.4.4 CONOPT

- New libraries 3.16B.
 - The new option `Lsusdf` was added. If turned on (the default) CONOPT's preprocessor will look for definitional constraints which are constraints of the form $\mathbf{x} = \mathbf{f}(\mathbf{y})$ where the bounds on \mathbf{x} are wider than the range of the function \mathbf{f} , given the bounds on \mathbf{y} . CONOPT will search for and select a maximal set of independent definitional constraints. The dependent variable in a definitional constraints will be selected for the initial basis and CONOPT will try to use the definition to initialize \mathbf{x} . There are two other options associated with this procedure: If `Lsuqdf` is enabled (default), then only unique definitional constraints are selected. If it is disabled, then option `Lfusdf` specifies a limit (default 2) on the number of candidates a definitional constraint can have.
 - The option `Lsflsh` – flush the buffer, has now been implemented and is automatically turned on if there is a systems error.
 - The lower bound on option `Rtipvr` changed from 1.e-3 to 1.e-10.

3.24.1.4.5 Convert

- The AMPL writer supports special ordered sets, semicontinuous variables, and semiinteger variables now.
- Row names in `.lp` and `.mps` files now start with 'e' instead of 'c', so they match the names written by the `dict` option.

3.24.1.4.6 CPLEX

- New libraries 12.6.0.1.

3.24.1.4.7 CPLEX, SCIP, XPRESS

- Fixed handling of indicator constraints when specified with explicit labels.

3.24.1.4.8 DE

- New option `VarBigM` to control the Big M for a Value at Risk reformulation.
-

3.24.1.4.9 EMPSP

- New keywords `VaRUp` (=VaR) and `VaRLo`: These keywords can be used to optimize the Value at Risk for a certain confidence level. The syntax is similar to the one from `cVaRUp` (=cVaR) and `cVaRLo`:

```
VaR [rv var] scalar
```

More information can be found [here](#).

- Changed the order of the parameters for the triangular distribution from

```
randvar <name> triangular <low> <high> <mid>
```

to

```
randvar <name> triangular <low> <mid> <high>
```

3.24.1.4.10 Examiner2

- Fixed a bug in processing special ordered sets.

3.24.1.4.11 GUSS/Scenario Solver

- GUSS/Scenario solver can now be combined with the GAMS Grid Facility (see example `GUSSGRID` in the GAMS Model Library).
- New option `RestartType` to determines restart point for the scenarios:
 - 0: Restart from last solution (default)
 - 1: Restart from solution of base case
 - 2: Restart from input point
- New option `SolveEmpty` (default 0) to limit the number of empty scenarios (no scenario data) that are being solved. When the limit is reached, further empty scenarios will be skipped. Skipped scenarios will be reported to the log and listing file.

3.24.1.4.12 Ipopt

- New libraries.

3.24.1.4.13 Knitro

- As Ziena Optimization has dropped support for Knitro on Solaris (x86) a while ago, we plan to drop GAMS/Knitro on Solaris with the next release.

3.24.1.4.14 Lindo/LindoGlobal

- New libraries 8.0.550.
 - LindoGlobal is no longer available for Sparc Solaris (as announced).
-

3.24.1.4.15 Mosek

- New libraries 7.0.0.121 (Linux, Mac OS X) and 7.0.0.123 (Windows).

3.24.1.4.16 OQNLP

- OQNLP is no longer available for Linux (as announced).

3.24.1.4.17 OS

- GAMS to OSiL conversion now creates more compact instances, especially for quadratic equations and long sums or products in general nonlinear expressions.

3.24.1.4.18 SCIP

- New libraries [3.1 #695c979](#).
 - Added new primal heuristics "random rounding", "proximity", and "dual value", new branching rule "cloud branching", and new node selectors "breadthfirst" and "uct".
 - Added support for strong branching with domain propagation in full strong and reliability pseudo cost branching.
 - Improved numerical stability (now taking the rank of cuts into account; more checks on LP solution; disabled scaling in feasibility check of nonlinear constraints).
 - Many improvements in presolving.
 - Strong branching LP solutions are now checked for feasibility.
 - Changed or removed parameters:
 - * branching/relpscost/maxlookahead: default changed from 9 to 8.
 - * branching/relpscost/maxreliable: default changed from 8 to 5.
 - * constraints/bivariate/scaling: default changed from TRUE to 'o' (type changed to character).
 - * constraints/quadratic/scaling: default changed from TRUE to 'o' (type changed to character).
 - * constraints/soc/scaling: default changed from TRUE to 'o' (type changed to character).
 - * constraints/varbound/maxlpcoef: default changed from 1E6 to 1E9.
 - * heuristics/crossover/minnodes: default changed from 500 to 50.
 - * heuristics/dins/minnodes: default changed from 500 to 50.
 - * heuristics/feaspump/objfactor: default changed from 1 to 0.1.
 - * heuristics/rens/minnodes: default changed from 500 to 50.
 - * heuristics/rins/freq: default changed from -1 to 25.
 - * heuristics/rins/freqofs: default changed from 5 to 0.
 - * heuristics/rins/minfixingrate: default changed from 0 to 0.3.
 - * heuristics/rins/minnodes: default changed from 500 to 50.
 - * heuristics/shiftandpropagate/sortkey: default changed from 'u' to 'v'.
 - * lp/checkfeas: replaced by new parameters lp/checkdualfeas and lp/checkprimfeas.
 - * numerics/dualfeastol: default changed from 1E-6 to 1E-7.
 - * presolving/dualfix/*: replaced by propagating/dualfix/*
 - * propagating/pseudoobj/presoldelay: default changed from TRUE to FALSE.
 - * propagating/pseudoobj/timingmask: default changed from 5 to 7.
 - * propagating/redcost/timingmask: default changed from 2 to 6.
 - * separating/cgmip/objweighsize: renamed to separating/cgmip/objweightsize and default changed from FALSE to TRUE.
 - * separating/minefficacyroot: default changed from 0.01 to 0.001.
 - * separating/closecuts/relintnormtype: removed

3.24.1.4.19 SoPlex

- New libraries 2.0.0.

3.24.1.4.20 XPRESS

- New libraries 26.01.08.

3.24.1.5 Tools

3.24.1.5.1 GDX2SQLITE

- GDX2SQLITE is a new tool to dump the complete contents of a GAMS GDX file into a SQLite database file.

3.24.1.5.2 GDXDUMP

- New option SymbolsAsSet to write the symbol table for a set as data.

3.24.1.5.3 GDXMRW

- New utilities `irgdx` and `iwgdx` for exchanging indexed GDX data with Matlab.

3.24.1.5.4 GDXRENAME

- New utility to rename the same unique elements in a GDX file using a mapping given by a second GDX file.

3.24.1.5.5 GDXXRW

- New option to allow the use of R1C1 notation to specify a cell or a range.
- Reading a set using the option `Values=string` now skips empty cells.

3.24.1.6 Expert Level APIs

3.24.1.6.1 GMO

- Removed previously deprecated function `gmoDirtyExtractDefVar`.
 - Added a number of functions to access information from an EMP info file, to compute the optimality gap, to access extrinsic function libraries, and to get the name of the GAMS input file.
-

3.24.1.7 Object Oriented APIs

- New example `transport14`.
- New method `GAMSSymbolRecord.Key(int index)` (Java: `GAMSSymbolRecord.getKey`, Python: `_GamsSymbolRecord.key(int index)`) to retrieve the key of `GAMSSymbolRecord` (Python: `_GamsSymbolRecord`) for a given positional index.
- `GAMSSymbol.CopySymbol` now works for the universe of a `GAMSDatabase` (`GAMSDatabase.GetSet("*")`). When copying into the Universe, a merge will be performed.
- Real domains are now registered when exporting a `GAMSDatabase` to GDX (so far, only relaxed domains were registered).
- `GAMSJob.Run` (Python: `GamsJob.run`) now creates `OutDB` (Python: `out_db`) also if it raises a `GAMSExceptionExecution`.
- `GamsModelInstance.Solve` (Java/Python: `GamsModelInstance.solve`) now also works for solvers which require a subsolver, e.g., `DICOPT`.

3.24.1.7.1 .NET

- Fixed default value for `systemDirectory` argument in `GAMSWorkspace` constructor when using `MONO`: If no value is given, first the `PATH` and then the `(DY)LD_LIBRARY_PATH` is checked for a valid GAMS system directory.

3.24.1.7.2 Java

- It is no longer necessary to specify `-Djava.library.path` when running a program. If `java.library.path` is specified, the shared libraries will be loaded from `java.library.path`. Otherwise, the shared libraries will be loaded from the class path that contains `GAMSJavaAPI.jar`.
 - It is no longer necessary to set up environment variables (`PATH`, `(DY)LD_LIBRARY_PATH`) before running a program to find the GAMS system directory, as it can now be specified during run time.
 - In the `GAMSWorkspace` default constructor, the default setting for finding the GAMS system directory from environment variables in the following order (depends on the target platform) are applied:
 - Windows: first from `PATH` environment variable. If not found, then from the Windows registry `gams.location`,
 - Mac OS X: first from `PATH` environment variable. If not found, then from `DYLD_LIBRARY_PATH`,
 - other Unix: from `PATH` environment variable. If not found, then from `LD_LIBRARY_PATH`.
 - In the non-default `GAMSWorkspace` constructor, the following rules are applied:
 - In case a user specifies a system directory, the API will verify the directory and will not search for GAMS system directory from an environment variable, even when the directory is invalid.
 - In case the specified system directory is `null` or a user does not specify a system directory, the API will apply the default setting from above.
 - A memory leak in `GAMSDatabaseIterator` has been closed.
 - Issues when using a non-standard locale (`LANG` environment variable) have been fixed.
 - All deprecated classes and methods since 24.1 have been removed.
-

3.24.1.7.3 Python

- New behavior on determining a system directory automatically when a workspace is created.
 - Linux: If no system directory is specified in the `GamsWorkspace` constructor, check `PATH` first. If no system directory was found, check `LD_LIBRARY_PATH`.
 - Mac OS X: If no system directory is specified in the `GamsWorkspace` constructor, check `PATH` first. If no system directory was found, check `DYLD_LIBRARY_PATH`.
 - Windows: If no system directory is specified in the `GamsWorkspace` constructor, check the Windows registry.

3.24.1.8 Model Libraries

3.24.1.8.1 GAMS Data Library

- `MakeQL`: Moved querylibrary generator into `trisource.zip`, which comes with Test Library models `trilib01`, `trilib02`, `trilib03`, and `trilib04`. Removed `MakeQL` model.
- `invert1.gms` : Matrix inversion via R (89)
- `invert2.gms` : Matrix inversion via Matlab (90)

3.24.1.8.2 GAMS Model Library

- `clad.gms` : Computation of Fairs extramarital affairs model estimates (397)
- `gussex1.gms` : Simple GUSS example (398)
- `gussrisk.gms` : Simple investment example with varying weight for risk using GUSS (399)
- `gussgrid.gms` : Simple GUSS Grid example (400)
- `circpack.gms` : Pack circles in the smallest possible rectangle (401)
- `tablelayout.gms` : Configuring text layout in table cells to minimize table height (402)
- `asyncjobs.gms` : Execute asynchronously several GAMS jobs and collect the fastest (403)

3.24.1.8.3 GAMS Test Library

- `trilib01`: Reworked `triclib.c` source code. Rewrote querylibrary generator.
 - `single01.gms` : Check handling of singleton sets (639)
 - `execerr1.gms` : Test for `execerr` option (640)
 - `single02.gms` : Check assignment to singleton sets (641)
 - `scensol4.gms` : Basic GUSS Test (642)
 - `gdxmrw06.gms` : run a battery of `GDXMRW` tests (643)
 - `single03.gms` : Check singleton sets in `put` statement (644)
-

- `unload11.gms` : Check that GAMS does not crash when writing to non-existing folder (645)
- `refact00.gms` : Check that GAMS produces expected workfile with option `sys14=1` (646)
- `refact01.gms` : Refactor suite test 1 (647)
- `scenempty.gms` : Empty scenario GUSS Test (648)
- `obfusc01.gms` : Test use if obfuscated workfile (649)
- `load11.gms` : Load UEL Table (650)
- `gusskip.gms` : Simple GUSS example with skipped scenario (651)
- `refact02.gms` : Refactor suite test 2 (653)
- `cpplib03.gms` : Test extrinsic functions in `cppcplib` (654)
- `cpplib04.gms` : Test extrinsic functions in `cppcplib` (655)
- `cpplib05.gms` : Test extrinsic functions in `cppcplib` (656)
- `cpplib00.gms` : Test build of CPP library (657)
- `syschk2.gms` : Test impact of `sys10` setting (658)
- `scensol5.gms` : Test handling of scenario dictionary sets with more than 50 entries (659)
- `call5.gms` : Check that `gams` works with `COMSPEC` unset (660)
- `idxoper1.gms` : Test indexed operations (661)
- `gdxsqlite1.gms` : Test basic functionality of `GDX2SQLITE` tool (662)

3.24.2 24.3.2 Minor release (August 29, 2014)

3.24.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Alvaro Lorca Galvez, Scott McDonald, Tom Rutherford, Nick Sahinidis, and Uwe Schneider.

3.24.2.2 GAMS System

3.24.2.2.1 GAMS

- Allow empty scalar data statements:

```
$onempty
scalar xyz / /;
```

3.24.2.2.2 Extrinsic Function libraries

- Pass on parameter file name via `LibInit` call.
-

3.24.2.3 Solvers

3.24.2.3.1 BARON

- New libraries 14.0.3.

3.24.2.3.2 CBC

- New libraries.

3.24.2.3.3 CONOPT

- New libraries 3.16C.
 - Added checks for internal intermediate results being NaN (Not A Number). If this happens, CONOPT will stop and return a message about it. The solver status will return 4 "Terminated by Solver" and model status 6 or 7, "Intermediate Infeasible" or "Intermediate Feasible."

3.24.2.3.4 CONVERT

- Fixed bug in interval evaluations for functions and gradients.
- The interval evaluations are now triggered by their own option (e.g. `intervalEval=yes`) instead of being part of every Jacobian or Hessian dump.

3.24.2.3.5 Cplex

- Some Cplex tuning parameters had no or the wrong effect. This has been fixed.
- The BCH usercutcall was not called in case of new constrains only for true cuts (see e.g. GAMS Model library model bchtsp). This has been fixed.

3.24.2.3.6 Examiner2

- Fixed error in processing options file.
- Fixed error in trace file generation.

3.24.2.3.7 Ipopt

- New libraries.

3.24.2.3.8 Mosek

- New libraries 7.0.0.126.
 - Fixed an issue with using the Mosek extended license for MIP solving on Mac OS X.
-

3.24.2.3.9 Osi links

- Fixed writing MPS files with row and column names.

3.24.2.3.10 SCIP

- New libraries 3.1 #322574a
 - Changed default of option `heuristics/proximity/minimprove` from 0.25 to 0.02.
 - Changed default of option `heuristics/proximity/usefinallp` from TRUE to FALSE.

3.24.2.3.11 XPRESS

- New libraries 26.01.14 for Linux and Windows.

3.24.2.4 Tools

3.24.2.4.1 GDXDUMP

- When generating `$GDXIN filename`, the filename now includes the full path of the GDX input file.

3.24.2.4.2 GDXXRW

- In the previous release, we changed the behavior that when reading with `Values=String`, the empty cells no longer created an entry. Because reading with this option was the default for the cases with `RDim=0` or `CDim=0`, we changed this default to `Values=NoData` in order not to break existing code.

3.24.2.4.3 Shellexecute

- Fixed error causing problems during parameter processing.

3.24.2.5 Expert Level APIs

- Delphi: Distinguish between 32 bit and 64 bit compiler.
-

3.24.2.6 Object Oriented APIs

- Make more GAMS options available through the GAMSOptions class:
 - GAMSOptions.AppendExpand: Expand file append option
 - GAMSOptions.AppendOut: Output file append option
 - GAMSOptions.DumpOpt: Writes preprocessed input to the file input.dmp
 - GAMSOptions.DumpParms: GAMS parameter logging
 - GAMSOptions.ErrMsg: Placing of compilation error messages
 - GAMSOptions.Expand: Expanded (include) input file name
 - GAMSOptions.FErr: Alternative error message file
 - GAMSOptions.JobTrace: Job trace string to be written to the trace file at the end of a Gams job
 - GAMSOptions.LimCol: Maximum number of columns listed in one variable block
 - GAMSOptions.LimRow: Maximum number of rows listed in one equation block
 - GAMSOptions.LogLine: Amount of line tracing to the log file
 - GAMSOptions.On115: Generate errors for unknown unique element in an equation
 - GAMSOptions.Output: Output file
 - GAMSOptions.PageContr: Output file page control option
 - GAMSOptions.PageSize: Output file page size (=0 no paging)
 - GAMSOptions.PageWidth: Output file page width
 - GAMSOptions.Reference: Symbol reference file
 - GAMSOptions.ScriptExit: Program or script to be executed at the end of a GAMS run
 - GAMSOptions.Suppress: Compiler listing option
 - GAMSOptions.Symbol: Symbol table file
 - GAMSOptions.TraceLevel: Solvestat threshold used in conjunction with a=GT

3.24.2.7 Model Libraries

3.24.2.7.1 GAMS Data Library

- Fixed some errors in some Matlab examples.

3.24.3 24.3.3 Minor release (September 19, 2014)

3.24.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Henrik Dahl.

3.24.3.2 Solvers

3.24.3.2.1 ANTIGONE, Bonmin, CBC, Couenne, Ipopt, SCIP

- Fixed issue loading MKL libraries on Linux machines with AVX2 instruction set.
-

3.24.3.3 Tools

3.24.3.3.1 ASK, GDXVIEWER, SQL2GMS, XLS2GMS

- Fixed problem with character set used for error messages.

3.24.3.3.2 GDXXRW

- Fixed error when reading special values from Excel.

3.24.3.3.3 MDB2GMS, SQL2GMS

- Fixed problem when using comma as decimal separator.

3.24.3.4 Object Oriented APIs

3.24.3.4.1 Java

- Fixed a location of listing file when creating a job from (full-path) file without giving a job name.
-

3.25 24.2 Distribution

3.25.1 24.2.1 Major release (December 09, 2013)

3.25.2 24.2.2 Maintenance release (March 04, 2014)

3.25.3 24.2.3 Maintenance release (May 22, 2014)

3.26 24.1 Distribution

3.26.1 24.1.1 Major release (May 30, 2013)

3.26.2 24.1.2 Maintenance release (June 16, 2013)

3.26.3 24.1.3 Maintenance release (July 26, 2013)

3.27 24.0 Distribution

3.27.1 24.0.1 Major release (December 24, 2012)

3.27.2 24.0.2 Maintenance release (February 14, 2013)

3.28 23.9 Distribution

3.28.1 23.9.1 Major release (July 04, 2012)

3.28.2 23.9.2 Maintenance release (August 29, 2012)

3.28.3 23.9.3 Maintenance release (September 26, 2012)

3.28.4 23.9.4 Maintenance release (October 20, 2012)

3.28.5 23.9.5 Maintenance release (November 09, 2012)

3.29 23.8 Distribution

3.29.1 23.8.1 Major release (March 17, 2012)

3.29.2 23.8.2 Maintenance release (April 05, 2012)

- Bugfix for models with =X= rows and MCP (i.e. MPSGE)
 - GloMIQO resets OptCR=0 properly to 1e-9 and accepts now Ctrl-C on Windows
 - Knitro handles MINLP failures better
 - XPRESS handles =E= quadratic constraints better now
 - Changed position of Library Form in GAMSIDE (avoid hang in corner to corner screen setup)
 - Model Trnsxc11 added to GAMS Data Library
 - Model ps5_s_mn added to GAMS Model Library
-

3.30 23.7 Distribution

3.30.1 23.7.1 Major release (July 14, 2011)

3.30.2 23.7.2 Maintenance release (July 22, 2011)

- Alphaecp: Alphaecp v2.04.02
- Conopt3: Fixed a system error 2003
- Dicopt: Fixed a bug for accidentally determined crossovers
- Inclib: `put_reorderit.gms` update from Bruce McCarl
- Cbc: Disabled preprocessing in case of semicont/semiint variables, it seems buggy
- Cplex: Does no longer require finite bounds on semicont variables
- Gamsinst: Fix problem with blanks in sysdir and IDE error when not having a license

3.30.3 23.7.3 Maintenance release (August 23, 2011)

- alphaecp: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
 - apifiles:
 - get rid of warnings in cc interface,
 - fix problem with compilation of fat binaries on Darwin in cc interface
 - fix error in `gdxSymbolGetDomain` in Python interface
 - fix errors with constant definitions in C# interface
 - add constant definitions and additional constructor (which gets a handle) in Java interfaces
 - conopt3: Version 3.15A maintenance release
 - cplex:
 - fix for interrupt (Ctrl-C) when running with `solveLink=5`
 - fix memory leak
 - dicopt:
 - fix reporting of `object` in case of a crossover
 - fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
 - gamscmex: fix bug related to the internal organization of non-linear code, affects two-argument functions in rare cases
 - gamside:
 - close chart files too when changing system directory
 - GAMS project file name independent of casing
 - gdxdump: suppress on/off empty when writing single symbol
 - gdxmrw: was missing on 64bit Linux
 - grid: fix potential problem with scaling
-

- kestrel: added Xpress support
- minos fix: for interrupt (Ctrl-C)
- sbb: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- snopt fix: for interrupt (Ctrl-C)
- xpress: update global search to use callbacks called during root node processing and improve scheme to stop XPRESS when gap is achieved or on user interrupt

3.31 23.6 Distribution

3.31.1 23.6.2 Major release (December 13, 2010)

3.31.2 23.6.3 Maintenance release (February 15, 2011)

- Cmx: Fix for variable level projection
- Bonmin: Several fixes for outer-approximation based algorithms
- Cplex: New version 12.2.0.2
- Gurobi: New version 4.0.1
- Knitro: Documentation update
- Scip: New version 2.0.1
- Xpress: Fix for crash on 64 bit Solaris
- McCarl Guide: Updates for 23.6
- Gdxxrw: Includes system error message when we cannot start Excel
- Gdxmrw: Minor bugfixes

3.31.3 23.6.4 Maintenance release (April 01, 2011)

- CMEX: Maximal nested includes were raised to 40
 - Mosek: New Version6 Rev 105
 - Lindoglobal: New Version 6.1.1.553
 - Conopt: New Version 3.14W
 - Xpress: Memory leak fix
 - Coin: Solver fixes
 - JAMS: Updates for disjunctions
 - GDXXRW: Fixes
 - GDXMRW: Updates
 - McCarl and GDXUtils: Documentation updates
 - Model Libraries: Updates
-

3.31.4 23.6.5 Maintenance release (April 08, 2011)

- CMEX: Bug fix related to situations with very large number of labels in connection with a restart with continued compilation

3.32 23.5 Distribution

3.32.1 23.5.1 Major release (July 05, 2010)

3.32.2 23.5.2 Maintenance release (August 18, 2010)

- AlphaECP: Fix for crash running under IDE
- API: Updated Python and Java APIs and examples
- Baron: Fixed issue with output formatting under Linux
- Baron: Memory leak when using BARON with external NLP solver
- Gdxmerge: Do not use path when checking for `merged.gdx`
- Gurobi: Fixed typo for option `displayinterval`
- McCarl Guide: Updates for 23.5
- Mosek 6 rev 85 libraries
- MPS2GMS: Removed `mps2gms` debug message
- Snopt: Fix for wrong return code (`local,global`)
- Xlsdump utility added

3.33 23.4 Distribution

3.33.1 23.4.1 Major release (May 21, 2010)

3.33.2 23.4.3 Maintenance release (May 24, 2010)

3.34 23.3 Distribution

3.34.1 23.3.1 Major release (November 01, 2009)

3.34.2 23.3.2 Maintenance release (November 18, 2009)

- Gurobi 2.0.1 library with bug fixes
 - MOSEK 6 rev 53 library with bug fixes
 - Updated CoinOS library with bug fixes
 - Solver optfile bug fix in GAMSCHK
 - Synchronized `tolproj` (1e-8) option for `solverlink=3`
-

3.34.3 23.3.3 Maintenance release (December 17, 2009)

- MOSEK 6 rev 55 library with bug fixes
- 32bit HAR utilities available in 64bit Windows System
- Slow solution reporting in GAMS/Gurobi and other solvers fixed

3.35 23.2 Distribution**3.35.1 23.2.1 Minor release (August 14, 2009)****3.36 23.1 Distribution****3.36.1 23.1.1 Major release (July 13, 2009)****3.36.2 23.1.2 Maintenance release (July 23, 2009)**

- MPSGE: MPSGE ignored the `m.workspace` and `m.workfactor` settings
- GAMSCHK: Fixed a problem with the layout of the reports in some models

3.37 23.0 Distribution**3.37.1 23.0.2 Major release (February 14, 2009)****3.38 22.9 Distribution****3.38.1 22.9.2 Major release (December 01, 2008)****3.39 22.8 Distribution****3.39.1 22.8.1 Major release (August 01, 2008)****3.40 22.7 Distribution****3.40.1 22.7.1 Major release (May 01, 2008)****3.40.2 22.7.2 Maintenance release (May 13, 2008)**

- DICOPT/ALPHAECP/LOGMIPLBOA: Fixed Cplex scaling bug
 - GAMS/CPLEX: Small cosmetic Cplex bug fix. We got "CPLEX Error 3003: Not a mixed-integer problem." In case we cannot solve the fixed problem. This was due to some query calls about nodes and iteration.
 - GAMSIDE: Fixed a bug that could cause an out of memory error when moving a row or column to the plane index in the.gdx data viewer
 - GAMS/DEA: Avoid writing zeros to GDX files
 - GAMS/LGOLIB: Fixed a memory leak
 - Minor documentation updates
 - Note: AIX and Mac OS X PPC were not updated.
-

-
- 3.41 22.6 Major release (December 24, 2007)
 - 3.42 22.5 Major release (June 01, 2007)
 - 3.43 22.4 Major release (February 12, 2007)
 - 3.44 22.3 Major release (November 27, 2006)

 - 3.59 20.4 Maintenance release (January 21, 2002)
 - 3.60 20.3 Major release (December 24, 2001)
 - 3.61 20.2 Maintenance release (November 22, 2001)
 - 3.62 20.1 Major release (October 31, 2001)
-

Chapter 4

User's Guide

This documentation guides GAMS users through several topics in the GAMS system.

4.1 Installation and Licensing

This part leads step by step through the installation process on three main platforms and describes the GAMS licensing system:

- [Supported Platforms](#)
- [Installation Notes for Mac OS X](#)
- [Installation Notes for Unix](#)
- [Installation Notes for Windows](#)
- [Standard Locations](#)
- [Licensing](#)

4.2 Tutorials and Examples

This part describes step by step through several selected tutorials and a small number of examples.

- [A GAMS Tutorial by Richard E. Rosenthal](#)
- [Quick Start Tutorial](#)
- [Good Coding Practices](#)
- [Fixing Compilation Errors](#)
- [Finding and Fixing Execution Errors and Performance Problems](#)
- [Comparative Analyses with GAMS](#)
- [Good NLP Formulations](#)
- [Data Exchange with Other Applications](#)

- [Data Exchange with Text Files](#)
- [Data Exchange with Microsoft Excel](#)
- [Data Exchange with Databases](#)
- [Executing GAMS from other Environments](#)
- [Using GAMS Studio](#)

There are also tutorials and examples of the [Application Programming Interfaces](#)

- [.NET Tutorial](#) and [Examples](#)
- [C++ Tutorial](#) and [Examples](#)
- [Java Tutorial](#) and [Examples](#)
- [Python Tutorial](#) and [Examples](#)

4.3 GAMS Language and Environment

This part introduces the components of the GAMS language in an ordered way, interspersed with detailed examples that are often drawn from the model library.

- [Introduction](#) - an introduction to the GAMS User's Guide.
 - [GAMS Programs](#) - The structure of the GAMS language and its components
 - [Set Definition](#) - The declaration and initialization of sets, subsets, and domain checking.
 - [Dynamic Sets](#) - The membership assignment, the usage of dollar controls, and set operations.
 - [Sets as Sequences: Ordered Sets](#) - Special features used to deal with a set as if it were a sequence.
 - [Data Manipulations with Parameters](#) - The declaration and assignment of GAMS parameters.
 - [Data Entry: Parameters, Scalars and Tables](#) - Three basic forms of GAMS data types : Parameters, Scalars and Tables.
 - [Variables](#) - The declaration and attributes of GAMS variables.
 - [Equations](#) - The definition and declaration of GAMS equations.
 - [Model and Solve Statements Model](#) - The specification of a GAMS model and how to solve it.
 - [Conditional Expressions, Assignments and Equations](#) - The conditional assignments, expressions and equations in GAMS.
 - [The Display Statement](#) - The syntax, control, and label order in display.
 - [Programming Flow Control Features](#) - The GAMS programming flow control features : loop, if-elseif, while, and for statements.
 - [The Option Statement](#) - The list and detailed description of options.
 - [System Attributes](#) - The system attributes
 - [The Grid and Multi-Threading Solve Facility](#) - The basic concepts and Grid Features.
 - [Special Features for Mathematical Programs](#) - Special features in GAMS that do not translate across solvers, or are specific to certain model types.
-

The following discusses the execution of GAMS, the use of special features, and other miscellaneous topics.

- [GAMS Output](#) - The control of GAMS compilation output, execution output, output produced by a solve statement, and error reporting.
- [GAMS Log](#)
- [The GAMS Call and Command Line Parameters](#) - The list and detailed description of GAMS command line parameters.
- [Dollar Control Options](#) - The list and detailed description of dollar control options.
- [The Put Writing Facility](#) - The put writing facility of the GAMS language.
- [Solver Usage](#) - Controlling solvers.
- [The Save and Restart Feature](#) - The GAMS save and restart feature and the work file.
- [Embedded Code Facility](#) - The Embedded Code Facility (e.g. how to embed Python code into GAMS).
- [Extrinsic Functions](#) - The extrinsic function library and comparison with external equations.
- [External Equations](#) - A facility for connecting code written in different programming languages to equations and variables in a GAMS model.
- [GAMS Return Codes](#) - The structure of error codes, the return codes of the GAMS compiler and execution system, and the driver return codes.
- [GAMS Data eXchange \(GDX\)](#) - GAMS Data eXchange (GDX) facilities and utilities for Binary Data Exchange.
- [Extended Mathematical Programming \(EMP\)](#) - Extended Mathematical Programming (EMP).
- [Accessing Model Libraries](#) - Introduction of GAMS Model Library.
- [Mathematical Programming System for General Equilibrium analysis \(MPSGE\)](#) - A mathematical programming system for general equilibrium analysis which operates as a subsystem within GAMS.
 - [Introduction to MPSGE](#)
 - [MPSGE Models in GAMS](#)
 - [Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE](#)
 - [Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae](#)
 - [A Library of Small Examples for Self-Study](#)
 - [Linking Implan Social Accounts to MPSGE](#)
 - The MPSGE guide is also available as [PDF](#)

4.4 Glossary

An alphabetical list of GAMS terms is available in the [Glossary](#).

4.5 Supported Platforms

GAMS divides the set of supported platforms into so-called *core* platforms and *peripheral* platforms to recognize and better describe how the two sets of platforms have evolved. The user communities for core platforms are large, active, and well-identified, but not so for the peripheral platforms. For the core platforms, GAMS will continue to make each new release of GAMS directly available for download, while the peripheral platforms will be available by request only. Finally, changes in the availability of core platforms will be announced well in advance of the event, while changes to support for peripheral platforms may occur with little or no notice.

The core platforms are the following:

Core Platform	Description
x86 64 bit Linux	AMD- or Intel-based 64-bit (x86_64) Linux systems with glibc 2.17 or higher.
x86 64 bit Mac OS X	Intel-based 64-bit (x86_64) Macintosh system with 10.15 (Catalina), 11 (Big Sur), or 12 (Monterey).
x86 64 bit MS Windows	Windows 8.1 or newer on AMD- or Intel-based (x86_64) architectures.

Note

Compared to most of the GAMS system, [GAMS Studio](#) has some additional system requirements which are detailed [here](#).

There are currently no peripheral platforms.

While the GAMS execution system itself is available on all supported platforms, for certain solvers, tools, and APIs, different availabilities can apply. For details, see

- [Supported Platforms for Solvers](#)
- [Supported Platforms for Tools](#)
- [Supported Platforms for High-level APIs](#)
- [Supported Platforms for Low-level APIs](#)

4.6 Installation Notes for Mac OS X

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Furthermore, we recommend to use the PKG installer for Mac OS X because it includes the GAMS Studio and it integrates GAMS into Mac OS X, e.g. it is possible to open the GAMS Studio via the Launchpad.

Two installation procedures are available for GAMS on Mac OS X:

- [Installation using the PKG installer \(GAMS38.0.0.pkg\)](#)
- [Installation using the self-extracting archive \(osx_x64_64_sfx.exe\)](#)

4.6.1 Installation using the PKG installer (GAMS38.0.0.pkg)

1. Obtain the GAMS PKG file, which is available from <http://www.gams.com/download>.
 2. Double click the package and follow the instructions. By clicking on **Customise** in the tab **Installation Type** you can decide to add GAMS to the PATH as well as to reject the installation of [GAMS Studio](#). Note that adding GAMS to the PATH is done by modifying your shell profile file (`~/.zprofile`, `~/.bash_profile` etc.). A backup of your old profile is saved (`~/.zprofile.gamsbackup`, `~/.bash_profile.gamsbackup` etc.).
 3. In order to test the GAMS installation with [GAMS Studio](#) open the **Launchpad** and click the **GAMS Studio 38** icon to open the application. Alternatively, go to **Applications** and open the **GAMS Studio 38** application.
-

4. Install your license via the [corresponding GAMS Studio dialog](#). The license file is nowadays sent via email, with instructions. You can also request a demo license from <http://www.gams.com/download>.

Optionally, you can create the license file 'gamslice.txt' in a directory that GAMS searches to find a license. GAMS searches a couple of system wide and user specific [standard locations](#) for a license file.

5. Open the Model Library Explorer and open the TRANSPORT model (sequence number 001). Run the model and check the contents of the process log, which should be similar to the Terminal output listed in the next bullet point.
6. In order to test the GAMS installation without using GAMS Studio open a Terminal window. Execute the following commands to see if everything works as expected:

```
gamslib trnsport
gams trnsport
```

The output should be similar to this:

```
--- Job trnsport Start 06/26/14 11:24:56 24.3.1 r46409 DEX-DEG Mac x86_64/Darwin
GAMS 24.3.1 Copyright (C) 1987-2014 GAMS Development. All rights reserved

```

4.6.2 Uninstall PKG installation

To uninstall a GAMS installation that was installed using the PKG installer, run the following command from the terminal: `sudo bash /Library/Frameworks/GAMS.framework/Versions/38/Resources/uninstall.sh`. Additionally, you can remove GAMS from the PATH in your shell profile file (`~/.zprofile`, `~/.bash_profile`) if GAMS was added to the PATH during installation.

4.6.3 Installation using the self-extracting archive (`osx_x64_64_sfx.exe`)

1. Obtain the GAMS distribution file, which is available from <http://www.gams.com/download>, in one large self-extracting zip archive with a `.sfx.exe` file extension, e.g., `osx_x64_64_sfx.exe`. Check that it has the execute permission set. If you are not sure how to do this, just type in the command `chmod 755 osx_x64_64_sfx.exe`.

Attention

The common way to install GAMS on a Mac is the [PKG installer](#). When one tries to run the sfx installer (e.g. for unattended installation) under macOS 10.15 (Catalina) or newer, the installer and several related files will be tagged with the `com.apple.quarantine` flag. There are different solutions to this problem:

- The flag can be removed by the following command:

```
xattr -rd com.apple.quarantine osx_x64_64_sfx.exe
```
- Instead of downloading the sfx installer through the browser, use a command line tool such as `curl` (note that by downloading the software, you agree to the [License Agreement](#)). The download link may need to be adjusted, depending on the distribution that should be downloaded.

```
curl https://d37drm4t2jghv5.cloudfront.net/distributions/29.1.0/macosx/osx_x64_64_sfx.e
```

2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in `/Applications/GAMS`, the installer will create the GAMS system directory `/Applications/GAMS/gams24.3_osx_x64_64_sfx`. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.
3. Create the directory that should contain the GAMS system directory, for instance `/Applications/GAMS`. Change to this directory (`cd /Applications/GAMS`). Make sure `pwd` returns the name of this directory correctly.
4. Run the distribution file, either from its current location or after transferring it to the directory that should contain the GAMS system directory. By executing the distribution file, the GAMS distribution should be extracted. For example, if you downloaded the distribution file into your home directory, you might execute the following commands:

```
mkdir /Applications/GAMS
cd /Applications/GAMS
~/osx_x64_64_sfx.exe
```

5. Create the license file `gamslice.txt` in a directory GAMS searches to find a license. The license file is nowadays sent via email, with instructions. You can also request a demo license from <http://www.gams.com/download>.

Attention

Do not store the `gamslice.txt` in the GAMS system directory. This invalidates the code signature and cause Gatekeeper to reject the bundle!

GAMS searches a couple of system wide and user specific locations for a license file. For Mac OS X these locations include `/Library/Application Support/GAMS` and `/Users/username/Library/Application Support/GAMS`. The locations can vary due to different system configuration. One can get an ordered list of data directories GAMS searches for `gamslice.txt` by running the program `./gamsinst -listdirs` from the GAMS system directory. Even though this list might contain locations in the system directory, e.g. `/Applications/GAMS31.1` we strongly discourage to place `gamslice.txt` here.

6. Change to the GAMS system directory and run the program `./gamsinst`. It will prompt you for default solvers to be used for each class of models. If possible, choose solvers you have licensed since unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or overridden by:
 - a. rerunning `./gamsinst` and resetting the default values
 - b. setting a command line default, e.g., `gams transport lp=soplex`
 - c. an option statement in the GAMS model, e.g: `option lp=soplex;`
7. Add the GAMS system directory to your path (see [below](#)).
8. To test the installation, log in as a normal user and run a few models from your home directory, but not the GAMS system directory:

```
LP:      transport (objective value: 153.675)
NLP:     chenery   (objective value: 1058.9)
MIP:     bid       (optimal solution: 15210109.512)
MINLP:   procsel  (optimal solution: 1.9231)
MCP:     scarfmcp (no objective function)
MPSGE:   scarfmge (no objective function)
```

9. If you move the GAMS system to another directory, remember to rerun `./gamsinst`. It is also good practice to rerun `./gamsinst` when you change your license file if this has changed the set of licensed solvers.

4.6.3.1 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory. There are several ways to do this. Remember that the GAMS system directory in the examples below may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (`csh`) and its variants you can modify your `.cshrc` file by adding the second of the two lines given below:

```
set path = (/your/previous/path/setting )
set path = ( $path /Applications/GAMS/gams24.3_osx_x64_64_sfx ) # new
```

2. Those of you using the Bourne (`sh`) or Korn (`ksh`) shells and their variants can modify their `.profile` file by adding the second of the three lines below:

```
PATH=/your/previous/path/setting
PATH=$PATH:/Applications/GAMS/gams24.3_osx_x64_64_sfx # new
export PATH
```

If the `.profile` file does not exist yet, it needs to be created. You should log out and log in again after you have made any changes to your path.

3. You may prefer to use an alias for the names of the programs instead of modifying the path as described above. C shell users can use the following commands on the command line or in their `.cshrc` file:

```
alias gams /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
alias gamslib /Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
```

The correct Bourne or Korn shell syntax (either command line or `.profile`) is:

```
alias gams=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
alias gamslib=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
```

Again, you should log out and log in in order to put the alias settings in `.cshrc` or `.profile` into effect.

4. Casual users can always type the absolute path names of the GAMS programs, e.g.:

```
/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams trnsport
```

4.6.3.2 Example

The following shows the log of a session, where a user downloads a GAMS 24.3.1 system and installs it under `Applications/GAMS/gams24.3_osx_x64_64_sfx`. It is assumed that a GAMS license file has been stored as `/Users/does/gamslice.txt`.

```
doe@mac:/Users/does$ curl -L -k -O \
  http://d37drm4t2jghv5.cloudfront.net/distributions/24.3.1/macosx/osx_x64_64_sfx.exe
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 148M  100 148M    0     0 4374k      0  0:00:34  0:00:34  --:--:-- 5906k

doe@mac:/Users/does$ chmod 755 osx_x64_64_sfx.exe

doe@mac:/Users/does$ cd /Applications/GAMS

doe@mac:/Applications/GAMS$ ~/osx_x64_64_sfx.exe
UnZipSFX 5.52 of 28 February 2005, by Info-ZIP (http://www.info-zip.org).
  creating: gams24.3_osx_x64_64_sfx/
  inflating: gams24.3_osx_x64_64_sfx/sp2full.m
  inflating: gams24.3_osx_x64_64_sfx/optpathnlp.def
  inflating: gams24.3_osx_x64_64_sfx/MessageReceiverWindow.exe

  inflating: gams24.3_osx_x64_64_sfx/optdicopt.html

doe@mac:/Applications/GAMS$ cd gams24.3_osx_x64_64_sfx
doe@mac:/Applications/GAMS/gams24.3_osx_x64_64_sfx$ ./gamsinst -license ~/gamslice.txt
```

```
gamsinst run on Wed Jun 25 19:25:29 2014
GAMS sysdir is "/Applications/GAMS/gams24.3_osx_x64_64_sfx"
```

LP (Linear Programming) models can be solved by:

1. CBC (demo or student license)
2. CONOPT (demo or student license)
3. CPLEX (demo or student license)
4. GUROBI (demo or student license)
5. IPOPT (demo or student license)
6. IPOPTH (demo or student license)

...

Installed defaults:

```
LP: CPLEX
MIP: CPLEX
RMIP: CPLEX
NLP: CONOPT
MCP: PATH
MPEC: NLPEC
RMPEC: NLPEC
CNS: CONOPT
DNLP: CONOPT
RMINLP: CONOPT
MINLP: DICOPT
QCP: CONOPT
MIQCP: SBB
RMIQCP: CONOPT
EMP: JAMS
```

We are now prepared to set read and execute permissions on the GAMS system files. If you are not sure which option to choose, we recommend option 3.

You can set read (and execute) permission for:

1. user only.
2. user and group.
3. user, group, and world.

Enter your choice now

3

The files "gams", "gamslib", etc., are now executable.

You can run these commands in a number of ways:

1. Call them using an absolute path (i.e. /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams).
2. Create your own aliases for them.
3. Add the GAMS system directory "/Applications/GAMS/gams24.3_osx_x64_64_sfx" to your path.

Method 3. is recommended.

```
doe@mac:/Applications/GAMS/gams24.3_osx_x64_64_sfx$cd
```

```
doe@mac:/Users/does/Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib trnsport
Copy ASCII: trnsport.gms
```

```

doe@mac:/Users/does/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams trnsport.gms license ~/gamslice.

4.7 Installation Notes for Unix

4.7.1 Installation

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Additionally, a video on how to install GAMS on Linux is available at https://www.youtube.com/watch?v=Mx_tYI3wyP4.

1. Obtain the GAMS distribution file, which is available from <http://www.gams.com/latest>, in one large self-extracting zip archive with a `_sfx.exe` file extension, e.g., `linux_x64_64_sfx.exe` on a Linux 64bit system. Check that it has the execute permission set. If you are not sure how to do this, just type in the command, e.g., `chmod 755 linux_x64_64_sfx.exe`.

2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in `/opt/gams`, the installer will create the GAMS system directory `/opt/gams/gams24.3_linux_x64_64_sfx`. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.
3. Create the directory that should contain the GAMS system directory, for instance `/opt/gams`. Change to this directory (`cd /opt/gams`). Make sure `pwd` returns the name of this directory correctly.
4. Run the distribution file, either from its current location or after transferring it to the directory that should contain the GAMS system directory. By executing the distribution file, the GAMS distribution should be extracted. For example, if you downloaded the distribution file into your home directory, you might execute the following commands:

```
mkdir /opt/gams
cd /opt/gams
~/linux_x64_64_sfx.exe
```

5. Create the license file `gamslice.txt` in a directory GAMS searches to find a license or use the [corresponding GAMS Studio dialog](#). The license file is nowadays sent via email, with instructions. You can also request a demo license from <http://www.gams.com/download>. GAMS searches a couple of system wide and user specific [standard locations](#) for a license file.
6. Change to the GAMS system directory and run the program `./gamsinst`. It will prompt you for default solvers to be used for each class of models. If possible, choose solvers you have licensed since unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or overridden by:
 - a. rerunning `./gamsinst` and resetting the default values
 - b. setting a command line default, e.g., `gams trnsport lp=soplex`
 - c. an option statement in the GAMS model, e.g: `option lp=soplex;`
7. Add the GAMS system directory to your path (see [below](#)).
8. To test the installation, log in as a normal user and run a few models from your home directory, but not the GAMS system directory:

```
LP:      trnsport (objective value: 153.675)
NLP:     chenery  (objective value: 1058.9)
MIP:     bid      (optimal solution: 15210109.512)
MINLP:   procsel  (optimal solution: 1.9231)
MCP:     scarfmcp (no objective function)
MPSGE:   scarfmge (no objective function)
```

9. If you move the GAMS system to another directory, remember to rerun `./gamsinst`. It is also good practice to rerun `./gamsinst` when you change your license file if this has changed the set of licensed solvers.

4.7.2 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory. There are several ways to do this. Remember that the GAMS system directory in the examples below may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (`csh`) and its variants you can modify your `.cshrc` file by adding the line
-

```
set path = ( $path /opt/gams/gams24.3_linux_x64_64_sfx )
```

- Those of you using the Bourne (`sh`) or Korn (`ksh`) shells and their variants can modify their `.profile` or `.bashrc` file by adding the line

```
PATH=$PATH:/opt/gams/gams24.3_linux_x64_64_sfx
```

If neither `.profile` nor `.bashrc` exist yet, `.profile` needs to be created. You should log out and log in again after you have made any changes to your path.

- You may prefer to use an alias for the names of the programs instead of modifying the path as described above. C shell users can use the following commands on the command line or in their `.cshrc` file:

```
alias gams /opt/gams/gams24.3_linux_x64_64_sfx/gams
alias gamslib /opt/gams/gams24.3_linux_x64_64_sfx/gamslib
```

The correct Bourne or Korn shell syntax (either command line or `.profile`) is:

```
alias gams=/opt/gams/gams24.3_linux_x64_64_sfx/gams
alias gamslib=/opt/gams/gams24.3_linux_x64_64_sfx/gamslib
```

Again, you should log out and log in in order to put the alias settings in `.cshrc` or `.profile` into effect.

- Casual users can always type the absolute path names of the GAMS programs, e.g.:

```
/opt/gams/gams24.3_linux_x64_64_sfx/gams transport
```

4.8 Installation Notes for Windows

4.8.1 Installation

- Run `windows_x64_64.exe` (Windows 64bit): This file is available from <https://www.gams.com/latest>. Please note that the installation may require administrative privileges on your machine.

You have two options to run the installer: In default or advanced mode. In the default mode, the installer will prompt you for the name of the directory in which to install GAMS. We call this directory the **GAMS directory**. You may accept the default choice or pick another directory. Please remember: if you want to install two different versions of GAMS, they must be in separate directories.

If you choose to use the advanced mode, the installer will also ask you for a name of a start menu folder, if GAMS should be installed for all users, if the **GAMS directory** should be added to the `PATH` environment variable and which desktop icons should be created.

The **GAMS License** page allows to select a GAMS license. The installer tries to find GAMS licenses in different locations and automatically selects a license to be used with the following precedence:

- Clipboard
- `C:\Users\username\Documents\GAMS`
- Previous GAMS installation found from the registry (User)
- Previous GAMS installation found from the registry (System)

In addition it is possible to browse for a license file (`gamslice.txt`) or to skip all license related actions (`No License`) and install one after the installation process. Note that the use of GAMS requires a license. A free demo license can be requested at <https://www.gams.com/download>. A license file is written to `C:\Users\username\Documents\GAMS` when installing for `Current User` (default). Installing for `All Users` or checking `Write License to System Directory` will write the license to the GAMS system directory instead.

For automating the installation of GAMS, it is possible to provide the command line parameters `/SP- /SILENT`. This will install GAMS in a non-interactive manner using default settings. Note that depending on the security settings, the User Account Control asking for permission might still be active. The following command line parameters are available to further customize the non-interactive installation:

- `/installAllUsers=yes|no` (default: `no`): Can be used in order to install for `All Users` instead of `Current User`.
- `/noLicense=yes|no` (default: `no`): Can be used in order to prevent any GAMS license from being written.
- `/noIcons` can be used in order to check the `Don't create a Start Menu folder` checkbox on the `Select Start Menu Folder` page.
- `/desktopIcons=yes|no` (default: `yes`) can be used in order to turn on/off the creation of Desktop icons.
- `/allUsers`: Perform installation in administrative install mode.
- `/currentUser`: Perform installation in non administrative install mode. If specified, `/installAllUsers=yes` has no effect.

Attention

Under Windows 10 the Windows Installer package may not update system environment variables (see [Microsoft Forum](#)). To work around this issue, log off of Windows after the installation, and then log on again.

Note

The installer can be run unattended with the switches `/SILENT` or `/VERYSILENT` and might require some post installation task (like copying the license file to an appropriate location). This unattended mode also skips execution of some code in the installer that can cause failures on exotically configured systems.

2. During the installation of GAMS, the setup process helps in setting up the license to be used with GAMS. In case no license has been selected during this process it is required to set this up manually. The license file is nowadays sent via email, with instructions. You can also request a demo license from <https://www.gams.com/download>. If you don't have a license file yet, choose `No license` when asked for the GAMS license options. You can install a license later by either manually creating the license file `gamslice.txt` in a directory GAMS searches to find a license or use the [corresponding GAMS Studio dialog](#).

GAMS searches a couple of system wide and user specific [standard locations](#) for a license file.

3. Choose the default solvers: Run [GAMS Studio](#) by double clicking `studio.exe` from the GAMS system subdirectory `Studio`. To view or edit the default solvers, open the [GAMS Configuration Editor](#) in Studio. You can also skip this and thus accept the existing defaults if you wish, but most users want to select new default solvers for each model type.
4. Run a few models to test the GAMS system: The [Model Library Explorer](#) allows you to pick some models from the GAMS model library easily. After selecting one, press `F9` to run it, and view the solution. To test your installation, run the following models from the GAMS model library:

```
LP:      trnsport (objective value: 153.675)
NLP:     chenery (objective value: 1058.9)
MIP:     bid      (optimal solution: 15210109.512)
MINLP:   procsel (optimal solution: 1.9231)
MCP:     scarfmcp (no objective function)
MPSGE:   scarfmge (no objective function)
```

4.8.2 Visual C++ Redistributable Dependency

- Some solvers in the system as well as [GAMS Studio](#) have dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio or when solving a model, please run the installer `vcredist_x64.exe` for these libraries, which can be found in the GAMS installation folder in directory `[GAMS system]\apifiles\C++\lib\vs2017`.

4.8.3 Command Line Use of GAMS

Users wishing to use GAMS from the command line (aka the console mode) may want to perform the following steps. These steps are not necessary to run GAMS via Studio.

1. We recommend to add the GAMS directory to your environment path in order to avoid having to type in an absolute path name each time you run GAMS. Run the installer in advanced mode and mark the check-box `Add GAMS directory to PATH environment variable`.
2. Run the program `gamsinst`: `gamsinst` is a command line program used to configure GAMS. It prompts the user for default solvers to be used for each model type. If possible, choose solvers you have licensed, since unlicensed solvers will only run in demonstration mode. The solver defaults can be changed by:
 - a. rerunning `gamsinst` and resetting the default values
 - b. setting a command line default, e.g. `gams transport lp=soplex`
 - c. by an option statement in the GAMS model, e.g: `option lp=soplex;`

The system wide solver defaults are shared by the command line and GAMS Studio, so you can also choose to set these defaults using GAMS Studio.

4.8.4 Warning from Microsoft SmartScreen Filter

The SmartScreen is a feature that is used in several Microsoft products, including the Internet Explorer, Microsoft Edge, as well as in Windows 8 and newer versions of Windows. It is supposed to help to protect your computer against unwanted software. It uses a reputation-based system to rate files downloaded from the internet. That means that a file gets a better reputation when it gets download more often. As a result you might get a warning like this, especially for GAMS distributions that were recently released:

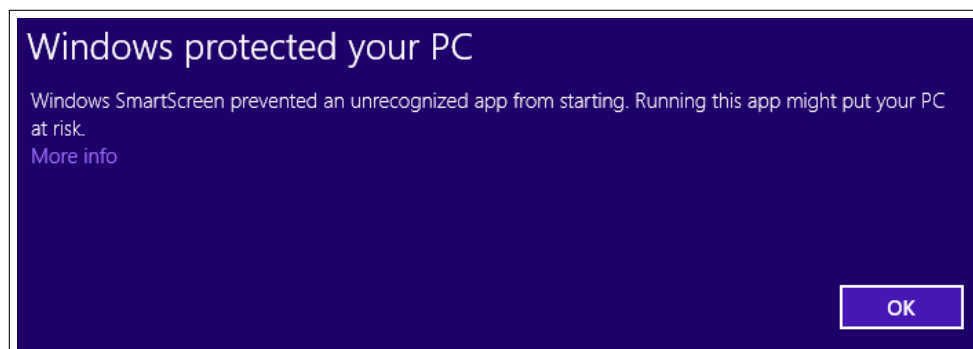

Figure 4.1 SmartScreen Filter Warning

clicking on “More info” will display an option to continue the installation process.

4.9 Standard Locations

GAMS looks for specific files in some system-wide and user-specific locations which are independent of the GAMS installation. This allows the user to store these files in one place without the need to adjust anything when moving from one GAMS version to another. These folders are referred to as *standard locations* and are split into two groups: *configuration directories* and *data directories*. Here are some examples of files, which will be found in the data directories (or subfolders of these):

- The GAMS [license file](#)
- [LibInclude](#) files
- [External Equation](#) libraries
- [Extrinsic Function](#) libraries

The GAMS [configuration file](#) is expected in one of the configuration directories.

The exact location depends on the operating system used and user specific settings. Running `gamsinst -listdirs` on the command line shows the folders searched explicitly.

4.9.1 Standard Locations on Mac OS X

4.9.1.1 Configuration Directories

These folders get searched on Mac OS X (in the listed order):

- The GAMS system directory
- The subfolder GAMS in `$HOME/Library/Preferences` (`$HOME` usually contains the user's home directory)

Here is an example output of `gamsinst -listdirs`:

```
Config directories (searched for e.g. gamsconfig.yaml):
/Users/JaneDoe/GAMS32
/Users/JaneDoe/Library/Preferences/GAMS
```

4.9.1.2 Data Directories

These folders get searched on Mac OS X (in the listed order):

- The subfolder GAMS in `$HOME/Library/Application Support` (`$HOME` usually contains the user's home directory)
- The subfolder GAMS in `/Library/Application Support`
- The subfolder `Resources` next to the GAMS system directory
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
/Users/JaneDoe/Library/Application Support/GAMS
/Library/Application Support/GAMS
/Users/JaneDoe/Resources
/Users/JaneDoe/GAMS32
```

4.9.2 Standard Locations on Unix

4.9.2.1 Configuration Directories

On Unix the environment variables `XDG_CONFIG_HOME` and `XDG_CONFIG_DIRS` (see [XDG Base Directory Specification](#)) influence the search directories. These folders get searched on Unix (in the listed order):

- The GAMS system directory
- The subfolder `GAMS` of folders from `$XDG_CONFIG_DIRS` or the subfolder `GAMS` in `/etc/xdg`
- The folder `$XDG_CONFIG_HOME` or the subfolder `GAMS` in `$HOME/.config` (`$HOME` usually contains the user's home directory)

Here is an example output of `gamsinst -listdirs`:

```
Config directories (searched for e.g. gamsconfig.yaml):
/home/JohnDoe/GAMS32
/etc/xdg/GAMS
/home/JohnDoe/.config/GAMS
```

4.9.2.2 Data Directories

On Unix the environment variables `XDG_DATA_HOME` and `XDG_DATA_DIRS` (see [XDG Base Directory Specification](#)) influences the search directories. These folders get searched on Unix (in the listed order):

- The folder `$XDG_DATA_HOME` or the subfolder `GAMS` in `$HOME/.local/share` (`$HOME` usually contains the user's home directory)
- The subfolder `GAMS` of folders from `$XDG_DATA_DIRS` or the subfolder `GAMS` in `/usr/local/share` and the subfolder `GAMS` in `/usr/share`
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
/home/JohnDoe/.local/share/GAMS
/usr/local/share/GAMS
/usr/share/GAMS
/home/JohnDoe/GAMS32
```

4.9.3 Standard Locations on Windows

4.9.3.1 Configuration Directories

These folders get searched on Windows (in the listed order):

- The GAMS system directory
- The subfolder `GAMS` in `C:\ProgramData`
- The subfolder `GAMS` in `AppData\Local` in the User's directory
- The subfolder `GAMS` in `Documents` in the User's directory

Here is an example output of `gamsinst -listdirs`:

```
Config directories (searched for e.g. gamsconfig.yaml):
C:\GAMS\32
C:\ProgramData\GAMS
C:\Users\JohnDoe\AppData\Local\GAMS
C:\Users\JohnDoe\Documents\GAMS
```

4.9.3.2 Data Directories

These folders get searched on Windows (in the listed order):

- The subfolder `GAMS` in `Documents` in the User's directory
- The subfolder `GAMS` in `AppData\Roaming` in the User's directory
- The subfolder `GAMS` in `C:\ProgramData`
- The subfolder `data` in the GAMS system directory
- The subfolder `data\GAMS` in the GAMS system directory
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
C:\Users\JohnDoe\Documents\GAMS
C:\Users\JohnDoe\AppData\Roaming\GAMS
C:\ProgramData\GAMS
C:\GAMS\32\data
C:\GAMS\32\data\GAMS
C:\GAMS\32
```

4.10 Licensing

4.10.1 General Information

The GAMS system and all connected solvers can be downloaded from the GAMS website at <https://www.gams.com/download>. The use of the software is governed by the GAMS End User License Agreement, which is available on our [website](#) and can also be found in the GAMS System directory (`eula.pdf`). Without a valid GAMS license the system will not run and produces the following output:

```
*** No license specified and no gamslice.txt found in standard locations.
```

You can request a free demo license at <https://www.gams.com/download>. The demo license lets you generate and solve linear models (LP, RMIP, and MIP) that do not exceed 2000 variables and 2000 constraints. For all other model types the model cannot be larger than 1000 variables and 1000 constraints. Some solvers might enforce additional limits for the demo license. The demo license of MIRO connector allows up to 10 indexed input and output symbols.

GAMS will terminate with an error message, if it hits one of the limits above:

```
*** Status: Terminated due to a licensing error
***          Inspect listing file for more information
```

The demo license is time-limited for 12 months and on expiration you need to request a new license. Moreover, a valid free demo license requires a recent GAMS version (not older than 18 months).

4.10.2 GAMS Community License

Users can request a free community license from sales@gams.com. The community license lets you generate and solve linear models (LP, MIP, and RMIP) that do not exceed 5000 variables and 5000 constraints. For all other model types the model cannot be larger than 2500 variables and 2500 constraints. Restrictions you experience with the demo license, i.e. additional limits enforced by some solvers, time-limitation of 12 months, and a recent GAMS system also apply to the community license. The free demo and community license cannot be combined with a professional license. These free demo and community licenses are for demonstration and evaluation but not for commercial and production work.

4.10.3 GAMS Licenses

GAMS licenses beyond the free demo and community license require a license for the GAMS Base Module and for most of the GAMS/Solvers and the GAMS/Solver-Links:

- The **GAMS Base Module** includes the GAMS Language Compiler, GAMS-APIs, many utilities, some solvers without size restrictions, and most solvers in "demo" mode with a model size limitation. See details [below](#).
- A **GAMS/Solver** connects the GAMS Base module to a particular solver and includes a license for this solver to be used through GAMS. It is not necessary to install additional software. A **GAMS/Solver-Link** connects the GAMS Base Module to a particular solver, but does not include a license for the solver. It may be necessary to install additional software before the solver can be used.

We distinguish between academic and commercial licenses. Academic licenses can only be used for teaching and research at degree granting institutions. Moreover, we distinguish between time-limited and perpetual licenses. For perpetual licenses the first year of maintenance, support and updates is included in the initial purchase of the software. Maintained licenses qualify for free updates, adding components, platform-switching without additional charge, and multi-copy discounts on the same platform. After the first year maintenance can be extended by paying a fee. Licenses are typically limited to a single computer platform type (e.g. Windows or Linux), but there are also licenses available, which will work on all major platform supported by GAMS. Free academic licenses are available for certain solvers. Please visit the [GAMS website](#) for further information about the pricing of an appropriate license.

4.10.4 Installing or updating a license file

A GAMS license file is an ASCII file of six lines, which was sent to you via e-mail. Please copy all six lines into a file `gamslice.txt` and place this into a location searched by GAMS. Details can be found in the installation notes of the specific operating system:

- [GAMS Installation Notes for Windows](#)
- [GAMS Installation Notes for Mac OS X](#)
- [GAMS Installation Notes for Unix](#)

Before installing a new GAMS version, please check whether it will work with your current GAMS license. The utility `CHK4UPD` can be used to see if a newer GAMS version is available and what the newest version is that can be used with a given license. This is done by running `CHK4UPD` without arguments or by giving the name of a local license file. `CHK4UPD` is also available through [GAMS Studio](#) and can be accessed through: `Help -> Check for Update`. Below is a sample output for a license, which is still under maintenance:

```
D:\>chk4upd
*** Processing GAMS system directory C:\gams\win64\24.8
*** Reading license file C:\ProgramData\GAMS\gamslice.txt
*** Your system is up to date
D:\>
```

If your license is no longer under maintenance, you will receive a message like the one below:

```
*** Processing GAMS system directory C:\GAMS\win64\23.9
*** Reading license file C:\ProgramData\GAMS\gamslice.txt
*** Your license is 1276 days too old to run with the most recent system
*** The version of your GAMS system is 23.9.5
*** The last GAMS version you can use is 24.1.3
*** Please request the download of an older version from sales@gams.com
*** For ordering an update to use the most recent version (24.8.5)
*** please contact your distributor
```

4.10.5 License Problems

Errors or warnings triggered by a problem with the GAMS license file (gamslice.txt) are reported both in the log file and in the lst file. Below are some typical error and warning messages and instructions how to overcome them.

4.10.5.1 No License File present

Without a license file GAMS will not work. If you have received a license file (gamslice.txt), follow the instruction from the previous section. Do not try to rename it or to modify the contents of the license file. Without a license GAMS will give you an error message like the one below:

```
*** No license specified and no gamslice.txt found in standard locations.
```

4.10.5.2 License File Invalid or Corrupted

Running GAMS with an invalid license will give you an error message like the one below:

```
*** License File validation failed
```

Do not try to modify your license file, any change will break it. If the original license file is no longer available, please contact sales@gams.com and ask for a copy of your license file. Please attach the license file you are currently using. This error also pops up, if you are using a license file, which was issued for a different platform.

4.10.5.3 License File expired

If are trying to run an old license file with a newer GAMS distribution, you may get an error message stating:

```
*** License file too old for this version of GAMS.
*** Maintenance expired 2840 days ago.
*** More than 60 days since expiration, sorry...
*** Run an older GAMS system or renew the license
```

Replace that GAMS system with the one you got together with your license file (use the CHK4UPD utility mentioned above to find out the latest version you can use with the current license; old systems are available on request from sales@gams.com) or update your license to the current version.

4.10.5.4 No License (for a particular Solver) found

If one of the solvers you are trying to use (or is selected as the default solver) is not included in your license file and the size of the model exceed the limits of the free demo or community version, you will get an error stating:

```
*** No license found
*** To update your license, please contact your distributor.
```

Check whether the default solvers for a particular problem class are included in the license. Please note that some of the solvers call other solvers as a sub-solver, e.g.:

- GAMS/DICOPT requires an NLP and a MIP solver
- GAMS/SBB requires an NLP solver
- MPSGE: If GAMS/PATH is not included in your license, please select GAMS/MILES, which is included in the base system as the default solver for MCP problems.

4.10.6 Warnings

4.10.6.1 License file too old for this version of GAMS

The complete message is:

```
*** License file too old for this version of GAMS.
*** Maintenance expired xx days ago.
```

If GAMS continues working, you can ignore this warning. However, any forthcoming GAMS distribution will most likely not work, but downgrade to the limits of the free demo system.

4.10.6.2 License File has expired xx days ago

This warning (without further error messages) indicates that the time limited license (e.g. an evaluation license) will stop working soon.

4.10.7 The GAMS/BASE Module

The GAMS/BASE module includes:

- **Language Compiler and Execution System**
 - **GAMS IDE(Integrated Development Environment) (Windows only)**
 - Project Management
 - Editor, Syntax coloring, Spell checking
 - Launching and monitoring of (multiple) GAMS processes
 - Listing file / Tree view / Syntax-error navigation
 - Solver selection / option selection
-

- GDX Viewer: Data cube and export (e.g. to MS Excel), charting facilities
 - **GAMS Studio (platform independent, Beta version)**
 - Editor, Syntax coloring
 - Launching and monitoring of (multiple) GAMS processes
 - Listing file / Tree view / Syntax-error navigation

4.10.8 Additional Limits for the Demo and Community License

The model size limits enforced by GAMS are:

- 2000 variables and 2000 constraints for linear (LP, RMIP, and MIP) models with a demo license
- 1000 variables and 1000 constraints for all other model types with a demo license
- 5000 variables and 5000 constraints for linear (LP, RMIP, and MIP) models with a community license
- 2500 variables and 2500 constraints for all other model types with a community license

In addition to the GAMS model size limits, the solvers might impose stricter limits when running with a demo or community license. We use m for the number constraints, n for the number variables, nd for the number of discrete variables, nz for the number nonzeros, and nlz for the number nonlinear nonzeros:

- [Antigone](#), [Baron](#), [LindoGlobal](#), and [Octeract](#) require $m \leq 50$, $n \leq 50$, and $nlz \leq 50$ with a demo license.
- [Antigone](#), [Baron](#), [LindoGlobal](#), and [Octeract](#) require $m \leq 300$, $n \leq 300$, and $nlz \leq 100$ with a community license.
- [Cplex](#) and [ODHCPLEX](#) require $m \leq 2000$ and $n \leq 2000$ with a *pro-bono* community license.
- [Decis](#) and [Knitro](#) require $m \leq 300$, $n \leq 300$, $nd \leq 50$, $nz \leq 2000$, and $nlz \leq 1000$ with a demo and community license.
- [LGO](#) requires $m \leq 20$ and $n \leq 20$ with a demo and $m \leq 300$ and $n \leq 300$ with a community license.
- [Xpress](#) requires $m+n \leq 5000$ with a community license.
- In addition [Gurobi](#) requires a license file from the vendor to operate.

4.11 A GAMS Tutorial by Richard E. Rosenthal

4.11.1 Introduction

Richard E. Rosenthal of the Naval Postgraduate School in Monterey, California wrote a detailed example of the use of GAMS for formulating, solving, and analyzing a small and simple optimization problem. The example is a quick overview of GAMS and its main features. Many references are made to other parts of the documentation, but they are only to tell you where to look for more details; the material here can be read profitably without reference to the rest of the documentation.

The example is an instance of the transportation problem of linear programming, which has historically served as a *'laboratory animal'* in the development of optimization technology. [See, for example, Dantzig (1963)¹.] It is a good choice for illustrating the power of algebraic modeling languages like GAMS because the transportation problem, no matter how large the instance at hand, possesses a simple, exploitable algebraic structure. You will see that almost all of the statements in the GAMS input file we are about to present would remain unchanged if a much larger transportation problem were considered.

In the familiar transportation problem, we are given the supplies at several plants and the demands at several markets for a single commodity, and we are given the unit costs of shipping the commodity from plants to markets. The economic question is: how much shipment should there be between each plant and each market so as to minimize total transport cost?

The algebraic representation of this problem is usually presented in a format similar to the following.

Indices:

¹Dantzig, George B. (1963). *Linear Programming and Extensions*, Princeton University Press, Princeton N.J.

i = plants
 j = markets

Given Data:

a_i = supply of commodity of plant i (in cases)
 b_j = demand for commodity at market j
 c_{ij} = cost per unit shipment between plant i and market j

Decision Variables:

x_{ij} = amount of commodity to ship from plant i to market j
 where $x_{ij} \geq 0$, for all i, j

Constraints:

Observe supply limit at plant i : $\sum_j x_{ij} \leq a_i$ for all i (cases)
 Satisfy demand at market j : $\sum_i x_{ij} \geq b_j$ for all j (cases)
 Objective Function: Minimize $\sum_i \sum_j c_{ij} x_{ij}$ (\$K)

Note that this simple example reveals some modeling practices that we regard as good habits in general and that are consistent with the design of GAMS. First, all the entities of the model are identified (and grouped) by type. Second, the ordering of entities is chosen so that no symbol is referred to before it is defined. Third, the units of all entities are specified, and, fourth, the units are chosen to a scale such that the numerical values to be encountered by the optimizer have relatively small absolute orders of magnitude. (The symbol \$K here means thousands of dollars.)

The names of the types of entities may differ among modelers. For example, economists use the terms *exogenous variable* and *endogenous variable* for *given data* and *decision variable*, respectively. In GAMS, the terminology adopted is as follows: indices are called **sets**, given data are called **parameters**, decision variables are called **variables**, and constraints and the objective function are called **equations**.

The GAMS representation of the transportation problem closely resembles the algebraic representation above. The most important difference, however, is that the GAMS version can be read and processed by a computer.

Table 1: Data for the transportation problem (adapted from Dantzig, 1963) illustrates Shipping Distances from Plants to Markets (1000 miles) as well as Market Demands and Plant Supplies.

<i>Plants</i> ↓	New York	Chicago	Topeka	← <i>Markets</i>
Seattle	2.5	1.7	1.8	350
San Diego	2.5	1.8	1.4	600
<i>Demands</i> →	325	300	275	<i>Supplies</i> ↑

As an instance of the transportation problem, suppose there are two canning plants and three markets, with the data given in table [Table 1](#). Shipping distances are in thousands of miles, and shipping costs are assumed to be \$90.00 per case per thousand miles. The GAMS representation of this problem is as follows:

```
$title a transportation model
Sets
  i  canning plants / seattle, san-diego /
  j  markets        / new-york, chicago, topeka / ;
```

Parameters

```

a(i)  capacity of plant i in cases
/      seattle    350
      san-diego   600 /

```

```

b(j)  demand at market j in cases
/      new-york   325
      chicago    300
      topeka     275 / ;

```

Table d(i,j) distance in thousands of miles

	new-york	chicago	topeka
seattle	2.5	1.7	1.8
san-diego	2.5	1.8	1.4 ;

Scalar f freight in dollars per case per thousand miles /90/ ;

Parameter c(i,j) transport cost in thousands of dollars per case ;

```

c(i,j) = f * d(i,j) / 1000 ;

```

Variables

```

x(i,j)  shipment quantities in cases
z       total transportation costs in thousands of dollars ;

```

Positive Variable x ;

Equations

```

cost      define objective function
supply(i) observe supply limit at plant i
demand(j) satisfy demand at market j ;

```

```

cost ..   z =e= sum((i,j), c(i,j)*x(i,j)) ;

```

```

supply(i) .. sum(j, x(i,j)) =l= a(i) ;

```

```

demand(j) .. sum(i, x(i,j)) =g= b(j) ;

```

Model transport /all/ ;

Solve transport using lp minimizing z ;

Display x.l, x.m ;

If you submit a file containing the statements above as input to GAMS , the transportation model will be formulated and solved. Details vary on how to invoke GAMS on different of computers, but the simplest ('no frills') way to call GAMS is to enter the word GAMS followed by the input file's name. You will see a number of terse lines describing the progress GAMS is making, including the name of the file onto which the output is being written. When GAMS has finished, examine this file, and if all has gone well the optimal shipments will be displayed at the bottom as follows.

	new-york	chicago	topeka
seattle	50.000	300.000	
san-diego	275.000		275.000

You will also receive the marginal costs (simplex multipliers) below.

	chicago	topeka
seattle		0.036
san-diego	0.009	

These results indicate, for example, that it is optimal to send nothing from Seattle to Topeka, but if you insist on sending one case it will add .036 \$K (or \$36.00) to the optimal cost.

4.11.2 Structure of a GAMS Model

For the remainder of the tutorial, we will discuss the basic components of a GAMS model, with reference to the example above. The basic components are listed in table [Table 2](#).

Table 2: The basic components of a GAMS model

Type	Component
Inputs	Sets Declaration Assignment of members
	Data (Parameters, Tables, Scalars) Declaration Assignment of values
	Variables Declaration Assignment of type
	Assignment of Variable Bounds and/or Initial Values (optional)
	Equations Declaration Definition
	Model and Solve Statements
	Display Statements (optional)
Outputs	Echo Prints
	Reference Maps
	Equation Listings
	Status Reports
	Solution Reports

There are optional input components, such as edit checks for bad data and requests for customized reports of results. Other optional advanced features include saving and restoring old models, and creating multiple models in a single run, but this tutorial will discuss only the basic components.

Before treating the individual components, we give a few general remarks.

1. A GAMS model is a collection of statements in the GAMS Language. The only rule governing the ordering of statements is that an entity of the model cannot be referenced before it is declared to exist.

2. GAMS statements may be laid out typographically in almost any style that is appealing to the user. Multiple lines per statement, embedded blank lines, and multiple statements per line are allowed. You will get a good idea of what is allowed from the examples in this tutorial, but precise rules of the road are given in the next Chapter.
3. When you are a beginning GAMS user, you should terminate every statement with a semicolon, as in our examples. The GAMS compiler does not distinguish between upper- and lowercase letters, so you are free to use either.
4. Documentation is crucial to the usefulness of mathematical models. It is more useful (and most likely to be accurate) if it is embedded within the model itself rather than written up separately. There are at least two ways to insert documentation within a GAMS model. First, any line that starts with an asterisk in column 1 is disregarded as a comment line by the GAMS compiler. Second, perhaps more important, documentary text can be inserted within specific GAMS statements.
5. As you can see from the list of input components above, the creation of GAMS entities involves two steps: a declaration and an assignment or definition. *Declaration* means declaring the existence of something and giving it a name. *Assignment* or *definition* means giving something a specific value or form. In the case of equations, you must make the declaration and definition in separate GAMS statements. For all other GAMS entities, however, you have the option of making declarations and assignments in the same statement or separately.
6. The names given to the entities of the model must start with a letter and can be followed by up to 62 more letters or digits.

4.11.3 Sets

Sets are the basic building blocks of a GAMS model, corresponding exactly to the indices in the algebraic representations of models. The Transportation example above contains just one **Set** statement:

Sets

```
i  canning plants / seattle, san-diego /
j  markets        / new-york, chicago, topeka / ;
```

The effect of this statement is probably self-evident. We declared two sets and gave them the names *i* and *j*. We also assigned members to the sets as follows:

$$i = \{\text{Seattle, San Diego}\}$$

$$j = \{\text{New York, Chicago, Topeka}\}.$$

You should note the typographical differences between the GAMS format and the usual mathematical format for listing the elements of a set. GAMS uses slashes '/' rather than curly braces '{}' to delineate the set simply because not all computer keyboards have keys for curly braces. Note also that multiword names like 'New York' have to be quoted ((e.g. 'New York' or "New York") or you must use hyphens instead of blanks (e.g. New-York').

The words after the set names in the **sets** statement above are called *text*. Text is optional. It is there only for internal documentation, serving no formal purpose in the model. The GAMS compiler makes no attempt to interpret the text, but it saves the text and '*parrots*' it back to you at various times for your convenience.

It was not necessary to combine the creation of sets *i* and *j* in one statement. We could have put them into separate statements as follows:

```
Set  i  canning plants / seattle, san-diego / ;
Set  j  markets        / new-york, chicago, topeka / ;
```

The placement of blank spaces and lines (as well as the choice of upper- or lowercase) is up to you. Each GAMS user tends to develop individual stylistic conventions. (The use of the singular `set` is also up to you. Using `set` in a statement that makes a single declaration and `sets` in one that makes several is good English, but GAMS treats the singular and plural synonymously.)

A convenient feature to use when you are assigning members to a set is the asterisk. It applies to cases when the elements follow a sequence. For example, the following are valid `set` statements in GAMS.

```
Set   t   time periods      /1991*2000/;
Set   m   machines         /mach1*mach24/;
```

Here the effect is to assign

$$t = \{1991, 1992, 1993, \dots, 2000\}$$

$$m = \{\text{mach}_1, \text{mach}_2, \dots, \text{mach}_{24}\}.$$

Note that set elements are stored as character strings, so the elements of t are not numbers.

Another convenient feature is the `alias` statement, which is used to give another name to a previously declared set. In the following example:

```
Alias (t, tp);
```

the name `tp` is like a t' in mathematical notation. It is useful in models that are concerned with the interactions of elements within the same set.

The sets `i`, `j`, `t`, and `m` in the statements above are examples of static sets, i.e., they are assigned their members directly by the user and do not change. GAMS has several capabilities for creating dynamic sets, which acquire their members through the execution of set-theoretic and logical operations. Dynamic sets are discussed in chapter [Dynamic Sets](#). Another valuable advanced feature is multidimensional sets, which are discussed in section [Multi-Dimensional Sets](#).

4.11.4 Data

The GAMS model of the transportation problem demonstrates three of the different formats that are allowable for entering data. The three formats are:

- Lists
- Tables
- Direct assignments

The next three subsections will discuss each of these formats in turn.

4.11.4.1 Data Entry by Lists

The first format is illustrated by the first Parameters statement of the example, which is repeated below.

Parameters

```

a(i)  capacity of plant i in cases
/     seattle      350
     san-diego    600 /

b(j)  demand at market j in cases
/     new-york    325
     chicago     300
     topeka      275 / ;

```

This statement has several effects. Again, they may be self-evident, but it is worthwhile to analyze them in detail. The statement declares the existence of two parameters, gives them the names *a* and *b*, and declares their *domains* to be *i* and *j*, respectively. (A domain is the set, or tuple of sets, over which a parameter, variable, or equation is defined.) The statement also gives documentary text for each parameter and assigns values of *a(i)* and *b(j)* for each element of *i* and *j*. It is perfectly acceptable to break this one statement into two, if you prefer, as follows.

```

Parameters a(i)  capacity of plant i in cases
/ seattle      350
  san-diego    600 / ;

Parameters b(j)  demand at market j in cases
/ new-york    325
  chicago     300
  topeka      275 / ;

```

Here are some points to remember when using the list format.

1. The list of domain elements and their respective parameter values can be laid out in almost any way you like. The only rules are that the entire list must be enclosed in slashes and that the element-value pairs must be separated by commas or entered on separate lines.
2. There is no semicolon separating the element-value list from the name, domain, and text that precede it. This is because the same statement is being used for declaration and assignment when you use the list format. (An element-value list by itself is not interpretable by GAMS and will result in an error message.)
3. The GAMS compiler has an unusual feature called [domain checking](#), which verifies that each domain element in the list is in fact a member of the appropriate set. For example, if you were to spell 'Seattle' correctly in the statement declaring `Set i` but misspell it as 'Seatlle' in a subsequent element-value list, the GAMS compiler would give you an error message that the element 'Seatlle' does not belong to the set *i*.
4. Zero is the default value for all parameters. Therefore, you only need to include the nonzero entries in the element-value list, and these can be entered in any order.
5. A scalar is regarded as a parameter that has no domain. It can be declared and assigned with a `Scalar` statement containing a *degenerate* list of only one value, as in the following statement from the transportation model.

```
Scalar f freight in dollars per case per thousand miles /90/;
```

If the domain of a parameter has two or more dimensions, it can still have its values entered by the list format. This is very useful for entering arrays that are sparse (having few non-zeros) and super-sparse (having few distinct non-zeros).

4.11.4.2 Data Entry by Tables

Optimization practitioners have noticed for some time that many of the input data for a large model are derived from relatively small tables of numbers. Thus, it is very useful to have the table format for data entry. An example of a two-dimensional table (or matrix) is provided in the transportation model:

```
Table d(i,j)  distance in thousands of miles
              new-york    chicago    topeka
seattle      2.5         1.7         1.8
san-diego    2.5         1.8         1.4  ;
```

The effect of this statement is to declare the parameter `d` and to specify its domain as the set of ordered pairs in the Cartesian product of `i` and `j`. The values of `d` are also given in this statement under the appropriate heading. If there are blank entries in the table, they are interpreted as zeroes.

As in the list format, GAMS will perform domain checking to make sure that the row and column names of the table are members of the appropriate sets. Formats for entering tables with more columns than you can fit on one line and for entering tables with more than two dimensions are given in [Chapter Data Entry: Parameters, Scalars and Tables](#).

4.11.4.3 Data Entry by Direct Assignment

The direct assignment method of data entry differs from the list and table methods in that it divides the tasks of parameter declaration and parameter assignment between separate statements. The transportation model contains the following example of this method.

```
Parameter c(i,j)  transport cost in thousands of dollars per case ;
              c(i,j) = f * d(i,j) / 1000 ;
```

It is important to emphasize the presence of the semicolon at the end of the first line. Without it, the GAMS compiler would attempt to interpret both lines as parts of the same statement. (GAMS would fail to discern a valid interpretation, so it would send you an error message.)

The effects of the first statement above are to declare the parameter `c`, to specify the domain `(i,j)`, and to provide some documentary text. The second statement assigns to `c(i,j)` the product of the values of the parameters `f` and `d(i,j)`. Naturally, this is legal in GAMS only if you have already assigned values to `f` and `d(i,j)` in previous statements.

The direct assignment above applies to all `(i,j)` pairs in the domain of `c`. If you wish to make assignments for specific elements in the domain, you enclose the element names in quotes. For example,

```
c('Seattle','New-York') = 0.40;
```

is a valid GAMS assignment statement.

The same parameter can be assigned a value more than once. Each assignment statement takes effect immediately and overrides any previous values. (In contrast, the same parameter may not be declared more than once. This is a GAMS error check to keep you from accidentally using the same name for two different things.)

The right-hand side of an assignment statement can contain a great variety of mathematical expressions and built-in functions. If you are familiar with a scientific programming language such as C, you will have no trouble in becoming comfortable writing assignment statements in GAMS. (Notice, however, that GAMS has some efficiencies not shared by C. For example, we were able to assign `c(i,j)` values for all `(i,j)` pairs without constructing 'loops'.)

The GAMS standard operations and supplied functions are given later. Here are some examples of valid assignments. In all cases, assume the left-hand-side parameter has already been declared and the right-hand-side parameters have already been assigned values in previous statements.

```

csquared      = sqrt(c);
e             = m*csquared;
w            = 1/lamda;
eq(i)        = sqrt( 2*demand(i)*ordcost(i)/holdcost(i));
t(i)         = min(p(i), q(i)/r(i), log(s(i)));
euclidean(i,j) = qrt(sqrt(xi(i) - xi(j) + sqrt(x2(i) - x2(j)));
present(j)   = future(j)*exp(-interest*time(j));

```

The summation and product operators to be introduced later can also be used in direct assignments.

4.11.5 Variables

The decision variables (or endogenous variables) of a GAMS-expressed model must be declared with a **Variables** statement. Each variable is given a name, a domain if appropriate, and (optionally) text. The transportation model contains the following example of a **Variables** statement.

```

Variables
  x(i,j)  shipment quantities in cases
  z       total transportation costs in thousands of dollars ;

```

This statement results in the declaration of a shipment variable for each (i,j) pair. (You will see in chapter [Equations](#), how GAMS can handle the typical real-world situation in which only a subset of the (i,j) pairs is allowable for shipment.)

The z variable is declared without a domain because it is a scalar quantity. Every GAMS optimization model must contain one such variable to serve as the quantity to be minimized or maximized.

Once declared, every variable must be assigned a type. A selection of permissible types are given in table [Table 3](#). For a full list, see section [Variable Types](#).

Table 3 : Permissible variable types

<i>Variable Type</i>	<i>Allowed Range of Variable</i>
free(default)	$-\infty$ to $+\infty$
positive	0 to $+\infty$
negative	$-\infty$ to 0
binary	0 or 1
integer	0, 1, ..., 100 (default)

The variable that serves as the quantity to be optimized must be a scalar and must be of the **free** type. In our transportation example, z is kept free by default, but x(i,j) is constrained to non-negativity by the following statement.

```
Positive variable x ;
```

Note that the domain of x should not be repeated in the type assignment. All entries in the domain automatically have the same variable type.

Section [The .lo, .l, .up, .m Database](#) describes how to assign lower bounds, upper bounds, and initial values to variables

4.11.6 Equations

The power of algebraic modeling languages like GAMS is most apparent in the creation of the equations and inequalities that comprise the model under construction. This is because whenever a group of equations or inequalities has the same algebraic structure, all the members of the group are created simultaneously, not individually.

4.11.6.1 Equation Declaration

Equations must be declared and defined in separate statements. The format of the declaration is the same as for other GAMS entities. First comes the keyword, `Equations` in this case, followed by the name, domain and text of one or more groups of equations or inequalities being declared. Our transportation model contains the following equation declaration:

```
Equations
    cost          define objective function
    supply(i)     observe supply limit at plant i
    demand(j)    satisfy demand at market j ;
```

Keep in mind that the word `Equation` has a broad meaning in GAMS. It encompasses both equality and inequality relationships, and a GAMS equation with a single name can refer to one or several of these relationships. For example, `cost` has no domain so it is a single equation, but `supply` refers to a set of inequalities defined over the domain `i`.

4.11.6.2 GAMS Summation (and Product) Notation

Before going into equation definition we describe the summation notation in GAMS. Remember that GAMS is designed for standard keyboards and line-by-line input readers, so it is not possible (nor would it be convenient for the user) to employ the standard mathematical notation for summations.

The summation notation in GAMS can be used for simple and complex expressions. The format is based on the idea of always thinking of a summation as an operator with two arguments: `Sum(index of summation, summand)`. A comma separates the two arguments, and if the first argument requires a comma then it should be in parentheses. The second argument can be any mathematical expression including another summation.

As a simple example, the transportation problem contains the expression

```
Sum(j, x(i,j))
```

that is equivalent to $\sum_j x_{ij}$.

A slightly more complex summation is used in the following example:

```
Sum((i,j), c(i,j)*x(i,j))
```

that is equivalent to $\sum_i \sum_j c_{ij}x_{ij}$.

The last expression could also have been written as a nested summation as follows:

```
Sum(i, Sum(j, c(i,j)*x(i,j)))
```

In section [Conditional Indexed Operations](#), we describe how to use the [dollar operator](#) to impose restrictions on the summation operator so that only the elements of *i* and *j* that satisfy specified conditions are included in the summation.

Products are defined in GAMS using exactly the same format as summations, replacing `Sum` by `Prod`. For example,

```
prod(j, x(i, j))
```

is equivalent to: $\prod_j x_{ij}$.

Summation and product operators may be used in direct assignment statements for parameters. For example,

```
scalar totsupply    total supply over all plants;
totsupply = sum(i, a(i));
```

4.11.6.3 Equation Definition

Equation definitions are the most complex statements in GAMS in terms of their variety. The components of an equation definition are, in order:

1. The name of the equation being defined
2. The domain
3. Domain restriction condition (optional)
4. The symbol '`..`'
5. Left-hand side expression
6. Relational operator: `=l=`, `=e=`, `=g=` or others. For a complete list, see [Table Equation Types](#).
7. Right-hand side expression

The transportation example contains three of these statements.

```
cost ..          z =e= sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..    sum(j, x(i,j)) =l= a(i) ;
demand(j) ..    sum(i, x(i,j)) =g= b(j) ;
```

Here are some points to remember.

- The power to create multiple equations with a single GAMS statement is controlled by the domain. For example, the definition for the `demand` constraint will result in the creation of one constraint for each element of the domain *j*, as shown in the following excerpt from the GAMS output.

```
demand(new-york)..x(seattle,new-york) + x(san-diego,new-york)=g=325 ;
demand(chicago).. x(seattle,chicago) + x(san-diego,chicago) =g=300 ;
demand(topeka).. x(seattle,topeka) + x(san-diego,topeka) =g=275 ;
```

- The key idea here is that the definition of the demand constraints is exactly the same whether we are solving the toy-sized example above or a 20,000-node real-world problem. In either case, the user enters just one generic equation algebraically, and GAMS creates the specific equations that are appropriate for the model instance at hand. (Using some other optimization packages, something like the extract above would be part of the input, not the output.)
- In many real-world problems, some of the members of an equation domain need to be omitted or differentiated from the pattern of the others because of an exception of some kind. GAMS can readily accommodate this loss of structure using a powerful feature known as the *dollar* or *such-that* operator, which is not illustrated here. The domain restriction feature can be absolutely essential for keeping the size of a real-world model within the range of solvability.
- The relational operators have the following meanings:
 - =l= less than or equal to
 - =g= greater than or equal to
 - =e= equal to
- It is important to understand the difference between the symbols '=' and '=e='. The '=' symbol is used only in direct assignments, and the '=e=' symbol is used only in equation definitions. These two contexts are very different. A direct assignment gives a desired value to a parameter before the solver is called. An equation definition also describes a desired relationship, but it cannot be satisfied until after the solver is called. It follows that equation definitions must contain variables and direct assignments must not.
- Variables can appear on the left or right-hand side of an equation or both. The same variable can appear in an equation more than once. The GAMS processor will automatically convert the equation to its equivalent standard form (variables on the left, no duplicate appearances) before calling the solver.
- An equation definition may appear anywhere in the GAMS input, provided the equation and all variables and parameters to which it refers were previously declared. (Note that it is permissible for a parameter appearing in the equation to be assigned or reassigned a value after the definition. This is useful when doing multiple model runs with one GAMS input.) The equations need not be defined in the same order in which they were declared.

4.11.7 Objective Function

This is just a reminder that GAMS has no explicit entity called the *objective function*. To specify the function to be optimized, you must create a variable, which is free (unconstrained in sign) and scalar-valued (has no domain) and which appears in an equation definition that equates it to the objective function.

4.11.8 Model and Solve Statements

The word `model` has a very precise meaning in GAMS. It is simply a collection of equations. Like other GAMS entities, it must be given a name in a declaration. The format of the declaration is the keyword `model` followed by the name of the model, followed by a list of equation names enclosed in slashes. If all previously defined equations are to be included, you can enter `/all/` in place of the explicit list. In our example, there is one `model` statement:

```
model transport /all/ ;
```

This statement may seem superfluous, but it is useful to advanced users who may create several models in one GAMS run. If we were to use the explicit list rather than the shortcut `/all/`, the statement would be written as

```
model transport / cost, supply, demand / ;
```

The domains are omitted from the list since they are not part of the equation name. The list option is used when only a subset of the existing equations comprises a specific model (or sub-model) being generated.

Once a model has been declared and assigned equations, we are ready to call the solver. This is done with a `solve` statement, which in our example is written as

```
solve transport using lp minimizing z ;
```

The format of the solve statement is as follows:

1. The key word `solve`
2. The name of the model to be solved
3. The key word `using`
4. An available solution procedure. A complete list is given below. For further details, see section [Classification of Models](#).

Solution	Description
lp	for linear programming
qcp	for quadratic constraint programming
nlp	for nonlinear programming
dnlp	for nonlinear programming with discontinuous derivatives
mip	for mixed integer programming
rmip	for relaxed mixed integer programming
miqcp	for mixed integer quadratic constraint programming
rmiqcp	for relaxed mixed integer quadratic constraint programming
minlp	for mixed integer nonlinear programming
rminlp	for relaxed mixed integer nonlinear programming
mcp	for mixed complementarity problems
mpec	for mathematical programs with equilibrium constraints
rmpec	for relaxed mathematical program with equilibrium constraints
cns	for constrained nonlinear systems
emp	for extended mathematical programming

5. The keyword 'minimizing' or 'maximizing'
6. The name of the variable to be optimized

4.11.9 Display Statements

The `solve` statement will cause several things to happen when executed. The specific instance of interest of the model will be generated, the appropriate data structures for inputting this problem to the solver will be created, the solver will be invoked, and the output from the solver will be printed to a file. To get the optimal values of the primal and/or dual variables, we can look at the solver output, or, if we wish, we can request a display of these results from GAMS. Our example contains the following statement:

```
display x.l, x.m ;
```

that calls for a printout of the final levels, `x.l`, and marginal (or reduced costs), `x.m`, of the shipment variables, `x(i, j)`. GAMS will automatically format this printout in to dimensional tables with appropriate headings.

4.11.10 The .lo, .l, .up, .m Database

GAMS was designed with a small database system in which records are maintained for the variables and equations. The most important fields in each record are:

```
.lo  lower bound
.l   level or primal value
.up  upper bound
.m   marginal or dual value
```

The format for referencing these quantities is the variable or equation's name followed by the field's name, followed (if necessary) by the domain (or an element of the domain).

GAMS allows the user complete read-and write-access to the database. This may not seem remarkable to you now, but it can become a greatly appreciated feature in advanced use. Some examples of use of the database follow.

4.11.10.1 Assignment of Variable Bounds and/or Initial Values

The lower and upper bounds of a variable are set automatically according to the variable's type (**free**, **positive**, **negative**, **binary**, or **integer**), but these bounds can be overwritten by the GAMS user. Some examples follow.

```
x.up(i,j)   = capacity(i,j) ;
x.lo(i,j)   = 10.0 ;
x.up('seattle','new-york') = 1.2*capacity('seattle','new-york') ;
```

It is assumed in the first and third examples that `capacity(i, j)` is a parameter that was previously declared and assigned values. These statements must appear after the variable declaration and before the `Solve` statement. All the mathematical expressions available for direct assignments are usable on the right-hand side.

In nonlinear programming it is very important for the modeler to help the solver by specifying as narrow a range as possible between lower and upper bound. It is also very helpful to specify an initial solution from which the solver can start searching for the optimum. For example, in a constrained inventory model, the variables are `quantity(i)`, and it is known that the optimal solution to the unconstrained version of the problem is a parameter called `eoq(i)`. As a guess for the optimum of the constrained problem we enter

```
quantity.l(i) = 0.5*eoq(i) ;
```

(The default initial level is zero unless zero is not within the bounded range, in which case it is the bound closest to zero.)

It is important to understand that the `.lo` and `.up` fields are entirely under the control of the GAMS user. The `.l` and `.m` fields, in contrast, can be initialized by the user but are then controlled by the solver.

4.11.10.2 Transformation and Display of Optimal Values

(This section may be skipped on first reading if desired.)

After the optimizer is called via the `solve` statement, the values it computes for the primal and dual variables are placed in the database in the `.l` and `.m` fields. We can then read these results and transform and display them with GAMS statements.

For example, in the transportation problem, suppose we wish to know the percentage of each market's demand that is filled by each plant. After the solve statement, we would enter

```
parameter pctx(i,j)  perc of market j's demand filled by plant i;
pctx(i,j) = 100.0*x.l(i,j)/b(j) ;
display pctx ;
```

Appending these commands to the original transportation problem input results in the following output:

```
pctx      percent of market j's demand filled by plant I
           new-york    chicago    topeka
seattle    15.385     100.000
san-diego  84.615                100.000
```

For an example involving marginal, we briefly consider the *ratio constraints* that commonly appear in blending and refining problems. These linear programming models are concerned with determining the optimal amount of each of several available raw materials to put into each of several desired finished products. Let $y(i,j)$ be the variable for the number of tons of raw material i put into finished product j . Suppose the *ratio constraint* is that no product can consist of more than 25 percent of one ingredient, that is,

$$y(i,j)/q(j) \leq .25 ;$$

for all i, j . To keep the model linear, the constraint is written as

$$\text{ratio}(i,j) \dots y(i,j) - .25*q(j) \leq 0.0 ;$$

rather than explicitly as a ratio.

The problem here is that $\text{ratio.m}(i,j)$, the marginal value associated with the linear form of the constraint, has no intrinsic meaning. At optimality, it tells us by at most how much we can benefit from relaxing the linear constraint to

$$y(i,j) - .25*q(j) \leq 1.0 ;$$

Unfortunately, this relaxed constraint has no realistic significance. The constraint we are interested in relaxing (or tightening) is the nonlinear form of the ration constraint. For example, we would like to know the marginal benefit arising from changing the ratio constraint to

$$y(i,j)/q(j) \leq .26 ;$$

We can in fact obtain the desired marginals by entering the following transformation on the undesired marginals:

```
parameter amr(i,j)  appropriate marginal for ratio constraint ;
amr(i,j) = ratio.m(i,j)*0.01*q.l(j) ;
display amr ;
```

Notice that the assignment statement for `amr` accesses both `.m` and `.l` records from the database. The idea behind the transformation is to notice that

$$y(i,j)/q(j) \leq .26 ;$$

is equivalent to

$$y(i,j) - .25*q(j) \leq 0.01*q(j) ;$$

4.11.11 GAMS Output

The default output of a GAMS run is extensive and informative. For a complete discussion, see chapter [GAMS Output](#). This tutorial discusses output partially as follows:

- Echo Print
- Reference Maps
- Status Reports
- Error Messages
- Model Statistics
- Solution Reports

A great deal of unnecessary anxiety has been caused by textbooks and users' manuals that give the reader the false impression that flawless use of advanced software should be easy for anyone with a positive pulse rate. GAMS is designed with the understanding that even the most experienced users will make errors. GAMS attempts to catch the errors as soon as possible and to minimize their consequences.

4.11.11.1 Echo Prints

Whether or not errors prevent your optimization problem from being solved, the first section of output from a GAMS run is an echo, or copy, of your input file. For the sake of future reference, GAMS puts line numbers on the left-hand side of the echo. For our transportation example, which luckily contained no errors, the echo print is as follows:

```

2 Sets
3     i  canning plants  / seattle, san-diego /
4     j  markets        / new-york, chicago, topeka / ;
5
6 Parameters
7
8     a(i) capacity of plant i in cases
9         /   seattle    350
10        /   san-diego  600 /
11
12    b(j) demand at market j in cases
13        /   new-york   325
14        /   chicago    300
15        /   topeka    275 / ;
16
17 Table d(i,j) distance in thousands of miles
18           new-york      chicago      topeka
19  seattle      2.5         1.7         1.8
20  san-diego    2.5         1.8         1.4 ;
21
22 Scalar f  freight in dollars per case per thousand miles /90/ ;
23
24 Parameter c(i,j) transport cost in thousands of dollars per case ;
25
26         c(i,j) = f * d(i,j) / 1000 ;
27
28 Variables
```

```

29     x(i,j)  shipment quantities in cases
30     z      total transportation costs in thousands of dollars ;
31
32 Positive Variable x ;
33
34 Equations
35     cost      define objective function
36     supply(i) observe supply limit at plant i
37     demand(j) satisfy demand at market j ;
38
39 cost ..      z =e= sum((i,j), c(i,j)*x(i,j)) ;
40
41 supply(i) .. sum(j, x(i,j)) =l= a(i) ;
42
43 demand(j) .. sum(i, x(i,j)) =g= b(j) ;
44
45 Model transport /all/ ;
46
47 Solve transport using lp minimizing z ;
48
49 Display x.l, x.m ;
50

```

The reason this echo print starts with line number 2 rather than line number 1 is because the input file contains a *dollar-print-control* statement. This type of instruction controls the output printing, but since it has nothing to do with defining the optimization model, it is omitted from the echo. The dollar print controls must start in column 1.

```
$title a transportation model
```

The `$title` statement causes the subsequent text to be printed at the top of each page of output. Other available instructions are given in chapter [Dollar Control Options](#).

4.11.11.2 Error Messages

When the GAMS compiler encounters an error in the input file, it inserts a coded error message inside the echo print on the line immediately following the scene of the offense. These messages always start with `****` and contain a '\$' directly below the point at which the compiler thinks the error occurred. The '\$' is followed by a numerical error code, which is explained after the echo print. Several examples follow.

Example 1 : Entering the statement

```
set q quarterly time periods / spring, sos1, fall, wtr / ;
```

results in the echo

```

1 set q quarterly time periods / spring, sos1, fall, wtr / ;
****                                     $160

```

In this case, the GAMS compiler indicates that something is wrong with the set element sum. At the bottom of the echo print, we see the interpretation of error code 160:

```

Error Message
160 Unique element expected....

```

The problem is that `sos1` is a reserved word, which can not be used as identifiers in general. The complete list of reserved words is shown in [this chapter](#). Thus our set element must have a unique name like `'summer'`. This is a common beginner's error.

Example 2 : Another common error is the omission of a semicolon preceding a direct assignment or equation definition. In our transportation example, suppose we omit the semicolon prior to the assignment of `c(i,j)`, as follows.

```
Parameter c(i,j) transport cost in 1000s of dollars per case
c(i,j) = f * d(i,j) / 1000 ;
```

Here is the resulting output.

```
16 Parameter c(i,j) transport cost in 1000s of dollars per case
17          c(i,j) = f * d(i,j)/1000
****                $97          $195,96,409
Error Message
96 Blank needed between identifier and text
   (-or- illegal character in identifier)
   (-or- check for missing ';' on previous line)
97 Explanatory text can not start with '$', '=', or '..'
   (-or- check for missing ';' on previous line)
195 Symbol redefined with a different type
409 Unrecognizable item - skip to find a new statement
     looking for a ';' or a key word to get started again
```

It is not uncommon for one little offense like our missing semicolon to generate five intimidating error messages. The lesson here is: concentrate on fixing the first and ignore the other! The first error detected (in line 17), code 97, indicate that GAMS thinks the symbols in line 17 are a continuation of the documentary text at the end of line 16 rather than a direct assignment as we intended. The error message also appropriately advises us to check the preceding line for a missing semicolon.

Unfortunately, you cannot always expect error messages to be so accurate in their advice. The compiler cannot read your mind. It will at times fail to comprehend your intentions, so learn to detect the causes of errors by picking up the clues that abound in the GAMS output. For example, the missing semicolon could have been detected by looking up the `c` entry in the cross-reference list (to be explained in the next section) and noticing that it was never assigned.

SYMBOL	TYPE	REFERENCES
c	PARAM	declared 15 ref 17

Example 3 : Many errors are caused merely by spelling mistakes and are caught before they can be damaging. For example, with `'Seattle'` spelled in the table differently from the way it was introduced in the set declaration, we get the following error message.

```
4 sets
5     i   canning plants /seattle, san-diego /
6     j   markets /new-york, chicago, topeka / ;
7
8 table d(i,j) distance in thousand of miles
9     new-york  chicago  topeka
10    seatle    2.5      1.7      1.8
****          $170
11    san-diego  2.5      1.8          1.4 ;
Error Message
170 Domain violation for element
```

Example 4 : Similarly, if we mistakenly enter `dem(j)` instead of `b(j)` as the right-hand side of the demand constraint, the result is

```

45 demand(j) .. sum(i, x(i,j) ) =g= dem(j) ;
****                               $140
Error Message
140 Unknown symbol

```

Example 5 : The next example is a mathematical error, which is sometimes committed by novice modelers and which GAMS is adept at catching. The following is mathematically inconsistent and, hence, is not an interpretable statement.

$$\text{For all } i, \sum_i x_{ij} = 100$$

There are two errors in this equation, both having to do with the control of indices. Index i is over-controlled and index j is under-controlled.

You should see that index i is getting conflicting orders. By appearing in the quantifier '*for all i*', it is supposed to remain fixed for each instance of the equation. Yet, by appearing as an index of summation, it is supposed to vary. It can't do both. On the other hand, index j is not controlled in any way, so we have no way of knowing which of its possible values to use.

If we enter this meaningless equation into GAMS, both errors are correctly diagnosed.

```

meaninglss(i) .. sum(i, x(i,j)) =e= 100 ;
****                $125  $149
Error Messages
125 Set is under control already [This refers to set i.]
149 Uncontrolled set entered as constant [This refers to set j.]

```

More information about error reporting is given in section [Error Reporting](#). Comprehensive error detection and well-designed error messages are a big help in getting models implemented quickly and correctly.

4.11.11.3 Reference Maps

The next section of output, which is the last if errors have been detected, is a pair of *reference maps* that contain summaries and analyses of the input file for the purposes of debugging and documentation.

The first reference map is a *cross-reference map* such as one finds in most modern compilers. It is an alphabetical, cross-referenced list of all the entities (sets, parameters, variables, and equations) of the model. The list shows the type of each entity and a coded reference for each appearance of the entity in the input. The cross-reference map for our transportation example is as follows (we do not display all tables). To turn the *cross-reference map* on, please add the line

```
$onSymXRef
```

at the beginning of your model right after the `$title` statement.

SYMBOL	TYPE	REFERENCES
a	PARAM	declared 9 defined 10 ref 42
b	PARAM	declared 13 defined 14 ref 44
c	PARAM	declared 25 assigned 27 ref 40
cost	EQU	declared 36 defined 40 impl-asn 48 ref 46
d	PARAM	declared 18 defined 18 ref 27
demand	EQU	declared 38 defined 44 impl-asn 48 ref 46
f	PARAM	declared 23 defined 23 ref 27
i	SET	declared 4 defined 4 ref 9 18 25 27
j	SET	declared 5 defined 5 ref 13 18 25 27
supply	EQU	declared 37 defined 42 impl-asn 48 ref 46
transport	MODEL	declared 46 defined 46 impl-asn 48 ref 48
x	VAR	declared 30 impl-asn 48 ref 33 40 42 44
z	VAR	declared 31 impl-asn 48 ref 40 48

For example, the cross-reference list tells us that the symbol `a` is a parameter that was declared in line 9, defined (assigned value) in line 10, and referenced in line 42. The symbol `i` has a more complicated entry in the cross-reference list. It is shown to be a set that was declared and defined in line 4. It is referenced once in lines 9, 18, 25, 27, 30, 37, 44 and referenced twice in lines 40 and 44. Set `i` is also used as a controlling index in a summation, equation definition or direct parameter assignment in lines 27, 40, 42 and 44.

For the GAMS novice, the detailed analysis of the cross-reference list may not be important. Perhaps the most likely benefit he or she will get from the reference maps will be the discovery of an unwanted entity that mistakenly entered the model owing to a punctuation or syntax error.

The second part of the reference map is a list of model entities grouped by type and listed with their associated documentary text. For example, this list is as follows.

SETS

```
i      canning plants
j      markets
```

PARAMETERS

```
a      capacity of plant i in cases
b      demand at market j in cases
c      transport cost in thousands of dollars per case
d      distance in thousands of miles
f      freight in dollars per case per thousand miles
```

VARIABLES

```
x      shipment quantities in cases
z      total transportation costs in thousands of dollars
```

EQUATIONS

```
cost   define objective function
demand satisfy demand at market j
supply observe supply limit at plant i
```

MODELS

```
transport
```

4.11.11.4 Equation Listings

Once you succeed in building an input file devoid of compilation errors, GAMS is able to generate a model. The question remains, and only you can answer it, does GAMS generate the model you intended?

The equation listing is probably the best device for studying this extremely important question. A product of the solve command, the equation listing shows the specific instance of the model that is created when the current values of the sets and parameters are plugged into the general algebraic form of the model. For example, the generic demand constraint given in the input file for the transportation model is

```
demand(j) .. sum(i, x(i,j)) =g= b(j) ;
```

while the equation listing of specific constraints is

```
-----demand =g= satisfy demand at market j
demand(new-york).. x(seattle, new-york) +x(san-diego, new-york) =g= 325 ;
demand(chicago).. x(seattle, chicago) +x(san-diego, chicago ) =g= 300 ;
demand(topeka).. x(seattle, topeka) +x(san-diego, topeka) =g= 275 ;
```

The default output is a maximum of three specific equations for each generic equation. To change the default, insert an input statement prior to the solve statement:

```
option limrow = r ;
```

where *r* is the desired number.

The default output also contains a section called the column listing, analogous to the equation listing, which shows the coefficients of three specific variables for each generic variable. This listing would be particularly useful for verifying a GAMS model that was previously implemented in MPS format. To change the default number of specific column printouts per generic variable, the above command can be extended:

```
option limrow = r, limcol = c ;
```

where *c* is the desired number of columns. (Setting *limrow* and *limcol* to 0 is a good way to reduce the size of your *lst* file after your model has been debugged.) In nonlinear models, the GAMS equation listing shows first-order Taylor approximations of the nonlinear equations. The approximations are taken at the starting values of the variables.

4.11.11.5 Model Statistics

The last section of output that GAMS produces before invoking the solver is a group of statistics about the model's size, as shown below for the transportation example.

MODEL STATISTICS

BLOCKS OF EQUATIONS	3	SINGLE EQUATIONS	6
BLOCKS OF VARIABLES	2	SINGLE VARIABLES	7
NON ZERO ELEMENTS	19		

The **BLOCK** counts refer to the number of generic equations and variables. The **SINGLE** counts refer to individual rows and columns in the specific model instance being generated. For nonlinear models, some other statistics are given to describe the degree of non-linearity in the problem.

4.11.11.6 Status Reports

After the solver executes, GAMS prints out a brief *Solve Summary* whose two most important entries are SOLVER STATUS and the MODEL STATUS. For our transportation problem the solve summary is as follows:

```

                S O L V E      S U M M A R Y

MODEL   TRANSPORT      OBJECTIVE  z
TYPE    LP              DIRECTION MINIMIZE
SOLVER  CPLEX           FROM LINE 49

**** SOLVER STATUS      1 Normal Completion
**** MODEL STATUS      1 Optimal
**** OBJECTIVE VALUE    153.6750

RESOURCE USAGE, LIMIT    0.031      1000.000
ITERATION COUNT, LIMIT  4      2000000000

```

The status reports are preceded by the same **** string as an error message, so you should probably develop the habit of searching for all occurrences of this string whenever you look at an output file for the first time. The desired solver status is 1 NORMAL COMPLETION, but there are other possibilities, documented in section [The Solve Summary](#), which relate to various types of errors and mishaps.

There are eleven possible model statuses, including the usual linear programming termination states (1 Optimal, 3 Unbounded, 4 Infeasible), and others relating to nonlinear and integer programming. In nonlinear programming, the status to look for is 2 Locally Optimal. The most the software can guarantee for nonlinear programming is a local optimum. The user is responsible for analyzing the convexity of the problem to determine whether local optimality is sufficient for global optimality. In integer programming, the status to look for is 8 Integer Solution. This means that a feasible integer solution has been found. More detail follows as to whether the solution meets the relative and absolute optimality tolerances that the user specifies.

4.11.11.7 Solution Reports

If the solver status and model status are acceptable, then you will be interested in examining the results of the optimization. The results are first presented in as standard mathematical programming output format, with the added feature that rows and columns are grouped and labeled according to names that are appropriate for the specific model just solved. In this format, there is a line of printout for each row and column giving the lower limit, level, upper limit, and marginal. Generic equation block and the column output group the row output by generic variable block. Set element names are embedded in the output for easy reading. In the transportation example, the solver outputs for supply(i), demand(j), and x(i,j) are as follows:

```

---- EQU supply      observe supply limit at plant i

          LOWER      LEVEL      UPPER      MARGINAL

seattle      -INF      350.000  350.000      EPS
san-diego    -INF      550.000  600.000      .

---- EQU demand     satisfy demand at market j

          LOWER      LEVEL      UPPER      MARGINAL

```

chicago  300.000  300.000  +INF  0.153
topeka    275.000  275.000  +INF  0.126

```

```

---- VAR x          shipment quantities in cases

                LOWER    LEVEL    UPPER    MARGINAL

seattle .new-york    .      50.000  +INF     .
seattle .chicago   .      300.000 +INF     .
seattle .topeka     .        .    +INF     0.036
san-diego.new-york .      275.000 +INF     .
san-diego.chicago .        .    +INF     0.009
san-diego.topeka   .      275.000 +INF     .

```

The single dots '.' in the output represent zeroes. The entry **EPS**, which stands for *epsilon*, mean very small but nonzero. In this case, **EPS** indicates degeneracy. (The slack variable for the Seattle supply constraint is in the basis at zero level. The marginal is marked with **EPS** rather than zero to facilitate restarting the optimizer from the old basis.)

If the solvers results contain either infeasibilities or marginal costs of the wrong sign, then the offending entries are marked with **INFES** or **NOPT**, respectively. If the problem terminates unbounded, then the rows and columns corresponding to extreme rays are marked **UNBND**.

At the end of the solvers solution report is a very important *report summary*, which gives a tally of the total number of non-optimal, infeasible, and unbounded rows and columns. For our example, the report summary shows all zero tallies as desired.

```

**** REPORT SUMMARY :      0      NONOPT
                          0      INFEASIBLE
                          0      UNBOUNDED

```

After the solver's report is written, control is returned from the solver back to GAMS. All the levels and marginals obtained by the solver are entered into the GAMS database in the .l and .m fields. These values can then be transformed and displayed in any desired report. As noted earlier, the user merely lists the quantities to be displayed, and GAMS automatically formats and labels an appropriate array. For example, the input statement.

```
display x.l, x.m ;
```

results in the following output.

```

----      50 VARIABLE  x.L          shipment quantities in cases

                new-york    chicago    topeka

seattle      50.000    300.000
san-diego    275.000                275.000

----      50 VARIABLE  x.M          shipment quantities in cases

                chicago    topeka

seattle                0.036
san-diego      0.009

```

As seen in reference maps, equation listings, solution reports, and optional displays, GAMS saves the documentary text and '*parrots*' it back throughout the output to help keep the model well documented.

4.11.12 Summary

This tutorial has demonstrated several of the design features of GAMS that enable you to build practical optimization models quickly and effectively. The following discussion summarizes the advantages of using an algebraic modeling language such as GAMS versus a matrix generator or conversational solver.

- By using an algebra-based notation, you can describe an optimization model to a computer nearly as easily as you can describe it to another mathematically trained person.
- Because an algebraic description of a problem has generality, most of the statements in a GAMS model are reusable when new instances of the same or related problems arise. This is especially important in environments where models are constantly changing.
- You save time and reduce generation errors by creating whole sets of closely related constraints in one statement.
- You can save time and reduce input errors by providing formulae for calculating the data rather than entering them explicitly.
- The model is self-documenting. Since the tasks of model development and model documentation can be done simultaneously, the modeler is much more likely to be conscientious about keeping the documentation accurate and up to date.
- The output of GAMS is easy to read and use. The solution report from the solver is automatically reformatted so that related equations and variables are grouped together and appropriately labeled. Also, the `display` command allows you to modify and tabulate results very easily.
- If you are teaching or learning modeling, you can benefit from the insistence of the GAMS compiler that every equation be mathematically consistent. Even if you are an experienced modeler, the hundreds of ways in which errors are detected should greatly reduce development time.
- By using the *dollar* operator and other advanced features not covered in this tutorial, one can efficiently implement large-scale models. Specific applications of the dollar operator include:
 1. It can enforce logical restrictions on the allowable combinations of indices for the variables and equations to be included in the model. You can thereby screen out unnecessary rows and columns and keep the size of the problem within the range of solvability.
 2. It can be used to build complex summations and products, which can then be used in equations or customized reports.
 3. It can be used for issuing warning messages or for terminating prematurely conditioned upon context-specific data edits.

4.12 Quick Start Tutorial

GAMS (the General Algebraic Modeling System) is a high-level modeling system for mathematical programming problems. This tutorial is aimed at modelers who are new to GAMS and are looking for a quick introduction to the core features of GAMS. Note that the text contains many links to the GAMS User's Guide for further exploration. Observe that this tutorial is adapted from the Quick Start Tutorial from Bruce McCarl. Another introductory text is the tutorial [A GAMS Tutorial by Richard E. Rosenthal](#).

4.12.1 Three Basic Models

Most modelers who are interested in GAMS have one (or more) of the following backgrounds:

- They wish to solve constrained optimization problems with objective functions.
- They are looking for a system to solve general equilibrium problems that arise in various areas of economics.
- They wish to solve nonlinear systems of equations that arise in engineering.

GAMS is well equipped to model and solve all three types of problems. We will start by introducing examples for all three areas and the discussions that will follow will refer to these three basic examples.

4.12.1.1 First Example: Solving a Linear Programming Problem (LP)

The simplest constrained optimization problem is an LP. Assume we wish to solve the following LP that represents a simple farm model where profit is maximized:

$$\begin{array}{rllll}
 \max & 109X_{corn} & + & 90X_{wheat} & + & 115X_{cotton} & & \\
 s.t. & X_{corn} & + & X_{wheat} & + & X_{cotton} & \leq & 100 \quad (\text{land}) \\
 & 6X_{corn} & + & 4X_{wheat} & + & 8X_{cotton} & \leq & 500 \quad (\text{labor}) \\
 & & & & & X_{corn} & \geq & 0 \quad (\text{nonnegativity}) \\
 & & & & & X_{wheat} & \geq & 0 \quad (\text{nonnegativity}) \\
 & & & & & X_{cotton} & \geq & 0 \quad (\text{nonnegativity})
 \end{array}$$

Note that there are three decision variables: X_{corn} denotes the land assigned to growing corn, X_{wheat} is the land assigned to growing wheat and X_{cotton} represents the land where cotton is grown. In the first line the total profit is expressed as a function of the land allotted to the three crops, the multipliers represent the expected profit per acre depending of the type of crop. The first inequality imposes a limit on the available land, the second inequality imposes a limit on the available labor and the final three lines restrict the decision variables to nonnegative values.

This problem may be expressed in GAMS as follows:

```

Positive Variables   Xcorn, Xwheat, Xcotton;
Variables           Z;

Equations           obj, land, labor;

obj..  Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
land..           Xcorn + Xwheat + Xcotton =l= 100;
labor..          6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;

Model farmproblem / obj, land, labor /;

solve farmproblem using LP maximizing Z;

```

We will analyze this formulation and discuss every part of it after introducing the other two basic examples.

4.12.1.2 Second Example: Solving for an Economic Equilibrium

The simplest general equilibrium model is the single good, single market problem. Assume we wish to solve the following equilibrium problem:

$$\begin{array}{ll}
 \text{Demand Price:} & P \geq P_d = 6 - 0.3Q_d \\
 \text{Supply Price:} & P \leq P_s = 1 + 0.2Q_s \\
 \text{Quantity Equilibrium:} & Q_s \geq Q_d \\
 \text{Nonnegativity:} & P \geq 0 \\
 & Q_s \geq 0 \\
 & Q_d \geq 0
 \end{array}$$

Here P is the market clearing price, P_d is the demand curve, Q_d denotes the quantity demanded, P_s the supply curve and Q_s the quantity supplied. Note that this is a problem in 3 equations and 3 variables. The variables are P , Q_d , and Q_s . Note that P_d and P_s are not variables, since they can be computed from the equality relations.

Usually all equality constraints are used for such a set up. However, we will use a more general setup, because it relaxes some assumptions and more accurately depicts a model ready to be implemented in GAMS. In particular, we permit the case where the supply curve price intercept may be above the demand curve price intercept and thus the market may clear with a nonzero price but a zero quantity. In addition, we allow the market price to be above the demand curve price and below the supply curve price. We also impose some additional conditions based on Walras' Law to ensure a proper solution in such cases.

$$\begin{array}{l}
 Q_d(P - P_d) = 0 \quad \text{or} \quad Q_d(P_d - (6 - 0.3Q_d)) = 0 \\
 Q_s(P - P_s) = 0 \quad \text{or} \quad Q_s(P_s - (1 + 0.2Q_s)) = 0 \\
 P(Q_s - Q_d) = 0
 \end{array}$$

Here the quantity demanded is nonzero only if the market clearing price equals the demand curve price, the quantity supplied is nonzero only if the market clearing price equals the supply curve price and the market clearing price is only nonzero if $Q_s = Q_d$.

The simplest GAMS formulation is given below. Note that we needed to rearrange the equation `Psupply` in order to achieve a greater than inequality, thus we accommodated the requirements of the solver `PATH`.

```

Positive Variables P, Qd , Qs;

Equations Pdemand, Psupply, Equilibrium;
Pdemand.. P =g= 6 - 0.3*Qd;
Psupply.. ( 1 + 0.2*Qs) =g= P;
Equilibrium.. Qs =g= Qd;

Model problem / Pdemand.Qd, Psupply.Qs, Equilibrium.P /;

solve problem using MCP;

```

We will analyze this formulation and discuss every component of it after introducing the third example.

4.12.1.3 Third Example: Solving a Nonlinear Equation System

Engineers often wish to solve a nonlinear system of equations. Examples include chemical equilibria or problems in the context of oil refining. Many other such problems of this type exist. The problem that follows is adapted from the paper Wall, T W, Greening, D, and Woolsey, R E D, "Solving Complex Chemical Equilibria Using a Geometric-Programming Based Technique" Operations Research 34, 3 (1987).

```

ba * so4 = 1

baoh / ba / oh = 4.8

hso4 / so4 / h = 0 .98

h * oh = 1

ba + 1e-7*baoh = so4 + 1e-5*hso4

2 * ba + 1e-7*baoh + 1e-2*h = 2 * so4 + 1e-5*hso4 + 1e-2*oh

```

Note that this is a nonlinear system of equations with the variables `ba`, `so4`, `baoh`, `oh`, `hso4` and `h`. The following formulation in GAMS is from the model `[WALL]` in the GAMS model library.

```

Variables ba, so4, baoh, oh, hso4, h ;

Equations r1, r2, r3, r4, b1, b2 ;

r1..  ba * so4 =e= 1 ;
r2..  baoh / ba / oh =e= 4.8 ;
r3..  hso4 / so4 / h =e= .98 ;
r4..  h * oh =e= 1 ;
b1..  ba + 1e-7*baoh =e= so4 + 1e-5*hso4 ;
b2..  2 * ba + 1e-7*baoh + 1e-2*h =e= 2 * so4 + 1e-5*hso4 + 1e-2*oh ;

Model wall / all / ;

ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;

solve wall using nlp minimizing ba;

```

4.12.2 Components of the Example Models

Now that we have our three basic models in place, we will analyze them and identify and discuss their components, including variables, [equations](#), [model definitions](#), [solve statements](#) and [starting points](#).

4.12.2.1 Variables in the Example Models

Variables in GAMS have to be declared as variables with a [variable statement](#). The variable statements in the examples above are repeated below:

- [First example](#):

```
Positive Variables  Xcorn, Xwheat, Xcotton;
Variables          Z;
```

- [Second example](#):

```
Positive Variables  P, Qd , Qs;
```

- [Third example](#):

```
Variables ba, so4, baoh, oh, hso4, h ;
```

Note that `variable(s)` is a [keyword](#) in GAMS. `Positive` is another keyword, it serves as a modifier to the keyword `variable` and has the effect that the variables that follow may take only nonnegative values. Variables that are declared with the keyword `variable` without a modifier are unrestricted in sign. For more details on variable declarations and variable types, see sections [Variable Declarations](#) and [Variable Types](#) respectively.

Observe that GAMS is not case sensitive and allows a line feed to be used instead of a comma. Thus, the following three variable declarations are all valid and have the same effect:

```
POSITIVE VARIABLES  Xcorn, Xwheat, Xcotton;
Positive Variables  xcorn,
                   xwheat,
                   xcotton;
positive variables  Xcorn
                   Xwheat , Xcotton;
```

In the GAMS formulation of the [first example](#), we have introduced the variable `Z` in addition to the three variables that featured in the mathematical formulation. Note that GAMS requires the optimization model

```
Maximize cx
```

to have the following form:

```
Maximize z
      z = cx
```

Here `z` is a variable, also called *objective variable*. Observe that it is the objective variable that is maximized, not the function `cx`. The name of the objective variable may be chosen freely by the user, like any other variable name. The objective variable is a [free variable](#), which means that it has no bounds. Hence, in each optimization problem there must always be at least one free variable.

Given the requirement of an objective variable in an optimization problem, we need to declare a new free variable and introduce an equation for it. In our first example we declared `Z` as a free variable, then we declared and specified the equation `obj` setting `Z` equal to the objective function expression and we instructed the solver to maximize `Z`. The relevant lines of code from the [first example](#) follow:

```
Variables      Z;

Equation      obj, land , labor;

obj..  Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;

solve farmproblem using LP maximizing Z;
```

Note

In some optimization problems users do not need to introduce a new variable to serve as an objective variable, but a free variable that already features in the model may be used. For example, in the [second example](#) above, `ba` is a free variable that is used as objective variable, since the model type [NLP](#) requires an objective variable. We will discuss this further below.

4.12.2.2 Equations in the Example Models

Each equation in a model must first be *declared* with a [equation declaration statement](#) and then *defined* with a [equation definition statement](#). We repeat the respective statement from the three examples below:

- [First example:](#)

```
Equations      obj, land, labor;

obj..  Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
land..                Xcorn +          Xwheat +          Xcotton =l= 100;
labor..             6 * Xcorn + 4 * Xwheat + 8 * Xcotton =l= 500;
```

- [Second example:](#)

```
Equations      Pdemand, Psupply, Equilibrium;

Pdemand..      P                =g= 6 - 0.3*Qd;
Psupply..      ( 1 + 0.2*Qs) =g= P;
Equilibrium..  Qs                =g= Qd;
```

- [Third example:](#)

```
Equations r1, r2, r3, r4, b1, b2 ;

r1..  ba * so4 =e= 1 ;
r2..  baoh / ba / oh =e= 4.8 ;
r3..  hso4 / so4 / h =e= .98 ;
r4..  h * oh =e= 1 ;
b1..  ba + 1e-7*baoh =e= so4 + 1e-5*hso4 ;
b2..  2 * ba + 1e-7*baoh + 1e-2*h =e= 2 * so4 + 1e-5*hso4 + 1e-2*oh ;
```

Note that the equation declaration statement begins with the [keyword](#) `Equation(s)`. Its main purpose is to name the equation(s). For further details on equation declarations, see section [Declaring Equations](#).

The algebraic structure of the equation is specified in the equation definition statement, where the name of the equation is followed by two dots `..` and the algebra. The relation between the left-hand side and right-hand side is specified by special symbols indicating the equation type. The most common symbols are `=e=` for equality, `=l=` for a less than or equal to relation and `=g=` for a greater than or equal to relation. An overview of all GAMS equation types is given in Table [Equation Types](#). For more information on equation definitions, see sections [Defining Equations](#) and [Conditional Equations](#).

4.12.2.3 Model Definitions in the Example Models

Once all structural elements of a model have been defined and specified, a [model statement](#) is used to define the model that will be solved. The model statement form the three examples follow.

- [First example:](#)

```
Model farmproblem / obj, land, labor /;
```

- [Second example:](#)

```
Model problem / Pdemand.Qd, Psupply.Qs, Equilibrium.P /;
```

- [Third example](#):

```
Model wall / all / ;
```

Note that a model statement always starts with the [keyword](#) `model`. It is followed by the name of the model which users may choose freely and a list of the equations that are part of the model. Observe that the list of equations in the [first example](#) contains all equations that were declared and defined. However, this need not be the case. It is possible to declare and define an equation and then not use it in a model. For example, users could define several models that contain different subsets of equations. If all equations that were previously declared and defined enter the model, the keyword `all` may be used as a shortcut, like in the [third example](#).

Attention

Only equations that have been declared may be listed in a model statement. All equations in a model must have been defined before the model can be solved.

Note that equilibrium problems like the [second example](#) are solved as [Mixed Complementarity Problems \(MCPs\)](#). MCPs require a special variant of the model statement where not only the equations are listed, but also their complementarity relationships. The complementarity relationship between an equation and its associated variable is marked with a dot `."`. Hence, in the second example, the equation `Pdemand` is perpendicular to the variable `Qd`, the equation `Psupply` is perpendicular to the variable `Qs` and the equation `Equilibrium` is perpendicular to the variable `P`.

In the three model statements above the name of the model was immediately followed by the list of the equations included in the model. Observe that an optional [explanatory text](#) may be inserted after the name of the model.

4.12.2.4 Solve Statements in the Example Models

After the model has been defined it remains to be solved, i.e. to find a solution for the variables. The [solve statement](#) directs GAMS to use a solver to optimize the model or solve the system of equations. The solve statements of the three examples follow:

- [First example](#):

```
solve farmproblem using LP maximizing Z;
```

- [Second example](#):

```
solve problem using MCP;
```

- [Third example](#):

```
solve wall using nlp minimizing ba;
```

Note that a solve statement always begins with the [keyword](#) `solve` followed by the name of the model, as previously specified with a model statement, the keyword `using` and the *type* of the model. We have an [LP](#) (linear programming problem) in the first example, an [MCP](#) (mixed complementarity problem) in the second example and an [NLP](#) (nonlinear programming program) in the third example. A complete list of GAMS model types is given in section [Classification of Models](#). After the model type the direction of the optimization is given: either `maximizing` as in the first example or `minimizing` as in the third example. In the final position is the name of the [objective variable](#) that is to be optimized.

Note

[MCPs](#) and systems of equations of the model type [Constrained Nonlinear System \(CNS\)](#) do not have objective variables. Therefore their solve statements end with the model type.

Observe that the system of nonlinear equations in the [second example](#) was expressed as an NLP that requires an objective function and a related objective variable. Actually this is an older practice in GAMS as the GAMS model type [CNS](#) was added after this example was initially formulated. Hence, we could alternatively use the following solve statement:

```
solve wall using cns;
```

However, note that the model type [CNS](#) can only be solved by select solvers and cannot incorporate integer variables. A formulation as an optimization problem relaxes these restrictions, thus allowing the use of the model type [MINLP](#) and all NLP solvers. If the model type [NLP](#) or one of its variants is chosen, one of the variables must be selected as [objective variable](#) to be optimized. Observe that which variable is chosen may not really have any effect since a feasible solution requires all of the simultaneous equations to be solved. Thus, while in the third example the variable `ba` is maximized, there is no inherent interest in attaining its maximum - it is just convenient.

4.12.2.5 Starting Points

In the [third example](#) we have the following line *before* the solve statement:

```
ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;
```

Note that this line provides starting points for the variables in the model. The suffix `.l` appended to a variable name denotes the level value of that variable. If a level value of a variable is specified before the solve statement, this value will act as a starting point for the search algorithms. The level value of a variable is one example of a *variable attribute*. Other examples include lower and upper bounds which may be set with the suffixes `.lo` and `.up`. For more information on variable attributes, see section [Variable Attributes](#). For guidance on how to choose good starting points, see the tutorial [Good NLP Formulations](#). Specifying starting points may be important for avoiding numerical problems in the model solution. For more on this topic, see the tutorial [Finding and Fixing Execution Errors and Performance Problems](#).

Observe that the statements above are the first examples of assignment statements in this tutorial. Assignment statements play a crucial role in GAMS, they are introduced in section [The Assignment Statement](#).

4.12.3 Running a GAMS Job

The model formulation of a GAMS model is saved in a text file with the extension `.gms`, say `myfile.gms`. Then the file is submitted to GAMS. GAMS will execute the instructions in the `.gms` file, with the result that calculations are done, solvers are used and an output file with the solution results is created. The output file is also called the *listing file*. By default, the name listing file of the input file `myfile.gms` will be `myfile.lst`.

There are two ways to submit a job to GAMS: via the command line and via the GAMS IDE.

4.12.3.1 Running GAMS on the Command Line

The model formulation of a GAMS model is saved in a text file with the extension `.gms`, say `myfile.gms`. This file may be run with GAMS using the following call:

```
> gams myfile
```

Note the extension `.gms` may be omitted. This basic GAMS call may be extended with arguments that are called *command line parameters*. The following example serves as illustration:

```
> gams transport pw=80 ps=9999 s=mysave
```

Note that there are three command line parameters: the first will set the page width to 80, the second will set the page length to 9999 and the third will have the effect that a work file named `mysave` is saved. GAMS offers many command line parameters, they are introduced and discussed in detail in chapter [The GAMS Call and Command Line Parameters](#).

4.12.3.2 Running GAMS with the IDE

The GAMS Integrated Development Environment is a graphical user interface for Windows that facilitates editing, development, debugging GAMS models and running GAMS jobs.

4.12.4 Examining The Output

The output of a GAMS run is saved in the output or listing file. The listing file may contain many parts. Some parts may be suppressed by the modeler, other parts are suppressed by default and need to be activated. For an introduction and detailed discussion, see chapter [GAMS Output](#).

In this section we will review the output that is generated by running the three example models.

4.12.4.1 The Echo Print

The listing file always begins with the echo print. The echo print is a copy of the input file with added line numbers. For example, the echo print of the [first example](#) is given below:

```
1 Positive Variables      Xcorn, Xwheat, Xcotton;
2 Variables              Z;
3
4 Equations              obj, land, labor;
5
6 obj..  Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
7 land..           Xcorn +      Xwheat +      Xcotton =l= 100;
8 labor..          6 * Xcorn +  4 * Xwheat +   8 * Xcotton =l= 500;
9
10 Model farmproblem / obj, land, labor /;
11
12 solve farmproblem using LP maximizing Z;
```

Note that the echo print of the other two examples follows the same principles. Note further, that the echo print serves as an important reference guide since GAMS reports the line numbers of any errors that were detected and of solve and display statements.

Observe that usually the code of even experienced GAMS modelers will contain compilation errors. They are marked in the echo print. For more information on compilation error and how to resolve them, see section [Compilation Errors](#) and the tutorial [Fixing Compilation Errors](#).

4.12.4.2 Model Generation Output

Once GAMS has successfully compiled the input file and any numerical computations in assignments have been performed, the solve statements will be executed. The first step is generating a computer readable version of the equations in the problem that will be passed on to an appropriate solver system. During the model generation phase GAMS creates the following output:

- A listing of the equations of the model.
- A listing of the variables of the model.
- A summary of the model structure.
- If errors were detected during model generation they will be reported as well.

4.12.4.2.1 The Equation Listing The equation listing is the first part of the output generated by a solve statement. By default, the first three equations in every block are listed. The equation listing of the first two equations of each of the three examples are given below:

- [First example:](#)

```
Equation Listing      SOLVE farmproblem Using LP From line 12

---- obj      =E=

obj..  - 109*Xcorn - 90*Xwheat - 115*Xcotton + Z =E= 0 ; (LHS = 0)

---- land     =L=

land..  Xcorn + Xwheat + Xcotton =L= 100 ; (LHS = 0)
```

- [Second example:](#)

```
Equation Listing      SOLVE problem Using MCP From line 10

---- Pdemand  =G=

Pdemand..  P + 0.3*Qd =G= 6 ; (LHS = 0, INFES = 6 ****)

---- Psupply  =G=

Psupply..  - P + 0.2*Qs =G= -1 ; (LHS = 0)
```

- [Third example:](#)

```
Equation Listing      SOLVE wall Using NLP From line 16

---- r1      =E=

r1..  (1)*ba + (1)*so4 =E= 1 ; (LHS = 1)

---- r2      =E=

r2..  - (1)*ba + (1)*baoh - (1)*oh =E= 4.8 ; (LHS = 1, INFES = 3.8 ****)
```

Note that the equation listing is a representation of the algebraic structure of the linear terms in the equation and a local representation containing the first derivatives of the nonlinear terms. The nonlinear terms are automatically placed in parentheses to indicate a local approximation. For further details, see section [The Equation Listing](#) in chapter [GAMS Output](#).

4.12.4.2.2 The Column Listing The column or variable listing contains a list of the individual coefficients sorted by column rather than by row (like in the equation listing). By default, the first three entries for each variable are shown, along with their lower bound `.lo`, upper bound `.up` and current level values `.l`. The column listing of the first two variables for each of the three examples are given below.

- [First example:](#)

```
Column Listing      SOLVE farmproblem Using LP From line 12
```

```
---- Xcorn
```

```
Xcorn
      (.LO, .L, .UP, .M = 0, 0, +INF, 0)
-109  obj
      1  land
      6  labor
```

```
---- Xwheat
```

```
Xwheat
      (.LO, .L, .UP, .M = 0, 0, +INF, 0)
-90   obj
      1  land
      4  labor
```

- [Second example:](#)

```

 -1   b1
 -2   b2

```

4.12.4.2.3 Model Statistics The final information generated while a model is being prepared for solution, is the statistics block. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of the [third example](#) follow.

MODEL STATISTICS

BLOCKS OF EQUATIONS	6	SINGLE EQUATIONS	6
BLOCKS OF VARIABLES	6	SINGLE VARIABLES	6
NON ZERO ELEMENTS	20	NON LINEAR N-Z	10
DERIVATIVE POOL	20	CONSTANT POOL	16
CODE LENGTH	22		

For more information on model statistics, see section [The Model Statistics](#) in chapter [GAMS Output](#).

4.12.4.3 The Solution Report

The final major component of the listing file is the solution output. It consists of a summary, some solver-specific output and a report of the solutions for equations and variables.

4.12.4.3.1 The Solve Summary The solve summary is very important since it contains an overview of key information of the solution. The solve summary of the [third example](#) is given below.

```

          S O L V E      S U M M A R Y

MODEL   wall              OBJECTIVE  ba
TYPE    NLP                DIRECTION MINIMIZE
SOLVER  CONOPT             FROM LINE 16

**** SOLVER STATUS      1 Normal Completion
**** MODEL STATUS      2 Locally Optimal
**** OBJECTIVE VALUE          1.0000

RESOURCE USAGE, LIMIT      0.034      1000.000
ITERATION COUNT, LIMIT     7      2000000000
EVALUATION ERRORS          0          0

```

For details on the solve summary including possible values for `SOLVER STATUS` and `MODEL STATUS`, see section [The Solve Summary](#) in chapter [GAMS Output](#).

4.12.4.3.2 The Solver Report The next part of the listing file is the solver report. It contains solver specific output. The respective output of the [third example](#) follows:

```
CONOPT 3          24.7.3 r58181 Released Jul 11, 2016 DEG x86 64bit/MacOS X
```

```

C O N O P T 3    version 3.17A
Copyright (C)   ARKI Consulting and Development A/S
                Bagsvaerdvej 246 A
                DK-2880 Bagsvaerd, Denmark

```

```

Pre-triangular equations:  0
Post-triangular equations: 0

```

```
** Optimal solution. There are no superbasic variables.
```

For more on solver reports, see section [Solver Report](#) in chapter [GAMS Output](#).

4.12.4.3.3 The Solution Listing The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed including their level and marginal values and their lower and upper bounds. The solution listing of the [first example](#) follows:

	LOWER	LEVEL	UPPER	MARGINAL
---- EQU obj	.	.	.	1.0000
---- EQU land	-INF	100.0000	100.0000	52.0000
---- EQU labor	-INF	500.0000	500.0000	9.5000
	LOWER	LEVEL	UPPER	MARGINAL
---- VAR Xcorn	.	50.0000	+INF	.
---- VAR Xwheat	.	50.0000	+INF	.
---- VAR Xcotton	.	.	+INF	-13.0000
---- VAR Z	-INF	9950.0000	+INF	.

Note that single dots '.' represent zeros. The [extended range arithmetic symbols](#) -INF and +INF denote minus and plus infinity respectively. EPS is another extended range arithmetic symbol that often appears in solution listings. In this context, it is used to indicate basis status in the degenerate case. For example, a basic variable is indicated by a zero (single dot) marginal, while a non-basic variable whose marginal is (nearly) zero is indicated by a marginal of EPS. For further details, see section [The Solution Listing](#) in chapter [GAMS Output](#).

4.12.5 Exploiting the Algebraic Structure

GAMS was deliberately designed to make it easy to express algebraic relationships. Thus it provides notation for [indexed operations](#) like sums. Assume that z is defined as the sum over x_i where $i = \{1, 2, 3\}$:

$$z = \sum_{i=1}^3 x_i = x_1 + x_2 + x_3$$

This can be expressed in GAMS in the following way:

```
z = sum(i, x(i));
```

Here i is a set with three elements, z is a scalar or variable and $x(i)$ is a parameter or variable defined over the set i . Note that the [keyword](#) `sum` automatically cycles through all elements of the set i .

Indexed operations like `sum` may be used in the algebraic specification of equations or in the context of assignments where the value of identifiers are computed. In the following two sections we will introduce revised versions of the first two examples, where we illustrate how using `sum` simplifies the code and enables more general formulations.

4.12.5.1 Revised First Example

Recall that the [first example](#) is the following LP:

$$\begin{array}{llllll}
 \max & 109X_{corn} & + & 90X_{wheat} & + & 115X_{cotton} & \\
 \text{s.t.} & X_{corn} & + & X_{wheat} & + & X_{cotton} & \leq 100 \quad (\text{land}) \\
 & 6X_{corn} & + & 4X_{wheat} & + & 8X_{cotton} & \leq 500 \quad (\text{labor}) \\
 & & & & & X_{corn} & \geq 0 \quad (\text{nonnegativity}) \\
 & & & & & X_{wheat} & \geq 0 \quad (\text{nonnegativity}) \\
 & & & & & X_{cotton} & \geq 0 \quad (\text{nonnegativity})
 \end{array}$$

Note that this is a special case of the general resource allocation problem that can be written as follows:

$$\begin{array}{ll}
 \max & \sum_j c_j X_j \\
 \text{s.t.} & \sum_j a_{ij} X_j \leq b_i \quad \text{for all } i \\
 & X_j \geq 0 \quad \text{for all } j,
 \end{array}$$

where

- $j = \{\text{corn, wheat, cotton}\}$
- $i = \{\text{land, labor}\}$
- $X_j = \{X_{\text{corn}}, X_{\text{wheat}}, X_{\text{cotton}}\}$
- $c_j = \{109, 90, 115\}$
- $a_{ij} = \begin{pmatrix} 1 & 1 & 1 \\ 6 & 4 & 8 \end{pmatrix}$
- $b_i = \{100, 500\}$.

This model may be formulated in GAMS in the following way:

```

Set      j          / corn, wheat, cotton /
        i          / land, labor /;

Parameter c(j)      / corn 109, wheat 90, cotton 115 /
        b(i)        / land 100 , labor 500 /;

Table    a(i,j)
        corn      wheat      cotton
land     1         1         1
labor    6         4         8      ;

```

```

Positive Variables x(j);
Variables          profit;

Equations          objective
                  constraint(i) ;

objective..       profit =e= sum(j, (c(j))*x(j));
constraint(i)..   sum(j, a(i,j) *x(j)) =l=  b(i);

Model resalloc /all/;
solve resalloc using LP maximizing profit;

```

We will discuss the components of this model in section [Components of the Revised Example Models](#) below.

4.12.5.2 Revised Second Example

Recall that the [second example](#) is an economic equilibrium model with a single commodity:

$$\begin{array}{ll}
 \text{Demand Price:} & P \geq P_d = 6 - 0.3Q_d \\
 \text{Supply Price:} & P \leq P_s = 1 + 0.2Q_s \\
 \text{Quantity Equilibrium:} & Q_s \geq Q_d \\
 \text{Nonnegativity:} & P \geq 0 \\
 & Q_s \geq 0 \\
 & Q_d \geq 0
 \end{array}$$

A more general formulation of this model accomodates multiple commodities. Consider the following formulation where c denotes the commodities:

$$\begin{array}{llll}
 \text{Demand Price for } c: & P_c \geq P_{d_c} = Id_c - \sum_{cc} Sd_{c,cc} Qd_{cc} & \text{for all } c \\
 \text{Supply Price for } c: & P \leq P_{s_c} = Is_c + \sum_{cc} Ss_{c,cc} Qs_{cc} & \text{for all } c \\
 \text{Quantity Equil. for } c: & Qs_c \geq Qd_c & \text{for all } c \\
 \text{Nonnegativity:} & P_c \geq 0 & \text{for all } c \\
 & Qs_c \geq 0 & \text{for all } c \\
 & Qd_c \geq 0 & \text{for all } c,
 \end{array}$$

where

- P_c is the price of commodity c ,
- Qd_c is the quantity demanded of commodity c ,
- P_{d_c} is the price from the inverse demand curve for commodity c ,
- Qs_c is the quantity supplied of commodity c ,
- P_{s_c} is the price from the inverse supply curve for commodity c ,
- cc is an alternative notation for the commodities and is equivalent to c ,
- Id_c is the inverse demand curve intercept for c ,
- $Sd_{c,cc}$ is the slope of the inverse demand curve. It is used to model the effect of buying one unit of commodity cc on the demand price of commodity c . When $c = cc$ it is an own commodity effect and when $c \neq cc$ it is a cross commodity effect.

- Is_c is the inverse supply curve intercept for c ,
- Ssc, cc is the slope of the inverse supply curve. It is used to model the effect of supplying one unit of commodity cc on the supply price of commodity c . When $c = cc$ it is an own commodity effect and when $c \neq cc$ it is a cross commodity effect.

This model may be formulated in GAMS in the following way:

```

Set commodities / corn, wheat /;
Set curvetype   / supply, demand/;

Table intercepts(curvetype,commodities)
      corn  wheat
demand   4    8
supply   1    2;

Table slopes(curvetype,commodities,commodities)
      corn  wheat
demand.corn -.3  -.1
demand.wheat -.07 -.4
supply.corn  .5   .1
supply.wheat .1   .3 ;

Positive Variables P(commodities)
                  Qd(commodities)
                  Qs(commodities);

Equations         PDemand(commodities)
                  PSupply(commodities)
                  Equilibrium(commodities);

Alias (cc,commodities);

Pdemand(commodities)..
    P(commodities) =g= intercepts("demand",commodities)
                      + sum(cc,slopes("demand",commodities,cc)*Qd(cc));
Psupply(commodities)..
    intercepts("supply",commodities)
    + sum(cc,slopes("supply",commodities,cc)* Qs(cc)) =g= P(commodities);

Equilibrium(commodities)..
    Qs(commodities) =g= Qd(commodities);

Model problem / Pdemand.Qd, Psupply.Qs,Equilibrium.P /;
solve problem using MCP;

```

4.12.6 Components of the Revised Example Models

The revised example models have several new features including sets, specific data entry, and variables and equations that are defined over sets. In addition, if the models are run, modelers will notice some differences in the output. In this section we will discuss these new language features and the differences in the output they entail.

4.12.6.1 Sets in the Revised Examples

In the revised examples we used the subscripts `i`, `j`, `commodities` and `cc`. In GAMS, subscripts are sets. They have to be defined before they may be used as subscripts. Sets are defined with [set statements](#). Consider the set statement from the first revised example:

```
Set j / corn, wheat, cotton /
    i / land, labor /;
```

Note that the statement begins with the [keyword](#) `set` followed by the name of the set and a list of the elements of the set. Note further, that more than one set may be defined with one set statement. In addition, an optional [explanatory text](#) may be inserted after the name of the set and also after each set element. For more details on set definitions, see chapter [Set Definition](#).

Observe that the following line appears in the revised second example:

```
Alias (cc,commodities);
```

This is an [alias statement](#) that introduces a new alternative name for a set that was defined earlier. In our example, the set `commodities` was defined in the first line of the code and `cc` is the alias, the alternative name for the set `commodities`. Note that more than one alias may be defined in an alias statement. For further information on aliases, see section [The Alias Statement: Multiple Names for a Set](#).

Note that in our example the alias facilitates to consider both the effects of own and cross commodity quantity on the demand and supply price for an item.

4.12.6.2 Data Entry in the Revised Examples

GAMS provides three formats for data entry: [scalars](#), [parameters](#) and [tables](#). Usually scalars are defined with a [scalar statement](#), data vectors are defined with a [parameter statement](#) and matrices are defined with a [table statement](#).

Note that we used parameter and table statements in the revised examples. In this section we will discuss parameter and table statements. For details on scalar statements, see section [Scalars](#).

Parameters

The parameter format is used to enter items defined over sets. Generally, the parameter format is used for data items that are one-dimensional (vectors), but multi-dimensional data may be entered with a parameter statement as well. Consider the parameter statement from the first revised example:

```
Parameter c(j) / corn 109, wheat 90, cotton 115 /
          b(i) / land 100, labor 500 /;
```

Note that the statement begins with the [keyword](#) `parameter` followed by the name of the parameter and the set over which the parameter is defined, the *index* or *domain*. Then a list follows where a numerical value is assigned to each member of the index set. Note that the referenced elements must have been defined to be members of the respective set. By default, elements of the domain that are not listed in the parameter statement are assigned the value of zero. Note that more than one parameter may be defined with one parameter statement. For further details on parameter statements, see section [Parameters](#).

Tables

The table format is used to enter data that are dependent on two or more sets. Consider the following two [table statements](#) from the revised examples:

```
Table a(i,j) crop data
      corn  wheat  cotton
land   1     1     1
labor  6     4     8   ;
```

```
Table intercepts(curvetype,commodities)
      corn  wheat
demand  4     8
supply  1     2;
```

Note that the statement begins with the **keyword table** followed by the name of the table and the sets over which the table is defined. The next line serves as header for the columns of the table, the elements of the set in the *second* index position are listed here. The elements of the set in the *first* index position are the headers of the rows. Thus the elements of the two index positions span a grid where numerical values may be entered. Like in the parameter format, the referenced set elements must have been defined to be members of the respective set.

Note

Alignment is crucial in table statements. The numerical entries must be placed in one and only one column of the table.

By default, elements of the domain that are not listed in the table statement are assigned the value of zero. Note that only one table may be defined with a table statement. For further details on table statements, see section [Tables](#). Observe that data may also be entered with assignment statements. For more information, see section [Data Entry by Assignment](#).

4.12.6.3 Indexed Variables and Equations in the Revised Examples

When the algebraic structure of a problem is exploited in modeling, variables and equations are often defined over one or more sets, they are *indexed*. For example, in the first revised example we have the following lines:

```
Positive Variable x(j);
Equations          constraint(i);
```

Note that here the variable **x** is defined over the set **j** and the equation **constraint** is indexed over the set **i**. Similarly, in the second revised example we have the following variable and equation statements:

```
Positive Variables P(commodities)
                  Qd(commodities)
                  Qs(commodities) ;
Equations  PDemand(commodities)
           PSupply(commodities)
           Equilibrium(commodities) ;
```

Observe that here all positive variables and all equations are indexed over the set **commodities**. Such definitions indicate that the variables and equations are potentially defined for every element of the defining set. Thus, for example, a variable **P** could exist for each and every element of the set **commodities**. However, how many of these potential cases are activated is determined by the respective equation definition statement(s) where the variable **P** is used. For further details on indexed variables and equations, see chapter [Variables](#) and section [Indexed Equations](#) respectively.

Next, we will discuss the equation definition statements. The respective lines from the first revised example follow:

```
objective..      profit =e= sum(j, (c(j))*x(j));
constraint(i)..  sum(j, a(i,j) *x(j)) =l= b(i);
```

Note that the equation `constraint` is indexed over the set `i` and there are no restrictions specified in the equation definition statement. Thus, GAMS will generate a separate equation for every element of the set `i` in the model generation phase.

The same logic applies to the indexed equations of the second revised example whose definition statements are repeated below:

```
Pdemand(commodities)..
    P(commodities) =g= intercepts("demand",commodities)
        + sum(cc,slopes("demand",commodities,cc)*Qd(cc));

Psupply(commodities)..
    intercepts("supply",commodities) + sum(cc,slopes("supply",commodities,cc)* Qs(cc))
        =g= P(commodities);

Equilibrium(commodities)..
    Qs(commodities) =g= Qd(commodities);
```

Observe that equations may be defined over only a part of their domain. This restriction is usually achieved with dollar conditions. For details see section [Conditional Equations](#).

4.12.6.4 Differences in the Output

If variables and equations are defined over sets, some parts of the listing file will look different. In particular, there are some changes in the equation listing, the variable listing and the solution listing.

Revised Models: The Equation Listing

Note that indexed variables are given with their indices in the equation listing. In addition, the specific equations generated for each element of the domain are listed under the name of an indexed equation. To illustrate, we present the equation listing of the first revised example below:

```
---- objective =E=
objective..  - 109*x(corn) - 90*x(wheat) - 115*x(cotton) + profit =E= 0 ; (LHS = 0)

---- constraint =L=
constraint(land)..  x(corn) + x(wheat) + x(cotton) =L= 100 ; (LHS = 0)
constraint(labor).. 6*x(corn) + 4*x(wheat) + 8*x(cotton) =L= 500 ; (LHS = 0)
```

Revised Models: The Column Listing

Similar to indexed equations in the equation listing, each instance of a variable is listed under the name of an indexed variable in the variable listing. The respective output of the first revised model follows.

```

---- x

x(corn)
      (.LO, .L, .UP, .M = 0, 0, +INF, 0)
-109 objective
      1 constraint(land)
      6 constraint(labor)

x(wheat)
      (.LO, .L, .UP, .M = 0, 0, +INF, 0)
-90  objective
      1 constraint(land)
      4 constraint(labor)

x(cotton)
      (.LO, .L, .UP, .M = 0, 0, +INF, 0)
-115 objective
      1 constraint(land)
      8 constraint(labor)

```

Revised Models: The Solution Listing

In the solution listing of the revised models there is a separate line for each element of the index set. The respective output of the first revised model is given below:

```

---- EQU constraint

```

	LOWER	LEVEL	UPPER	MARGINAL
land	-INF	100.0000	100.0000	52.0000
labor	-INF	500.0000	500.0000	9.5000

```

---- VAR x

```

	LOWER	LEVEL	UPPER	MARGINAL
corn	.	50.0000	+INF	.
wheat	.	50.0000	+INF	.
cotton	.	.	+INF	-13.0000

4.12.7 Documenting the GAMS Code

We have now covered the essential GAMS features. However, any good code includes documentation, otherwise it might be useless if it is revisited after a longer time. GAMS offers three ways to document the code: comments, explanatory texts and naming.

Comments

There are several ways to add comments in GAMS. The most common are *single line comments* and *block comments*. Single line comments may be inserted on any line by placing an asterisk * in the first column position. The text that follows the asterisk will be completely ignored by the GAMS compiler and may contain any content including GAMS [keywords](#). Note that several successive lines may be single line comments. Block comments are marked with the dollar control option [\\$ontext](#) at the beginning of the comment block and the dollar control option [\\$offtext](#) at the end of the comment. Block comments usually

span several lines, but they may also contain just one line on the one hand and whole sections of the code on the other hand.

In addition, users may freely enter blank lines to set off certain sections of the code and generally enhance readability. For further details on comments, see section [Comments](#).

Explanatory Text

Declarations of sets, parameters, variables and equations may include an optional descriptive text that follows the name of the [identifier](#). In addition, the elements of sets may be accompanied by a text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the respective identifier in the output file. Note that the explanatory text may be quoted or unquoted and single or double quotes may be used, but they must match. An example is given below. For further details, see section [Text](#).

Naming

Apart from avoiding [reserved words](#), names for identifiers in GAMS may be freely chosen. Some modelers, particularly if they have a background in mathematics, prefer short names like $x(i)$. Other modelers strongly prefer longer descriptive names that makes it easier for them to recall what quantities are denoted. In this case naming is regarded as part of the documentation. GAMS accomodates both styles and modelers may choose which style works best for them. If short names are used, we recommend to generously use descriptive texts and comments for documentation.

To illustrate the virtues of comments, blank lines, explanatory text and long names we will repeat the code of the revised LP from above and then offer an alternative, documented formulation.

```

Set      j      / corn, wheat, cotton /
        i      / land , labor /;

Parameter c(j)  / corn 109, wheat 90, cotton 115 /
        b(i)    / land 100 , labor 500 /;

Table    a(i,j)
          corn   wheat   cotton
land     1       1       1
labor    6       4       8   ;

Positive Variables x(j);
Variables      profit;

Equations      objective
               constraint(i) ;

objective..    profit =e= sum(j, (c(j))*x(j));
constraint(i).. sum(j, a(i,j) *x(j)) =l=  b(i);

Model resalloc /all/;
solve resalloc using LP maximizing profit;

```

The documented version with longer names follows:

```

$ontext
  well formatted algebraic version of the first example model
$offtext
Set      products  'Items produced by farm'

```

```

        / corn  'in acres'
          wheat 'in acres'
          cotton 'in acres' /
resources 'Resources limiting farm production'
        / land  'in acres'
          labor 'in hours' /;

Parameter netreturns(products) 'Net returns per unit produced'
        / corn 109 , wheat 90, cotton 115 /
endowments(resources) 'Amount of each resource available'
        / land 100, labor 500 /;

Table    resourceusage(resources,products) 'Resource usage per unit produced'
          corn  wheat  cotton
        land    1     1     1
        labor   6     4     8    ;

Positive Variables  production(products) 'Number of units produced';

4.12.8 Guidelines on Ordering GAMS Statements and Formatting GAMS Programs

A GAMS program is a collection of [GAMS statements](#). In this section we will offer some general guidelines on ordering GAMS statements and formatting GAMS programs.

- GAMS is case insensitive. This applies to [GAMS keywords](#) as well as to user-defined names. For example, the keyword `VARIABLE` is identical to `Variable` and `variable` and the user-defined name `mincost` is identical to `minCost` and `minCOST`. However, note that the spelling in the output file is determined by the spelling in the first occurrence of an identifier or label.

- Individual GAMS statements may be formatted in almost any style. Multiple lines may be used for a statement, blank lines may be embedded and any number of spaces or tabs may be inserted. In addition, several statements may be placed on one line. Note that they have to be separated by semicolons ;.
- We recommend that every GAMS statement is terminated with a semicolon ;. However, note that semicolons are not mandatory if the next word is a [GAMS keyword](#).
- Identifiers like [sets](#), [parameters](#), [scalars](#), [tables](#), [acronyms](#), [variables](#), [equations](#), [models](#) and files must first be *declared* and *defined* before they may be used in the code. An identifier is named in a declaration statement and specific values are assigned to it when it is defined. Often identifiers are defined at the same time they are declared. Note that for equations the declaration and definition statements are always distinct.
- The names for identifiers and labels and the explanatory text must follow certain rules. See chapter [GAMS Programs](#) and the tutorial [Good Coding Practices](#) for more information.
- Statements must be ordered such that identifiers are declared before they are used. If identifiers are used on the right-hand side of an [assignment statement](#), they must also have been defined. If they are used in an equation and the equation is included in a model, then they must be assigned data before a solve statement for the respective model. Note that [compilation errors](#) will be triggered if this order is not followed.

4.12.9 Adding Complexity

There are several GAMS features that are widely used and serve to add subtlety and complexity to models. They include exception handling through [conditionals](#), [displaying data](#) in the output file and [report writing](#) where the information from the optimal solution is used to create reports that meet the needs of modelers and their clients.

4.12.9.1 Conditionals

Assignments are often valid only for certain cases and sometimes equations should reasonably be restricted to a subset of the domain over which they were defined. It is easy to model such assignments and equations in GAMS with conditionals. Conditional expressions in GAMS are introduced and discussed in detail in chapter [Conditional Expressions, Assignments and Equations](#). In this section we will only give a quick overview to demonstrate the capabilities of conditionals in GAMS.

Note that the [dollar condition](#) is at the heart of conditionals in GAMS. The general form of a conditional expression is as follows:

```
term $ logical_condition
```

This translates to: "Do something with 'term' only if the logical condition is true." Observe that **term** may be a number, a set, a parameter, a variable or an equation. The dollar operator **\$** is a GAMS speciality and one of the most powerful features of GAMS. The logical condition may take many different forms, see section [Logical Conditions](#) for details.

The following examples illustrate how conditionals in GAMS may be used.

Conditional Assignments

Consider the following example:

```
x $ (y > 0) = 10;
```

Note that `x` is assigned the value of ten only if the the scalar `y` is greater than zero, otherwise no assignment is made and `x` keeps its previous value. For more information, see section [Conditional Assignments](#).

Conditional Indexed Operations

Consider the following example:

```
z = sum[i $ (y(i) <> 0), x(i)];
```

Note that the term `x(i)` will only be included in the sum if `y(i)` is nonzero. For further information, see section [Conditional Indexed Operations](#).

Conditionals in the Domain of Definition of Equations

Consider the following equation definition statements:

```
Eq1 $ (qq > 0)..          xvar =e= 3;
Eq2 $ (sum(i, q(i)) > 0).. yvar =l= 4;
Eq3(i) $ (a(i) > 0)..     ivar(i) =g= -a(i);
```

Note that in each equation the domain of definition is restricted to those cases where the logical condition evaluates to TRUE. For further details, see section [Dollar Control over the Domain of Definition](#).

Conditionals in the Algebraic Formulation of Equations

Our last example illustrates how a dollar condition may be used in the body of an equation:

```
Eq4 . .    xvar + yvar $ (qq > 0) =e= 3;
```

Note that the term `yvar` is included in the equation only if `qq` is greater than zero, otherwise `yvar` is treated as if it were zero. For more information, see section [Dollar Operators within the Algebra of Equations](#).

4.12.9.2 Displaying Data

In GAMS, the [display statement](#) is a quick way to write data into the output file. For example, assume we add the following statement after the solve statement in the revised and documented version of the farm linear programming model [above](#):

```
display profit.l, production.l;
```

Recall that `profit` and `production` are variables. The suffix `.l` indicates that we wish to display the variable attribute level. The following output will be generated in the listing file:

```
----      47 VARIABLE profit.L              =      9950.000  Total sum of net returns
----      47 VARIABLE production.L  Number of units produced

corn  50.000,    wheat  50.000
```

Observe that the name of the variable, the explanatory text and the respective numerical values are given. In addition to data like parameters, sets, [variable attributes](#), [equation attributes](#) and [model attributes](#), quoted text may be displayed. Note that numerical entries that equal zero will not be displayed. For a more detailed introduction, see chapter [The Display Statement](#).

4.12.9.3 Report Writing

In many cases modelers wish to summarize the most important results of the solution in a table for a quick overview. GAMS allows post-solution computations where information from the solution may be used to assign values to new parameters that are then displayed. The information from the solution most often used for report writing includes the level values of variables and equations and the marginal values of equations (also called *dual values* or *shadow prices*). Note that variable and equation attributes are accessed as follows:

```
var_name.sfx
eqn_name.sfx
```

Here `var_name` and `eqn_name` is the name of the variable and equation in GAMS respectively. The *attribute* is denoted by `.sfx`, where `sfx` may be `l` for level and `m` for marginal. Note that the suffix `sfx` may take other values as well. For details see sections [Variable Attributes](#) and [Equation Attributes](#).

Observe that the numerical values of the levels and marginals of variables and equations are generally undefined until a solve statement is executed. After GAMS has retrieved the solution from the solver, the respective values from the solution are assigned to the attributes. These values remain unchanged until the next solve, where they are replaced with the values from the most recent solution.

In the remainder of this section we will present two examples to illustrate report writing. Assume we add the following report writing sequence after the solve statement to the revised and documented version of the farm linear programming model [above](#):

```
Set item / Total, "Use by", Marginal /;
Set qitem / Available, Corn, Wheat, Cotton, Value /;

Parameter Thisreport(resources,item,qitem) 'Report on resources';
Thisreport(resources,"Total","Available") = endowments(resources);
Thisreport(resources,"Use by",qitem) =
    sum(products$sameas(products,qitem),
        resourceusage(resources,products) * production.l(products));
Thisreport(resources,"Marginal","Value") =
    available.m(resources);

option thisreport:2:1:2;
display thisreport;
```

Note that both, equation marginals (`available.m(resources)`) and variable levels (`production.l(products)`) are included in the calculations. The function `sameas` in the logical condition above returns the value `TRUE` if the element of the set `products` is equivalent to the element of the set `qitem` and `FALSE` otherwise. Thus this condition ensures that the third index of the parameter `Thisreport` is identical to the element of the set `products` in the sum. Observe that with the option statement in the penultimate line the appearance of the display is customized. For details see section [Local Display Control](#). The following report will be generated by the display statement:

```
-----      61 PARAMETER Thisreport  Report on resources
              Total      Use by      Use by      Marginal
              Available    corn      wheat      Value
land          100.00      50.00      50.00      52.00
labor         500.00      300.00     200.00      9.50
```

Similarly, we could add the following report writing sequence to the revised version of the equilibrium model [above](#):

```
Set          qitem / Demand, Supply, "Market Clearing" /;
Set          item  / Quantity, Price /;

Parameter myreport(qitem,item,commodities);
myreport("Demand","Quantity",commodities) = Qd.l(commodities);
myreport("Supply","Quantity",commodities) = Qs.l(commodities);
myreport("Market Clearing","Price",commodities) = P.l(commodities);

display myreport;
```

Note that in the new parameter the level values for supply and demand as well as the market clearing price are saved. The resulting report follows:

```
----      39 PARAMETER myreport

Supply          .Quantity      Corn      Wheat
Demand          .Quantity      1.711    8.156
Market Clearing.Price      2.671    4.618
```

For more on report writing, see chapters [The Display Statement](#) and [The Put Writing Facility](#).

4.12.10 Advantages of Algebraic Modeling in General

We will conclude this tutorial with a discussion of the advantages of using algebraic modeling in general.

Algebraic modeling languages like GAMS facilitate model formulations in general algebraic terms, that are very concise and readable. Language elements that are essential include sets that may serve as indices, algebraic expressions, indexed operations, powerful sparse index and data handling variables and constraints with user-defined names. Model formulations are largely independent of the data and exact application contexts. Such formulations may be easily transferred to [different contexts](#), [data may be added](#) without the need to reformulate the model and the [model may be extended](#) to reflect additional complexity.

However, GAMS algebraic requirements and the summation notation are difficult for some users. Some modelers will always prefer the exact problem context, not an abstract general formulation. This may lead to a strategy most modelers use: Start with a small concrete formulations that capture the essence of the problem and support the development of more general GAMS models.

4.12.10.1 One Model - Different Contexts

In the linear programming problem [above](#) we modeled profit maximizing in a farm. This model may easily be transferred to another context as follows:

```

Set      products  'Items produced'
          / Chairs, Tables, Dressers /
resources 'Resources limiting production'
          / RawWood, Labor, WarehouseSpace /;

Parameter Netreturns(products) 'Net returns per unit produced'
          / Chairs 19, Tables 50, Dressers 75 /
Endowments(resources) 'Amount of each resource available'
          / RawWood 700, Labor 1000, WarehouseSpace 240 /;

Table    Resourceusage(resources,products) 'Resource usage per unit produced'
          Chairs  Tables  Dressers
RawWood      8      20      32
Labor        12      32      45
WarehouseSpace 4      12      10  ;

Positive Variables  Production(products) 'Number of units produced';
Variables           Profit                'Total sum of net returns' ;

Equations           ProfitAcct            'Profit accounting equation '
                   Available(resources) 'Resource availability limit';

ProfitAcct..
  Profit
  =e= sum(products, netreturns(products) * production(products)) ;
Available(resources)..
  sum(products,
    resourceusage(resources,products) * production(products))
  =l= endowments(resources);

Model resalloc /all/;

solve reasalloc using LP maximizing Profit;

```

Note that in this model we have chairs, tables and dressers instead of corn, wheat and cotton and raw wood, labor and warehouse space instead of land and labor, but the *algebraic structure* of the model is the same. Thus we still have sets for products and resources, parameters for net returns per unit produced and available resources, a table for resource usage per unit produced and exactly the same variables and equations, the same model and solve statement. Hence, if the algebraic structure for a type of problem is built, it may be used in another context of the same problem type with just minor modifications in the data.

4.12.10.2 Adding More Data

It is easy to add more data to a model. For example, we could add two new products and two new resources to the carpenter model [above](#) in the following way:

```

Set      products  'Items produced'
          / Chairs, Tables, Dressers, HeadBoards, Cabinets /
resources 'Resources limiting production'
          / RawWood, Labor, WarehouseSpace, Hardware, ShopTime /;

Parameter Netreturns(products) 'Net returns per unit produced'
          / Chairs 19, Tables 50, Dressers 75, HeadBoards 28, Cabinets 25 /
Endowments(resources) 'Amount of each resource available'

```

```
    / RawWood 700, Labor 1000, WarehouseSpace 240, Hardware 100, Shoptime 600 /;
```

```
Table      Resourceusage(resources,products) 'Resource usage per unit produced'
           Chairs   Tables   Dressers   HeadBoards   Cabinets
RawWood    8        20        32         22         15
Labor      12        32        45         12         18
WarehouseSpace 4        12        10          3          7
Hardware    1         1         3           0          2
Shoptime    6         8         30          5         12;
```

```
Positive Variables  Production(products) 'Number of units produced';
Variables           Profit           'Total sum of net returns' ;
```

```
Equations           ProfitAcct           'Profit accounting equation'
                   Available(resources) 'Resource availability limit';
```

```
ProfitAcct..
  Pofit
  =e= sum(products, netreturns(products) * production(products)) ;
```

```
Available(resources)..
  sum(products,
    resourceusage(resources,products) * production(products))
  =l= endowments(resources);
```

```
Model resalloc /all/;
```

```
solve reasalloc using LP maximizing Profit;
```

Observe that the elements `HeadBoards` and `Cabinets` were added to the set `Products` and the elements `Hardware` and `ShopTime` were added to the set `Resources`. In addition, the data in the two parameters and the table was updated to reflect these new labels. However, the model structure remained unchanged. Thus, GAMS models may easily be extended from smaller to larger data sets. Note that this feature may be exploited for model development. Users may develop a model with a small data set and test and debug it. Afterwards, they may move to the full problem data set without having to alter the algebraic structure of the model. For more details on this strategy, see section [Small to Large: Aid in Development and Debugging](#).

4.12.10.3 Extending the Model

Assume we wish to make a model more complex by adding new features. For example, we could extend the carpenter model [above](#) to reflect the possibility of renting or hiring additional resources subject to a maximum limit. Consider the following code:

```
Set      products 'Items produced'
         / Chairs, Tables, Dressers /
resources 'Resources limiting production'
         / RawWood, Labor, WarehouseSpace/
hireterms 'Resource hiring terms'
         / Cost, Maxavailable /;

Parameter Netreturns(products) 'Net returns per unit produced'
         / Chairs 19, Tables 50, Dressers 75 /
Endowments(resources) 'Amount of each resource available'
         / RawWood 700, Labor 1000, WarehouseSpace 240 /;
```

```
Table      Resourceusage(resources,products) 'Resource usage per unit produced'
           Chairs   Tables   Dressers
RawWood    8         20      32
Labor     12         32      45
WarehouseSpace 4         12      10 ;
```

```
Table      Hiredata(resources,hireterms) 'Resource hiring data'
           Cost    Maxavailable
RawWood    3         200
Labor     12         120
WarehouseSpace 4         112;
```

```
Positive Variables  Production(products) 'Number of units produced'
                   HireResource(resources) 'Resources hired';
Variables           Profit 'Total sum of net returns' ;

Equations           ProfitAcct 'Profit accounting equation'
                   Available(resources) 'Resource availability limit'
                   Hirelimit(resources) 'Resource hiring limit';
```

```
ProfitAcct..
  Profit
  =e= sum(products, Netreturns(products) * Production(products))
      - sum(resources, Hiredata(resources,"cost") * HireResource(resources)) ;
```

```
Available(resources)..
  sum(products,
    Resourceusage(resources,products) * Production(products))
  =l= Endowments(resources) + HireResource(resources);
```

```
Hirelimit(resources)..
  HireResource(resources) =l= Hiredata(resources,"Maxavailable");
```

```
Model resalloc /all/;
```

```
solve reasalloc using LP maximizing Profit;
```

Observe that we introduced the set `hireterms`, the table `Hiredata`, the positive variable `HireResource` and the equation `Hirelimit`. In addition, we included new terms in the equations `Profit` and `Available` to reflect that through hiring the resources are increased, but hiring comes with a cost diminishing the profit. Thus the algebraic structure of the earlier model could be used as the core for this model that has additional features.

Note that this method may also be exploited for model development. Users may adapt models from other studies customizing them for the problem at hand and thus speeding up the development process. In addition to adapting models from related earlier studies that were done by the modeler or his group, model development may be jumpstarted by adapting models from the extensive GAMS Model Library.

4.13 Good Coding Practices

The GAMS language is quite flexible regarding the syntax and format of the code it accepts, offering users considerable latitude in how they organize and format their GAMS code. Most modelers develop their own style as they gain experience with the GAMS system. This tutorial reflects the coding preferences of Bruce A. McCarl (currently professor of Agricultural Economics at Texas A&M University). Note that Bruce has extensive experience with GAMS, both as a modeler and an educator, and many GAMS users

know, use, and benefit from his work. The goal of this tutorial is *not* to present a rigid set of rules to follow arbitrarily, but rather to help users develop their own coding preferences and style. The larger goal is to build self-documenting models that are easy to read and understand, to edit, and to debug: both for the developer working in the present, and for a larger group of colleagues and consultants working with the model over a span of months or years.

We will cover the following topics:

- [Using Longer Names and Descriptive Text](#)
- [Including Comments](#)
- [Choosing Raw Data Instead Of Computed Data](#)
- [Avoiding the Universal Set in the Context of Data Input](#)
- [Defining Sets and Subsets Wisely](#)
- [Structuring and Formatting Files to Improve Readability](#)
- [Other Suggestions](#)

4.13.1 Using Longer Names and Descriptive Text

The readability of GAMS code may be significantly improved by using longer self-explanatory names for identifiers (e.g. names of sets, parameters, variables, etc). Consider the following lines of code from the production and inventory model [ROBERT]:

```
Sets p      'products'      / low, medium, high /
     r      'raw materials' / scrap, new /
     tt     'long horizon'  / 1*4 /
     t(tt)  'short horizon' / 1*3 /;
```

```
Table a(r,p) input 'coefficients'
```

	low	medium	high
scrap	5	3	1
new	1	2	3;

```
Table c(p,t) 'expected profits'
```

	1	2	3
low	25	20	10
medium	50	50	50
high	75	80	100;

```
Variables x(p,tt) 'production and sales'
          s(r,tt) 'opening stocks'
          profit;
```

```
Positive variables x, s;
```

```
Equations cc(t)    'capacity constraint'
          sb(r,tt) 'stock balance'
          pd        'profit definition' ;
```

```
cc(t)..      sum(p, x(p,t)) =l= m;
```

```

sb(r,tt+1).. s(r,tt+1) =e= s(r,tt) - sum(p, a(r,p)*x(p,tt));

pd.. profit =e= sum(t, sum(p, c(p,t)*x(p,t))
               - sum(r, misc("storage-c",r)*s(r,t)))
               + sum(r, misc("res-value",r)*s(r,"4"));

s.up(r,"1") = misc("max-stock",r);

```

These lines may be reformatted in the following way (see ([good.gms](#))):

```

Sets process          'available production process'
  / low      'uses a low amount of new materials',
    medium  'uses a medium amount of new materials',
    high    'uses a high amount of new materials' /
rawmaterial          'source of raw materials' / scrap, new /
Quarters            'long horizon'             / spring, summer, fall, winter /
quarter(Quarters)  'short horizon'            / spring, summer, fall /

Table usage(rawmaterial,process) 'input coefficients'
      low  medium  high
scrap    5     3     1
new      1     2     3

Table expectprof(process,quarters) 'expected profits'
      spring summer fall
low     25     20    10
medium  50     50    50
high    75     80   100;

Variables production(process,Quarters)  'production and sales'
  openstock(rawmaterial,Quarters)  'opening stocks'
  profit ;

Positive variables production, openstock;

Equations capacity(quarter)          'capacity constarint'
  stockbalan(rawmaterial,Quarters)  'stock balance'
  profitacct                          'profit definition' ;

capacity(quarter)..
  sum(process, production(process,quarter)) =l= mxcapacity;

stockbalan(rawmaterial,Quarters+1)..
  openstock(rawmaterial,Quarters+1) =e=
  openstock(rawmaterial,Quarters)
  - sum(process, usage(rawmaterial,process)
          *production(process,Quarters));

profitacct.. profit =e=
  sum(quarter,
      sum(process, expectprof(process,quarter)
            *production(process,quarter))
  - sum(rawmaterial, miscdata("store-cost",rawmaterial)*
        openstock(rawmaterial,quarter)))
  + sum(rawmaterial, miscdata("endinv-value",rawmaterial)
        *openstock(rawmaterial,"winter"));

```

```
openstock.up(rawmaterial,"spring") = miscdata("max-stock",rawmaterial);
```

Note that the two formulations are equivalent in their effect, but in the second formulation longer, more descriptive names were used for the sets, tables, variables and equations. In addition, longer names were used for the set elements and in the definition of the set `process` the set elements have additional explanatory text. Observe that the second formulation is easier to understand. This will be particularly useful if and when the code is revisited in 5 years' time.

Note

- Recall that GAMS allows long names for [identifiers](#) and [labels](#) (set elements). Users may exploit this feature to introduce long descriptive names. However, note that names for labels that are longer than 10 characters do not work well in multi-column displays. See the paragraph on customizing [display width](#) for details.
- Use explanatory text for identifiers to indicate units, sources, descriptions, etc. It's not that hard to do and it pays dividends later.
- Similarly, use explanatory text for set elements as appropriate.

For example, the descriptive text in the in the second line in the following code snippet is much more informative than the text in the first line:

```
Parameter vehsales(r)   'regional vehicle sales';
Parameter vehsales(r)   'regional vehicle sales ($ millions/yr)';
```

Note that the descriptive text will be displayed whenever the respective identifier is displayed. Hence, including units in the text will save time if results will have to be interpreted later.

4.13.2 Including Comments on Procedures and the Nature and Sources of Data

We recommend that the documentation of the code offers answers to the following questions:

- What are the units of the variables and parameters?
- Where did the data come from?
- What are the characteristics of the data such as units and year of applicability?
- Why was a constraint set up in the way it is implemented?

In addition, it is often helpful to add comments that describe assumptions, the intent of equation terms, data sources, including document name, page number, table number, year of applicability, units, URL etc.

Consider the following example where various forms of comments are illustrated:

```

* this is a one line comment that could describe data
$ontext
My data could be described in this multi-line comment
This is the second line
$offtext

* The following dollar control option activates end-of-line comments
* and redefines the symbol for end-of-line comments
$eolCom #
x = sum(i, z(i)) ; # this is an end-of-line comment

* The following dollar control option activates in-line comments
* and redefines the symbols for in-line comments
$inLineCom (* *)
x = sum(i, z(i)) ; (* this is an in-line comment *) r = sum(i, z(i)) ;

```

For more information on comments in GAMS, see section [Comments](#).

4.13.3 Choosing Raw Data Instead Of Computed Data

Modelers often have a choice how they enter data: they could either use raw data and transform it to the extent needed inside GAMS or process data externally and enter the final results into GAMS.

The second choice may be attractive if the raw data is available in a spreadsheet where it can be manipulated before it is introduced to GAMS. However, over time spreadsheets and other data manipulation programs change or get lost and often these programs are not documented well. Therefore, we recommend to enter data into GAMS in a form that is as close as possible to the actual collected data and then manipulate the data with GAMS to obtain the desired form. This will make it much easier to update models later or to work out implicit assumptions.

4.13.4 Avoiding the Universal Set in the Context of Data Input

While GAMS permits using the [universal set](#) `*` as an index in a parameter or table statement, in most cases it is *not* advisable to do so. Consider the following example from the production and inventory model **[ROBERT]**:

```

Sets   r           'raw materials' / scrap, new / ;

Table  misc(*,r)  'other data'
          scrap  new
max-stock  400  275
storage-c   .5   2
res-value   15  25  ;
...

pd.. profit =e= sum(t, sum(p, c(p,t)*x(p,t))
                - sum(r, misc("storage-c",r)*s(r,t)))
                + sum(r, misc("res-value",r)*s(r,"4"));

```

Note that the definition of the table `misc` indicates that any entry in the first index position is allowed. There is no [domain checking](#). Consequently, if the label `res-value` is misspelled as `res-val` in the equation `pd`, GAMS will compile and execute the program without signaling an error, but instead of the expected values (i.e. `misc(r,"res-value")`), the values of `misc(r,"res-val")` will be used in the equation. These zero values will lead to faulty results, and the modeler will not be alerted to this fact. To ensure that the results of a GAMS run are reliable and trustworthy, we strongly recommend to use domain checking by introducing a new set for the labels in the first index position of the table `misc`:

```
Sets  r          'raw materials'
      / scrap, new /
miscitem 'misc input items'
      / max-stock, storage-c, res-value /;
```

```
Table misc(miscitem,r) 'other data'
      scrap new
max-stock  400 275
storage-c   .5  2
res-value   15 25  ;
```

Observe that the new set `miscitem` contains exactly the labels that appear in the rows of the table `misc`. Hence the set `miscitem` may be used in the first index position of the definition of `misc` without loss of generality, but with the benefit of domain checking.

4.13.5 Defining Sets and Subsets Wisely

Generally, the elements of a set have a feature in common or they are similar in some way. In this section we will give some guidance on how to partition the labels in the data into sets. In addition, we will discuss in which contexts it is useful to introduce subsets. For an introduction to sets in GAMS, see chapter [Set Definition](#).

For example, suppose we have three grades of oil and three processes to crack it. The question arises whether we should introduce one set with nine elements or two sets with three elements and a two-dimensional set. We recommend the second alternative.

In another example, we consider a budget for farm spending: we have annual (i.e. cumulative yearly) spending for fertilizer and for seed and also monthly spending for labor and for water. There are 26 decisions or items in the budget. We could introduce a set with 26 elements or we could use the following formulation:

```
Sets resources / fertilizer, seed, labor, water /
      periods  / jan, feb, mar, apr, may, jun, jul, aug, sep, oct, nov, dec, annual /
use(resources,periods)
      / (fertilizer,seed).annual
      (labor,water) .(jan,feb,mar,apr,may,jun,jul,aug,sep,oct,nov,dec) /;
```

We recommend the formulation above and to err on the side of being more extensive or exact with set definitions.

Occasionally it is necessary to group some labels into one set for a certain purpose and then single out some of them for another purpose. [Subsets](#) facilitate modeling such a case. For example, a set of all cities in a model may be needed to enter distances and compute related transportation costs. In addition, a subset can be used to specify the cities that are hubs for some activity, since some equations should be restricted to these hubs.

4.13.6 Structuring and Formatting Files to Improve Readability

In this section we will offer some guidelines on structuring and formatting the GAMS code to make it easy to read.

There are several ways to structure the GAMS code. Two styles are outlined in section [Organization of GAMS Programs](#). The following recommendation to enter the sections of the code in a fixed order is an extended version of the first style:

1. Set definitions for sets that are data related
2. Parameter, scalar and table definitions, possibly intermixed with calculations
3. Variable definitions
4. Equation declarations
5. Equation definitions (algebraic specification of equations)
6. Model and solve statement(s)
7. Definitions of sets and parameters for report writing
8. Calculations for report writing
9. Display statement(s) for reports

Note that the code will be easiest to navigate if each section of the code contains only one type of statements. For example, interspersing set definitions with parameter definitions will make the code unnecessarily difficult to read.

In addition to following a fixed structure, it is also essential to properly format the code. Of course, formatting is in many respects a matter of taste. The following list offers some ideas:

- Align the names of identifiers and descriptive text, as demonstrated in the examples in this tutorial and in the GAMS User's Guide in general.
- Use spacing and indents.
- Use blank lines to highlight something and to mark sections of the code.
- Ensure that variables and all their index positions are on one line in equation definitions.
- Indent in indexed operations like sums and programming flow control structures like [loops](#) and [if statements](#) to delineate terms. The structure of a long and complex statement may be revealed through careful indentation and thoughtful placement of closing parentheses.

We will demonstrate the effect of proper formatting with the following two examples. The first example contains valid GAMS code, but is deliberately poorly formatted:

```
Sets products 'available production process' / low 'uses low new materials'
medium 'uses medium new materials', high 'uses high new materials'/
rawmaterial 'source of raw materials' / scrap, new /
Quarters 'long horizon' / spring, summer, fall ,winter /
quarter(Quarters) 'short horizon' / spring, summer, fall / ;
Variables production(products,Quarters) 'production and sales' ;
openstock(rawmaterial,Quarters) 'opening stocks', profit ;
Positive variables production, openstock;
Equations capacity(quarter) 'capacity constraint',
stockbalan(rawmaterial,Quarters) 'stock balance',
profitacct profit definition ;
profitacct.. profit =e= sum(quarter, sum(products, expectprof(
products,quarter) *production(products,quarter))-sum(
rawmaterial,miscdata("store-cost",rawmaterial)*openstock(rawmaterial
,quarter)))+ sum(rawmaterial, miscdata("endinv-value",rawmaterial) *openstock(rawmaterial,"winter"))
```

The second example contains the same code as the first example, but is carefully formatted:

```

Sets products          'available production process'
  / low   'uses a low amount of new materials',
    medium 'uses a medium amount of new materials',
    high  'uses a high amount of new materials' /
rawmaterial          'source of raw materials' / scrap, new /
Quarters             'long horizon'           / spring, summer, fall, winter /
quarter(Quarters)   'short horizon'          / spring, summer, fall / ;

Variables production(products,Quarters)  'production and sales'
        openstock(rawmaterial,Quarters)  'opening stocks'
        profit ;
Positive Variables production, openstock ;

Equations capacity(quarter)              'capacity constraint'
        stockbalan(rawmaterial,Quarters) 'stock balance'
        profitacct                       'profit definition' ;

profitacct..
  profit =e=
  sum(quarter,
    sum(products, expectprof(products,quarter)
      *production(products,quarter)
    )
    - sum(rawmaterial, miscdata("store-cost",rawmaterial)*
      openstock(rawmaterial,quarter)
    )
  )
  + sum(rawmaterial, miscdata("endinv-value",rawmaterial)
    *openstock(rawmaterial,"winter")
  )
  )
;

```

Observe that inserting blank lines, aligning the names of identifiers and descriptive text, and indenting and formatting closing parentheses in the sums makes the code much easier to read and understand (both now and in the future) and is well worth adopting as standard practice when writing GAMS code.

4.13.7 Other Suggestions

We will complete this tutorial by offering some other useful suggestions that may help modelers develop their own conventions.

Even though GAMS is case insensitive, it is advisable to establish some convention on the use of upper and lower case letters. For example, Paul N. Leiby (currently at Oak Ridge National Laboratory) uses lower case for texts and comments, and upper case for GAMS reserved words and variable and parameter names. The casing used when an identifier or label is first encountered in a GAMS program is the casing stored by GAMS and used in subsequent outputs like the listing file or a GDX file. Any casing can be used (so `noWhere` is equivalent to `nowHere`) but the casing stored is determined by first use.

A similar situation holds for label quoting: the type of quotes stored (if any) are determined by first use.

Note that the dollar control option `$onSymList` will cause a list of all identifier names to be displayed in the compilation output of the output file. This list may be used to review the spelling and casing of the identifiers as they will appear in output files. Similarly, the dollar control option `$onUeLList` will cause

an ordered list of all labels to be displayed in the compilation output of the output file. This is useful for checking both the case and order of the labels used in the GAMS program. For more on issues related to label ordering, see section [Ordered and Unordered Sets](#).

To keep track of the data types of identifier names, some modelers always start set names with `s_`, names of parameters with `d_` (for "data"), variables names with `v_` and equation names with `e_`.

Some experienced GAMS users always surround explanatory text with quotes: this makes the text stand out, prevents it from being interpreted as a label or identifier, and allows special characters like `$`, `-` and `&` to be used.

If a file is used by several modelers and is updated occasionally, a file modification log at the top of the file will be in order. It should contain the following information: the modification date, version number, modification(s) made and who made the modification. For example, a set called `version` may be used to keep track of the dates the input files were modified:

```
Set version(*,*,*,*);
. . .
version("my_file","May","19","2016") = yes;
version("my_include_file","Sep","30","2016") = yes;
. . .
display version;
```

Note that the display statement will generate a display of all elements of the set `version`, each indicating on which day a component of the model was modified.

4.14 Fixing Compilation Errors

As detailed in chapter [GAMS Output](#), the execution of a GAMS program passes through several stages, where the *compilation* is the first stage. Often when a program is run for the first time, it cannot be solved successfully because of compilation errors. This can be very frustrating, especially for new users. In this tutorial we will explain the causes of the most common compilation errors and offer some advice on how to fix them. For an introduction to compilation errors, see section [Compilation Errors](#). In addition, the tutorial [A GAMS Tutorial by Richard E. Rosenthal](#) offers some detailed material on this topic.

Note

Frequently, many compilation errors in the latter part of the code are actually consequential errors that will disappear as soon as the compilation errors in the beginning have been resolved. Therefore we recommend to start with fixing the first few errors and to run the program again. More often than not, many subsequent compilation errors will have vanished.

4.14.1 Preliminary Remarks

Before we will turn to an overview of the most common errors, examples that illustrate them and advice how to resolve them, we will provide some basic information on compilation errors and error messages.

4.14.1.1 Finding Compilation Errors

Compilation errors are marked with four asterisks (****) in the [compilation output](#) of the GAMS listing file (also called output file or lst file, since it has the extension `.lst`), hence it is easy to detect lines where compilation errors occurred by inspection.

Note

Compilation error messages also appear in the LOG file. And, if the GAMS IDE is used, a double-click at an error message in the LOG will navigate directly to the problematic code in the source file.

Consider the following simple example:

```
Set c "crops" / barley, wheat, soy, wheat, rice /;
```

If this set statement appears in a program, the resulting compilation output will contain the following lines:

```
1 Set c "crops" / barley, wheat, soy, wheat, rice /;
****                                     $172
```

...

Error Messages

```
172 Element is redefined
```

Note that in the [echo print](#) of the input file a line starting with **** is inserted and the dollar sign \$ followed by a number appears on this line. This indicates that a compilation error - in this case error 172 - was discovered in the line above. In addition, a list of all errors with explanatory error messages is given at the end of the echo print.

In our example, the error refers to `wheat` and the error message addresses the cause of the error: the respective element is redefined. Thus we check the other elements of the set and quickly realize that `wheat` appears a second time. If we delete the second instance of `wheat` and run the code again, this line will not cause any errors anymore. Note that many compilation errors are as easy to fix as demonstrated here.

4.14.1.2 Repositioning Compilation Error Messages

By default, the error messages are listed at the end of the echo print. GAMS allows to customize this position with the command line parameter [ErrMsg](#): the value of 1 for `ErrMsg` will move the error messages directly beneath the line where the respective error is marked and the value of 2 will suppress the error messages in the lst file completely. Note that the default is 0.

Consider the following simple example.

```
Set      a      / a1 * a7 /;
Set      b(a)   / a7 * a9 /;
Parameter p(k) / i3 47 /;
```

The resulting compilation output will contain the following lines:

```

1 Set      a      / a1 * a7 /;
2 Set      b(a)   / a7 * a9 /;
****                      $170
3 Parameter p(k) / i3 47 /;
****                      $120

```

...
Error Messages

```

120 Unknown identifier entered as set
170 Domain violation for element

```

Next, we run the same code with the following call:

```
> gams test ErrMsg=1
```

The resulting compilation output follows.

```

1 Set      a      / a1 * a7 /;
2 Set      b(a)   / a7 * a9 /;
****                      $170
**** 170 Domain violation for element
3 Parameter p(k) / i3 47 /;
****                      $120
**** 120 Unknown identifier entered as set

```

Observe that the error messages are now placed on the line after the error is marked. This can be especially useful if the program contains many lines of code.

Note

Users may change the system level defaults by entering the line `ErrMsg=1` in the file `gmsprmnt.txt` on Windows, or `gmsprmun.txt` on Unix machines as in the following example:

```

*****
* GAMS 2.50 Default Parameterfile for Windows NT           *
* Gams Development Corp.                                   *
* Date : 20 Mar, 1998                                     *
*****
* entries required by CMEX, put in by gams.exe:
* SYSDIR
* SCRDIR
* SCRIPTNEXT
* INPUT
errmsg=1

```

4.14.2 Resolving Common Compilation Errors

There are hundreds of compilation errors in GAMS, but some of them are particularly frequent. In the table below we present these common errors, with a brief description of the possible cause and a link to a subsection below where examples and more details are given. We recommend that users also read the error messages, since they often contain additional hints.

GAMS Error	Common Cause of Error	Subsections with Examples and More Details
8	Closing parentheses, square brackets or braces are missing.	H
36	The two dots . . are missing in the equation definition.	I
37	The equation type (eg. =L=) is missing in the body of the equation.	I
51-60	There are prohibited nonlinear expressions.	J
66	A data item which has not been given numerical values appears in an equation.	K
71	The equation has been declared, but not defined.	I
96, 97	A statement followed by another statement is not terminated with ;.	B
120	GAMS cannot find a set with this name. Check for typos in the set name and set elements that are referenced without quotes.	C, L
125	The set is controlled more than once, e.g., by an indexed operation like <code>sum</code> and by an equation definition.	F
140	GAMS is looking for a keyword or declared item and cannot find it. Check spelling and declarations.	A, C, K, M
141	The parameter without data is used or problems with <code>solve</code> and therefore attributes <code>.l</code> and <code>.m</code> are empty.	K
148	The identifier is referenced with more or less indexed sets than in the declaration.	E
149	The set is not controlled, neither by an indexed operation like <code>sum</code> , nor by an equation definition, nor by a loop or similar.	G, L
170	The referenced set element cannot be found in the set defined for this index position. Check for typos, omissions in the set declaration, missing quotes and references to the wrong set.	C, D
171	A domain error. The wrong set is referenced for the respective index position.	E, L
195	The name used here was already used for another identifier .	N
198	Using the operation <code>ord</code> or a lag/lead operation with a set that is not ordered.	O
256	Something is wrong with the model specification. This is often a consequential error of another error. Look for other error messages immediately after the solve statement.	I, J
257	The solver is not checked. This may be a consequential error of any GAMS error.	
340	Probably the quotes in a set element reference are missing.	L

GAMS Error	Common Cause of Error	Subsections with Examples and More Details
408	Surplus closing parentheses, square brackets or braces.	H

4.14.2.1 Error A: Misplaced Semicolons

Maybe the most common error for new users is related to semicolons. Consider the following example adapted from the well-known transportation model [[TRANSPORT](#)]:

```
Sets i  "canning plants"  / Seattle, San-Diego / ;
      j  "markets"         / New-York, Chicago, Topeka / ;
```

The resulting compilation output will contain the following lines:

```

20  Sets i  canning plants  / Seattle, San-Diego / ;
21      j  markets         / New-York, Chicago, Topeka / ;
****      $140           $36
...
Error Messages

36  '=' or '..' or ':=' or '$=' operator expected
      rest of statement ignored
140  Unknown symbol
```

What went wrong? GAMS statements like the [set statement](#) in our example have to terminate with a semicolon, unless the next line of code begins with a [reserved word](#). Now, set statements may extend over several lines and define several sets. In our example, the set statement extends over two lines and two sets are declared. However, there is a semicolon at the end of the first line, therefore GAMS assumes that the set statement ends there. The symbol `j` at the beginning of the next line has not been declared yet and it is not a GAMS keyword, thus it is marked as `Unknown symbol`. Note that error 36 is a consequential error that will disappear as soon as the first error has been resolved.

How do we fix this? There are two ways: either we could drop the semicolon at the end of the first line and thus indicate that the set statement continues to the second line or we could insert the keyword `Set` at the start of the second line and thus introduce a new set statement. These two alternatives are illustrated below:

```
Sets i  "canning plants"  / Seattle, San-Diego /
      j  "markets"         / New-York, Chicago, Topeka / ;
```

or

```
Sets i  "canning plants"  / Seattle, San-Diego / ;
Set  j  "markets"         / New-York, Chicago, Topeka / ;
```

Note

- In general, [GAMS statements](#) have to be terminated with a semicolon. The semicolon may be omitted if the next line starts with a [GAMS keyword](#).
- Even if it is not required, it is good practice to always end a statement with a semicolon.

4.14.2.2 Error B: Missing Semicolons

Consider the following example adapted from the well-known transportation model [TRANSPORT]:

```
Equations
    cost          "define objective function"
    supply(i)     "observe supply limit at plant i"
    demand(j)     "satisfy demand at market j"

cost ..          z =e= sum((i,j), c(i,j)*x(i,j)) ;
```

The resulting compilation output will contain the following lines:

```
52  Equations
53      cost          define objective function
54      supply(i)     observe supply limit at plant i
55      demand(j)     satisfy demand at market j
56
57  cost ..          z =e= sum((i,j), c(i,j)*x(i,j)) ;
****      $97              $195,96,195,96 $195,96
```

...
Error Messages

```
96  Blank needed between identifier and text
    (-or- illegal character in identifier)
    (-or- check for missing ';' on previous line)
97  Explanatory text can not start with '$', '=', or '..'
    (-or- check for missing ';' on previous line)
```

What went wrong? [GAMS statements](#) like the [equation declaration](#) in our example have to terminate with a semicolon, unless the next line of code begins with a [GAMS keyword](#). In our example, we omitted the semicolon at the end of the equation declaration statement and started a new statement after a blank line.

How do we fix this? We simply add a semicolon after the last explanatory text at the end of the equation declaration statement.

Note

A missing semicolon is often associated with error 96 or 97.

4.14.2.3 Error C: Spelling Mistakes

This error occurs if sets, set elements, parameters, etc. are referenced with a different name than the name they were declared with. Note that differences in capitalization are not considered spelling mistakes since GAMS is case insensitive.

Consider the following example adapted from the well-known transportation model [TRANSPORT]:

```

Sets i   "canning plants" / Seattle, San-Diego /
      j   "markets"       / New-York, Chicago, Topeka / ;

Parameters a(i) "capacity of plant i in cases"
           /   Seattle     350
           san-diego  600 / ;
...
Equations
  cost      "define objective function"
  supply(i) "observe supply limit at plant i"
  demand(j) "satisfy demand at market j" ;

cst ..      z =e= sum((i,j), c(i,j)*x(i,j)) ;

```

The resulting compilation output will contain the following lines:

```

20   Sets i   canning plants / Seattle, San-Diego /
21       j   markets       / New-York, Chicago, Topeka / ;
22
23   Parameters a(i) capacity of plant i in cases
24       /   Seattle     350
****          $170
25       san-diego  600 / ;
...
49   Equations
50       cost      define objective function
51       supply(i) observe supply limit at plant i
52       demand(j) satisfy demand at market j ;
53
54   cst ..      z =e= sum((i,j), c(i,j)*x(i,j)) ;
****          $140
...
Error Messages

140   Unknown symbol
...
170   Domain violation for element

```

What went wrong? Note that in line 24 the set element `Seattle` was referenced as `Seattle`. GAMS does not recognize this symbol as an element of the set `i` and thus marks this with error 170: **Domain violation**. GAMS catches this error since it automatically performs [domain checking](#). The typo in line 54, where the equation `cost` is referenced as `cst`, is marked with error 140 (**Unknown symbol**), since `cst` was *not* declared before.

Note

Set name misspellings are associated with error 120, set element misspellings with 170 and other misspellings with 140.

Fixing errors like these is as easy as fixing typos.

4.14.2.4 Error D: Missing Set Elements

Sometimes users forget to include an element in a set statement, but reference it later. Consider the following simple example:

```
Set      c      "crops"                / barley, wheat, soy /;
Parameter d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
```

The resulting compilation output will contain the following lines:

```
1 Set      c      "crops"                / barley, wheat, soy /;
2 Parameter d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
****
...
Error Messages

170 Domain violation for element
```

What went wrong? Note that the symbol `rice` was not defined as an element of the set `c`, thus GAMS does not recognize it and marks it with error 170: `Domain violation`. GAMS catches this error since it automatically performs [domain checking](#).

Note

If symbols are not defined as set elements, but are referenced as if they belong to the set later, error 170 will occur.

This is easy to fix: we just add the missing element(s) to the elements of the respective set.

4.14.2.5 Error E: Problems with Indices

Recall that variables, sets, parameters and equation may be defined over one or more indices. If the identifiers are referenced later in the program, the indices must appear exactly in the order that was specified in the respective definition statement. Consider the following example adapted from the well-known transportation model `[TRANSPORT]`:

```
Sets i  "canning plants"  / seattle, san-diego /
     j  "markets"         / new-york, chicago, topeka / ;
```

```
Table d(i,j) "distance in thousands of miles"
           new-york    chicago    topeka
seattle   2.5         1.7         1.8
san-diego 2.5         1.8         1.4 ;
```

```
Scalar  f      "freight in dollars per case per thousand miles" /90/ ;
Parameter c(i,j) "transport cost in thousands of dollars per case" ;
c(i,j,j) = f * d(j,i) / 1000 ;
```

The resulting compilation output will contain the following lines:

```

40   Parameter c(i,j)  transport cost in thousands of dollars per case ;
41   c(i,j,j) = f * d(j,i) / 1000 ;
****           $148           $171,171
...
Error Messages

```

```

148 Dimension different - The symbol is referenced with more/less
      indices as declared
171 Domain violation for set

```

What went wrong? Note that the parameter `c` was declared over two indices, but in the assignment statement in line 41 it is referenced with three indices. Such a mistake is marked with error 148. Note further, that the indices of `d` are referenced in the wrong order, which is marked with error 171.

Note

If an identifier is referenced with more or less indices as declared, then the error 148 will be triggered. If the indices are in the wrong order, the error 171 will be triggered.

This is easy to fix: we just check the declaration or definition statement(s) and adjust the reference.

Observe that the domain error 171 is also triggered if an identifier is referenced with index say `i`, but was defined over say `j`. However, there will be no domain error if `i` is a subset of `j` or `i` and `j` reference the same set since they are [aliases](#).

4.14.2.6 Error F: Summing over Sets that are Already Indexed

Consider the following equation definition that is adapted from the well-known transportation model [TRANSPORT]:

```
supply(i) .. sum((i,j), x(i,j)) =l= a(i) ;
```

The resulting compilation output will contain the following lines:

```

59   supply(i) .. sum((i,j), x(i,j)) =l= a(i) ;
****           $125
...
Error Messages

```

```
125 Set is under control already
```

What went wrong? Note that the equation is indexed over the set `i`, therefore the indexed operation `sum` in the body of the equation may not be controlled by the index `i` again.

Note

Summing over sets that are already indexed will trigger error 125.

How do we fix this? We need to carefully check the indexed operation and drop the surplus index. In other cases the controlling index may have to be dropped from the equation name. Note that an error like this is often indicative of a lack of clarity in thinking.

4.14.2.7 Error G: Uncontrolled Sets

Consider the following equation definition that is adapted from the well-known transportation model [TRANSPORT]:

```
demand .. sum(i, x(i,j)) =g= b(j) ;
```

The resulting compilation output will contain the following lines:

```
61 demand .. sum(i, x(i,j)) =g= b(j) ;
****                $149          $149
```

...

Error Messages

```
149 Uncontrolled set entered as constant
```

What went wrong? Note that the variable x is indexed over the sets i and j , but, while i is the index of the indexed operation `sum`, j is "free": it does neither appear as index of the equation nor as controlling index in `sum`. Therefore it was entered as if it were a constant. Note further, that j is also used as an index on the right-hand side of the equation without being controlled.

Note

Error 149 marks instances when an index is not controlled in the context of an equation or an indexed operation like `sum` or `prod`.

How do we fix this? We have to think what we actually want to model. In this case we need to enter j as a controlling index for the equation. But it would also be possible to add it as a controlling index for `sum` (but not both!). In the latter case there would still be the error on the right-hand side which needed to be taken care of with another indexed operation, e.g., `sum` again. Both approaches would remove the compilation error, but one has to think about what actually should be modeled to decide which is the right fix here.

4.14.2.8 Error H: Mismatched Parentheses

Consider the following two equations adapted from the model [CHENERY]:

```
mb(i).. x(i) =g= y(i) + sum(j, aio(i,j)*x(j)) + ( e(i) - m(i) )$t(i) ;
...
dvv(i)$ (sig(i) <> 0).. vv(i) =e= (pi*(1-del(i))/del(i))**(-rho(i)/(1+rho(i))) ;
```

The resulting compilation output will contain the following lines:

```
137 mb(i).. x(i) =g= y(i) + sum(j, aio(i,j)*x(j)) + ( e(i) - m(i) )$t(i) ;
****                $408,409
...
155 dvv(i)$ (sig(i) <> 0).. vv(i) =e= (pi*(1-del(i))/del(i))**(-rho(i)/(1+rho(i))) ;
****                $8
```

Error Messages

```
8  ')' expected
...
408 Too many ),] or }
409 Unrecognizable item - skip to find a new statement
      looking for a ';' or a key word to get started again
```

What went wrong? Note that in the first equation we have one surplus closing parenthesis, this is marked with error 408. The error marked with 409 is a consequential error, it will disappear once the first error has been fixed. In the second equation, one closing parenthesis is missing resulting in error 8.

Attention

Opening and closing parentheses (), square brackets [] and braces (curly brackets) { } must match.

Note

Surplus closing parentheses, brackets and braces are marked with error 408 and missing closing parenthesis, brackets and braces are marked with error 8. *Missing opening* parentheses, brackets and braces may result in GAMS marking *surplus closing* parentheses, brackets and braces; *surplus opening* parentheses, brackets and braces may result in GAMS marking *missing closing* parentheses, brackets and braces.

While fixing errors like these entails carefully counting opening and closing parentheses, there are strategies that help to prevent mismatching parentheses errors. Many text editors (like the GAMS IDE) offer a feature that identifies matching parentheses and will issue a warning if there is a mismatch. We recommend to use this feature. Further, we recommend to also use the alternatives to parentheses: square brackets and braces. They are especially useful if there are several opening parentheses since it is easier to determine by inspection if each has a matching closing symbol.

4.14.2.9 Error I: Mistakes Relating to Equations

Recall that each declared [equation](#) must be defined if it is to be used in a [model statement](#). If the equation definition is missing, GAMS will mark an error beneath the solve statement that refers to a model which references the respective undefined equation. Consider the following example adapted from the well-known transportation model [TRANSPORT]:

```
Equations
    cost          "define objective function"
    supply(i)     "observe supply limit at plant i"
    demand(j)     "satisfy demand at market j" ;

cost ..          z =e= sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..     sum(j, x(i,j)) =l= a(i) ;

Model transport /all/ ;
solve transport using lp minimizing z ;
```

The resulting compilation output will contain the following lines:

```
60 Model transport /all/ ;
61 solve transport using lp minimizing z ;
****                               $71,256
**** The following LP errors were detected in model transport:
**** 71 demand is an undefined equation
...
Error Messages

71 The symbol shown has been declared as an equation, but no
   Symbolic equation (..) was found. hint - look for commas in the
   Documentation text for the equations. use quotes around the
   Text or eliminate the commas.
256 Error(s) in analyzing solve statement. More detail appears
   Below the solve statement above
```

What went wrong? Note that the equation `demand` was declared and included in the model `transport`, but it was not defined. GAMS detects that the equation definition is missing when it compiles the solve statement that relates to the model `transport`. Therefore the error 71 appears only there. The error 256 is a consequential error, it will disappear once the missing equation definition has been added (*before* the solve statement).

Note

Error 71 marks a missing equation definition. The message associated with this error is a nice example of an error message that is very descriptive and offers advice on how to fix the error.

Apart from forgetting to define a declared equation and forgetting to terminate the equation definition statement with a semicolon (see [above](#)), two other mistakes relating to equations are frequent: omitting the syntax element `..` after the name of the equation and not properly defining the [equation type](#) in the equation definition statement. The following simple example adapted from the portfolio analysis model [ALAN] illustrates these mistakes:

```
fsum      sum(i, x(i))          =e= 1.0;
dmean..   sum(i, mean(i)*x(i))  = target;
```

The resulting compilation output will contain the following lines:

```
45 fsum      sum(i, x(i))          =e= 1.0;
****                $36
46 dmean..   sum(i, mean(i)*x(i))  = target;
****                $37
```

...

Error Messages

```
36 '=' or '..' or ':=' or '$=' operator expected
    rest of statement ignored
37 '=1=' or '=e=' or '=g=' operator expected
```

What went wrong? Note that in the first equation the two dots `..` are missing, which is marked with error 36, and in the second equation the equation type is not properly specified, which leads to error 37.

4.14.2.10 Error J: Issues with Nonlinear Expressions

The compilation error messages 51 to 60 refer to issues with nonlinear expressions involving variables in equations. For example, nonlinear expressions in an LP model will cause errors of this sort. So will discontinuous functions with endogenous arguments in an NLP model. For information on endogenous arguments in functions, see section [Functions in Equation Definitions](#). For an overview of GAMS model types, see section [Classification of Models](#).

Consider the following simple artificial example:

```
Variables x, y, z ;
Equations eq1, eq2 ;

eq1.. x**2 - y =e= z ;
eq2.. min(x,y) =1= 20 ;

Model silly / all / ;
solve silly using lp maximizing z ;
```

The resulting compilation output will contain the following lines:

```

7 Model silly / all / ;
8 solve silly using lp maximizing z ;
****                               $54,51,256
**** The following LP errors were detected in model silly:
**** 54 equation eq1.. VAR operands for **
**** 51 equation eq2.. the function MIN is called with non-constant arguments

```

Error Messages

```

51 Endogenous function argument(s) not allowed in linear models
54 Endogenous operands for ** not allowed in linear models
256 Error(s) in analyzing solve statement. More detail appears
    Below the solve statement above

```

Note that error 54 marks the nonlinear expression x^2 in a linear model and error 51 refers to the discontinuous function `min` that may be used with variables only in models of the type DNLP. The error 256 is a consequence of the two previous errors.

4.14.2.11 Error K: Using Undefined Data

Referencing data items that were not declared with a scalar, parameter or table statement will cause error 140: GAMS will indicate that the respective symbol is unknown. More often data items are declared, but not defined, i.e. they are not initialized with values.

Consider the following example adapted from the well-known transportation model [TRANSPORT]. Assume that the scalar `f` is declared, but has no numerical value. The resulting compilation output will contain the following lines:

```

40 Scalar f freight in dollars per case per thousand miles ;
41
42 Parameter c(i,j) transport cost in thousands of dollars per case ;
43
44           c(i,j) = f * d(i,j) / 1000 ;
****                               $141
...
61 Model transport /all/ ;
62 solve transport using lp minimizing z ;
****                               $257
63
64 display x.l, x.m ;
****                               $141
...

```

Error Messages

```

141 Symbol declared but no values have been assigned. Check for missing
    data definition, assignment, data loading or implicit assignment
    via a solve statement.
    A wild shot: You may have spurious commas in the explanatory
    text of a declaration. Check symbol reference list.
257 Solve statement not checked because of previous errors

```

What went wrong? Note that the scalar `f` was declared, but there was no value assigned to it. Thus, when it is referenced in the calculation in line 44, the "empty" scalar causes error 141. Error 257 is a consequential error and leads to the second error 141. This error occurs in the context of variable attributes in the display statement. Recall that [variable attributes](#) are data associated with variables. As the solve statement could not be checked, the level and marginal values of the variable `x` are not defined and hence error 141 follows.

Note

Error 141 marks places where data items, that have not been defined, are referenced in computations in the context of assignment statements. It also marks places where undefined variable (or equation) attributes are referenced.

In addition, undefined data items may be referenced in the context of equation definitions. Suppose we declare the parameter `c` in model `[TRANSPORT]`, but forget the corresponding assignment statement. Then the compilation output will contain the following lines:

```

57   cost ..          z =e= sum((i,j), c(i,j)* x(i,j)) ;
...
62   solve transport using lp minimizing z ;
****                               $66,256
**** The following LP errors were detected in model transport:
**** 66 equation cost.. symbol "c" has no values assigned
...
Error Messages

66 The symbol shown has not been defined or assigned
   A wild shot: You may have spurious commas in the explanatory
   text of a declaration. Check symbol reference list.
256 Error(s) in analyzing solve statement. More detail appears
   Below the solve statement above

```

Note that the missing data in the body of the equation `cost` is marked with error 66 and the following error is a consequential error which will disappear once 66 has been fixed.

Note

Referencing undefined data items in the body of an equation causes error 66.

4.14.2.12 Error L: Referencing Set Elements Without Quotes

Recall that if set elements are referenced, they need to appear in single or double quotes. Omitting the quotes may cause different errors depending on the context. The following example is adapted from the well-known transportation model `[TRANSPORT]`. Suppose we start by defining the two sets and the two parameters and then add the following statements:

```

Scalar s;
s = a(seattle);

```

The resulting compilation output will contain the following lines:

```

37  Scalar s;
38  s = a(seattle);
****          $120,340,149,171
...
Error Messages

120  Unknown identifier entered as set
149  Uncontrolled set entered as constant
171  Domain violation for set
340  A label/element with the same name exist. You may have forgotten
      to quote a label/element reference. For example,
      set i / a,b,c /; parameter x(i); x('a') = 10;

```

What went wrong? On the right-hand side of the assignment statement we have a reference with missing quotes. Note that this creates four (!) errors:

- 120 - GAMS expects a controlling set and `Seattle` is not recognized and therefore considered an unknown identifier.
- 340 - Then GAMS realizes that actually there is a label called `Seattle` in the program and helpfully offers a hint: You may have forgotten to quote a label/element reference.
- 149 - See section [Error G: Uncontrolled Sets](#) above.
- 171 - See section [Error E: Problems with Indices](#) above.

This is a nice example for one mistake triggering several errors that may look daunting. However, fixing them is as easy as adding single or double quotes.

4.14.2.13 Error M: Missing Declaration Statements

Recall that sets, parameters, variables and equations have to be declared before they may be used in definition or assignment statements. Suppose the equation `demand` in the well-known transportation model `[TRANSPORT]` was defined but not declared. Then the compilation output would contain the following lines:

```

59  demand(j) .. sum(i, x(i,j)) =g= b(j) ;
****          $140
...
Error Messages

140  Unknown symbol

```

Note that as `demand` was not declared, GAMS does not recognize it and therefore marks it with error 140: `Unknown symbol`.

Note

If error 140 is reported, the respective declaration statement is probably missing. However, the underlying cause may also be a simple typo.

4.14.2.14 Error N: Using the Same Name for Different Identifiers

Recall that each [GAMS identifier](#) must have a unique name. If the same name is used more than once, an error will be triggered. Consider the following modification of the transportation model [\[TRANSPORT\]](#):

```
Parameters  capacity(i)  "capacity of plant i in cases"
              / Seattle 350, San-Diego 600 /

              demand(j)  "demand at market j in cases"
              / New-York 325, Chicago 300, Topeka 275 /;

...
Equations
  cost      "define objective function"
  supply(i) "observe supply limit at plant i"
  demand(j) "satisfy demand at market j" ;
```

The resulting compilation output will contain the following lines:

```
47  Equations
48      cost      define objective function
49      supply(i) observe supply limit at plant i
50      demand(j) satisfy demand at market j ;
****          $195
...
Error Messages
```

```
195 Symbol redefined with a different type
```

What went wrong? Note that `demand` was first declared as a parameter and later as an equation. GAMS will mark this repeated use of the same name with error 195.

4.14.2.15 Error O: Using ORD with an Unordered Set

Recall that the operation [ord](#) is only defined for [ordered sets](#). If `ord` is used with an unordered set, error 198 will be triggered.

Consider the following example:

```
Set  a  "a couple of the elements" / r2, r3 /;
Set  b  "more elements"           / r1*r4 /;
Scalar c  "counter"                / 0 /;

loop( b $ (ord(b) > 3),
      c = c + 1 );
display c;
```

The resulting compilation output will contain the following lines:

```

5 loop( b $ (ord(b) > 3),
****          $198
6      c = c + 1 );
...
Error Messages

```

```

198 Set used in 'ord' or lag is not ordered.
    Hint: Some of the elements of the set were used before this
    was initialized and the order was different from the order used
    in this set. Try to initialize the set earlier.
    $offOrder allows lag operations on dynamic sets, reset with
    $onOrder

```

What went wrong? Two elements of the set `b` featured already in set `a` that was defined before set `b`. Therefore the order of the elements in set `b` is as follows:

```
r2 r3 r1 r4
```

Obviously, this set is not ordered and hence GAMS marks error 198 when the operator `ord` is applied to it.

How do we fix this? In this case it is easy: we just define the set `b` before set `a` and `b` will be an ordered set.

Consider one last example:

```

Set   a   "all elements"           / r1*r10 /;
Set   b   "elements in different order" / r3, r1, r4, r7 /;
Scalar c  "counter"                / 0 /;

loop( b $ (ord(b) > 3),
      c = c + 1 );
display c;

```

The resulting compilation output will contain the following lines:

```

5 loop( b $ (ord(b) > 3),
****          $198
6      c = c + 1 );

```

What went wrong? Note that even though all elements in set `b` are also elements of set `a`, they are not specified in the same order. Therefore the set `b` is unordered. For more details, see section [Ordered and Unordered Sets](#).

4.15 Finding and Fixing Execution Errors and Performance Problems

This tutorial is structured in four main parts: we will discuss how to find and resolve [errors that are detected during execution](#) of a GAMS model, we will give some guidance for [model development and debugging](#) and we will present techniques to increase efficiency by reducing GAMS [execution time](#) and [memory use](#).

4.15.1 Resolving Execution Errors

Recall that GAMS passes through a program file several times in the process of generating and solving a model. Errors may occur in each phase. In this section we will give some guidance on how to resolve errors that occur during execution, so after compilation. For advice on resolving compilation errors, see the tutorial [Fixing Compilation Errors](#). For more information on the process of generating and solving a model in GAMS, see the introduction to chapter [GAMS Output](#).

At execution, several things could go wrong and cause an error. We will look at these potential error sources separately in this section. First we look at [arithmetic errors](#) and [exceeded internal limits](#) during data manipulation, we will continue with problems during [model generation](#) and [model solution](#). At the end, we will briefly discuss how execution errors may be managed with the function `execError`.

4.15.1.1 Arithmetic Errors

GAMS execution errors may be caused by illegal arithmetic operations like a negative argument for `log`, division by zero and [exponentiation](#) where the base is a negative number. The following simple example serves as illustration:

```
Set      s      / s1*s5 / ;
Parameter p(s)  "data to be exponentiated"
          d(s)  "divisors"
          r(s)  "result";

p(s)    = 1;
p("s2") = -1;
d(s)    = 1;
d("s3") = 0;
r(s)    = p(s)**2.1 / d(s)
display r;
```

The first sign that something in the execution went wrong is the following flag in the log output:

```
*** Status: Execution error(s)
```

The resulting [execution output](#) will contain the following lines:

```
E x e c u t i o n

**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)

----      11 PARAMETER r      result

s1 1.000,    s2 UNDF,    s3 UNDF,    s4 1.000,    s5 1.000
```

Observe that the execution output begins with two error messages that can be easily found since they are marked with four asterisks `****`. The error messages are very informative: they indicate the line where the errors occurred and provide details about the nature of the errors. Further, the output generated by the display statement shows that the errors occurred when the values for `r("s2")` and `r("s3")` were computed. Inspecting the assignment statement for these two values, we realize that in the first instance

the base for the exponentiation is -1, which obviously is a negative number and hence is not allowed in this operation. In the second instance, the problem is that we divide by `d("s3")` which equals zero.

In this example, the errors are easily resolved with data revisions. In general, we recommend to use [conditional assignments](#) to prevent errors like these.

Note that in the example above the error messages indicated exactly where the problem was and it was easy to find the cause of the error. However, this is not always the case. In particular, if the problem is within a multi-dimensional item the user will need more patience. Usually it helps to display the results of the problematic operation and look for faulty entries. In addition, displaying the input data to the respective operation will help to investigate the numerical properties of the data that was entered in the computation. Often more displays will be needed to trace faulty input data through the program. Eventually this will lead the user to understand why the data has taken on the specific numerical values it has.

4.15.1.2 Exceeding GAMS Limits

By default, GAMS stops the solve of a model after 1000 seconds (wall clock time) or $2e9$ iterations. These limits may be adjusted with the options [reslim](#) and [iterlim](#) respectively. Note that both options are also available as [command line parameters](#) and [model attributes](#). In addition, the workspace may be limited with the command line parameters [WorkFactor](#) and [WorkSpace](#). Note that these options are also available as [model attributes](#). If any of these limits are exceeded, the execution of the [solve statement](#) will be interrupted.

For example, we could add the following option statement somewhere *before* the solve statement in the production model `[CHENERY]`:

```
option iterlim = 20;
```

Note that this statement reduces the iteration limit to just 20. The log output will contain the following lines:

```
** Feasible solution. Value of objective =    1033.34069261

** The iteration limit has been reached.

--- Restarting execution
--- chenery.gms(228) 2 Mb
--- Reading solution for model chenrad
*** Status: Normal completion
--- Job chenery.gms Stop 11/21/16 16:52:43 elapsed 0:00:00.106
```

Also the [solve summary](#) in the listing file notes the interrupt:

```

                S O L V E      S U M M A R Y

MODEL   chenrad                OBJECTIVE  td
TYPE    NLP                    DIRECTION MAXIMIZE
SOLVER  CONOPT                 FROM LINE 228

**** SOLVER STATUS      2 Iteration Interrupt
**** MODEL STATUS      7 Feasible Solution
**** OBJECTIVE VALUE   1058.9199

RESOURCE USAGE, LIMIT      0.078      1000.000
ITERATION COUNT, LIMIT    20          20
EVALUATION ERRORS        0           0

```

Observe that the solver status `Iteration Interrupt` indicates that the execution terminated because the iteration limit has been reached resulting in a feasible solution, but not the optimal solution. The line `ITERATION COUNT, LIMIT ...` reports that 20 iterations were performed and that 20 was also the limit for the number of iterations. Setting `iterlim` to a larger value will resolve this issue.

Similarly, allocating too little work space will cause the solver to terminate with no solution. For example, restricting the work space for the nonlinear test model [MHW4D] to just 0.1 MB and running it with the solver MINOS will produce the following lines in the log output:

```
Work space requested by solver --    0.77 Mb
Work space requested by user   --    0.10 Mb
Work space allocated          --    0.10 Mb
```

```
Reading Rows...
Reading Columns...
Reading Instructions...
```

```
EXIT - Not enough storage to solve the model.
       Request at least    0.19 Mbytes.
```

The [solve summary](#) in the listing file will contain the following information:

```

                S O L V E      S U M M A R Y

MODEL   wright                OBJECTIVE  m
TYPE    NLP                   DIRECTION MINIMIZE
SOLVER  MINOS                 FROM LINE 32

**** SOLVER STATUS      9 Setup Failure
**** MODEL STATUS      13 Error No Solution
```

Note that increasing the work space to at least the minimum amount requested by the solver will resolve this issue.

4.15.1.3 Resolving Model Generation Errors

Further execution errors may be detected when GAMS is generating the model before passing it to the solver. These errors may be [arithmetic errors](#) in the *body* of equations or errors in the structure of the model that cause the model to be inherently infeasible.

Consider the following simple example with arithmetic errors in the body of the equations. They are similar to the errors in the assignment in the example in section [Arithmetic Errors](#) above.

```
Set      s      / s1*s5 / ;
Parameter p(s)  "data to be exponentiated"
          d(s)  "divisors"
          m(s)  "multipliers";

p(s)     = 1;
p("s2") = -1;
d(s)     = 1;
d("s3") = 0;
```

```

m(s)      = 1;
m("s4") = 0;

Positive variable x(s);
Variable      z;

Equations obj "objective function"
            xlim;

obj..      z =e= sum(s,p(s)**2.2*x(s));
xlim(s)..  m(s) / d(s)*x(s) =e= 1;

Model mymodel / all /;
solve mymodel using lp maximizing z;

```

If we run this model, the log output will contain the following lines:

```

*** SOLVE aborted
--- Executing CPLEX: elapsed 0:00:00.006
--- test.gms(23) 4 Mb 3 Errors
*** Status: Execution error(s)
--- Job test.gms Stop 11/21/16 19:10:12 elapsed 0:00:00.006

```

Observe that the solve was aborted since there are 3 execution errors. The [equation listing](#) in the listing file will contain further details about these execution errors:

```

Equation Listing      SOLVE mymodel Using LP From line 23

**** Exec Error at line 19: rPower: FUNC DOMAIN: x**y, x < 0

---- obj =E= objective function

obj..  - x(s1) + UNDF*x(s2) - x(s3) - x(s4) - x(s5) + z =E= UNDF ; (LHS = UNDF)

**** Exec Error at line 20: division by zero (0)
**** Exec Error at line 20: Equation infeasible due to rhs value

**** INFEASIBLE EQUATIONS ...

---- xlim =E=

xlim(s4)..  0 =E= 1 ; (LHS = 0, INFES = 1 ****)

REMAINING 4 ENTRIES SKIPPED

```

Note that there is an arithmetic error relating to [exponentiation](#) in the first equation and an arithmetic error and an infeasibility in the second equation.

In our example, it was easy to detect the execution errors and their cause. However, an error in a multi-dimensional equation block may be much more difficult to find. Note that by default, only the first three entries in each equation block are shown in the equation listing. We recommend to use the option [limrow](#) to get a full listing, as this is the easiest way to inspect execution errors in the body of equations.

4.15.1.4 Resolving Solve Errors

In the solution phase, an external solver program processes the model and creates output with details about the solution process. Solve errors may be either [function evaluation errors](#) or [presolve errors](#).

4.15.1.4.1 Resolving Function Evaluation Errors Some solve statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the [solution report](#).

Function evaluation errors are numerical errors like those discussed in section [Arithmetic Errors](#) above. Other examples include square roots of negative variables and squaring a negative term, say x , using the syntax $x**2$.

Attention

Squaring a negative term, say x , using the syntax $x**2$ will cause an error. However, the alternatives $\text{sqr}(x)$ and $x*x$ will work (see [here](#) for an explanation).

Note that by default the solver subsystems will interrupt the solution process if arithmetic errors are encountered. Users may wish to permit a certain number of arithmetic errors and have reported *error warnings* instead. The option [domlim](#) facilitates this modification. Note that the default value for `domlim` is zero.

The best way to avoid evaluating functions outside their domain of definition is to specify reasonable variable bounds. However, there are cases when bounds are not enough. Consider the following simple example:

```
Set      i / i1*i5 /;
Variables x(i), z;
Equations r1, r2(i);

r1..    z =e= log(sum(i, x(i)));
r2(i).. x(i) =l= 10;
x.lo(i) = 0;
x.l(i)  = 5;

Model takelog / all /;
solve takelog using nlp minimizing z;
```

If we try to solve this little program with the solver MINOS, the log output will contain the following line:

```
EXIT - Function evaluation error limit exceeded.
```

The [solution report](#) in the listing file will have more detailed information:

```

                S O L V E      S U M M A R Y

MODEL   takelog           OBJECTIVE  z
TYPE    NLP               DIRECTION MINIMIZE
SOLVER  MINOS             FROM LINE 12

**** SOLVER STATUS      5 Evaluation Interrupt
**** MODEL STATUS       7 Feasible Solution
**** OBJECTIVE VALUE    0.0000

RESOURCE USAGE, LIMIT      0.183      1000.000
ITERATION COUNT, LIMIT    0      2000000000
EVALUATION ERRORS        2          0

...

EXIT - Function evaluation error limit exceeded.

**** ERRORS/WARNINGS IN EQUATION r1
      2 error(s): log: FUNC DOMAIN: x < 0 (RETURNED 0)

...

**** REPORT SUMMARY :      1      NONOPT ( NOPT)
                           0 INFEASIBLE
                           0 UNBOUNDED
                           1      ERRORS ( ****)

```

Note that the [solver status](#) has a value of 5 ([Evaluation Interrupt](#)), which means that the solver has been interrupted as more evaluation errors have been encountered than specified with the option [domlim](#). In our case `domlim` equals its default value zero, thus one error is enough to cause the interruption. The equation in which the evaluation error occurred and the type of error is reported a few lines later. In our example, the equation `r1` is problematic, since we take the logarithm of the expression `sum(i, x(i))`, an expression which may become zero.

Note that in models such as this each individual variable `x(i)` should be allowed to become zero, but the sum should not. This may be achieved by introducing an intermediate variable, say `xsum`, adding a lower bound greater than zero for it and using this variable as the argument for the function `log`:

```

Variable xsum;
xsum.lo = 0.0001;

Equations defxsum, r1;

defxsum ..    xsum =e= sum(i, x(i));
r1..        z =e= log(xsum);

```

For more information on intermediate variables, see section [Avoiding Expressions in Nonlinear Functions](#) in the tutorial [Good NLP Formulations](#).

Observe that solvers report the type of arithmetic problem encountered and the problematic equation, but do not identify the particular offending variable or the labels in the index of an equation that cause the error. If the cause is not obvious, users will have to investigate the numerical properties of the variables, labels and parameters in the body of the respective equation. This may involve the following:

- Displaying the input data items to the nonlinear terms in the respective equation.

- Searching the solution for equations that are infeasible (INFES) and variables that are nonoptimal (NOPT) in order to see where problems are present and which variables were being manipulated at the end of the run.
- Investigating variables and equations whose level values are zero, negative or very large at the end of the run.
- Deactivating part of the code to narrow down the problem as discussed in section [Isolating Terms in Slow Statements](#) below.

Resolving function evaluation errors will usually entail the following techniques:

- Adding lower bounds to variables to keep them above zero.
- Adding upper bounds to variables to prevent them from getting too large.
- Reformulating the model, for example, introducing intermediate variables.
- Providing better starting points that direct the solver search to a more relevant region. See section [Specifying Initial Values](#) in tutorial [Good NLP Formulations](#) for details.
- Fixing faulty input data.

4.15.1.4.2 Presolve Errors Some solvers use a pre-processing step where the program is presolved to make the main solution process faster. During this step model errors could already be discovered, as in the following example:

```
Variables          z;
Integer Variables y1,y2;

Equations          r1,r2,r3,r4;

r1.. z=e=y1+y2;
r2.. y1=g=0.10;
r3.. y2=g=0.10;
r4.. y1+y2=l=1;

Model badpresol /all/;
solve badpresol using mip maximizing z;
```

For this problem, Cplex detects in the presolve already, that there is no feasible integer solution. This is reported in the log:

```
Row 'r4' infeasible, all entries at implied bounds.
Presolve time = 0.00 sec. (0.00 ticks)

...

CPLEX Error 1217: No solution exists.
Problem is integer infeasible.
```

Here, Cplex makes it clear, where we have a problem: Row **r4** is infeasible, because all entries are at their "implied bounds". Lets look at **r2** and **r3** to see what this means: These equations set a lower bound of 0.1 for **y1** and **y2**. Since both variables are defined as **Integer Variables**, they get an implicit lower bound of 1. Given that, equation **r4** must be infeasible.

4.15.1.4.3 Solver Specific Limits Many solvers have internal limits that may be exceeded and may cause the listing file to report an execution error. These errors may be resolved by using either GAMS options or solver specific options to increase the respective limits. Usually, the listing file will contain information about which options to use. Note that the solver manuals distributed with GAMS list the options that may be specified for each solver. For example, to relax the MINOS major iteration limit, the user may create a file named `minos.opt` with the following line:

```
Major iterations 1000
```

More about solver option files can be found in section [The Solver Options File](#).

4.15.1.5 Managing Execution Errors with the Function `execError`

The function `execError` facilitates implementing procedures that manage execution errors. Consider the following example, which is an extension of the example in section [Arithmetic Errors](#) above.

```
Set      s      / s1*s5 / ;
Parameter p(s)  "data to be exponentiated"
          d(s)  "divisors"
          r(s)  "result";

p(s)    = 1;
p("s2") = -1;
d(s)    = 1;
d("s3") = 0;
r(s)    = p(s)**2.1 / d(s)
display r;

*cause z to be undefined
Scalar z;
z = 1/0;

if(execError > 0,
    r(s)$(r(s) = z) = 0;);
display r;
```

Observe that we introduced a new scalar `z` that is deliberately undefined. In the `if statement` that follows, we use the function `execError` in the logical condition and the undefined scalar in the `conditional assignment`. The `if statement` has the effect that undefined entries are removed from the array of the parameter `r`, as illustrated in the following lines of the execution output:

```
E x e c u t i o n

**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)

----      11 PARAMETER r      result

s1 1.000,    s2 UNDF,    s3 UNDF,    s4 1.000,    s5 1.000

**** Exec Error at line 16: division by zero (0)

----      20 PARAMETER r      result

s1 1.000,    s4 1.000,    s5 1.000
```

In addition, the function `execError` may be used to reset the count of the number of execution errors. Typically, it is reset to zero so that GAMS will terminate with the status message `Normal completion`. For example, we could add the following line at the end of the code in the example above:

```
execError = 0;
```

Note

Setting `execError = 0;` will not only result in a `normal completion` in the example above. A `solve statement` will not be executed if there were execution errors before by default. Setting `execError = 0;` before the solve statement, will allow to execute it again.

Setting `execError = 0;` results also in a notification in the log:

```
*****
*** Errors have been cleared ***
*****
*** Status: Normal completion
```

4.15.2 Small to Large: Aid in Development and Debugging

Many GAMS users are overly impressed with how easily GAMS handles large models. Modelers often feel such a facility means they should always work on the full model. The result is often a large, sometimes extremely large, model in the early stages of model development. Debugging such large formulations is not easy.

The algebraic modeling style employed in GAMS is inherently expandable. This offers interesting possibilities in terms of the strategy that may be employed for model development and debugging which are discussed herein.

4.15.2.1 An Illustrative Example

The set based algebraic modeling style implemented in GAMS is by its very nature easy to expand. It is easy to use the same model formulation on differently sized data sets. We will illustrate this based on the transportation model [TRANSPORT]. Note that we included some post-solution calculations at the end.

```
* Data section
Sets  i  "canning plants"  / Seattle, San-Diego /
      j  "markets"         / New-York, Chicago, Topeka / ;

Parameters  a(i)  "capacity of plant i in cases"
            / Seattle 350, San-Diego 600/

            b(j)  "demand at market j in cases"
            / New-York 325, Chicago 300, Topeka 275 /;

Table      d(i,j)  "distance in thousands of miles"

                New-York      Chicago      Topeka
Seattle      2.5              1.7          1.8
San-Diego    2.5              1.8          1.4  ;
```

```

Scalar f "freight in dollars per case per thousand miles" /90/ ;

Parameter c(i,j) "transport cost in thousands of dollars per case" ;
c(i,j) = f * d(i,j) / 1000 ;

* Model Section
Positive Variable x(i,j) "shipment quantities in cases";
Variable z "total transportation costs in thousands of dollars";

Equations cost "define objective function"
supply(i) "observe supply limit at plant i"
demand(j) "satisfy demand at market j";

cost .. z =e= sum((i,j), c(i,j) * x(i,j)) ;
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Parameter m(*,*) "commodity movement";
m(i,j) = x.l(i,j);
m("total",j) = sum(i, x.l(i,j));
m(i,"total") = sum(j, x.l(i,j));
m("total","total") = sum(j, m("total",j));
option decimals = 0;
display m;

```

This model may be easily extended by adding more data:

```

* Data section
Sets i "canning plants" / Seattle, San-Diego, Baltimore, Dallas /
j "markets" / New-York, Chicago, Topeka, Boston, Miami /;

Parameters a(i) "capacity of plant i in cases"
/ Seattle 350, San-Diego 600, Baltimore 450, Dallas 750 /

b(j) "demand at market j in cases"
/ New-York 325, Chicago 300, Topeka 275, Boston 330, Miami 290 /;

Table d(i,j) "distance in thousands of miles"

```

	New-York	Chicago	Topeka	Boston	Miami
Seattle	2.5	1.7	1.8	3.1	3.3
San-Diego	2.5	1.8	1.4	3.0	2.7
Baltimore	0.2	0.7	1.8	0.4	1.1
Dallas	1.5	0.9	0.5	1.8	1.3

```

Scalar f "freight in dollars per case per thousand miles" /90/ ;

Parameter c(i,j) "transport cost in thousands of dollars per case" ;
c(i,j) = f * d(i,j) / 1000 ;

* Model Section
Positive Variable x(i,j) "shipment quantities in cases";
Variable z "total transportation costs in thousands of dollars";

```

```

Equations cost      "define objective function"
      supply(i)    "observe supply limit at plant i"
      demand(j)   "satisfy demand at market j";

cost ..      z =e= sum((i,j), c(i,j) * x(i,j)) ;
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Parameter  m(*,*) "commodity movement";
m(i,j) = x.l(i,j);
m("total",j) = sum(i, x.l(i,j));
m(i,"total") = sum(j, x.l(i,j));
m("total","total")=sum(j, m("total",j));
option decimals = 0;
display m;

```

Observe that the two sets (*i* and *j*) were enlarged, the capacity (**a**) and demand (**b**) data were expanded to cover the new plant and market entries and the distance table (**d**) was adjusted accordingly. However, the data calculation, equations, model definition, model solution and report writing sections are identical in the two models.

4.15.2.2 Motivation and Step by Step Guide

As we have demonstrated in the example above, GAMS allows the model structure, calculations and report writing to be developed and implemented using a small data set, that may be easily expanded to larger data sets. Thus, we strongly recommend to start with a representative purposefully small data set and enlarge it to its full size once the work of model development, testing and debugging has been done. In short: work from small to large.

The larger the model the longer it takes to compile it, generate the model, execute and solve it. Generally, time expands exponentially. Working with a large model from the start will often lead to frustration even when the user is trying to find some relatively small data problems.

If a model that has already been completed needs some modification, it will be tempting to use the large data set instead of developing the modifications on a small data set. We strongly advise to use a small data set in this case, as experience shows that this way a considerable amount of time may be saved.

We recommend to follow these steps in model development:

1. Set up a small data set representing the full model with all structural features, set names, parameters etc.
 2. Implement all data calculations, model features and report writing calculations.
 3. Test the results of step 2 thoroughly.
 4. Save the small model. Then implement a larger version with the full data set. Create separate files for data, calculation, model definition and report writing to maintain size independence. Use [include files](#) or the [save and restart feature](#).
 5. Test the larger model. Use the modeling techniques discussed [below](#) to facilitate your work.
 6. Keep the small model current. As additional structural features are added to the large model, use it to test them. See section [Introducing Strategical Subsets](#) below for an easy way to maintain a small model.
-

4.15.2.3 Modeling Techniques

If users follow the steps for model development outlined in section [Motivation and Step by Step Guide](#) above, they will notice that it will not always be possible to model every needed feature with the small model. It is important to carefully choose the small data set so that it has all features of the larger data set. However, occasionally the peculiarities and interrelationships of the full data set cannot be reproduced in the small data set. In this section we will introduce some modeling techniques for finding problems that arise *only* when the full data set is used. They include saving and restarting to isolate the problem area, strategically introducing subsets and data reduction.

4.15.2.3.1 Isolating Problem Areas through Saving and Restarting Suppose we have a model with a large data set that takes several hours to run and we wish to add some lines of code in a relatively small segment. The best way to do this is by isolating the relevant part. Isolating the part we wish to modify makes it possible to do tests and repairs without having to input data, do initial calculations and solve the whole model with each run. We recommend to use [save and restart files](#).

For example, in chapter [The Save and Restart Feature](#) we demonstrate how to split the transportation model [TRANSPORT] in three parts: the file `tranmodel.gms` contains the data and the model, the file `transolve.gms` contains the solve statement and the file `tranreport.gms` contains a display statement. To run the whole model we use the following sequence, saving and restarting from the saved file:

```
> gams tranmodel s=s1
> gams transolve r=s1 s=s2
> gams tranreport r=s2
```

Assume we want a more elaborate report than just the display of some level values. As the file `tranreport.gms` contains the code relevant for reporting, we will modify only this file. Then we will test the result by running only this file, restarting from `s2`, without having to solve the whole model repeatedly.

4.15.2.3.2 Introducing Strategical Subsets When full data sets are used in debugging or development, it is often helpful to narrow the focus on a few items in a set by introducing [subsets](#). The following example is a modified version of the extended transportation model from section [An Illustrative Example](#) above.

```
* Data section
Sets  i  "canning plants"  / Seattle, San-Diego, Baltimore, Dallas /
      j  "markets"         / New-York, Chicago, Topeka, Boston, Miami / ;

Sets  plants(i)  "a reduced set of canning plants"
           / Seattle, San-Diego /
      markets(j)  "a reduced set of demand markets"
           / New-York, Chicago, Topeka / ;

*plants(i) = yes; markets(j) = yes;

Parameters  a(i)  "capacity of plant i in cases"
           / Seattle 350, San-Diego 600, Baltimore 450, Dallas 750 /

           b(j)  "demand at market j in cases"
           / New-York 325, Chicago 300, Topeka 275, Boston 330, Miami 290 /;

Table      d(i,j)  "distance in thousands of miles"
```

	New-York	Chicago	Topeka	Boston	Miami
Seattle	2.5	1.7	1.8	3.1	3.3
San-Diego	2.5	1.8	1.4	3.0	2.7
Baltimore	0.2	0.7	1.8	0.4	1.1
Dallas	1.5	0.9	0.5	1.8	1.3;

Scalar f "freight in dollars per case per thousand miles" /90/ ;

Parameter c(i,j) "transport cost in thousands of dollars per case" ;
c(plants,markets) = f * d(plants,markets) / 1000 ;

* Model section

Positive Variable x(i,j) "shipment quantities in cases";
Variable z "total transportation costs in thousands of dollars";

Equations cost "define objective function"
supply(i) "observe supply limit at plant i"
demand(j) "satisfy demand at market j";

cost .. z =e= sum((plants,markets), c(plants,markets) * x(plants,markets)) ;
supply(plants) .. sum(markets, x(plants,markets)) =l= a(plants) ;
demand(markets) .. sum(plants, x(plants,markets)) =g= b(markets) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Observe that we introduced the subsets `plants` and `markets` that contain only some of the elements of their supersets `i` and `j`. Note that all tables, parameters and variables are defined with the supersets, the equations are *declared* over the supersets, but *defined* over the subsets and the calculation of the parameter `c` is also restricted to the subsets. Hence the model is restricted to the elements of the subsets. However, it is easy to change the restricted model back to the full model by removing the asterisks indicating a comment line:

```
plants(i) = yes; markets(j) = yes;
```

Observe that the sets `plants` and `markets` are now [dynamic sets](#). Note that this assignment could be inserted anywhere in the code. Thus, introducing strategic subsets may be combined with isolating problem areas, as detailed in section [Isolating Problem Areas through Saving and Restarting](#) above.

Introducing strategic subsets has proven to be an effective way of maintaining a small data set with little effort. Users only have to choose elements that are representative for model development and debugging from the full sets.

4.15.2.3.3 Reducing Data Recall that GAMS skips cases where data items equal zero. Thus a large model may be reduced by temporarily removing data from data sets by simply setting items to zero. Consider the following example:

```
Sets      o          'origin'                / o1*o100 /
          d          'destination'          / d1*d100 /;
Parameter dist(o,d) 'distance';
dist(o,d) = 120 + 50*ord(d) - 0.5*ord(o);

Sets      so(o)      'small set of origins for testing' / o4, o47, o91 /
```

```

sd(d)      'small set of destinations'      / d3, d44, d99 /;

dist(o,d) $ (not (so(o) and sd(d))) = 0;

Parameter cost(o,d) 'transportation cost';
cost(o,d) $ dist(o,d) = 3 + 2*dist(o,d);
display cost, dist;

```

Note that we introduced [strategic subsets](#) and used them in the logical condition of a [conditional assignment](#) to set almost all entries of the parameter `dist` to zero. Note further, that the assignment for the parameter `cost` is conditioned on nonzero entries for the distance. Now, if the model were conditioned on nonzero transportation costs, the size of the whole model would be greatly reduced.

4.15.3 Increasing Efficiency: Reducing GAMS Execution Time

GAMS can take a long time for computations and model generation. There are some signs which indicate that it may be possible to reduce the execution time, e.g., an execution time that is unexpectedly long in general or a long execution of a single line, which could be seen, if the log shows the same line number for a long time.

In this section we will discuss how to [find the causes for slow program execution](#) and how to [eliminate the main causes for slow execution](#).

4.15.3.1 Finding the Causes for Slow Program Execution

The best strategy for discovering the causes for slow execution is a combination of the techniques discussed in section [Small to Large: Aid in Development and Debugging](#) above and the techniques that we will introduce in this section, including [generating an execution profile](#) and [isolating terms in slow statements](#). We will also touch briefly on [observing the log file](#) and we will point out why this is not the first choice.

4.15.3.1.1 Generating an Execution Profile The quickest way to find GAMS statements that take particularly long to execute, is generating an execution profile in the output file. The execution profile contains the individual and cumulative time required to execute the sections of the GAMS model as well as information on memory use. An execution profile is generated when the option `profile` is assigned a value larger than zero (zero is the default). This can be done either by setting a [command line parameter](#) or by using the [option statement](#). We will show an example of an execution profile below. For more information on execution profiles, further examples and details on the values the option `profile` may take, see the detailed description [here](#).

Consider the following example:

```

option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets      a / 1*22 /, b / 1*22 /, c / 1*20 /,
          d / 1*20 /, e / 1*22 /;

Parameters x(e,d,c,b,a), y, z(a,b,c,d,e);
x(e,d,c,b,a) = 10;
z(a,b,c,d,e) = x(e,d,c,b,a);
y              = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a));

```

```

Variable obj;
Positive Variable var(e,b,a);

Equations objeq, r(b,c,d), q(a,b,c);

objeq..      obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a) * var(e,b,a));
r(b,c,d)..   sum((a,e), var(e,b,a)) =l= sum((a,e), x(e,d,c,b,a)*z(a,b,c,d,e));
q(a,b,c)..   sum((d,e), var(e,b,a)/x(e,d,c,b,a)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a)*var.l(e,b,a));
display sumofvar;

```

The listing file will contain an execution profile like this (spread over the file):

----	9	Assignment x	0.374	0.374 SECS	109 MB	4259200
----	10	Assignment z	2.231	2.605 SECS	286 MB	4259200
----	11	Assignment y	2.324	4.929 SECS	286 MB	0
----	23	Solve Init slow	0.000	4.961 SECS	286 MB	
----	18	Equation objeq	3.510	8.471 SECS	287 MB	1
----	19	Equation r	3.088	11.559 SECS	464 MB	8800
----	20	Equation q	5.741	17.300 SECS	470 MB	9680
----	23	Solve Fini slow	0.780	18.080 SECS	470 MB	4482809
----	23	GAMS Fini	0.359	0.359 SECS	470 MB	
----	1	InitE	0.032	0.032 SECS	213 MB	
----	1	ExecInit	0.000	0.032 SECS	213 MB	
----	23	Solve Alg slow	0.000	0.032 SECS	213 MB	
----	23	Solve Read slow	0.000	0.032 SECS	215 MB	
----	26	Assignment sumofvar	2.620	2.652 SECS	287 MB	0
----	27	Display	0.032	2.684 SECS	287 MB	
----	27	GAMS Fini	0.000	0.000 SECS	287 MB	

The first column shows the line number in the input file of the GAMS statement that is executed. The second column reports the type of statement. For an overview of all GAMS statements, see section [Classification of GAMS Statements](#). The next two columns give the individual time needed to execute the respective statement and the cumulative time spent so far. The memory use follows and finally, the number of assignments generated in the respective line is shown.

In addition, there is a **Profile Summary** at the end of the lst file showing the most expensive statements:

```

---- Profile Summary (19 records processed)
5.741 0.470GB      20 Equation q (9680)
3.510 0.287GB      18 Equation objeq (1)
3.088 0.464GB      19 Equation r (8800)
2.620 0.287GB      26 Assignment sumofvar (0)
2.324 0.286GB      11 Assignment y (0)
2.231 0.286GB      10 Assignment z (4259200)
0.780 0.470GB      23 Solve Fini slow (4482809)
0.374 0.109GB      9 Assignment x (4259200)
0.359 0.470GB      23 GAMS Fini
0.032 0.213GB      1 InitE

```

This shows that the execution of the statements in line numbers 20, 18, 19, 26, 11 and 10 are the most expensive ones (in this order). One reason is an inconsistent order when sets are referenced; we will discuss this topic in section [Ordering Indices Consistently](#) below.

Note that the execution profile may contain many lines that are not informative since the execution times reported are negligible. These lines may be suppressed by using the option `profileTol` to specify the minimum execution time (in seconds) that is to be included. Observe that the option `profileTol` is available as command line parameter and option statement.

Note further, that the command line parameter `profileFile` facilitates writing the profiling information to a separate file (instead of the listing file).

4.15.3.1.2 Isolating Terms in Slow Statements In some cases the [execution profile](#) shows that the cause for a long execution time is connected with a very long statement. For example, the objective function in some models and some report calculations may take hundreds of lines of code and can contain many terms that are added. If such a long statement is problematic in terms of execution time, it will be necessary to deactivate parts of the code and run the program repeatedly to find the precise lines that are at the root of the problem. This can be done by using [comments](#).

4.15.3.1.3 Observing the Log File Some modelers choose to examine the log file or watch the screen during execution to find the causes for slow program execution. However, we advise against this approach for the following reasons:

- Statements that are executed slowly are easily missed and often statements are misidentified. In addition, screen watchers may be distracted and will have to repeat the process.
- GAMS line reporting can be misleading if [flow control statements](#) like [if statements](#) and [loop statements](#) are executed. For example, individual calculations in a loop are not reported to the screen. A user watching the screen would notice that the loop takes a lot of time, but there is no indication which statement within the loop is problematic. This applies to all GAMS control structures.

Therefore we recommend to use the option `profile` as the main tool for finding the causes for slow program execution. For details, see section [Generating an Execution Profile](#) above. In addition, see the techniques outlined in section [Advice for Repairing Puzzling Nonworking Code](#) below.

4.15.3.2 Eliminating the Main Causes for Slow Program Execution

The main reasons for a slow program execution include an [inconsistent index order](#) when sets are referenced and [taking irrelevant cases into consideration](#). In this section we will give some guidance on how to eliminate these causes, and also point to problems due to the [scaling of a model](#) which could cause a unnecessarily long execution time for the solver.

4.15.3.2.1 Ordering Indices Consistently GAMS employs a sparse matrix data storage scheme. For example, consider the parameter $p(\mathbf{a}, \mathbf{b}, \mathbf{c})$. Assume that the set \mathbf{a} has k elements, the set \mathbf{b} has n elements and \mathbf{c} has m elements. Then the entries for p are stored in the following order:

```

a1 b1 c1
a1 b1 c2
...
a1 b1 cm
a1 b2 c1
...
a1 b2 cm
...
a1 bn cm
a2 b1 c1
...
ak bn cm

```

Note that it is a systematic order where the last entry varies the fastest and the first the slowest. Observe that GAMS will withdraw entries from memory fastest if they are referenced in an order consistent with the storage order. Thus, in the following example, the first assignment statement will be processed faster than the second assignment statement.

```

x(a,b,c) = p(a,b,c);
y(b,c,a) = p(a,b,c);

```

Note

GAMS will execute a program fastest if the sets are always referenced in the same order in definitions, assignments and equations.

The example that follows illustrates this principle. First we will solve a program where the indices appear in an arbitrary order and we will record the output generated by setting the option `profile` to 1. Then we will reformulate the program so that the indices will always appear in an alphabetical order and solve it again, recording the `profile` output. In the final step, we will compare the execution times of the two runs. We will use the example introduced [above](#).

Note that the indices in the parameters and equations appear in a random order. Here is the profile from the six most expensive statements again:

```

----      10 Assignment z           2.231      2.605 SECS    286 MB  4259200
----      11 Assignment y           2.324      4.929 SECS    286 MB      0
----      18 Equation  objeq         3.510      8.471 SECS    287 MB      1
----      19 Equation   r           3.088     11.559 SECS    464 MB    8800
----      20 Equation   q           5.741     17.300 SECS    470 MB   9680
----      26 Assignment sumofvar     2.620      2.652 SECS    287 MB      0

```

In the next step we reformulate the program such that the indices always appear in the same order. For example, we define the parameter `x` as `x(a,b,c,d,e)` instead of `x(e,d,c,b,a)`. Here is the complete rewritten model:

```

option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets    a / 1*22 /, b / 1*22 /, c / 1*20 /,
        d / 1*20 /, e / 1*22 /;

```

```

Parameters x(a,b,c,d,e), y, z(a,b,c,d,e);
x(a,b,c,d,e) = 10;
z(a,b,c,d,e) = x(a,b,c,d,e);
y
    = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e));

Variable obj;
Positive Variable var(a,b,e);

Equations objeq, r(b,c,d), q(a,b,c);

objeq..    obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e) * var(a,b,e));
r(b,c,d).. sum((a,e), var(a,b,e)) =l= sum((a,e), x(a,b,c,d,e)*z(a,b,c,d,e));
q(a,b,c).. sum((d,e), var(a,b,e)/x(a,b,c,d,e)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e)*var.l(a,b,e));
display sumofvar;

```

After running the modified program, the profile for expensive statements looks like this:

----	10	Assignment	z	0.593	0.983 SECS	215 MB	4259200
----	11	Assignment	y	0.671	1.654 SECS	215 MB	0
----	18	Equation	objeq	1.778	3.432 SECS	215 MB	1
----	19	Equation	r	2.215	5.647 SECS	392 MB	8800
----	20	Equation	q	1.763	7.410 SECS	398 MB	9680
----	26	Assignment	sumofvar	0.952	0.983 SECS	216 MB	0

Observe that executing for example the assignment to z took just 0.593 seconds compared to 2.231 seconds in the first run. Substantial percentage reductions were achieved in all time consuming cases by consistently referencing the sets in the same order.

4.15.3.2.2 Replace loops with assignments The following statement assigns a constant value to a parameter.

```
loop((i,j,k),p(i,j,k)=2;)
```

The following assignment is preferred instead.

```
p(i,j,k)=2;
```

4.15.3.2.3 Restricting Assignments and Equations to Relevant Cases

4.15.3.2.3.1 Assignments Assume that we have a set of cities with different production capacities and demands for various products. We want to know the maximum transportation cost (which depends on the distance, the amount shipped and a fixed factor) from each city to all others. This cost can be calculated in the following way:

```
Sets c "cities" / c1*c800 /
      p "products" / p1*p10 /;
Alias (c,cc);

Parameter capacity(c,p) "Production capacity for product p in city c"
          demand(c,p) "Demand for product p in city c"
          distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
capacity(c,p)$ (uniform(0,1)<0.05) = uniformInt(150,250);
demand(c,p)$ (uniform(0,1)<0.025) = uniformInt(50,150);
distance(c,cc)$ (not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities";

maxCost(c,cc) = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);
```

The performance [profile](#) will tell us something like this:

```
----      16 Assignment maxCost          0.265      0.436 SECS      19 MB      8756
```

Since we know, that the parameter `maxCost` will be zero for a pair of cities if there is no product with production capacity in the first city and demand in the second one, we could reduce the execution time for the last assignment:

```
Sets c "cities" / c1*c800 /
      p "products" / p1*p10 /;
Alias (c,cc);

Parameter capacity(c,p) "Production capacity for product p in city c"
          demand(c,p) "Demand for product p in city c"
          distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
capacity(c,p)$ (uniform(0,1)<0.05) = uniformInt(50,150);
demand(c,p)$ (uniform(0,1)<0.025) = uniformInt(50,150);
distance(c,cc)$ (not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities";

maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))
  = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);
```

So we did not do the calculation of `maxCost` if we knew before, that it must be zero anyway. This results in a reduced runtime:

```
----      17 Assignment maxCost          0.031      0.187 SECS      19 MB      8756
```

Note

To restrict computations in assignment to the relevant cases, we recommend using [dollar conditions](#) and [filtering sets](#). These concepts are introduced and discussed in detail in chapter [Conditional Expressions, Assignments and Equations](#).

For more examples, see sections [Conditional Assignments](#) and [Conditional Indexed Operations](#).

4.15.3.2.3.2 Variables and Equations Like assignments, variables and equations need to be restricted to relevant cases to avoid unnecessary inefficiencies. [Dollar conditions](#) and [filtering sets](#) may be used over the domain of definition as well as in the body of an equation.

Lets extend the assignment example from the previous paragraph and use the generated data in a transportation model:

```
Sets c "cities" / c1*c800 /
    p "products" / p1*p10 / ;
Alias (c,cc);

Parameter capacity(c,p) "Production capacity for product p in city c"
    demand(c,p) "Demand for product p in city c"
    distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
capacity(c,p)$ (uniform(0,1)<0.05) = uniformInt(150,250);
demand(c,p)$ (uniform(0,1)<0.025) = uniformInt(50,150);
distance(c,cc)$ (not sameas(c,cc)) = uniformInt(10,800);

Parameter shipCost(c,cc) "Transportatin costs between two cities per case"
    maxCost(c,cc) "Maximum transportatin costs between two cities";

shipCost(c,cc) = distance(c,cc)*90;
maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))
    = sum(p, min(capacity(c,p), demand(cc,p))*shipCost(c,cc));

Variables
    x(c,cc,p) "shipment quantities in cases"
    z "total transportation costs in thousands of dollars" ;

Positive Variable x ;

Equations
    cost "define objective function"
    supply(c,p) "observe supply limit at plant i"
    dem(cc,p) "satisfy demand at market j" ;

cost.. z =e= sum((c,cc,p), shipCost(c,cc)*x(c,cc,p)) ;
supply(c,p).. sum(cc, x(c,cc,p)) =l= capacity(c,p) ;
dem(cc,p).. sum(c, x(c,cc,p)) =g= demand(cc,p) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;
```

The Profile Summary tells us, that the equations are rather expensive to generate and also the reading of the solution takes some time because of the size of the model:

```
---- Profile Summary (18 records processed)
98.780  1.070GB      34 Equation  dem (8000)
26.864  0.515GB      38 Solve Read transport
25.303  0.454GB      32 Equation  cost (1)
6.599   0.813GB      33 Equation  supply (8000)
```

However, as in the previous example, we know, that a product p won't be shipped from city c to city cc if there is either no production capacity in the first city or no demand in the second one. So we could reduce the size of our model by not generating variables and equations from which we know, that they are irrelevant for the solution. Here is a improved formulations of the equations:

```
cost..          z =e= sum((c,cc,p)$capacity(c,p)*demand(cc,p), shipCost(c,cc)*x(c,c
supply(c,p)$capacity(c,p).. sum(cc$demand(cc,p), x(c,cc,p)) =l= capacity(c,p) ;
dem(cc,p)$demand(cc,p)..   sum(c$capacity(c,p), x(c,cc,p)) =g= demand(cc,p) ;
```

This decreases the size of the model and thus the execution time to generate the model and load the solution significantly:

```
---- Profile Summary (18 records processed)
      0.031  0.035GB      33 Equation  cost (1)
      0.031  0.034GB      39 Solve Read transport
      0.016  0.035GB      34 Equation  supply (380)
```

Note that the equation `dem` does not even show up in the summary anymore since its generation was done to quickly.

For more details on conditions in equations, see section [Conditional Equations](#).

4.15.3.2.4 Keep the model well scaled Model solutions within GAMS frequently require manipulation of large matrices and many computations. The heart of most solvers includes many numerical procedures such as a sparse matrix inverter and sets of convergence and infeasibility tolerances. Numerical problems often arise within such procedures. Poorly scaled models can cause excessive time to be taken in solving or can cause the solver to fail. GAMS can assist the user to formulate a well scaled model. Details about this can be found in the sections [Model Scaling - The Scale Option](#) and [Scaling Variables and Equations](#).

4.15.3.3 Other Approaches

In addition to the techniques discussed in section [Eliminating the Main Causes for Slow Program Execution](#) above, the following approaches may help to reduce the time needed for program execution:

- Trying another appropriate solver.
- Reformulating the model. This may yield particularly good results, if the model is reformulated in such a way that another model type is used, that is easier to solve or for which more advanced solver technology is available.
- Using starting points for NLP models, as discussed in section [Specifying Initial Values](#).
- Trading memory for time.

We conclude the discussion of this topic with an example that demonstrates how memory may be traded for time. If an extensive calculation is repeated many times in a model, it may be possible to restructure the code so that the calculation is performed only once, then the result is saved and accessed later. Consider the following equation:

```
obj..   z =e= sum[(i,j,k,l), a(i,j,k,l)*sum(m, u(m,i))];
```

The execution time may be substantially reduced by defining a new parameter, say p , for the second sum and using this parameter in the equation:

```
Parameter p(i);
p(i) = sum(m, u(m,i));
...
obj.. z =e= sum[(i,j,k,l), a(i,j,k,l)*p(i)];
```

There is only one caveat: Users need to carefully consider whether the input data, here $u(m,i)$, is modified between the assignment for the new parameter p and the equation where p is used. If u is updated, then the assignment statement needs to be repeated, otherwise the data that enters the equation will not be current.

4.15.4 Increasing Efficiency: Reducing Memory Use

Besides slow program execution, excessive memory use may be of concern for modelers. In this section we will present some approaches on how to find the causes for extraordinary memory use and give some advice on [eliminating the main causes](#) for it.

4.15.4.1 Finding the Causes for Excessive Memory Use

The main techniques for finding the causes for excessive memory use are the same as those for finding the causes for slow program execution. We discussed these techniques in section [Finding the Causes for Slow Program Execution](#) above.

In addition, the option `dmpUserSym` is useful in this context. GAMS will report the number of records stored for each symbol at the point in the program where the option `dmpUserSym` is inserted together with some rough memory estimate.

Consider the following example:

```
Sets i /1*5 /, j /1*5 /, k /1*5 /, l /1*5 /,
      m /1*5 /, n /1*5 /, o /1*5 /;
Parameters y(i,j,k,l,m,n,o)
           q(i,j,k);
Variables x(i,j,k,l,m,n,o)
          f(i,j,k)
          obj;
y(i,j,k,l,m,n,o) = 10;
q(i,j,k) = 10;
x.up(i,j,k,l,m,n,o) = 10;
x.scale(i,j,k,l,m,n,o) = 1000;

Equations z(i,j,k,l,m,n,o)
          res(i,j,k)
          obj;

obj.. obj =e= sum((i,j,k,l,m,n,o), x(i,j,k,l,m,n,o));
z(i,j,k,l,m,n,o).. x(i,j,k,l,m,n,o) =l= 8;
res(i,j,k).. f(i,j,k) =l= 7;

Model memory /all/;
option dmpUserSym;
solve memory maximizing obj using lp;
```

Note that an option statement with `dmpUserSym` was added before the solve statement. It generates the following *memory dump* that is included in the [execution output](#) of the listing file:

```

SYMBOL TABLE DUMP (USER SYMBOLS ONLY), NR ENTRIES = 16
ENTRY          ID   TYPE DIM  LENGTH MEMORYEST  DEFINED  ASSIGNED  DATAKNOWN
  135           i    SET   1     5      0 MB     TRUE     FALSE     TRUE
  136           j    SET   1     5      0 MB     TRUE     FALSE     TRUE
  137           k    SET   1     5      0 MB     TRUE     FALSE     TRUE
  138           l    SET   1     5      0 MB     TRUE     FALSE     TRUE
  139           m    SET   1     5      0 MB     TRUE     FALSE     TRUE
  140           n    SET   1     5      0 MB     TRUE     FALSE     TRUE
  141           o    SET   1     5      0 MB     TRUE     FALSE     TRUE
  142           y  PARAM  7   78125    3 MB    FALSE     TRUE     FALSE
  143           q  PARAM  3    125     0 MB    FALSE     TRUE     FALSE
  144           x   VAR   7   78125    5 MB    FALSE     TRUE     FALSE
  145           f   VAR   3     0     0 MB    FALSE     TRUE     FALSE
  146           obj  VAR   0     0     0 MB    FALSE     TRUE     FALSE
  147           z   EQU   7     0     0 MB    FALSE     TRUE     FALSE
  148           res  EQU   3     0     0 MB    FALSE     TRUE     FALSE
  149           ob   EQU   0     0     0 MB    FALSE     TRUE     FALSE
  150           memory MODEL  0     3              TRUE     TRUE     TRUE
END OF SYMBOL TABLE DUMP

```

The column ID contains the names of the symbols, the column TYPE gives the [data type](#) of the respective entry, the column DIM reports the number of indices and the column LENGTH gives the number of records that is related to memory use, which is estimated in the column MEMORYEST. Note that the other columns are not relevant for this discussion.

Observe that the rows with high counts in column LENGTH indicate symbols within the GAMS program which have large numbers of internal records that must be stored. This is associated with corresponding memory requirements. Note also that not all length counts are of equal significance. In particular, variables and equations use more memory per element than parameters, since they have bounds, levels, marginals and scales that are associated with them. Parameters use more memory per element than sets, since sets may need just one indicator for **yes** or **no**. However, the explanatory text for set elements might increase the memory requirements for set elements.

Nevertheless, users may use this report to identify items with many records and verify that all of them are actually needed. For more details, see section [Eliminating the Main Causes for Excessive Memory Use](#) below.

4.15.4.2 Eliminating the Main Causes for Excessive Memory Use

As detailed in section [Eliminating the Main Causes for Slow Program Execution](#) above, the main causes for a slow program execution include an [inconsistent index order](#) when sets are referenced and [taking irrelevant cases into consideration](#). These programming habits also tend to cause excessive memory use. In this section we will give some advice on [avoiding memory traps](#) and show how the [memory may be cleared](#) of data that is no longer needed.

4.15.4.2.1 Avoiding Memory Traps Users may inadvertently use a lot of memory if they import data from a database with long explanatory text for sets or set elements. In addition, setting variable attributes for scaling or bounds may be problematic. Consider the following example:

```

x.scale(i,j,k,l,m) = 100;
x.lo(i,j,k,l,m) = 10;
x.up(i,j,k,l,m) = 77;

```

These assignments will probably set many more values than are relevant for a particular problem. Therefore we recommend to carefully consider which label combinations are actually necessary and to restrict the assignments to these cases by the use of dollar conditions or filtering sets. For more information, see section [Conditional Assignments](#).

4.15.4.2.2 Clearing Memory of Unneeded Data Sometimes a lot of memory space is used for data that is needed at some point, but not later. Consider the following simple example:

```
set i /1*1000/
    j /1*1000/;
parameter distance(i,j)
    cost(i,j);
distance(i,j) = 100+ord(i)+ord(j);
cost(i,j)      = 4+8*dist(i,j);
```

Assume that the parameter `distance` is used only here, but nowhere else in the program. Therefore users may wish to free the memory space occupied by the data connected with `distance`. The option `clear` may be used to achieve this:

```
option clear = distance;
```

This will reset all entries in the matrix associated with `distance` to zero.

Alternatively, an identifier that is no longer needed could be reset to its default value(s) with an assignment statement. In the example above, we could write:

```
distance(i,j) = 0;
```

This statement will have the same effect as the option statement. The advantage of the option statements is that they offer a more compact alternative that is particularly useful if equations or variables are to be cleared and multiple `equation attributes` or `variable attributes` are affected.

Note that the dollar control options `$clear` and `$kill` may also be used to free memory. These are compile time directives, which have a similar effect on the memory consumption but have different side effects: while `$clear` will reset the values to their defaults, `$kill` will completely remove the identifier from the program. Hence an identifier that was "killed" may be used later in another declaration and definition statement. For example, the following code snippet is legal:

```
Set i /1, 2 ,3/;
$kill i
Set i /a, b, c/;
```

With `$clear` instead of `$kill` this would cause a compilation error.

4.15.4.3 Setting Memory Limits with HEAPLIMIT

In a server environment and in other cases (e.g. to avoid the use of virtual memory) the amount of memory a GAMS run is allowed to use may have to be limited. The command line parameter `heapLimit` serves this purpose: the amount of memory for GAMS compilation and execution is limited to a specified number (in MB). If the data storage exceeds this limit, the job will be terminated with `return code 10, out of memory`. In addition, the function `heapLimit` may be used to interrogate the current limit and to reset it.

Note that limiting memory use for *solver execution* is not possible from within the GAMS program. However, some solvers like the NLP solver CONOPT have their own `heapLimit` option which ensures that the solver will not use more dynamic memory than specified.

4.15.4.4 Advice for Repairing Puzzling Nonworking Code

Assume a GAMS run was terminated and we cannot get a [profile output](#) (e.g. because GAMS ran out of memory and crashes). A memory overrun error causes the operating system buffer handling procedures to generally lose the last few lines of profile information when the job malfunctioned. How do we find the problem in this case?

We recommend to use the techniques outlined in section [Modeling Techniques](#) above. In addition, successively deactivating code in search for the last GAMS statement that worked will help in most cases. This can be done by using [comments](#). If at some point the run terminates properly, the user will slowly activate parts of the last statements that were deactivated until the code performance will get worse again. By iteratively activating and deactivating terms, the precise problematic terms may be found. The [save and restart feature](#) could also be used to save the results until a certain statement and then to execute only the statements that are suspected to be problematic.

4.16 Comparative Analyses with GAMS

Once a model is completed, it is almost always used to investigate alternative scenarios where the analyst compares the results of various scenario assumptions. In this tutorial we will show how such *comparative analyses* (also called *sensitivity analyses*) are done with GAMS. We will first demonstrate an easy approach, where we will manually change input parameters, use repeated solves and generate reports. In a second step, we will introduce another approach, where a [loop structure](#) will be used to automatically cycle through the scenarios. We recommend to read the sections on the manual approach first, since the sections on the automated approach build on code blocks developed in the early sections.

4.16.1 Manual Approach

Suppose we wish to do a comparative analysis by altering some input data in a model. We will use as an example the farm profit-maximizing model [farmcomp.gms](#). The following vector of prices for primary commodities is a part of the input data:

```
Parameter price(primary) 'prices for products in USD'
      / corn 2.20, soybeans 5.00, beef 0.50 /;
```

We will use these data as a base case and compare it with two alternative scenarios: in the first scenario we will change the price of beef to \$0.70 and in the second scenario we will change the price of corn to \$2.70.

The GAMS file [farmrep.gms](#) is related to our example model. It contains only calculations for report writing and may be included with the dollar control option [\\$include](#). It will generate a report based on the solution of the last solve that was executed in the GAMS program [farmcomp.gms](#). The report consists of several tables. We will focus on the table `Farm Summary` that is associated with the parameter `summary`. The relevant code is given below:

```
Set alli 'allitems'
  / corn, soybeans, beef, cattle,
    water, cropland, pastureland,
    fertilizer, seed, othercost, veterinary, supplement,
    "April labor", "May labor", "summer labor", "Sept labor", "Oct labor",
    cattlefeed, total / ;
```

```
Set measures 'output measures'
  / "Net Income", "Land Use", "Dry Cropping", "Irr Cropping",
    "Livestock", "Resource Value", "Product Value" /
```

```
Parameter summary(alli,measures) 'Farm Summary';
```

Note that the table for the parameter `summary` will contain rows for the commodities which are elements of the set `alli` and columns for all elements of the set `measures`.

We will use a third GAMS file, `mancomp.gms`, for our comparative analysis. The code of this third GAMS file follows:

```
$include farmcomp.gms
display price;
$include farmrep.gms

price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms

price("corn") = 2.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms
```

Note that this code first solves the original model that also contains the set definitions for the report, displays the initial prices and generates a report. In a second step the price for `beef` is changed to \$0.70, the modified model is solved, the prices for the first alternative scenario are displayed and a report is generated. In a third step the price for `corn` is changed to \$2.70, the model is solved again, the prices for the second alternative scenario are displayed and a third report is generated. Note that in the second alternative scenario (the third solve) the beef price is \$0.70, since it was not reset to base levels after the second run.

There will be three tables associated with the parameter `summary` in the listing file, one for each solve. The first table reports the results associated with the base case:

```
----- 279 PARAMETER summary Farm Summary
```

	Net Income	Land use	Dry Cropp~	Irr Cropp~	Livestock	Resource ~	Product V~
Corn			20.00	200.00			2.20
Soybeans			480.00				5.00
Beef							0.50
cattle					615.79		
Water						16.83	
Cropland		700.00				128.49	
Pastureland		130.00				84.26	
April Labor						32.34	
May Labor						27.01	
Oct Labor						11.50	
Cattlefeed							4.71
Total	162685.05		500.00	200.00			

The second table reports the results from the first alternative scenario where the price for beef was changed to \$0.70:

```
----- 351 PARAMETER summary Farm Summary
```

	Net Income	Land use	Dry Cropp~	Irr Cropp~	Livestock	Resource ~	Product V~
--	------------	----------	------------	------------	-----------	------------	------------

Corn		22.84	160.85		2.34
Soybeans		489.86			5.00
Beef					0.70
cattle				866.67	
Cropland	673.55				
Pastureland	130.00			1456.90	
April Labor				82.29	
May Labor				80.53	
Sept Labor				53.57	
Oct Labor				46.21	
Cattlefeed					4.89
Total	373686.10	512.70	160.85		

And the third table reports the results from the second alternative scenario where the price for corn was changed to \$2.70 and the price for beef stayed at \$0.70:

---- 423 PARAMETER summary Farm Summary

	Net Income	Land use	Dry Cropp~	Irr Cropp~	Livestock	Resource ~	Product V~
Corn			31.98	200.00			2.70
Soybeans			410.24				5.00
Beef							0.70
cattle					866.67		
Water						15.99	
Cropland		642.22					
Pastureland		130.00				1316.09	
April Labor						61.39	
May Labor						61.72	
Sept Labor						84.92	
Oct Labor						87.21	
Cattlefeed							5.36
Total	375839.30		442.22	200.00			

This quick way to do a comparative analysis has the following drawbacks:

- The relevant output is spread over more than 140 lines.
- There is no cross-scenario report.
- The price of beef in the second alternative scenario is problematic, since it was not automatically reset to the original base price.
- The handling of solves and report writing is repetitive.

The first two issues will be addressed in section [Writing Cross-Scenario Reports](#), a solution for the third issue will be given in section [Resetting Data to Base Levels](#) and an alternative approach that will resolve the last issue is presented in section [An Automated Approach - Avoiding Repeated Work](#).

Scenario Setup	.price	.Corn	2.20	2.20	2.70
Scenario Setup	.price	.Soybeans	5.00	5.00	5.00
Scenario Setup	.price	.Beef	0.50	0.70	0.70
Scenario Results	.Net Income	.Total	162685.05	373686.10	375839.30
Scenario Results	.Land use	.Cropland	700.00	673.55	642.22
Scenario Results	.Land use	.Pastureland	130.00	130.00	130.00
Scenario Results	.Dry Cropping	.Corn	20.00	22.84	31.98
Scenario Results	.Dry Cropping	.Soybeans	480.00	489.86	410.24
Scenario Results	.Dry Cropping	.Total	500.00	512.70	442.22
Scenario Results	.Irr Cropping	.Corn	200.00	160.85	200.00
Scenario Results	.Irr Cropping	.Total	200.00	160.85	200.00
Scenario Results	.Livestock	.cattle	615.79	866.67	866.67
Scenario Results	.Resource Value	.Water	16.83		15.99
Scenario Results	.Resource Value	.Cropland	128.49		
Scenario Results	.Resource Value	.Pastureland	84.26	1456.90	1316.09
Scenario Results	.Resource Value	.April Labor	32.34	82.29	61.39
Scenario Results	.Resource Value	.May Labor	27.01	80.53	61.72
Scenario Results	.Resource Value	.Sept Labor		53.57	84.92
Scenario Results	.Resource Value	.Oct Labor	11.50	46.21	87.21
Scenario Results	.Product Value	.Corn	2.20	2.34	2.70
Scenario Results	.Product Value	.Soybeans	5.00	5.00	5.00
Scenario Results	.Product Value	.Beef	0.50	0.70	0.70
Scenario Results	.Product Value	.Cattlefeed	4.71	4.89	5.36

In this cross-scenario report all output is in one table and it is easy to compare the base case with the two alternative scenarios.

We could also add percentage change calculations by introducing a further parameter, `savsummp`:

```
Parameter savsummp(ordr,*,alli,scenarios) 'Comparative Farm Summary (percent chg)';

savsummp(ordr,measures,alli,scenarios)$savsummp(ordr,measures,alli,"base") =
  round{ [savsummp(ordr,measures,alli,scenarios) - savsummp(ordr,measures,alli,"base")]*100
    / savsummp(ordr,measures,alli,"base"),1 };

savsummp(ordr,measures,alli,scenarios)
  $[(savsummp(ordr,measures,alli,"base") = 0) and (savsummp(ordr,measures,alli,scenarios) <> 0)]
  = na;

option savsummp:1:3:1;
display savsummp;
```

Note that both assignment statements are [conditional assignments](#). The first assignment computes percentage changes rounded to one decimal place and the second assignment sets the percentage change to `NA` if the value in the base case is zero. The output generated by the display statement follows:

```
---- 450 PARAMETER savsummp Comparative Farm Summary (percent chg)

                                         beefp  beefcorn
Scenario Results.Irr Cropping .Corn      -19.6
Scenario Results.Irr Cropping .Total    -19.6
Scenario Results.Livestock    .cattle    40.7      40.7
Scenario Results.Resource Value.Water -100.0      -5.0
Scenario Results.Resource Value.Cropland -100.0     -100.0
```

Scenario Results.Resource Value.Pastureland	1629.0	1461.9
Scenario Results.Resource Value.April Labor	154.4	89.8
Scenario Results.Resource Value.May Labor	198.1	128.5
Scenario Results.Resource Value.Sept Labor	NA	NA
Scenario Results.Resource Value.Oct Labor	301.8	658.4
Scenario Results.Product Value .Corn	6.4	22.7
Scenario Results.Product Value .Beef	40.0	40.0
Scenario Results.Product Value .Cattlefeed	3.9	13.8

4.16.1.2 Resetting Data to Base Levels

In the example above the price for beef was changed to \$0.70 for the first alternative scenario and it stayed at \$0.70 in the second alternative scenario, since we did not reset it manually to the base level. However, in most cases users find it preferable to reset all data to base levels before a new scenario is run. This may be done by saving the base level data in a new parameter, say `saveprice`, and then resetting the data to base levels before each scenario. In the following final version of the third GAMS file, `mancomp.gms`, the levels of the commodity prices are reset before each new run:

```

$include farmcomp.gms
$include farmrep.gms

Parameter saveprice(all) 'saved prices';
saveprice(all) = price(all);

Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,all,scenarios) 'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,all,"base") = summary(all,measures);

price(all) = saveprice(all);
price("beef" ) = 0.70;
solve farm using LP maximizing netincome;
display price ;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beefp") = price(primary);
savsumm("Scenario Results",measures,all,"beefp") = summary(all,measures);

price(all) = saveprice(all);
price("corn") = 2.70;
display price ;
solve farm using LP maximizing netincome;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beefcorn" ) = price(primary);
savsumm("Scenario Results",measures,all,"beefcorn") = summary(all,measures);

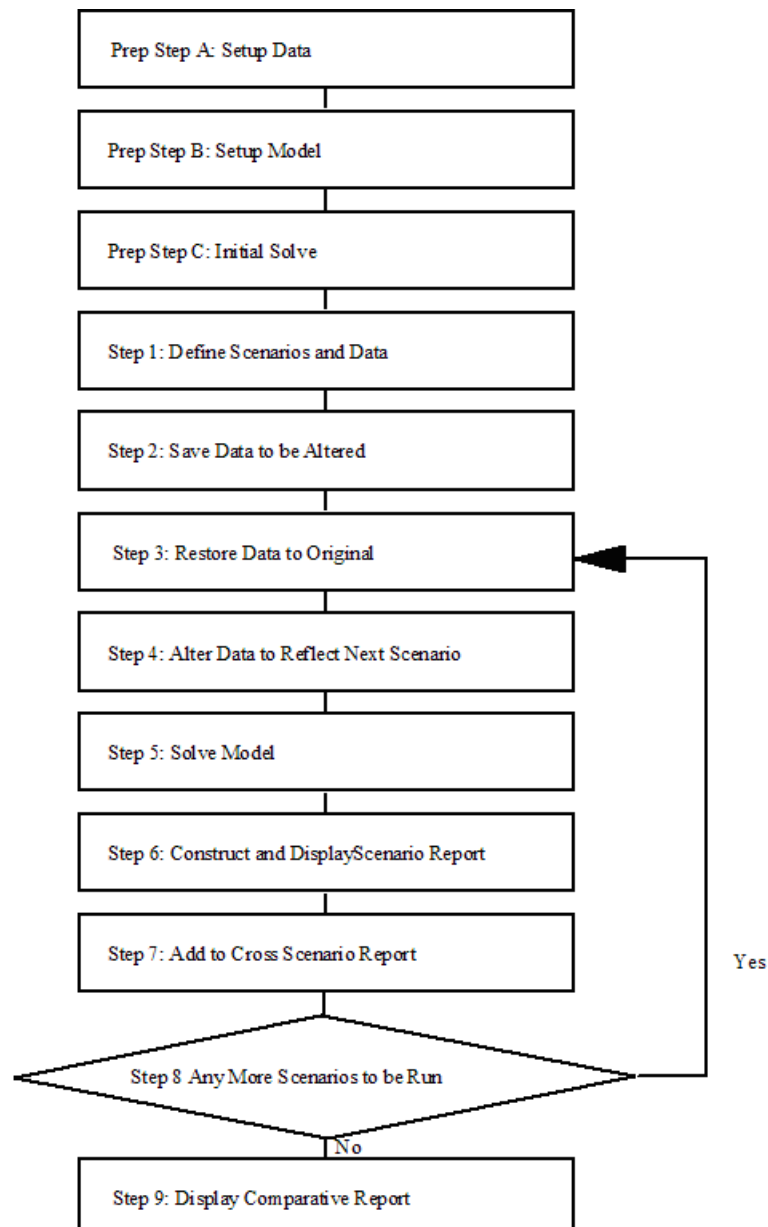

option savsumm:2:3:1;
display savsumm;

```

In this section we demonstrated how to do a comparative analysis manually, including a cross-scenario report and resetting the data before each new scenario is run. However, there is still a lot of repetition in how the solves and reports are handled. This issue will be addressed in the next section.

4.16.2 An Automated Approach - Avoiding Repeated Work

The basic structure of a comparative analysis that avoids repetitive instructions for solves and report writing is outlined in the [Figure below](#). Note that the first three boxes represent preparatory steps that are the usual parts of a GAMS program: the initial data is set up, the model is defined and solved. The comparative model analysis begins with the box labeled "Step 1". In Step 1 names for the scenarios are introduced and the scenario data is defined. In Step 2 the base data that will be changed during the scenario runs are saved in a new parameter. We will use this parameter later to restore the data to their base levels before each new scenario run. Starting with Step 3 we enter a loop, where the looping set is the set of scenarios introduced in Step 1. As usual, the statements in the loop are executed for each scenario to be analyzed. The first statement restores the data to their base levels (Step 3). Thus we will always start with the same data. In Step 4 the data and the model is updated for the current scenario and in Step 5 the model solved. In Step 6 a report for the individual scenarios is generated. In Step 7 parameters for cross-scenario comparative reports are saved. In Step 8 we check if more scenarios are to be solved and if this is the case, we return to repeat Steps 3-8 until all scenarios are completed. Finally, we display a comparative report that presents the information saved across scenarios.

This flow chart is implemented in the file `compare.gms` that is given below. Note that it is based on the farm profit-maximizing example discussed in section [Manual Approach](#) above. All sets and parameters were introduced in the sections above, only the table `scenprice` in the implementation of Step 1 is new.

```

*Step 1 - Setup scenarios
Set ordr      / "Scenario Setup", "Scenario Results" /;
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
Table  scenprice(primary,scenarios) 'price changes by scenario'
      base  beefp  beefcorn
corn                2.70
soybeans
beef                0.70      ;

*Step 2 - Save data
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);

*Step 3 - Reset data to base level
loop(scenarios,
      price(primary) = savprice(primary);

*Step 4 - Change data to levels needed in scenario
price(primary)$scenprice(primary,scenarios) = scenprice(primary,scenarios);
display price;

*Step 5 - Solve model
solve farm using LP maximizing netincome;

*Step 6 - Single scenario report writing
$include farmrep.gms

*Step 7 - Cross-scenario report writing
savsumm("Scenario Setup","price",primary,scenarios) = price(primary);
savsumm("Scenario Results",measures,alli,scenarios) = summary(alli,measures);

*Step 8 - End of loop
);

*Step 9 - Compute and display final results
option savsumm:2:3:1;
display savsumm;

```

Note that the main feature that facilitates this automatic approach is a loop statement. Loop statements are introduced and discussed in section [The Loop Statement](#). Note further, that in Step 4 we used a conditional assignment to restrict the change of data to those primary commodities that have nonzero entries for the respective scenario in parameter `scenprice`. For details on conditional assignments, see section [Conditional Assignments](#).

4.16.2.1 Adding A Scenario

Given the implementation of an automated comparative analysis above, it is easy to add a new scenario. Only two small modifications are needed: a name for the new scenario has to be added to the set `scenarios` and the respective data has to be added to the table `scenprice`. Both changes are in Step 1. The lines of the respective code are given below:

```

Set scenarios / base, beefp, beefcorn, new/;
Table scenprice(primary,scenarios) 'price alterations by scenario'
      base    beefp    beefcorn    new
corn                2.70
soybeans                        4.32
beef                0.70                ;

```

Note that we added a third alternative scenario called `new`, where the price of soybeans is changed to \$4.32. Note further, that the remainder of the code is not changed. Once the new scenario is added to the set `scenarios` and the respective data is specified in the table, it will enter the loop and thus all the statements in the loop will be executed for the new scenario.

Observe that the new scenario above was similar to the other scenarios: the price for a primary commodity was modified. However, in some cases new scenarios require that other data, like resources, are changed. For example, assume that in a new scenario the landtype "cropland" is increased by 30%. Note that the available resources were defined in the parameter `available(alli)`, where `available("cropland")` equals 700. To accommodate this new scenario we will add the following lines of code to Steps 1 to 4:

```

*Step 1 - Setup scenarios
Set scenarios / base, beefp, beefcorn, new /;
Table scenavailable(alli,scenarios) 'resource alterations by scenario'
      base    beefp    beefcorn    new
cropland                1.3;

*Step 2 - Save data
Parameter saveavailable (alli) 'save available resources';
saveavailable (alli) = available (alli);

*Step 3 - Reset data to base level
loop(scenarios,
      available (alli) = saveavailable (alli);

*Step 4 - Change data to levels needed in scenario
available(alli)$scenavailable(alli,scenarios) =
      available(alli)*scenavailable(alli,scenarios);
display price, available;

```

Note that in Step 1 we added a new table, `scenavailable`, to specify the resource alternations by scenario. Observe that the values of `scenavailable` will be used as multipliers in Step 4. In Step 2 we introduced the parameter `saveavailable`, that will play a similar role for the available resources like the parameter `saveprice` does for the prices of the primary commodities: the base levels are saved in this parameter and we will use it to restore the values of `available` to their base levels before each new scenario run. This is implemented with the new assignment in Step 3. In Step 4 the data levels of the parameter `available` are modified as required for the current scenario using a [conditional assignment](#). Note the similarities to the assignment for updating the values of `price` in Step 4 above. Steps 5 to 9 remain unchanged. Thus we achieved an automated comparative analysis with an additional scenario where another parameter is modified by adding just a few lines of code. The full code is given in the GAMS file `compareother.gms`.

4.16.2.2 Changing the Structure of a Model

Many studies require modifications of the *structure* of a model. In GAMS, context-sensitive model structures may be implemented with [dollar conditions](#). Dollar conditions may be used to control equations as well as specific terms.

To illustrate, we will extend the profit-maximizing farm model from the previous sections to include a conditional constraint that limits the number of cattle. This constraint will be only active if a scalar that varies with the scenarios is nonzero. Consider the lines of code that follow. Note that the set `animals` is a subset of the set `alli`, the elements of the set `livemanage` denote various ways of managing crops and animals, and `liveprod` is a positive variable for livestock production.

```

$include farmcomp.gms
$include farmrep.gms

Scalar  cowlim  'activates cowlimit constraint' /1/;
Equation cowlimit 'conditional equation on cow limits;
cowlimit$cowlim..  sum((animals,livemanage), liveprod(animals,livemanage)) =l= 100;
Model farmcowlim /all/;

Set ordr      / "Scenario setup", "Scenario Results" /;
Set scenarios / base, cowlim /;
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);
Parameter cowlims(scenarios) 'cowlimit by scenario'
          / base 0, cowlim 1/;

loop(scenarios,
      cowlim = cowlims(scenarios);
      solve farmcowlim using LP maximizing netincome;
);

```

Note that in the loop the value of the scalar `cowlim` is updated before each scenario is run. Note further, that this value determines whether the new equation `cowlimit` will be active or not. The complete code is given in the GAMS file [comparemod.gms](#).

4.16.2.3 Monitoring Comparative Analyses

Suppose we are running a comparative analysis that takes a long time since many solves need to be executed, and we wish to monitor the progress of the run. The following lines of GAMS code will send the relevant information to the screen. First, we will specify where the information is to be sent depending on the operating system:

```

$set console con
$if %system.filesys% == UNIX $set console /dev/tty
file screen / '%console%' /;
file log /''/

```

Then, we will use the following loop to send information about the current scenario to the screen and the log file:

```

loop(scenarios,
      put screen;
      put 'I am on scenario ' Scenarios.tl;
      putclose;
      put log;
      put 'I am on scenario ' Scenarios.tl;
      putclose;
);

```

4.16.3 Ranging analysis

Some users are interested in getting ranging output in the form of LP cost and right hand side ranging results. Unfortunately, the base version of GAMS does not yield such information. The user wishing such information has two alternatives. First, one may cause the model to be repeatedly solved under a set of values for the key parameter using the procedures discussed above, but this is cumbersome if a lot of parameters are involved. Second, one can use solver dependent features of GAMS that can be retrieved into a GAMS parameter. Please refer to the solver manuals (e.g. for GAMS/CPLEX: [Sensitivity Analysis](#)) for further information how to use them.

4.17 Good NLP Formulations

In this tutorial we offer some advice and guidance on how to set up or formulate an NLP model so that a solver will be able compute a good solution and do so quickly, reliably, and predictably. Much of this applies to other model classes allowing nonlinear functions, but for ease and simplicity of exposition we focus on the NLP case here.

A good formulation for an NLP model typically involves several things, including [specifying sensible initial values](#), [setting variable bounds](#), and [scaling variables and equations](#). Other factors to consider are techniques for [blocking degenerate cycling](#) and the potential benefits of [avoiding expressions in nonlinear functions](#). Finally we look at reformulations and approximations for discontinuous functions like `abs`, `max` and `min` in section [Reformulating DNLP Models](#).

4.17.1 Specifying Initial Values

The variable levels and equation marginals in GAMS are typically passed to a solver to be used as the initial point. The initial values specified are especially important for NLP models for several reasons:

- Non-convex models may have multiple local solutions. Local NLP solvers search for a local solution and return it when it is found. An initial point in the neighborhood of a desired solution is more likely to return that solution.
- Initial values that (almost) satisfy many of the constraints reduce the work involved in finding a first feasible solution.
- Initial values that are close to a local optimum reduce the work required to find that local optimum, therefore reducing solution time.
- The progress of the optimization algorithm is based on good directional information, i.e on good derivatives. The derivatives in a nonlinear model depend on the current point, so an improved initial point can improve solver performance.

Variable levels and equation marginals are specified by setting the [variable attribute](#) `.L` and the [equation attribute](#) `.m` before solution. This is often done with assignments that occur *before* the solve statement, e.g.:

```
domPrice.L(i,region,t) = domPrice0(i,region,t);
flowLim.m(arcs) = 1;
```

Note

The default value for the variable levels and equation marginals is 0.

The variable *bounds* also play a role in determining the initial point passed to the NLP solver. When a solve occurs, the levels for all variables *in the model* are first projected onto the set defined by the variable bounds. Thus, setting a variable's lower bound to a positive value ensures that the initial value of this variable will never be zero. This is very useful, since in many cases zero is an unsuitable initial value for nonlinear variables. For example, based on the product term $x \cdot y$, an initial value of zero for x will lead to an initial derivative value of zero wrt y , so it will appear as if the function does not depend on y . Variables at zero can also cause numerical difficulties with logarithms, real powers, or divisions. These difficulties occur not just at zero but also for very small values (i.e. values very close to zero) as well.

We recommend to specify as many sensible initial values for the nonlinear variables as possible. It may be desirable to initialize all variables to 1 or to the scale factor if the GAMS [scaling option](#) is used. A better alternative is to first select reasonable values for some variables that are known from context or experience to be important and then to use some of the equations of the model to compute the values for other variables. For example, consider the following equation, where `pm`, `pwm` and `er` are variables and `tm` is a parameter:

```
pmDef(i).. pm(i) =e= pwm(i)*er*(1+tm(i));
```

The following assignment statements use the equation to derive consistent initial values for the variable `pm` from sensible initial values for the variables `pwm` and `er`:

```
pwm.L(i) = 1;
er.L = 1;
pm.L(i) = pwm.L(i)*er.L*(1+tm(i));
```

It would be a mistake to assign only to `pwm` and `er` and assume that the solver will choose to adjust the variable `pm` to make the equation feasible: it could choose to adjust `pwm` or `er` instead. With all the assignments above made, we can be assured that the equation `pmDef` will be satisfied at the initial point.

Setting the initial point by [loading a prior solution](#) that has been saved via the [savepoint](#) mechanism is also an effective strategy that is very easy to implement.

4.17.2 Setting Variable Bounds

Lower and upper bounds on variables are set by assigning values to the [variable attributes](#) `.lo` and `.up` in the following way:

```
price.lo(i,region,t) = 1e-4;
flow.up(arcs) = arcCap(arcs);
```

Lower and upper bounds on variables in nonlinear models serve multiple purposes. Some bounds represent constraints based on the reality that is being modeled. For example, a certain production level must be non-negative or an arc in a network has a flow capacity of at most ten. These bounds are called *model bounds*. Other bounds help the algorithm by preventing it from moving far away from any optimal solution and/or into regions with singularities in the nonlinear functions or unreasonably large function or derivative values. These bounds are called *algorithmic bounds*. Solver performance can be improved and execution errors (see [domLim](#) and [domUsd](#)) avoided when algorithmic bounds on variables are introduced.

Model bounds are determined by the reality being modeled and do not cause any problems. However, algorithmic bounds must be carefully chosen by the modeler. We recommend to pay particular attention if a variable is the argument in `log(x)`, `log10(x)` or `exp(x)` and if a variable occurs in the denominator of a division. If `log(x)` or `log10(x)` appears in a model, where `x` is a variable, we recommend a lower bound of `1.e-3` for `x` since `log(x)` gets very small as `x` approaches zero and is undefined for negative values of `x`. In addition, the first derivative gets very large as `x` approaches zero. If `exp(x)` features in a model, where `x` is a variable, we recommend an upper bound between 20 and 25 for `x`. If a variable `x` appears in the denominator, we recommend a lower bound of `1.e-2` for `x`, since `1/x` is extremely nonlinear for small arguments. Small values for variables used with negative exponents are also not desirable. Solver performance can be improved and execution errors avoided when one introduces algorithmic bounds on variables.

Note that lower and upper bounds facilitate finding a feasible solution as most solvers will honor bounds at all times, but inequalities are not necessarily satisfied at intermediate points. A further advantage of variable bounds compared to inequalities is improved presolve performance: NLP solver preprocessors will typically incur little or no computational overhead due to variable bounds.

4.17.3 Avoiding Expressions in Nonlinear Functions

It is often useful to avoid nonlinear functions of expressions (e.g. a division by the sum of many variables). Instead, an *intermediate* variable can be used for the expression. This applies in particular if the expressions depend on many variables. Consider the following example:

```
variable x(i), y;
equation ydef;
ydef.. y =e= 1 / sum(i, x(i));
```

This example could be reformulated via the intermediate variable `xsum` and its defining equation `xsumdef` in the following way:

```
variable x(i), y, xsum;
equation xsumdef, ydef;
xsumdef.. xsum =e= sum(i, x(i));
ydef .. y =e= 1/xsum;
xsum.lo = 1.e-2;
```

In the equation `ydef`, the intermediate variable `xsum` appears in the denominator instead of the original summation. This allows us to impose a lower bound on the variable `xsum` to avoid dividing by zero. Of course, the model will contain more rows and columns if intermediate variables are introduced, but this increase in size is offset by a decrease in complexity and, in many cases, by an increase in sparsity as well.

4.17.4 Scaling Variables and Equations

Recall that nonlinear programming algorithms use the derivatives of the objective function and the constraints to find good search directions and they use function values to determine if constraints are satisfied or not. The *relative size* of the derivatives and the function values is influenced by the units of measurement that are used for the variables and constraints, and will have an effect on the performance of the solver and the result computed. Therefore, a proper, consistent scaling of the model is important to the success of the solution algorithm and the quality of the answer returned.

For example, assume that two goods are equally costly: both cost \$1 per kg. However, the first is specified in grams and the second in metric tons, so that their coefficients in the cost function will be vastly different: \$1000 per gram and \$0.001 per ton respectively. If cost is measured in \$1000 units, then the coefficients will be 1 and 1.e-6 respectively. This discrepancy in size may cause the algorithm to ignore the variable with the smaller coefficient, since the coefficient is comparable to some of the zero tolerances. To avoid such problems, the units of measurements need to be carefully chosen, that is, variables and constraints need to be properly scaled.

We recommend scaling with the following goals in mind:

- Solution level values of variables should fall into a range around 1, e.g. from 0.01 to 100.
 - The magnitude of the nonzero constraint marginals at solution should fall into a range around 1, e.g. from 0.01 to 100.
 - The magnitude of the derivatives of the nonlinear terms (i.e. the Jacobian elements) should fall into a range around 1, e.g. from 0.01 to 100, both at the initial point and at the solution.
 - The constants in the equations should have absolute values around 1, e.g. from 0.01 to 100.
-

Well-scaled variables are measured in appropriate units. In most cases users should select the unit of measurement for the variables such that their expected value is around unity. Of course, there will always be some variation. For example, if $x(i)$ is the production at location i , one could select the same unit of measurement for all components of x , say, a value around the average capacity.

In well-scaled equations the individual terms are measured in appropriate units. After choosing units for the variables users should choose the unit of measurement for the equations such that the expected values of the individual terms are around 1. For example, if these rules are followed, material balance equations will usually have coefficients of 1 and -1.

Usually well-scaled variables and equations result in well-scaled derivatives. To check whether the derivatives are well-scaled, we recommend running the model with a positive value for the option [limrow](#) and inspecting the coefficients in the [equation listing](#) of the GAMS list file.

For more about scaling in GAMS, see section [Model Scaling - The Scale Option](#). Note that while many solvers have internal scaling procedures, a better result can generally be achieved by a judicious choice of units by the model developer.

4.17.5 Blocking Degenerate Cycling

Most commercial linear programming solvers use a perturbation technique to avoid degenerate cycling during the solution process: they temporarily add small numbers to the right-hand sides of equations. In general, NLP solvers do not have such an internal feature. Sometimes the success and performance of an NLP solver can be enhanced by a manual perturbation formulation.

In particular, if users observe that the NLP solution process has a large number of iterations where the solver does not make significant progress in altering the objective function value, we recommend to modify the equations in the model by replacing the value of zero on the right-hand side with a small number. This may accelerate the solution process. Assume that we have the following equation:

$$f(x) \leq 0$$

This could be reformulated as:

$$f(x) \leq \delta * 0.001$$

Here we set δ to 1 if we wish to keep the addition and to zero otherwise. The value of 0.001 is just an example and needs to be adjusted based on the model context. The number should be chosen such that it does not introduce significant distortions into the problem solution. Such an addition quite frequently reduces solution time by helping the solver avoid degenerate cycling. If it is done correctly, the resulting model solution is not qualitatively different from the original model solution. Users may also first solve the model with $\delta = 1$ and subsequently with $\delta = 0$ to get rid of the effects of the small numbers.

We recommend that user avoid using the same number but instead use some systematically varying number or a random number. The technique of adding a small number on the right-hand side may also be used in problems where many equations have the same nonzero value on the right-hand side.

4.17.6 Reformulating DNLP Models

Nonlinear models in GAMS belong to one of the following two classes: *smooth* and *discontinuous*. Typically, all functions with endogenous arguments contained in the model are smooth functions (i.e. functions with continuous derivatives) like `sin`, `exp` and `log`. These models can be solved [using NLP](#). If any of the endogenous functions in the model are not smooth (i.e. are discontinuous), the model cannot be solved as an NLP: the [DNLP](#) model type must be used instead. Examples of non-smooth functions include `ceil` and `sign`, where the function itself is not continuous, and `max`, `min`, and `abs`, where the derivatives are not continuous. Typically, NLP solvers are designed to work with continuous derivatives, and much of the convergence theory behind them assumes this continuity. Discontinuous functions or derivatives may cause numerical problems, poor performance, spurious (i.e. wrong) solutions, and other issues, so they should be used with special care and only if necessary.

N.B.: to avoid a proliferation of model types, nonlinear programming is the only model type split into smooth ([NLP](#)) and nonsmooth ([DNLP](#)) variants. All other model types allowing nonlinear functions (e.g. [MINLP](#), [MCP](#), [CNS](#)) include both smooth and nonsmooth functions. This is **not** because nonsmooth functions are less problematic in these contexts. It simply became too unwieldy to maintain this distinction across all types of nonlinear models.

A powerful and effective way to model discontinuous functions is with binary variables, which results in a model of type [MINLP](#). The model [\[ABSMIP\]](#) demonstrates this formulation technique for the functions `abs`, `min`, `max` and `sign`. Alternatively, reformulations or approximations may be used to model discontinuous functions such that the resulting model is of type NLP. Here we offer some guidance on how to reformulate or approximate the discontinuous functions `abs`, `max` and `min` using only smooth functions and continuous variables and thus transform a DNLP model into an NLP. This transformation is generally more reliable than solving the original as a DNLP.

Note that some of the *reformulations* suggested below enlarge the feasible space. They rely on the objective function to choose a solution that is contained in the original feasible space, i.e. where the relationship defined by the nonsmooth function holds. If the objective cannot be relied on to do this, it is also possible to use one of the *smooth approximations* for the nonsmooth functions defined below.

4.17.6.1 Reformulating and Approximating the Function ABS

The function `abs(x)` returns the absolute value of the argument `x`. If we are minimizing an absolute value, then we can split this value into its positive and negative parts (both represented by positive variables) and minimize the sum of these variables. This formulation enlarges the feasible region but the optimal solution will be the one where the sum of the positive and negative parts is equal to the absolute value.

```
variables x, y, z;
equations
  obj '1-norm'
  f ;
obj.. abs(x) + abs(y) =E= z;
f .. sqr(x-3) + sqr(y+5) =L= 1;

model nonsmooth / obj, f /;
solve nonsmooth using dnlp min z;

positive variables xPlus, xMinus, yPlus, yMinus;
equations
  obj2 'smooth version of 1-norm'
  xDef
  yDef
  ;
obj2.. xPlus + xMinus + yPlus + yMinus =E= z;
```

```
xDef.. x =E= xPlus - xMinus;
yDef.. y =E= yPlus - yMinus;

model smooth / obj2, xDef, yDef, f /;
solve smooth using nlp min z;
```

Note that the discontinuity in the derivative of the function `abs` has been converted into lower bounds on the new variables `xPlus`, `xMinus`, etc: these bounds are handled routinely by any NLP solver. Note too that the feasible space is larger than before. For example, many pairs `xPlus` and `xMinus` satisfy our equation `x =E= xPlus - xMinus`; . However, our objective ensures that one of `xPlus` and `xMinus` will be zero at the solution so that the sum of `xPlus` and `xMinus` will be the absolute value of `x`.

In case the objective function does not contain a term that tries to minimize the absolute value, a smooth approximation can be used instead of the reformulation described above. This approximation should be close to the absolute value and also have smooth derivatives. Such an approximation for `abs(f(x))` is:

```
sqrt(sqr(f(x)) + sqr(delta))
```

Here `delta` is a small scalar. The value of `delta` controls the accuracy of the approximation and the curvature around `f(x)=0`. The approximation error is largest when `f(x)=0` and decreases as `f(x)` gets farther from zero. A value for `delta` ranging between `1.e-3` and `1.e-4` should be appropriate in most cases. Users could also use a larger value in an initial optimization, reduce it and solve the model again. If `delta` is reduced below `1.e-4`, then large second order terms might lead to slow convergence or even prevent convergence. An example of this approximation used for the previous example is below:

```
$macro MYABS(t,d) [sqrt(sqr(t)+sqr(d))]
equation obj3;
obj3.. MYABS(x,1e-4) + MYABS(y,1e-4) =E= z;

model approx / obj3, f /;
solve approx using nlp min z;
```

Note the use of the [macro facility](#) to encapsulate the smooth reformulation. As mentioned above, this approximation has its largest error where `f(x)=0`. If it is important to get accurate values at this point, then we recommend the following alternative approximation:

```
sqrt(sqr(f(x)) + sqr(delta)) - delta
```

Note that the only difference is the subtraction of the constant term `delta`. In this case, the error will equal zero at `f(x)=0` and it will increase to `-delta` as `f(x)` moves away from zero.

4.17.6.2 Reformulating and Approximating the Function MAX

The function `max(x1,x2,x3,...)` returns the maximum value of the arguments, where the number of the arguments may vary. Typically, the equation

```
t >= max(f(x),g(y))
```

is replaced by two inequalities:

```
t >= f(x)
t >= g(y)
```

Here x , y and t are variables and $f(x)$ and $g(y)$ are some functions depending x and y respectively. Provided the objective function has some term that tries to minimize t , one of the constraints will become binding at solution and t will equal the maximum of the two terms. The extension to more than two arguments in the function `max` should be obvious. A simple example follows:

```
variables
  x / LO 0, L 0.2, UP [pi/2] /
  mx 'max[sin(x),cos(x)]'
  z 'objective var'
;
equation oDef;
oDef.. x / 100 + max[sin(x),cos(x)] =E= z;

model nonsmooth / oDef /;
solve nonsmooth using dnlp min z;

equations oDef2, sinBnd, cosBnd;
oDef2.. x / 100 + mx =E= z;
sinBnd.. mx =G= sin(x);
cosBnd.. mx =G= cos(x);

model smooth / oDef2, sinBnd, cosBnd /;
solve smooth using nlp min z;
```

In case the objective function does not force the max-term to be minimized, a smooth approximation for $\max(f(x),g(y))$ can be used, as in the following example code:

```
[f(x) + g(y) + sqrt(sqrt(f(x)-g(y)) + sqrt(delta))] / 2

$macro MYMAX(t1,t2,d) [0.5 * [t1 + t2 + sqrt(sqrt(t1-t2) + sqrt(d))] ]
equation oDef3;
oDef3.. x / 100 + MYMAX(sin(x),cos(x),1e-4) =E= z;

model approx / oDef3 /;
solve approx using nlp min z;
```

Here δ is a small scalar, preferably ranging from $1.e-2$ to $1.e-4$. The approximation error takes its maximum of $\delta/2$ when $f(x)=g(y)$ and decreases as one moves away from this point. To shift the error away from the point of discontinuity, the following approximation can be used:

```
[f(x) + g(y) + sqrt(sqrt(f(x)-g(y)) + sqrt(delta)) - delta] / 2
```

4.17.6.3 Reformulating and Approximating the Function MIN

The reformulation of and approximation to the `min` function is similar to the `max` case above and will not be repeated in full here. Briefly,

```
t =e= min(f(x),g(y))
```

is replaced by:

```
t =l= f(x)
t =l= g(y)
```

and is effective as long as the objective maximizes t . If not, this smooth approximation for $\min(f(x),g(y))$ can be used:

```
[f(x) + g(y) - sqrt(sqrt(f(x)-g(y)) + sqrt(delta))] / 2
```

4.18 Data Exchange with Other Applications

- [Data Exchange with Text Files](#)
- [Data Exchange with Microsoft Excel](#)
- [Data Exchange with Databases](#)
 - [Data Exchange with DB2](#)
 - [Data Exchange with MS Access](#)
 - [Data Exchange with Oracle](#)
 - [Data Exchange with MySQL](#)
 - [Data Exchange with SQL Server](#)
 - [Data Exchange with SQLite](#)
 - [Data Exchange with Sybase](#)

4.18.1 Data Exchange with Text Files

This tutorial describes some ways on how to exchange data between GAMS and text files (usually in [ASCII](#) format).

4.18.1.1 Reading Text Files During Compilation

GAMS can read arbitrary text files during compile time by inserting them into the compiler input stream. The file content is then assumed to be GAMS code. Thus, including a text file within a data statement (see also [Data Entry: Parameters, Scalars and Tables](#)) allows for an easy way to include data from a text file, as long as the syntax in the text file can be understood by the GAMS compiler. This way, model specification and data input can be separated into different files.

The `$include` compile-time command is used to instruct the GAMS compiler to include the context of a different file at the current position of the input stream. As a result, the GAMS code behaves as if the `$include` statement has been replaced by the content of the file to be included. This can be very handy when including data from a separate text file. For instance, when data for a table is actually coming from another environment, one could replace the `TABLE` statement by an include statement. A GAMS table is in fact very well suited for a human being to be read or written, but it is rather awkward for programs to generate (e.g., the numbers have to be approximately below the corresponding headers). Therefore, often parameters are used and long series of [assignment statements](#) are generated. For instance, consider the following fragment from model `[TRANSPORT]`:

```
Table d(i,j) 'distance in thousands of miles'
      new-york      chicago      topeka
seattle      2.5          1.7          1.8
san-diego    2.5          1.8          1.4 ;
```

When the data for this table is coming from a program it is more convenient to say in the main program:

```
Parameter d(i,j) 'distance in thousands of miles';
$include data.inc
display d;
```

and to have the include file `data.inc` contain the machine generated statements:

```
d("seattle","new-york") = 2.5;
d("san-diego","new-york") = 2.5;
d("seattle","chicago") = 1.7;
d("san-diego","chicago") = 1.8;
d("seattle","topeka") = 1.8;
d("san-diego","topeka") = 1.4;
```

In fact, GAMS can deal quite comfortably with a large number of such assignment statements.

Note, that since the included file is considered as part of the GAMS input stream, it is also [echoed in the listing file](#). When including large text files with data statements, echoing these files in the listing file can be undesired. To suppress echoing to the listing file, the `$include` statement can be surrounded by `$offlisting` and `$onlisting` instructions:

```
parameter d(i,j) 'distance in thousands of miles';
$offlisting
$include data.inc
$onlisting
display d;
```

In the listing file, line numbers are skipped where the `$offlisting` is in effect.

In some cases it may be more convenient to use the [initialization syntax of parameters](#). That is, the main GAMS file could contain the fragment:

```
parameter d(i,j) 'distance in thousands of miles' /
$include data2.inc
/;
display d;
```

and the data file contains the following records:

```
seattle .new-york 2.5
san-diego.new-york 2.5
seattle .chicago 1.7
san-diego.chicago 1.8
seattle .topeka 1.8
san-diego.topeka 1.4
```

This approach is preferable for large data sets as it is more efficient for GAMS.

Note

[Tables](#) and [parameters](#) are handled exactly the same way by GAMS internally. The only difference is in the specification of data.

When using a [table statement](#), data can also be specified in [CSV](#) (Comma-separated values) format if the `$ondelim` command has been issued. This format can, for instance, be generated by spreadsheet programs.

As example, consider again the following fragment from model `[TRANSPORT]`:

```
Table d(i,j) 'distance in thousands of miles'
      new-york    chicago    topeka
seattle    2.5      1.7      1.8
san-diego  2.5      1.8      1.4 ;
```

A file `data.csv` that specifies the data of this table in CSV format would have the content

```
,new-york,chicago,topeka
seattle,2.5,1.7,1.8
san-diego,2.5,1.8,1.4
```

Notice the empty first element in the first line, which corresponds to the top-left blank in the above table.

This file can now be included directly into GAMS by using the `$ondelim` and `$offdelim` commands:

```
Table d(i,j) 'distance in thousands of miles'
$ondelim
$include data.csv
$offdelim
;
```

Attention

The `$ondelim` command only enables the use of *commas* as a separation symbol. The use of a different separation character is not supported by GAMS. This can become an issue if, for example, a CSV file has been generated with a language setting where commas are used as decimal point and semicolons are used for separating entries in the CSV file. In such a situation, `data.csv` would have the content

```
,new-york;chicago;topeka
seattle;2,5;1,7;1,8
san-diego;2,5;1,8;1,4
```

Therefore, such text files need to be preprocessed before read into GAMS. The following code uses the `POSIX tool` `tr` to (simultaneously) replace commas by dots and semicolons by commas:

```
$call "tr ,; ., < data.csv > data2.csv"
Table d(i,j) 'distance in thousands of miles' ;
$ondelim
$include data2.csv
$offdelim
```

CSV files can also be used to input higher dimensional data into GAMS. For instance, consider the 3 dimensional table `yieldt1` from model `[TURKEY]`:

```
Table yieldt1(l,c1,ty) 'livestock yield time series (kg per head)'
```

	1974	1975	1976	1977	1978	1979
sheep.meat	10.60	11.42	10.60	9.38	8.97	6.93
sheep.milk	23.7	24.1	24.2	24.2	24.0	23.9
sheep.wool	1.3	1.3	1.3	1.3	1.3	1.3
sheep.hide	0.5	0.6	0.6	0.5	0.6	0.4
goat.meat	6.39	7.31	8.68	7.31	6.39	6.85

goat.milk	37.7	38.1	38.2	38.2	38.3	37.8
goat.wool	0.6	0.6	0.6	0.6	0.6	0.6
goat.hide	0.2	0.3	0.3	0.3	0.2	0.3
angora.meat	1.77	1.77	2.66	2.21	1.77	1.77
angora.milk	14.9	15.2	14.8	15.2	14.8	15.0
angora.wool	1.6	1.6	1.6	1.6	1.6	1.4
angora.hide	0.1	0.1	0.1	0.1	0.1	0.1
cattle.meat	24.59	25.12	21.42	23.00	18.25	25.12
cattle.milk	210.0	208.1	219.8	213.8	214.8	217.5
cattle.hide	3.3	3.4	2.9	3.0	2.6	3.3
buffalo.meat	43.73	45.42	40.61	37.21	32.20	32.68
buffalo.milk	267.1	269.2	263.8	219.6	275.5	285.1
buffalo.hide	4.1	3.4	3.0	2.4	2.5	2.6
poultry.meat	2.24	2.24	2.24	2.24	2.24	2.24
poultry.egg	62.4	62.2	64.2	78.3	76.4	73.3

;

When the data for this parameter is prepared by another application (such as a relational database), it may be more convenient to write it out in a comma-separated value form, e.g., a file `data.csv` could have the content

```
"sheep","meat","1974",10.60
"sheep","meat","1975",11.42
"sheep","meat","1976",10.60
"sheep","meat","1977",9.38
"sheep","meat","1978",8.97
"sheep","meat","1979",6.93
"sheep","milk","1974",23.70
"sheep","milk","1975",24.10
"sheep","milk","1976",24.20
"sheep","milk","1977",24.20
...
```

Including such formatted data into a GAMS model is possible by using [\\$ondelim](#) for [Parameter Data for Higher Dimensions](#). Thus, the GAMS code would be

```
Parameter yieldtl(l,c1,ty) 'livestock yield time series (kg per head)'
/
$ondelim
$include data.csv
$offdelim
/;
```

4.18.1.2 Writing Text During Compilation

The commands [\\$echo](#), [\\$onecho](#), and [\\$offecho](#) send text to named files during compilation. [\\$echo](#) sends one line and is invoked using the syntax:

```
$echo 'text to be sent' > externalfile
```

or

```
$echo 'text to be sent' >> externalfile
```

The use of ">" generates a new file, while ">>" appends to an existing file.

For multi-line messages, the commands `$onecho` and `$offecho` can be used, e.g.,

```
$onecho > externalfile
line 1 of text to be sent
line 2 of text to be sent
...
last line of text to be sent
$offecho
```

A typical example for the usage of these commands is the generation of a [solver options file](#).

Additionally, the `$log` command can be used to send messages to the log file during compilation.

4.18.1.3 Writing Text Files During Execution

The [put writing facility](#) allows customized text output. This is a fairly complex but powerful and flexible report writing facility.

Assume that the following GAMS code is added to the end of model `[TRANSPORT]`. It instructs GAMS to write the model and the solve status together with levels of the decision variables to a file `results.txt`:

```
File results / results.txt /;
put results;
put "Model status", transport.modelstat /;
put "Solver status", transport.solvestat /;
put "Objective", z.l /;
put "Shipments" /;
loop((i,j),
  put i.tl, j.tl, x.l(i,j) /
);
putclose;
```

First, a file object `results` is declared by using the `File` statement. The data of the file statement specifies the name of the file (`results.txt`). Next, line `put results;` instructs GAMS that for the following `put` statements, the file `results` should be used. In the following, the `model status` and the `solve status` are written, together with some descriptive text. These `model attributes` are set by a `solve statement`. The character `'/'` instructs GAMS to add a linebreak (newline character) to the results file. The next thing to write out are some variable values. Here, first the `level value` of variable `z` is written, followed by a `loop` that writes for each element of sets `i` and `j` the name of the elements (accessed via the `.tl attribute`) and the level value of `x(i,j)`. Finally, the `putclose;` statement instructs GAMS to close the current file. This will ensure that possibly cached data is flushed to the file.

The output will look like:

```
Model status      1.00
Solver status     1.00
Objective        153.67
Shipments
seattle  new-york      50.00
seattle  chicago       300.00
seattle  topeka         0.00
san-diego new-york     275.00
san-diego chicago       0.00
san-diego topeka       275.00
```

This form can be hard to read by other applications, e.g., because some space characters are to be considered as separators, while others are really part of a string (e.g. "Model status"). However, by using the [print control option](#) `.pc` of the `put` writing facility, comma-separated value files can be written. That is, by adding the line `results.pc = 5;`, i.e.,

```
File results / results.txt /;
results.pc = 5;
put results;
put "Model status", transport.modelstat /;
put "Solver status", transport.solvestat /;
put "Objective", z.l /;
put "Shipments" /;
loop((i,j),
  put i.tl, j.tl, x.l(i,j) /
);
putclose;
```

one obtains the following output:

```
"Model status",1.00
"Solver status",1.00
"Objective",153.67
"Shipments"
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

If several parameters of the same dimension should be written to a file in a customized format, the `put` statements can become rather repetitive. For example, the level and marginal values of variable `x` and the parameters `c` and `d` from model `[TRANSPORT]` should be written. This can be coded easily as:

```
file results / results.txt /;
results.pc = 5;
put results;
loop((i,j), put "distance", i.tl, j.tl, d(i,j) / );
loop((i,j), put "cost", i.tl, j.tl, c(i,j) / );
loop((i,j), put "levels", i.tl, j.tl, x.l(i,j) / );
loop((i,j), put "marginals", i.tl, j.tl, x.m(i,j) / );
putclose;
```

A separation of the code that writes the data (loop and `put` statements) from the data that is written (descriptive text, set names, etc.) can be achieved by using [\\$batinclude](#). This command works similar to the [\\$include](#) statement (see also Section [Reading Text Files During Compilation](#) above), but allows for additional arguments (separated by blanks). While including the file, markers `%1`, `%2`, etc., are replaced by the value of the 1st, 2nd, etc., argument.

By using [\\$batinclude](#), the above example could be simplified to

```
file results / results.txt /;
results.pc = 5;
put results;
$batinclude put.inc distance i j d
$batinclude put.inc cost i j c
$batinclude put.inc level i j x.l
$batinclude put.inc marginal i j x.m
putclose;
```

where the file `put.inc` contain the actual loop and put statements:

```
loop((%2,%3), put "%1", %2.t1, %3.t1, %4(%2,%3) / );
```

Finally, the [The Put Utility Statement](#) is referred, which is loosely connected to the put statement and allows the dynamic generation of file names, etc.

4.18.2 Data Exchange with Microsoft Excel

This tutorial gives an overview on how to exchange data between GAMS and Microsoft Excel.

GAMS can communicate with Microsoft Excel via [GDX \(GAMS Data Exchange\)](#) files. In order to write data from GAMS and to Excel, selected GAMS data can be written into a GDX file and then to an Excel file: [GAMS -> GDX -> Excel](#). Similarly selected Excel data can be written to a GDX file and then read into GAMS: [Excel -> GDX -> GAMS](#).

Some of [GAMS/Excel data exchange tools](#) that provide functionality to exchange data between GAMS and Excel are also discussed in the section [Data Exchange Tools](#). The data exchange between GAMS and a CSV (Comma-separated values) file format and GAMS is covered in [Data Exchange with Text Files](#).

4.18.2.1 From GAMS to Excel

Consider the following modification of the `[TRANSPORT]` model from the `gams` model library.

Sets

```
i  'canning plants' / seattle, san-diego /
j  'markets'        / new-york, chicago, topeka / ;
```

Parameters

```
a(i) 'capacity of plant i in cases'
/    seattle    350
    san-diego   600 /
```

```
b(j) 'demand at market j in cases'
/    new-york   325
    chicago    300
    topeka     275 / ;
```

Table `d(i,j)` 'distance in thousands of miles'

	new-york	chicago	topeka
seattle	2.5	1.7	1.8
san-diego	2.5	1.8	1.4

Scalar `f` 'freight in dollars per case per thousand miles' /90/ ;

Parameter `c(i,j)` 'transport cost in thousands of dollars per case' ;

```
c(i,j) = f * d(i,j) / 1000 ;
```

Variables

```
x(i,j) 'shipment quantities in cases'
z      'total transportation costs in thousands of dollars' ;
```

Positive Variable x ;

Equations

```
cost          'define objective function'
supply(i)     'observe supply limit at plant i'
demand(j)     'satisfy demand at market j' ;
```

```
cost ..      z =e= sum((i,j), c(i,j)*x(i,j)) ;
```

```
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
```

```
demand(j) .. sum(i, x(i,j)) =g= b(j) ;
```

Model transport /all/ ;

Solve transport using lp minimizing z ;

Display x.l, x.m ;

==== Export to Excel using GDX utilities

==== First unload to GDX file (occurs during execution phase)

```
execute_unload "results.gdx" x.L x.M
```

==== Now write to variable levels to Excel file from GDX

==== Since we do not specify a sheet, data is placed in first sheet

```
execute 'gdxrw.exe results.gdx o=results.xlsx var=x.L'
```

==== Write marginals to a different sheet with a specific range

```
execute 'gdxrw.exe results.gdx o=results.xlsx var=x.M rng=NewSheet!f1:i4'
```

After the solve statement, the data (x.L and x.M) from variable x can be written into a GDX file during the [execution time](#) using the command [execute_unload](#):

```
execute_unload "results.gdx" x.L x.M
```

The [execute_unload](#) command above is executed during the actual execution phase to create a GDX file called `results.gdx`. The solution x and the marginals of x in the GDX file can be written to the Excel file `results.xlsx` using [GDXXRW](#) tool:

```
execute 'gdxrw.exe results.gdx var=x.L'
```

```
execute 'gdxrw.exe results.gdx var=x.M rng=NewSheet!f1:i4'
```

For the first call for x.L, there is no range specified and the data is written in cell A1 and beyond in the first available sheet. For the second call for marginals x.M, data will be written to cells F1:I4 in the sheet named `NewSheet`.

Note that GAMS can also [write data into a GDX file](#) during [compile time](#). It is also possible to convert data stored in a GDX file into an Excel file spreadsheets using [GDX2XLS](#) tool and to write GAMS data to standard output formatted as a GAMS program with data statements using [GDXDUMP](#) tool.

4.18.2.2 From Excel to GAMS

Consider the following modification of the [TRANSPORT] model from the gams model library and the file results.xlsx file created from the [previous example](#).

Sets

```
i  'canning plants'  / seattle, san-diego /
j  'markets'         / new-york, chicago, topeka / ;
```

Parameters

```
a(i)  'capacity of plant i in cases'
      /  seattle    350
        san-diego  600 /

b(j)  'demand at market j in cases'
      /  new-york   325
        chicago    300
        topeka     275 / ;
```

Table d(i,j) 'distance in thousands of miles'

	new-york	chicago	topeka
seattle	2.5	1.7	1.8
san-diego	2.5	1.8	1.4

Scalar f 'freight in dollars per case per thousand miles' /90/ ;

Parameter c(i,j) 'transport cost in thousands of dollars per case' ;

```
c(i,j) = f * d(i,j) / 1000 ;
```

Variables

```
x(i,j)  'shipment quantities in cases'
z        'total transportation costs in thousands of dollars' ;
```

Positive Variable x ;

Equations

```
cost      'define objective function'
supply(i) 'observe supply limit at plant i'
demand(j) 'satisfy demand at market j' ;
```

```
cost ..   z =e= sum((i,j), c(i,j)*x(i,j)) ;
```

```
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
```

```
demand(j) .. sum(i, x(i,j)) =g= b(j) ;
```

Model transport /all/ ;

==== Import from Excel using GDX utilities

==== First unload to GDX file (occurs during compilation phase)

```
$call gdxrw.exe results.xlsx par=Level rng=sheet1!A1:D3
```

==== Now import data from GDX

```

Parameter Level(i,j);
$gdxin results.gdx
$load Level
$gdxin

*=== Fix variables to values from Excel file
x.FX(i,j) = Level(i,j);
display Level, x.L;

Solve transport using lp minimizing z ;

Display x.l, x.m ;

```

The data in the Excel file can be loaded into a GDX file using the [\\$call](#) command and [GDXXRW](#) tool:

```
$call gdxrw.exe results.xlsx par=Level rng=A1:D3
```

The command [\\$call](#) above executes a program called [GDXXRW](#) during compile time. The [GDXXRW](#) reads data from the range A1:D3 in [results.xlsx](#) into a GAMS parameter called [Level](#) in the GDX file [results.gdx](#). As an output GDX file is not specified when calling [GDXXRW](#), the output file will be derived from the input file by changing the file extension of the input file and removing any path information.

To import data from a GDX file into a parameter, the parameter must be defined over appropriate sets before read. The data from a GDX file can be read during the compile time using the commands [\\$gdxin](#) and [\\$load](#):

```

Parameter Level(i,j);
$gdxin results.gdx
$load Level
$gdxin

```

The first command [\\$gdxin](#) specifies the name of the GDX file [results.gdx](#) to be read. The command [\\$load](#) reads parameter [Level](#) from the GDX file. The second command [\\$gdxin](#) closed the GDX file.

GAMS can [read from a GDX file](#) either during [compile time](#) or during [execution time](#). See [Example 4 - Reading a GDX File](#) when reading data with domain information and [Example 5 - Reading a GDX File](#) when reading from a GDX file during execution time.

Note that it is also possible to write all worksheets of an Excel workbook into a GDX file using [XLSDUMP](#) tool.

4.18.2.3 Data Exchange Tools

There are a number of tools that provide functionality to exchange data between GAMS and an Excel file. This section discusses some of the data exchange tools with some examples. The complete list of the tools can be found at [GAMS/Excel Data Exchange tools](#).

4.18.2.3.1 GDXXRW [GDXXRW](#) is a tool to read and write Excel spreadsheet data. [GDXXRW](#) can read multiple ranges in a spreadsheet and write the data to a 'GDX' file, or read from a 'GDX' file, and write the data to different ranges in a spreadsheet.

How to use [GDXXRW](#) to exchange data between GAMS and Excel is covered in the section [From GAMS to Excel](#) and the section [From Excel to GAMS](#). More details on usage and examples of [GDXXRW](#) tool is covered in [GDXXRW](#).

4.18.2.3.2 XLS2GMS [XLS2GMS](#) is a simple utility that allows you to extract data from an Excel spreadsheet and convert it into a GAMS include file. [XLS2GMS](#) can be run [interactively](#) or in [batch mode](#).

Consider the Excel data from the following spreadsheet:

	city	value
	new york	100
	los angeles	120
	san francisco	105
✎	washington dc	102
*		0

Record: 4 of 4

The data can be imported from the Excel file into a GAMS include file by calling [XLS2GMS](#) tool and inserted an include file as parameter data elements using the command [\\$include](#):

```
set ssi /
    'new york', 'washington dc', 'los angeles', 'san francisco'
/;
parameter ssdata(ssi) /
$call =d:\util\xls2gms I="c:\my documents\test2.xlsx" B 0=d:\tmp\x.inc
$include d:\tmp\x.inc
/;
display ssdata;
```

Notice the B parameter, which is needed as there are embedded blanks in the labels.

Sometimes a translation between the labels used in the model and the ones used in the is needed. One way to do this is to use a mapping set in GAMS. Suppose the rest of the model is defined in terms of the set I which is defined as:

```
set i / ny, dc, la, sf/;
```

To map a parameter data defined over this set, the following simple GAMS fragment can be used:

```

set map(i,ssi) mapping set /
  ny.'new york'
  dc.'washington dc'
  la.'los angeles'
  sf.'san francisco'
/;
display map;

parameter data(i);
data(i) = sum(map(i,ssi), ssdata(ssi));
display data;

```

4.18.2.3.3 SQL2GMS In some cases it is convenient to consider tabular data in an Excel spreadsheet as a database table and to import it via GDX file using the [SQL2GMS](#) tool.

Consider the following spreadsheet:

	A	B	C	D	E
1	year	loc	prod	sales	profit
2	1997	la	hardware	80	5
3	1997	la	software	60	10
4	1997	nyc	hardware	100	15
5	1997	nyc	software	130	25
6	1997	sfo	hardware	50	9
7	1997	sfo	software	60	6
8	1997	was	hardware	80	7
9	1997	was	software	90	8
10	1998	la	hardware	88	5,25
11	1998	la	software	66	10,5
12	1998	nyc	hardware	110	15,75
13	1998	nyc	software	143	26,25
14	1998	sfo	hardware	55	9,45
15	1998	sfo	software	66	6,3
16	1998	was	hardware	88	7,35
17	1998	was	software	99	8,4
18					

This table can be read using an SQL query:

```

SELECT year,loc,prod,'sales',sales FROM [profitdata$] \
  UNION SELECT year,loc,prod,'profit',profit FROM [profitdata$]

```

The table name is equal to the sheet name(profitdata). We can pass the query to the Excel ODBC driver using the tool [SQL2GMS](#) tool as follows:

```

set y 'years'    /1997,1998/;
set c 'city'     /la,nyc,sfo,was/;
set p 'product' /hardware,software/;
set k 'key'      /sales,profit/;

$onecho > excelcmd.txt
c=DRIVER=Microsoft Excel Driver (*.xls,*.xlsx,*.xlsm,*.xlsb);dbq=%system.fp%profit.xlsx;
q=SELECT year,loc,prod,'sales',sales FROM [profitdata$] \
  UNION SELECT year,loc,prod,'profit',profit FROM [profitdata$]
x=fromexcel.gdx
$offecho
$call =sql2gms @excelcmd.txt
parameter d(y,c,p,k) ;
$gdxin excel.gdx
$load d=p
display d;

```

and the DISPLAY results will be:

```
---      21 PARAMETER d FROM SQL2GMS
```

```
INDEX 1 = 1997
```

	sales	profit
la .hardware	80.000	5.000
la .software	60.000	10.000
nyc.hardware	100.000	15.000
nyc.software	130.000	25.000
sfo.hardware	50.000	9.000
sfo.software	60.000	6.000
was.hardware	80.000	7.000
was.software	90.000	8.000

```
INDEX 1 = 1998
```

	sales	profit
la .hardware	88.000	5.250
la .software	66.000	10.500
nyc.hardware	110.000	15.750
nyc.software	143.000	26.250
sfo.hardware	55.000	9.450
sfo.software	66.000	6.300
was.hardware	88.000	7.350
was.software	99.000	8.400

4.18.2.3.4 GDXVIEWER [GDXVIEWER](#) is a tool to view and convert data contained in GDX files. It can also export to csv, xlsx, xml-files and pivot tables. The usage and examples are covered in [GDXVIEWER](#).

4.18.2.3.5 GDX2XLS [GDX2XLS](#) tool to convert the contents of a GDX file into an Excel file or an xml-file. The usage and examples are covered in [GDX2XLS](#).

4.18.3 Data Exchange with Databases

This tutorial provides a guidance on how to exchange data between GAMS and various Database Management System.

4.18.3.1 Data Exchange with DB2

DB2 is one of IBM's relational database management systems.

4.18.3.1.1 Import from DB2 DB2 has an EXPORT command that can be used to generate comma delimited files. An example of a DB2 session illustrating this is shown below:

```
----- Command Entered -----
describe table db2admin.dist
;
```

Column name	Type schema	Type name	Length	Scale	Nulls
LOCA	SYSIBM	VARCHAR	10	0	No
LOCB	SYSIBM	VARCHAR	10	0	No
DISTANCE	SYSIBM	DOUBLE	8	0	Yes

3 record(s) selected.

```
----- Command Entered -----
select * from dist ;
```

LOCA	LOCB	DISTANCE
seattle	new-york	+2.500000000000000E+000
seattle	chicago	+1.700000000000000E+000
seattle	topeka	+1.800000000000000E+000
san-diego	new-york	+2.500000000000000E+000
san-diego	chicago	+1.800000000000000E+000
san-diego	topeka	+1.400000000000000E+000

6 record(s) selected.

```
----- Command Entered -----
export to c:\tmp\export.txt of del select * from dist ;
```

```
SQL3104N The Export utility is beginning to export data to file
"c:\tmp\export.txt".
```

```
SQL3105N The Export utility has finished exporting "6" rows.
```

Number of rows exported: 6

The resulting data file **export.txt** will look like:

```
"seattle","new-york",+2.500000000000000E+000
"seattle","chicago",+1.700000000000000E+000
"seattle","topeka",+1.800000000000000E+000
"san-diego","new-york",+2.500000000000000E+000
"san-diego","chicago",+1.800000000000000E+000
"san-diego","topeka",+1.400000000000000E+000
```

This file can be read into GAMS using `$include` :

```
parameter d(i,j) 'distance in thousands of miles' /
  $ondelim
  $include export.txt
  $offdelim
/;
display d;
```

4.18.3.1.2 Export to DB2 DB2 has an `IMPORT` command that can read delimited files. As an example consider the file generated by GAMS `PUT` statements:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

A transcript of a DB2 session to read this file, is given below:

```
----- Command Entered -----
create table results(loca varchar(10) not null,
                    locb varchar(10) not null,
                    shipment double not null) ;
-----
DB20000I  The SQL command completed successfully.

----- Command Entered -----
import from c:\tmp\import.txt of del insert into results ;
-----
SQL3109N  The utility is beginning to load data from file "c:\tmp\import.txt".

SQL3110N  The utility has completed processing.  "6" rows were read from the
input file.

SQL3221W  ...Begin COMMIT WORK. Input Record Count = "6".

SQL3222W  ...COMMIT of any database changes was successful.

SQL3149N  "6" rows were processed from the input file.  "6" rows were
successfully inserted into the table.  "0" rows were rejected.
```

```

Number of rows read          = 6
Number of rows skipped      = 0
Number of rows inserted     = 6
Number of rows updated      = 0
Number of rows rejected     = 0
Number of rows committed   = 6

```

For very large data sets it is advised to use the LOAD command:

```

----- Command Entered -----
load from c:\tmp\import.txt of del insert into results ;
-----

SQL3501W The table space(s) in which the table resides will not be placed in
backup pending state since forward recovery is disabled for the database.

SQL3109N The utility is beginning to load data from file "c:\tmp\import.txt".

SQL3500W The utility is beginning the "LOAD" phase at time "03-20-2000
18:11:50.213782".

SQL3519W Begin Load Consistency Point. Input record count = "0".

SQL3520W Load Consistency Point was successful.

SQL3110N The utility has completed processing. "6" rows were read from the
input file.

SQL3519W Begin Load Consistency Point. Input record count = "6".

SQL3520W Load Consistency Point was successful.

SQL3515W The utility has finished the "LOAD" phase at time "03-20-2000
18:11:50.337092".

```

```

Number of rows read          = 6
Number of rows skipped      = 0
Number of rows loaded       = 6
Number of rows rejected     = 0
Number of rows deleted      = 0
Number of rows committed   = 6

```

For smaller data sets one can also generate a series of INSERT statements using the [PUT facility](#).

4.18.3.2 Data Exchange with MS Access

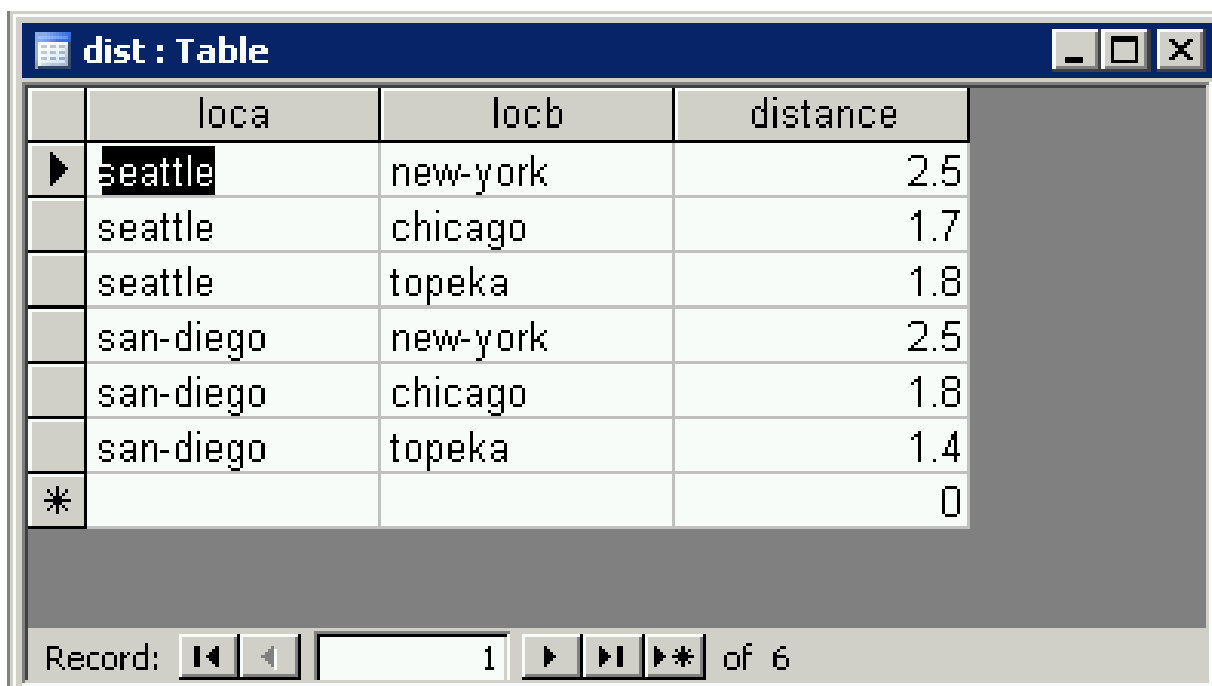

Microsoft Office Access, previously known as Microsoft Access, is a relational database management system from Microsoft. It is a member of the Microsoft Office system.

4.18.3.2.1 Import from MS Access

4.18.3.2.1.1 MDB2GMS [MDB2GMS](#) is a tool to convert data from an Microsoft Access database into GAMS readable format. The source is an MS Access database file (*.mdb or *.accdb) and the target is a GAMS Include File or a GAMS GDX File. [MDB2GMS](#) is part of the [GAMS Data eXchange Tools](#), see [documentation](#) for more information.

4.18.3.2.1.2 SQL2GMS [SQL2GMS](#) is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft's Data Access components including ADO, ODBC and OLEDB. The target is a GAMS Include File or a GAMS GDX File. [SQL2GMS](#) is part of the [GAMS Data eXchange Tools](#), see [documentation](#) for more information.

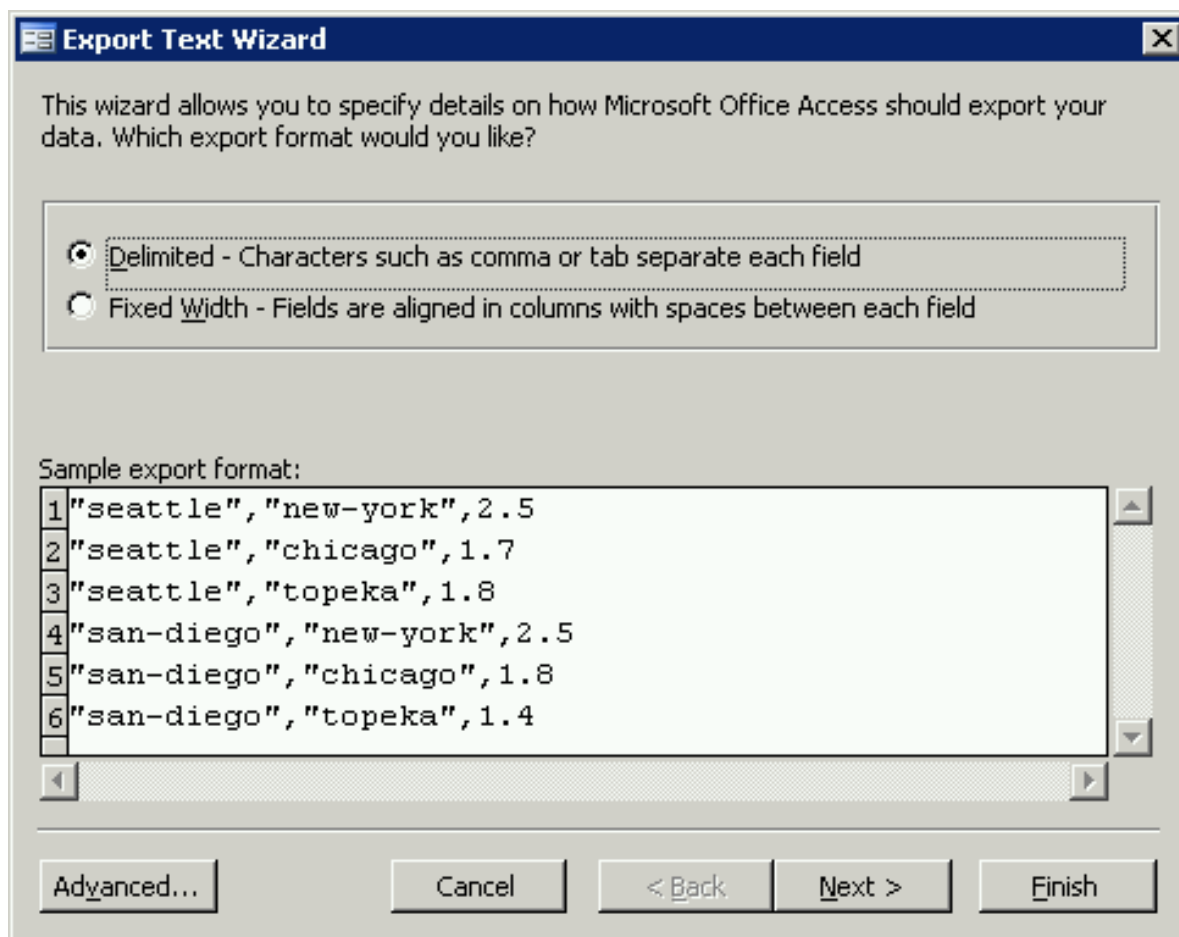

4.18.3.2.1.3 CSV Files Microsoft Access can export tables into comma delimited text files using its **Save As/Export** menu. Suppose we have the following table:

	loca	locb	distance
▶	seattle	new-york	2.5
	seattle	chicago	1.7
	seattle	topeka	1.8
	san-diego	new-york	2.5
	san-diego	chicago	1.8
	san-diego	topeka	1.4
*			0

Record: 1 of 6

After choosing **Save As/Export** and selecting **Text Files** we get the following window:

Just using the default settings, we get the following file:

```
"seattle","new-york",2.50
"seattle","chicago",1.70
"seattle","topeka",1.80
"san-diego","new-york",2.50
"san-diego","chicago",1.80
"san-diego","topeka",1.40
```

which can be handled in GAMS by `$ondelim/$offdelim` and `$include`:

```
parameter d(i,j) 'distance in thousands of miles' /
    $ondelim
    $include dist.txt
    $offdelim
/;
display d;
```

4.18.3.2.1.4 Import Dates from Access GAMS dates are one day off when importing from MS Access. Suppose we have an MS Access table with one single date column:

```
datefield
-----
3/12/2007
3/13/2007 10:00:00 AM
3/14/2007 8:30:00 PM
```

The date data above can be imported into GAMS using `$call` and `MDB2GMS` tool as follows:

```
$call =mdb2gms I="%system.fp%Sample.accdb" Q="select datefield,Cdbl(datefield) from datetable" O=x.in
parameter p(*) /
    $include x.inc
/;
display p;
alias(*,i);
parameter q(*,*);
loop(i$p(i),
    q(i,'year') = gyear(p(i));
    q(i,'month') = gmonth(p(i));
    q(i,'day') = gday(p(i));
    q(i,'hour') = ghour(p(i));
    q(i,'minute') = gminute(p(i));
);
display q;
```

Note that the `Cdbl()` function converts the date to a floating point number (double precision). The generated include file looks like:

```
* -----
* MDB2GMS Version 2.8, January 2007
* Erwin Kalvelagen, GAMS Development Corp
* -----
* DAO version: 3.6
* Jet version: 4.0
* Database:    D:\mdb2gms\examples\Sample.accdb
* Query:      select datefield,Cdbl(datefield) from datetable
* -----
'3/12/2007' 39153
'3/13/2007 10:00:00 AM' 39154.4166666667
'3/14/2007 8:30:00 PM' 39155.8541666667
* -----
```

which looks o.k. However, when we look at the GAMS results in the listing file we see:

```
----      28 PARAMETER p
3/12/2007      39153.000,    3/13/2007 10:00:00 AM 39154.417,    3/14/2007 8:30:00 PM 39155.854

----      39 PARAMETER q

                year      month      day      hour      minute
3/12/2007      2007.000      3.000      13.000
3/13/2007 10:00:00 AM 2007.000      3.000      14.000      10.000
3/14/2007 8:30:00 PM 2007.000      3.000      15.000      20.000      30.000
```

Clearly the dates are off by one day: see the column `day`. We can fix this problem in different places, e.g. in the query or in the GAMS model by subtracting 1.0 from an imported date. This problem occurs not only in MS Access but also with other software packages.

4.18.3.2.2 Export to MS Access

4.18.3.2.2.1 GDX2ACCESS **GDX2ACCESS** is a tool to dump the whole contents of a GDX file to a new MS Access file (.mdb or .accdb file). **GDX2ACCESS** is part of the [GAMS Data eXchange Tools](#), see [documentation](#) for more information.

4.18.3.2.2.2 GDXVIEWER Access tables in MS Access files can be directly generated by the **GDXVIEWER** tool. The **GDXVIEWER** tool uses OLE automation to export data to an MS Access database. This means that MS Access needs to be installed for the Access Export facility to work. **GDXVIEWER** is part of the [GAMS Data eXchange Tools](#), see [documentation](#) for more information.

4.18.3.2.2.3 VBScript **VBScript** is a scripting tool that can be used to talk to COM objects. In this case we use it to tell Access to import a CSV file.

```
$ontext
    Import a table into MS Access using VBscript
$offtext
$if exist new.accdb $call del new.accdb
set i /i1*i10/;
alias (i,j);
parameter p(i,j);
p(i,j) = uniform(-100,100);
display p;
file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
    put i.tl, j.tl, p(i,j):12:8/
);
putclose;

execute "=cscript access.vbs";

$onecho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"
dbLangGeneral = ";LANGID=0x0409;CP=1252;COUNTRY=0"
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=%system.fp%;FMT=Delimited].[data#csv]"
Wscript.Echo "Query : " & strSQL
Set oJet = CreateObject("DAO.DBEngine.36")
Wscript.Echo "Jet version : " & oJet.version
Set oDB = oJet.createDatabase("new.accdb",dbLangGeneral)
Wscript.Echo "Created : " & oDB.name
oDB.Execute strSQL
Set TableDef = oDB.TableDefs("mytable")
Wscript.Echo "Rows inserted in mytable : " & TableDef.RecordCount
oDB.Close
Wscript.Echo "Done"
$offecho
```

The CSV file contains a header row with the names of the fields:

```
"i","j","p"
"i1","i1",-65.65057360
"i1","i2",68.65334160
"i1","i3",10.07507120
"i1","i4",-39.77241920
"i1","i5",-41.55757660
....
```

The text driver specification `HDR=Yes` makes sure the first row in the CSV file is treated specially. The log will look like:

```
U:\temp>gams vbaccess.gms
--- Job vbaccess.gms Start 01/28/08 16:57:37
GAMS Rev 149 Copyright (C) 1987-2007 GAMS Development. All rights reserved
...
--- Starting compilation
--- vbaccess.gms(4) 2 Mb
--- call del new.accdb
--- vbaccess.gms(38) 3 Mb
--- Starting execution: elapsed 0:00:00.109
--- vbaccess.gms(18) 4 Mb
Microsoft (R) Windows Script Host Version 5.6
Copyright (C) Microsoft Corporation 1996-2001. All rights reserved.

Running script: access.vbs
Query : SELECT * INTO mytable FROM [Text;HDR=Yes;Database=U:\temp\;FMT=Delimited
].[data#csv]
Jet version : 3.6
Created : U:\temp\new.accdb
Rows inserted in mytable : 100
Done
--- Putfile f U:\temp\data.csv
*** Status: Normal completion
--- Job vbaccess.gms Stop 01/28/08 16:57:38 elapsed 0:00:00.609
U:\temp>
```

Please note that although the `$onecho/$offecho` is at the bottom of the GAMS file, the file `access.vbs` is created at compile time. I.e. before the executable statements like `PUT`, `EXECUTE` are executed.

4.18.3.2.2.4 JScript The same script using `JScript` is similar to the one with `VScript`. We only price the script itself.

```
$ontext
    Import a table into MS Access using JScript
$offtext
$if exist new.accdb $call del new.accdb

set i /i1*i10/;
alias (i,j);
parameter p(i,j);

p(i,j) = uniform(-100,100);
display p;

file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
    put i.tl, j.tl, p(i,j):12:8/
);
putclose;

execute "=cscript access.js";
```

```

$onecho > access.js
// this is a JScript script
WScript.Echo("Running script: access.js");

dbLangGeneral = ";LANGID=0x0409;CP=1252;COUNTRY=0";
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=.;FMT=Delimited].[data#csv]";
WScript.Echo("Query : ",strSQL);

oJet = new ActiveXObject("DAO.DBEngine.36");
WScript.Echo("Jet version : ",oJet.version);

oDB = oJet.createDatabase("new.accdb",dbLangGeneral);
WScript.Echo("Created : ",oDB.name);

oDB.Execute(strSQL);
TableDef = oDB.TableDefs("mytable");
WScript.Echo("Rows inserted in mytable : ",TableDef.RecordCount);

oDB.Close();

WScript.Echo("Done");
$offecho

```

4.18.3.2.2.5 Combining GDX2ACCESS and VBscript Data in a GDX file do not contain domain information. I.e. a parameter $c(i,j)$ is really stored as $c(*,*)$. As a result [GDX2ACCESS](#) will invent field names like `dim1`, `dim2`, `Value`. In some cases this may not be convenient, e.g. when more descriptive field names are required. We will show how a small script in VBscript can handle this task. The script will rename the fields `dim1`, `dim2`, `Value` in table `c` to `i`, `j`, and `transportcost`.

```

$call "gamslib 1"
$include trnsport.gms
*
* export to gdx file.
* The domains i,j are lost: gdx only stores c(*,*)
execute_unload "c.gdx",c;
*
* move to access database
* column names are dim1,dim2
*
execute "=gdx2access c.gdx";
*
* rename columns
*
execute "=cscript access.vbs";

$onecho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"

' Office 2000 DAO version
' Change to local situation.
Set oDAO = CreateObject("DAO.DBEngine.36")
script.Echo "DAO version : " & oDAO.version

Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name

```

```

Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name

' rename fields
oTable.Fields.Item("dim1").name = "i"
oTable.Fields.Item("dim2").name = "j"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"

oDB.Close
Wscript.Echo "Done"
$offecho

```

The above VBScript fragment needs to be adapted according to the DAO **Data Access Objects** version available on the client machine. This can be implemented in a more robust fashion by letting MS Access find the DAO engine:

```

'this is a VBscript script
WScript.Echo "Running script: access.vbs"

set oa = CreateObject("Access.Application")
set oDAO = oa.DBEngine
Wscript.Echo "DAO Version: " & oDAO.version

Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name

Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name

' rename fields
oTable.Fields.Item("dim1").name = "i"
oTable.Fields.Item("dim2").name = "j"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"

oDB.Close

Wscript.Echo "Done"

```

Please note that the macro %system.fp% is replaced by GAMS by the working directory (this is the project directory when running GAMS from the IDE).

4.18.3.3 Data Exchange with MySQL

MySQL is a multi-threaded, multi-user SQL database management system.

4.18.3.3.1 Import from MySQL MySQL can write the results of a **SELECT** statement to a file as follows:

```
mysql> select * from dist;
+-----+-----+-----+
| loca   | locb   | distance |
+-----+-----+-----+
| seattle | new-york |      50 |
| seattle | chicago |     300 |
| seattle | topeka  |       0 |
| san-diego | new-york |     275 |
| san-diego | chicago |       0 |
| san-diego | topeka  |     275 |
+-----+-----+-----+
6 rows in set (0.01 sec)

mysql> select * from dist into outfile '/tmp/data.csv'
-> fields terminated by ','
-> optionally enclosed by '"'
-> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)
```

The resulting CSV file looks like:

```
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275
```

which can be read by GAMS directly. This approach can be automated as follows:

```
[erwin@localhost erwin]$ cat myscript
use test
select * from dist into outfile '/tmp/data.csv'
    fields terminated by ','
    optionally enclosed by '"'
    lines terminated by '\n';
[erwin@localhost erwin]$ cat x.gms
set i /seattle, san-diego/;
set j /new-york, chicago, topeka/;

$call 'mysql -u root < myscript'
parameter dist(i,j) /
$ondelim
$include /tmp/data.csv
$offdelim
/;
display dist;
[erwin@localhost erwin]$ gams x
GAMS Rev 132 Copyright (C) 1987-2002 GAMS Development. All rights reserved
Licensee: GAMS Development Corporation, Washington, DC G871201:0000XX-XXX
Free Demo, 202-342-0180, sales@gams.com, www.gams.com DC9999
--- Starting compilation
--- x.gms(5) 1 Mb
--- call mysql -u root < myscript
--- .data.csv(6) 1 Mb
--- x.gms(15) 1 Mb
```

```

--- Starting execution
--- x.gms(18) 1 Mb
*** Status: Normal completion
[erwin@localhost erwin]$

```

The listing file shows that the table is read correctly:

```

1
2 set i /seattle, san-diego/;
3 set j /new-york, chicago, topeka/;
4
6 parameter dist(i,j) /
INCLUDE    /tmp/data.csv
9 "seattle","new-york",50
10 "seattle","chicago",300
11 "seattle","topeka",0
12 "san-diego","new-york",275
13 "san-diego","chicago",0
14 "san-diego","topeka",275
16 /;
17
18 display dist;
19
20
21

```

SEQ	GLOBAL	TYPE	PARENT	LOCAL	FILENAME
1	1	INPUT	0	0	/home/erwin/x.gms
2	5	CALL	1	5	mysql -u root < myscript
3	8	INCLUDE	1	8	./tmp/data.csv

```

----      18 PARAMETER dist

```

	new-york	chicago	topeka
seattle	50.000	300.000	
san-diego	275.000		275.000

Instead of maintaining the MySQL script in a separate file, it can also be written by GAMS using [\\$onecho/\\$offecho](#) and a statement like:

```

$onecho > myscript
use test
select * from dist into outfile '/tmp/data.csv'
      fields terminated by ','
      optionally enclosed by '"'
      lines terminated by '\n';
$offecho

```

This will write the script at compile time.

4.18.3.3.2 Export to MySQL GAMS can export data to MySQL by creating a script containing a series of SQL INSERT statements, as shown in section [Oracle CSV Import](#) .

It is noted that MySQL does have a REPLACE statement which is a useful blend of an INSERT and UPDATE statement: update a row if it already exists, otherwise insert it. This is not standard SQL however, so it can cause problems when moving to another database.

For larger result sets it may be better to use the LOAD DATA INFILE command. This command can read directly ASCII text files such as comma delimited CSV files.

Consider again the data file created by the PUT statement:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

The following transcript shows how to import this into MySQL:

```
mysql> create table dist(loca varchar(10), locb varchar(10), distance double precision);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> show tables;
+-----+
| Tables_in_test |
+-----+
| dist           |
+-----+
1 row in set (0.00 sec)
```

```
mysql> describe dist;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| loca  | varchar(10) | YES  |     | NULL    |      |
| locb  | varchar(10) | YES  |     | NULL    |      |
| distance | double      | YES  |     | NULL    |      |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

```
mysql> load data infile '/tmp/data.txt' into table dist
-> fields terminated by ','
-> optionally enclosed by '"'
-> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)
Records: 6 Deleted: 0 Skipped: 0 Warnings: 0
```

```
mysql> select * from dist;
+-----+-----+-----+
| loca    | locb    | distance |
+-----+-----+-----+
| seattle | new-york | 50       |
| seattle | chicago | 300      |
| seattle | topeka  | 0        |
| san-diego | new-york | 275     |
```

```
| san-diego | chicago |      0 |
| san-diego | topeka  |     275 |
+-----+-----+-----+
6 rows in set (0.00 sec)
```

Note that we used no keys in our table definition. In practice it is of course highly recommended to define proper keys.

4.18.3.4 Data Exchange with Oracle

The **Oracle Database** (commonly referred to as Oracle RDBMS or simply as Oracle) is a relational database management system (RDBMS) software product released by Oracle Corporation.

4.18.3.4.1 Import from Oracle

4.18.3.4.1.1 SQL*Plus To export an Oracle table a simple solution is to write an SQL*Plus script. E.g. if our table looks like:

```
SQL> describe dist;
Name                                Null?    Type
-----
LOCA                                NOT NULL VARCHAR2(10)
LOCB                                NOT NULL VARCHAR2(10)
DISTANCE                            NUMBER
```

```
SQL> select * from dist;

LOCA      LOCB      DISTANCE
-----
seattle   new-york   2.5
seattle   chicago   1.7
seattle   topeka    1.8
san-diego new-york   2.5
san-diego chicago   1.8
san-diego topeka    1.4
```

6 rows selected.

SQL>

then the following script will export this table:

```
set pagesize 0
set pause off
set heading off
spool data
select loca||','||locb||','||distance from dist;
spool off
```

The resulting data file "data.lst" will look like:

```
seattle,new-york,2.5
seattle,chicago,1.7
seattle,topeka,1.8
san-diego,new-york,2.5
san-diego,chicago,1.8
san-diego,topeka,1.4
```

This almost looks like our data initialization syntax for parameters:

```
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
```

The only differences are in the delimiters that are being used. These differences are easily digested by GAMS once it is in [ondelim](#) mode. I.e. the following syntax can be used to read the *data.lst* file:

```
parameter d(i,j) 'distance in thousands of miles' /
$ondelim
$include data.lst
$offdelim
/;
display d;
```

4.18.3.4.1.2 SQL2GMS An alternative way to import data from Oracle is to use the tool [SQL2GMS](#) which can talk to any database with an ADO or ODBC interface.

4.18.3.4.1.3 Import dates from Oracle databases and converting them to GAMS dates For most softwares it is easy to generate dates that GAMS can import and understand. The most common issue is that GAMS is one day off compared to Excel, Delphi, Access, ODBC etc. Oracle is somewhat more involved. First it is useful to have the date/time exported as a Julian date. This can be done with the following stored procedure:

```
-- julian representation of a date/time
-- Erwin Kalvelagen, feb 2007
create or replace function to_julian(d IN TIMESTAMP)
return number
is
begin
return to_number(to_char(d,'J')) + to_number(to_char(d,'SSSS'))/86400;
end;
```

This function can be used to export dates as simple floating point numbers. In GAMS we need just a simple adjustment by adding a constant `'datediff'` defined by:

```
scalar
  refdategams "march 16, 2006, 00:00"
  refdateoracle "march 16, 2006, 00:00" /2453811/
  datediff "difference between GAMS and Oracle date"
;
refdategams = jdate(2006,3,16);
datediff = refdategams-refdateoracle;
```

This trick has been applied in a complex scheduling application where dates are important data types that must be exchanged between the application logic and database tier and the optimization engine.

4.18.3.4.2 Export to Oracle

4.18.3.4.2.1 Oracle CSV Import A familiar way of moving data into Oracle is to generate standard SQL INSERT statements. The [PUT facility](#) is flexible enough to handle this. For instance the following code:

```
file results /results.sql/;
results.lw=0;
results.nw=0;
put results;
loop((i,j),
      put "insert into result (loca, locb, shipment) ";
      put "values ('",i.tl,"',' ",j.tl,"',' ",x.l(i,j),")";"/
);
putclose;
```

will generate these SQL statements:

```
insert into result (loca, locb, shipment) values ('seattle','new-york',50.00);
insert into result (loca, locb, shipment) values ('seattle','chicago',300.00);
insert into result (loca, locb, shipment) values ('seattle','topeka',0.00);
insert into result (loca, locb, shipment) values ('san-diego','new-york',275.00);
insert into result (loca, locb, shipment) values ('san-diego','chicago',0.00);
insert into result (loca, locb, shipment) values ('san-diego','topeka',275.00);
```

The `.lw` and `.nw` attributes for the `put` file indicate that no extra spaces around the labels and the numeric values are needed. These field width attributes have a default value of 12 which would cause the values to look like:

```
'seattle      ','new-york      ',      50.00
```

If the amount of data is large the utility `SQL*Loader` can be used to import comma delimited input. I.e. the GAMS code:

```
file results /results.txt/;
results.pc=5;
put results;
loop((i,j),
      put i.tl, j.tl, x.l(i,j)/
);
putclose;
```

produces a file `results.txt`:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

The following `SQL*Loader` control file will read this file:

```
LOAD DATA
INFILE results.txt
INTO TABLE result
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
(loca,locb,shipment)
```

4.18.3.4.2.2 GDX to Oracle Database tables in an SQL RDBMS can be directly generated by the [GDXVIEWER](#) tool. The [GDXVIEWER](#) can use three methods to export to Oracle and other RDBMS:

1. The direct ADO/ODBC link can create a new table and populate it.
2. The SQL INSERT script generator can create a script with a number of INSERT statements.
3. The SQL UPDATE script generator can create a script with a number of UPDATE statements.

4.18.3.5 Data Exchange with SQL Server

4.18.3.5.1 Import from SQL Server [Microsoft SQL Server](#) is Microsoft's flagship database. It comes in different flavors, including SQL Server, MSDE and SQL Server Express.

4.18.3.5.1.1 Using SQL2GMS A good way to import SQL server data into GAMS is using the [SQL2GMS](#) tool. Below is an example of its use:

```
$set commandfile commands.txt
$onecho > %commandfile%
C=provider=sqloledb;data source=athlon\SQLExpress;Initial catalog=test;user id=sa;password=password
O=C:\WINNT\gamsdir\xx.inc
Q=SELECT * FROM x
$offecho
$call =sql2gms @%commandfile%
parameter p(i,j) /
$include "C:\WINNT\gamsdir\xx.inc"
/;
display p;
```

4.18.3.5.1.2 Using the BCP utility and CSV files To export SQL Server data to CSV files we can use the BCP utility.

```
C:\Program Files\Microsoft SQL Server\90\Tools\bin>bcpx test..results out x.csv \
-S athlon\sqlexpress -c -U sa -P password -t,
```

Starting copy...

```
6 rows copied.
Network packet size (bytes): 4096
Clock Time (ms.) Total      : 10      Average : (600.00 rows per sec.)
```

```
C:\Program Files\Microsoft SQL Server\90\Tools\bin>type x.csv
seattle,new-york,50.0
seattle,chicago,300.0
seattle,topeka,0.0
san-diego,new-york,275.0
san-diego,chicago,0.0
san-diego,topeka,275.0
```

It is somewhat more difficult to create a proper CSV file. A format specification file can help here. For an example see the next section on [Data Exchange with Sybase](#) . Other tools to export files include DTS (Data Transformation Services) and linked ODBC data sources.

4.18.3.5.1.3 A direct interface between SQL server tables and GAMS GDX files Finally we can program directly an interface between SQL server tables and GAMS GDX files. A small example in C# can look like:

```

gdxio = new csharpclient();
//
// read a set
//
gdxio.gdxdatawritestrstart(ap, "location", "from db", 1, csharpclient.dt.set, 0);
String q = "select distinct(location) from exporttable";
SqlCommand cmd = new SqlCommand(q, conn);
SqlDataReader myReader = cmd.ExecuteReader();
String[] astrelements = new String[10];
for (int i = 0; i < 10; ++i)
    astrelements[i] = "";
double[] avals = new double[5];
while (myReader.Read())
{
    astrelements[0] = myReader.GetString(0);
    avals[0] = 0.0;
    Boolean ok = gdxio.gdxdatawritestr(ap,astrelements,avals);
}
gdxio.gdxdatawritedone(ap);
myReader.Close();
//
// read a data table
//
gdxio.gdxdatawritestrstart(ap, "data", "from db", 2, csharpclient.dt.par, 0);
q = "select location, capacity, cost exporttable";
cmd = new SqlCommand(q, conn);
myReader = cmd.ExecuteReader();
while (myReader.Read())
{
    astrelements[0] = myReader.GetString(0);
    astrelements[1] = "capacity";
    avals[0] = myReader.GetInt32(1);
    Boolean ok = gdxio.gdxdatawritestr(ap, astrelements, avals);
    if (!myReader.IsDBNull(2)) {
        astrelements[1] = "cost";
        avals[0] = myReader.GetDouble(2);
        ok = gdxio.gdxdatawritestr(ap, astrelements, avals);
    }
}
gdxio.gdxdatawritedone(ap);
myReader.Close();
gdxio.gdxclose(ref ap);

```

4.18.3.5.2 Export to SQL Server SQL Server has two basic facilities to import CSV files: the BCP tool and the BULK INSERT statement. Advanced SQL Server users may also be able to use DTS (Data Transformation Services) or linked ODBC data sources. Of course for small data sets we can create standard [SQL INSERT](#) statements. In addition the tool [GDXVIEWER](#) can be used to get GAMS data into SQL Server.

4.18.3.5.2.1 Export using the BCP tool A transcript showing the use of BCP is shown below:

```

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test;
2> create table x(loca varchar(10), locb varchar(10), shipment float);
3> go
Changed database context to 'test'.
1> quit

```

```

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
seattle,new-york,50.00
seattle,chicago,300.00
seattle,topeka,0.00
san-diego,new-york,275.00
san-diego,chicago,0.00
san-diego,topeka,275.00

```

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>bcp test..x in c:\winnt\gamsdir\results.csv \
-S athlon\sqlexpress -c -U sa -P password -t,
```

Starting copy...

6 rows copied.

Network packet size (bytes): 4096

Clock Time (ms.) Total : 10 Average : (600.00 rows per sec.)

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
```

```
1> use test
```

```
2> select * from x;
```

```
3> go
```

Changed database context to 'test'.

loca	locb	shipment
seattle	new-york	50
seattle	chicago	300
seattle	topeka	0
san-diego	new-york	275
san-diego	chicago	0
san-diego	topeka	275

(6 rows affected)

```
1> quit
```

Unfortunately, dealing with quoted strings is not straightforward with this tool (an example using a format file is shown in the next section on [Data Exchange with Sybase](#)). The same thing holds for BULK INSERT, which can read:

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
```

```
seattle,new-york,50.00
```

```
seattle,chicago,300.00
```

```
seattle,topeka,0.00
```

```
san-diego,new-york,275.00
```

```
san-diego,chicago,0.00
```

```
san-diego,topeka,275.00
```

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
```

```
1> use test
```

```
2> create table x(loca varchar(10), locb varchar(10), shipment float)
```

```
3> go
```

Changed database context to 'test'.

```
1> bulk insert x from 'c:\winnt\gamsdir\results.csv' with (fieldterminator=',')
```

```
2> go
```

(6 rows affected)

```
1> select * from x
```

```
2> go
```

loca	locb	shipment
seattle	new-york	50
seattle	chicago	300
seattle	topeka	0
san-diego	new-york	275
san-diego	chicago	0
san-diego	topeka	275

```
(6 rows affected)
1> quit
```

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

4.18.3.5.2.2 Export using the ODBC Text Driver A slower but flexible way to load CSV files is to use a linked server through the ODBC Text Driver. First create an ODBC DSN using the Text Driver. This can be done through the ODBC Data Source Administrator Data Sources (ODBC) Then we can use the system procedure SP_AddLinkedServer.

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>type trnsport.sql
--
-- test database
--
use test

--
-- create table in SQL server
--
create table results(loca varchar(10), locb varchar(10), ship float)
GO

--
-- Create a linked server
--
EXEC sp_addlinkedserver txtsrv,'Jet 4.0','Microsoft.Jet.OLEDB.4.0','c:\winnt\gamsdir',NULL,'Text'
GO

--
-- copy data from text file c:\winnt\gamsdir\results.csv
--
insert into results(loca,locb,ship)
select * from txtsrv...results#csv
go

--
-- check if all arrived
--
select * from results
go

--
-- release linked server
--
EXEC sp_dropserver txtsrv
GO

--
```

```
-- clean up
--
drop table results
go

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> :r trnsport.sql
Changed database context to 'test'.

(6 rows affected)
loca      locb      ship
-----
seattle   new-york      50
seattle   chicago      300
seattle   topeka        0
san-diego new-york      275
san-diego chicago        0
san-diego topeka        275

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

A slightly different approach is the following:

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> create table t(loca varchar(10), locb varchar(10), ship float)
2> go
1> insert into t
2> select * from
3> OpenRowSet('Microsoft.Jet.OLEDB.4.0',
4> 'Text;Database=c:\winnt\gamsdir\;HDR=NO',
5> 'select * from results.csv')
6> go

(6 rows affected)
1> select * from t
2> go
loca      locb      ship
-----
seattle   new-york      50
seattle   chicago      300
seattle   topeka        0
san-diego new-york      275
san-diego chicago        0
san-diego topeka        275

(6 rows affected)
1> drop table t
2> go
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

This can be automated from GAMS as follows:

```

file results /results.csv/;
results.pc=5;
put results;
loop((i,j),
    put i.tl, j.tl, x.l(i,j)/
);
putclose;

file sqlinsert /insert.sql/;
put sqlinsert;
put "use test"/;
put "insert into t select * from OpenRowSet('Microsoft.Jet.OLEDB.4.0',"
    "'Text;Database=c:\winnt\gammdir\;HDR=NO','select * from results.csv')"/;
putclose;

execute '="C:\Progra~1\Microsoft SQL Server\90\Tools\bin\sqlcmd" -S athlon\SQLExpress -i insert.sql

```

4.18.3.5.2.3 Export using the GDXVIEWER When using [GDXVIEWER](#) to export data to MS SQL server it is noted that MSSQL Server does not accept the default SQL type double for double precision numbers. You will need to set this setting to float or double precision.

When we export variable x from the transport model, we see:

```

C:\Program Files\Microsoft SQL Server\90\Tools\bin>sqlcmd -S athlon\SQLExpress
1> use test
2> go
Changed database context to 'test'.
1> select * from x
2> go
dim1                dim2                level
-----
seattle             new-york             50
seattle             chicago              300
seattle             topeka               0
san-diego           new-york             275
san-diego           chicago              0
san-diego           topeka               275

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\bin>

```

4.18.3.6 Data Exchange with SQLite

See [GDX2SQLITE](#) for more information.

4.18.3.7 Data Exchange with Sybase

4.18.3.7.1 Import from Sybase

4.18.3.7.1.1 Import using the bcp utility Sybase is largely the same as SQL Server. For exporting ASCII files from a Sybase table, the utility ([Using the BCP utility and CSV files](#)) can be used.

An example of use of this utility is shown below:

```
[erwin@fedora sybase]$ isql -U sa -S LOCALHOST -D testdb -P sybase -J iso_1
1> select * from results
2> go
  loca      locb      shipment
-----
seattle    new-york      50.000000
seattle    chicago      300.000000
seattle    topeka        0.000000
san-diego  new-york      275.000000
san-diego  chicago        0.000000
san-diego  topeka        275.000000

(6 rows affected)
1> quit
[erwin@fedora sybase]$ cat bcp.fmt
10.0
4
1      SYBCHAR 0      0      "\"\"  1      loca
2      SYBCHAR 0      10     "\",\"  1      loca
3      SYBCHAR 0      10     "\",\"  2      locb
4      SYBCHAR 0      17     "\\n\"  3      shipment
[erwin@fedora sybase]$ bcp testdb..results out res.txt -S LOCALHOST -U sa -P sybase \
-J iso_1 -f bcp.fmt
```

Starting copy...

```
6 rows copied.
Clock Time (ms.): total = 1 Avg = 0 (6000.00 rows per sec.)
[erwin@fedora sybase]$ cat res.txt
"seattle","new-york",50.0
"seattle","chicago",300.0
"seattle","topeka",0.0
"san-diego","new-york",275.0
"san-diego","chicago",0.0
"san-diego","topeka",275.0
[erwin@fedora sybase]$
```

Note: the first column in the format file is a dummy (it has length 0). This is in order to write the leading quote, as bcp only allows for termination symbols.

This can be automated using the following GAMS code:

```
sets
  i  'canning plants' / seattle, san-diego /
  j  'markets' / new-york, chicago, topeka / ;
```

```
$onecho > bcp.fmt
10.0
4
1      SYBCHAR 0      0      "\"\"  1      loca
2      SYBCHAR 0      10     "\",\"  1      loca
```

```

3      SYBCHAR 0      10      "\",,"  2      locb
4      SYBCHAR 0      17      "\n"   3      shipment
$offecho
$call "bcp testdb..results out res.txt -S LOCALHOST -U sa -P sybase -J iso_1 -f bcp.fmt"
parameter d(i,j) 'distance in thousands of miles'
/
$ondelim
$include res.txt
$offdelim
/;
display d;

```

4.18.3.7.1.2 Import using the SQL2GMS utility The [SQL2GMS](#) tool uses ADO or ActiveX Data Objects to extract data from relational databases. It can connect to almost any database from any vendor as it supports standards like ODBC. See [documentation](#) for more information.

4.18.3.7.1.3 Import using a 'SQL2GMS' VBS script The following GAMS code will generate and execute a script written in VBScript. It mimics the behavior of SQL2GMS.EXE and can be used for debugging or the script can be passed on to the IT support people in case there are problems with accessing the database.

```

$ontext
  This script mimics SQL2GMS.

4.19 Executing GAMS from other Environments

4.19.1 Some General Comments

Nowadays the [objected-oriented APIs](#) are the most efficient and elegant way to interact with the GAMS system. They allow the effective communication of data, and do parameterized runs of GAMS. This whole chapter describes a much more basic interaction of GAMS through calling the GAMS executable from different environments. This still can be useful, e.g. if no object-oriented API is available for the particular target language (e.g. VBA).

While the principle of calling the GAMS executable holds for all operating systems, this chapter often focuses on the Windows platform.

One of the interesting problems one faces when spawning GAMS.EXE in a Windows environment is multi-threading. If one does not take precautions, a call to Shell (VB function) or CreateProcess (Win32 API function) causes GAMS to run asynchronously: the function will return while GAMS is still running. In order to read the results one would need to wait until the GAMS job has finished. The machinery for this requires some Windows trickery, and for Visual Basic version 6 and Delphi version 4 we have implemented some small examples that illustrate how this can be done.

Another issue that needs to be addressed is that GAMS needs a place to put its scratch files. By default this is the current directory, a concept that is not always clear in a windowing environment. A good way of dealing with this is to set both the current drive and the current directory before running the GAMS job. It should be noted that GAMS needs write permission there. In the examples we use the Windows TEMP directory for this, but in a real application you may want to use a designated directory. The Windows TEMP directory is found by calling the API function GetTempPath.

4.19.1.1 The GAMS architecture

GAMS itself is a console mode application. In fact it is not a single program, but a driver program (GAMS.EXE on Windows, otherwise GAMS) that executes in turn the GAMS language compiler (GAMSCMEX) or one of the solvers. For a model with a single solve statement, GAMS.EXE will first call GAMSCMEX to compile the GAMS model. Then GAMSCMEX will start executing the internal code that was generated by the compiler. As soon as it hits the instructions belonging to a SOLVE statement it will generate model instance, and GAMSCMEX will exit. Then GAMS.EXE will spawn a solver capable of solving the model. As soon as the solver is finished, GAMS.EXE will execute GAMSCMEX again so it can read the solution and can continue with executing instructions.

4.19.2 Spawning GAMS from VBA

Visual Basic for Applications (VBA) is a programming language that is built into most Microsoft Office applications, e.g. Excel and Access. A VBA program may include modules, which can be imported from files, i.e. in the VBA editor you can choose menu “File” → “Import File”. The GAMS distribution includes some VBA modules, which can be found from:

```
<GAMS System Directory>\apifiles\VBA\api, e.g. "C:\GAMS\win64\24.5\apifiles\VBA\api"
```

Attention

- In order to avoid issues, it's recommended to use the latest version of the modules , i.e. the modules found in the latest GAMS release.

For example, the following modules can be found:

- gamsglobals.bas: Global constants that are used in other modules
- gdxvba.bas: GAMS Data Exchange Object
- idxvba.bas: GAMS IDX Object
- optvba.bas: GAMS Option Object

For more information, see [Expert-Level APIs](#). VBA programs that use the API can be found from:

```
<GAMS System Directory>\apifiles\VBA, e.g. "C:\GAMS\win64\24.5\apifiles\VBA"
```

The models can also be retrieved via GAMSIDE -> Model Libraries -> GAMS Data Utilities Models.

4.19.2.1 Spawning GAMS from Excel

Calling GAMS out of Excel requires some more work than just [Data Exchange with Microsoft Excel](#). The application calling GAMS out of Excel has to:

1. Locate the GAMS system directory and adjust the system path accordingly.
2. Copy the GAMS model into a temporary directory (by default the temporary directory of Windows)
3. Extract the model data from the spreadsheet into a GAMS readable format (gdx)
4. Execute GAMS (solve the model, write the slution back to gdx file)
5. Import the model results back from the gdx files into the spread sheet
6. Update the spreadsheet (graphics, tables)

Using [VisualBasic for Applications \(VBA\)](#) this can be implemented with a few lines of code:

```
Sub solve()
  Dim WorkDir As String
  WorkDir = TempDir()
  Call ClearSolution
  If (Not AddGAMSPath()) Then ' needed to find gdxclib64.dll and gams.exe
    Exit Sub
  End If
  Call ExportGDXFile(WorkDir)
  Call WriteGAMSModel(WorkDir & "portfolio.gms")
  Call RunGAMS(WorkDir & "portfolio.gms", WorkDir)
  Call ReadListing(WorkDir & "portfolio.lst")
  Call ImportGDXFile(WorkDir)
End Sub
```

For further details, please inspecte the VBA part of the examples below.

4.19.2.2 A Simple Example

This very simple example shows how GAMS can be invoked from an Excel spreadsheet. The "example spreadsheet" has a button, which will cause GAMS to run the `trnsport.gms` model stored in `c:/tmp`. There is no data exchange.

A more complete application will write an include file for a GAMS model, and will import a comma delimited file with results when the run is finished. An example of such a complete application is described in <http://www.gams.com/mccarl/excelgams.pdf>.

4.19.2.3 Sudoku Example

This "spreadsheet" is a complete example that uses GDX files to exchange information solves a 25x25 Sudoku problem using CPLEX. You will need a GAMS/CPLEX license to be able to run the spreadsheet. The MIP model solves very easily: the solution is found in the presolve phase.

Note: This spreadsheet requires distribution 22.6 or younger to work properly. If you are using an older distribution, please download "this one".

4.19.2.3.1 Problem

4.19.2.3.2 Solution

4.19.2.4 Efficient frontier example

This "example" (screen shot below) solves a series of NLPs to create an efficient frontier of a portfolio optimization problem.

Note: This spreadsheet requires distribution 22.6 or younger to work properly. If you are using an older distribution, please download "this one".

4.19.3 Spawning GAMS from C

The example below shows an absolute minimal version of calling GAMS from a C program:

```
#include <stdio.h>

int main(int argc, char** argv)
{
    system("gams trnsport lo=2");
    return 0;
}
```

As can be seen the GAMS executable `gams.exe` is called via a simple invocation of `system()`. The extra command line parameter `lo=2` indicates that the log file is not written to the screen (this is the default) but to a file `model.log`.

If we want to generate some data from the application program (e.g. parameter `DEMAND`), we can use an include file which is written by the application. Of the way back results can be read from a PUT file. The GAMS file can now look like:

```

Sets
    i   canning plants   / seattle, san-diego /
    j   markets          / new-york, chicago, topeka / ;

Parameters
    a(i)  capacity of plant i in cases
          /   seattle      350
            san-diego    600 /

    b(j)  demand at market j in cases
          /

$include demand.inc
          / ;

Table d(i,j)  distance in thousands of miles
            new-york      chicago      topeka
seattle    2.5           1.7           1.8
san-diego  2.5           1.8           1.4 ;

Scalar f  freight in dollars per case per thousand miles /90/ ;

Parameter c(i,j)  transport cost in thousands of dollars per case ;

    c(i,j) = f * d(i,j) / 1000 ;

Variables
    x(i,j)  shipment quantities in cases
    z       total transportation costs in thousands of dollars ;

Positive Variable x ;

Equations
    cost      define objective function
    supply(i) observe supply limit at plant i
    demand(j) satisfy demand at market j ;

cost ..      z =e= sum((i,j), c(i,j)*x(i,j)) ;

supply(i) .. sum(j, x(i,j)) =l= a(i) ;

demand(j) .. sum(i, x(i,j)) =g= b(j) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;

Display x.l, x.m ;

file fout /results.txt/;
put fout;
loop((i,j),
    put x.l(i,j):17:5/;
);
putclose;

```

The corresponding C program could look like:

```

//
// example of running a GAMS model

```

```

//
#include <stdio.h>
// number of supply and demand locations
#define M 2
#define N 3
char* dist[M] = {"seattle", "san-diego" };
char* city[N] = {"new-york", "chicago", "topeka" };
double demand[N] = { 325.0, 300.0, 275.0 };
double ship[M][N];
int main(int argc, char** argv)
{
    FILE *f;
    int i,j;
    //
    // write include file
    //
    f = fopen("demand.inc","wt");
    if (f == NULL) {
        perror("fopen");
        exit(1);
    }
    for (i=0; i<N; ++i)
        fprintf(f,"%s %g\n",city[i],demand[i]);
    fclose(f);
    //
    // call GAMS
    //
    system("gams trnsport lo=2");
    //
    // read solution
    //
    f = fopen("results.txt","rt");
    if (f == NULL) {
        perror("fopen");
        exit(1);
    }
    for (i=0; i<M; ++i)
        for (j=0; j<N; ++j)
            fscanf(f,"%lg",&(ship[i][j]));
    fclose(f);
    //
    // display results
    //
    for (i=0; i<M; ++i)
        for (j=0; j<N; ++j)
            printf("%s->%s %g\n",dist[i],city[j],ship[i][j]);
    return 0;
}

```

4.19.4 Spawning GAMS from Visual Basic

This example shows how GAMS can be invoked from a VB program.

When executed a simple window appears where a GAMS model can be specified and possible other command line options. The [GAMS] button will execute the model.

When the Normal display is used, a console window will be opened. This console window will be closed automatically at the end of the run if the Close process window on completion check box is checked. Minimized does not show a window, but in the taskbar an icon will appear. If the job takes a long time, the user can click on this icon to make the console window visible. The Hidden option prevents any GAMS associated window or icon to appear.

Note: it is required for this program to work, that the GAMS system directory is in the path. If this is not the case, an error code of -1 is returned.

The main program is attached below, the full source for this example is "available for download".

```

Attribute VB_Name = "vbGAMS"
Option Explicit
' -----
' Module Name: VB_Gams
' File: gams.bas
' Version: 1.1
'
' Functions:
' VB_Gams32 - sets up process directory, parameter file, and console, and manages

```

```

'           looping of gams compiler and solver.
'
' -----

end;
end.

```

4.19.6 Spawning GAMS from Visual C++

In "this example" we call GAMS from a simple Visual C++ application.

The additional concern is here that we want to intercept the GAMS screen output so it can be written to a multi-line edit control. For more information about the used technique see the Microsoft publication: [HOWTO: Spawn Console Processes with Redirected Standard Handles \(Q190351\)](#) in the Microsoft Knowledge Base.

4.19.7 Spawning GAMS from C#

Below is a simple example:

```

using System.Diagnostics;
void RunGamsModel()
{
    Process p = new Process();
    p.StartInfo.FileName = gamsexec;
    p.StartInfo.WorkingDirectory = tempdir;
    p.StartInfo.Arguments = "\" + modelname + "\" L0=0 --runid="+runid;
    p.Start();
    p.WaitForExit();
}

```

The command line formed here is `gams modelname L0=0 --runid=xxx`. The option L0 (logoption) will disable writing a log, and the option `--runid` passes a parameter to the GAMS model (inside the model you can access this through `runid%`).

4.19.8 Spawning GAMS from Java

Java has a class *Runtime* that implements spawning of processes using the `Exec()` method. This is quite trivial to use in applications, but in applets the default security settings don't allow this operation (in general). The problem can be solved by loading the applet from a local drive or by using a signed applet. Similarly if the Java classes are loaded from inside a database, this operation may require additional privileges. For an example see the previous section, where GAMS is called from Oracle using a Java Stored Procedure. The relevant code may look like:

```

import java.io.File;
class RunGAMS {
    public static void main(String[] args) {
        System.out.println("Start");
        String[] cmdArray = new String[5];
        cmdArray[0] = "<PATH>/GAMS" + File.separator + "gams";
        cmdArray[1] = "<PATH>" + File.separator + "transport.gms";
        cmdArray[2] = "WDIR=<PATH>" + File.separator + "TMP";
        cmdArray[3] = "SCRDIR=<PATH>" + File.separator + "TMP";
        cmdArray[4] = "L0=2";
        try {
            Process p = Runtime.getRuntime().exec(cmdArray);
            p.waitFor();
        }
        catch (java.io.IOException e)
        {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        }
        catch (InterruptedException e)
        {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        }
        System.out.println("Done");
    }
}

```

```

    }
}

```

Below another example, which avoids problems, if the model has a long screen log (the buffer gets filled and locks the execution), which could happen if GAMS does not write the log to the file like above. This example is based on suggestion made by [Edson Valle](#).

```

import java.io.File;
import java.io.BufferedReader;
import java.io.InputStreamReader;
class RunGAMS {
    public static void main(String[] args) {
        System.out.println("Start");
        String[] cmdArray = new String[5];
        cmdArray[0] = "<PATH/TO/GAMS>" + File.separator + "gams.exe";
        cmdArray[1] = "<PATH>" + File.separator + "trnsport.gms";
        cmdArray[2] = "<PATH>" + File.separator + "tmp";
        cmdArray[3] = "LO=3";
        try {
            Process p = Runtime.getRuntime().exec(cmdArray);
            BufferedReader stdInput = new BufferedReader(new InputStreamReader(p.getInputStream()));
            String s = null;
            while((s=stdInput.readLine()) !=null){
                System.out.println(s);
            }
            p.waitFor();
        }
        catch (java.io.IOException e )
        {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        }
        catch (InterruptedException e )
        {
            System.err.println(">>>>" + e.getMessage() );
            e.printStackTrace();
        }
        System.out.println("Done");
    }
}

```

For an example of GAMS usage from a Java based server environment see Alexander Sokolov, [Information environment and architecture of decision support system for nutrient reduction in the Baltic Sea](#), Department of Systems Ecology, Stockholm University.

4.19.9 Spawning GAMS from a Web Server

Running GAMS remotely using a Web based thin-client architecture requires that GAMS is executed directly or indirectly from the Web server or HTTP server. A simple way of doing this is via a CGI process. [Common Gateway Interface](#) (CGI) programs can be written in many languages such as C, Perl or Delphi. CGI is relatively slow, as for each interaction, even the most simple one, a process needs to be started. Alternatives exist in the form of CGI extensions such as [FastCGI](#) or using DLLs or shared libraries. A basic algorithm for a CGI script could be:

- Create a unique directory, and CD to that directory.
 - Get information from user forms and save it as GAMS readable files.
 - Run GAMS making sure it does not write the log to the screen (i.e. use the option LO=2 (log to a file) or LO=3 (log to stdout)).
 - Let the model write solution info to text files using the PUT statement.
 - Read solution, and create formatted HTML to send back to the user.
 - Remove temp files and directory.
-

Complications arise when there is a need to show graphics (files need to be stored somewhere and discarded after a while), when jobs take a long time to finish (you will need to add a facility where the user can pick up results at a later moment) or when the server resources can be exhausted (e.g. because of a large number of simultaneous users or because of large models).

An important complicating issue in the above list are jobs that take more time to finish: web servers like to respond to the user within a short time, and time out errors will occur if a job takes a long time. The solution is to use a queue based approach. An actual implementation available is the [NEOS Server](#) - there is also a GAMS interface to NEOS: [KESTREL - Remote Solver Execution on NEOS Servers](#).

4.19.10 Spawning GAMS from PHP

A minimal example

index.html

```
<html>
  <body>
    <form action="calling_gams.php" method="post">
      Solve transport with f = <select name="f">
        <option>70</option>
        <option>80</option>
        <option>90</option>
        <option>100</option>
      </select>
      <input type="submit" value="call GAMS"/>
    </form>
  </body>
</html>
```

calling_gams.php

```
<?php
$f = $_POST['f'];
//some model data
$modelfile = 'trnsport_php.gms';
$city = array('new-york','chicago', 'topeka');
$demand = array(325.0, 300.0, 275.0);
//write demand.inc
$fh = fopen('./demand.inc', 'w+');
for($i=0; $i<count($city); $i++){
  fwrite($fh, $city[$i]." ".$demand[$i]."\n");
}
fclose($fh);
//write f.inc
$fh = fopen('./f.inc', 'w+');
fwrite($fh, $f);
fclose($fh);
//call gams
system('</path/to/gams>/gams '.$modelfile.' lo=2');
//read solutions
$fh = fopen('./results.txt', 'r');
echo '<p><b>result of '.$modelfile.' (f='.$f.') :</b></p>';
while (!feof($fh)){
  $line = fgets($fh);
  echo '<p>'.$line.</p>';
}
fclose($fh);
?>
```

trnsport_php.gms

Sets

```

i  canning plants    / seattle, san-diego /
j  markets           / new-york, chicago, topeka / ;
```

Parameters

```

a(i)  capacity of plant i in cases
/      seattle      350
       san-diego    600 /
```

```

        b(j)  demand at market j in cases
        /
$include demand.inc
        / ;

Table d(i,j)  distance in thousands of miles
           new-york      chicago      topeka
seattle    2.5          1.7          1.8
san-diego  2.5          1.8          1.4 ;

Scalar f  freight in dollars per case per thousand miles /
$include f.inc
        / ;

Parameter c(i,j)  transport cost in thousands of dollars per case ;

           c(i,j) = f * d(i,j) / 1000 ;

Variables
    x(i,j)  shipment quantities in cases
    z       total transportation costs in thousands of dollars ;

Positive Variable x ;

```

4.20 Using GAMS Studio

This tutorial on using [GAMS Studio](#) was written initially by and is distributed by courtesy of Bruce A. McCarl². Bruce has extensive experience with GAMS, both as a modeler and an educator, and many

²Specialist in Applied Optimization, Distinguished Professor of Agricultural Economics, Texas A&M University, Principal, McCarl and Associates, mccarl[at]tamu.edu, brucemccarl[at]gmail.com, <http://agecon2.tamu.edu/people/faculty/>

GAMS users know, use, and benefit from his work. This tutorial presents a guided tour to the usage of GAMS Studio and on some items it reflects Bruce's personal view and preferences.

4.20.1 What Is It?

A multi platform (not only PCs with Windows) graphical interface to run GAMS

GAMS uses two phases.

1. Text edit

First, one uses a **text editor** and creates a file which contains GAMS instructions.

2. File submission

Second, one **submits that file** to GAMS which executes those instructions causing calculations to be done, solvers to be used and a solution file of the execution results to be created.

Approaches to use GAMS.

1. More batch oriented traditional method use a text editor set up the model then use **DOS (or UNIX)** command line instructions to find errors in and run the model.
2. GAMS STUDIO or GAMS IDE alternatives. Graphical interfaces to create, debug, text edit and run GAMS files.

Summary of steps to using

1. Install GAMS and STUDIO on your computer

2. Open STUDIO through the icon
3. Open or create a file by going to the file selection in the upper left corner.
4. Prepare the file so you think it is ready for execution
5. Run the file with GAMS by clicking the run button or pressing F9
6. Open and navigate around the output

4.20.2 Installation

Install GAMS and STUDIO

GAMS STUDIO is **automatically installed** when GAMS is installed and you get the **choice of whether to use STUDIO or the IDE as primary editor**. To install do the following steps

1. Download the GAMS installation file from www.gams.com under **Resources and Download**

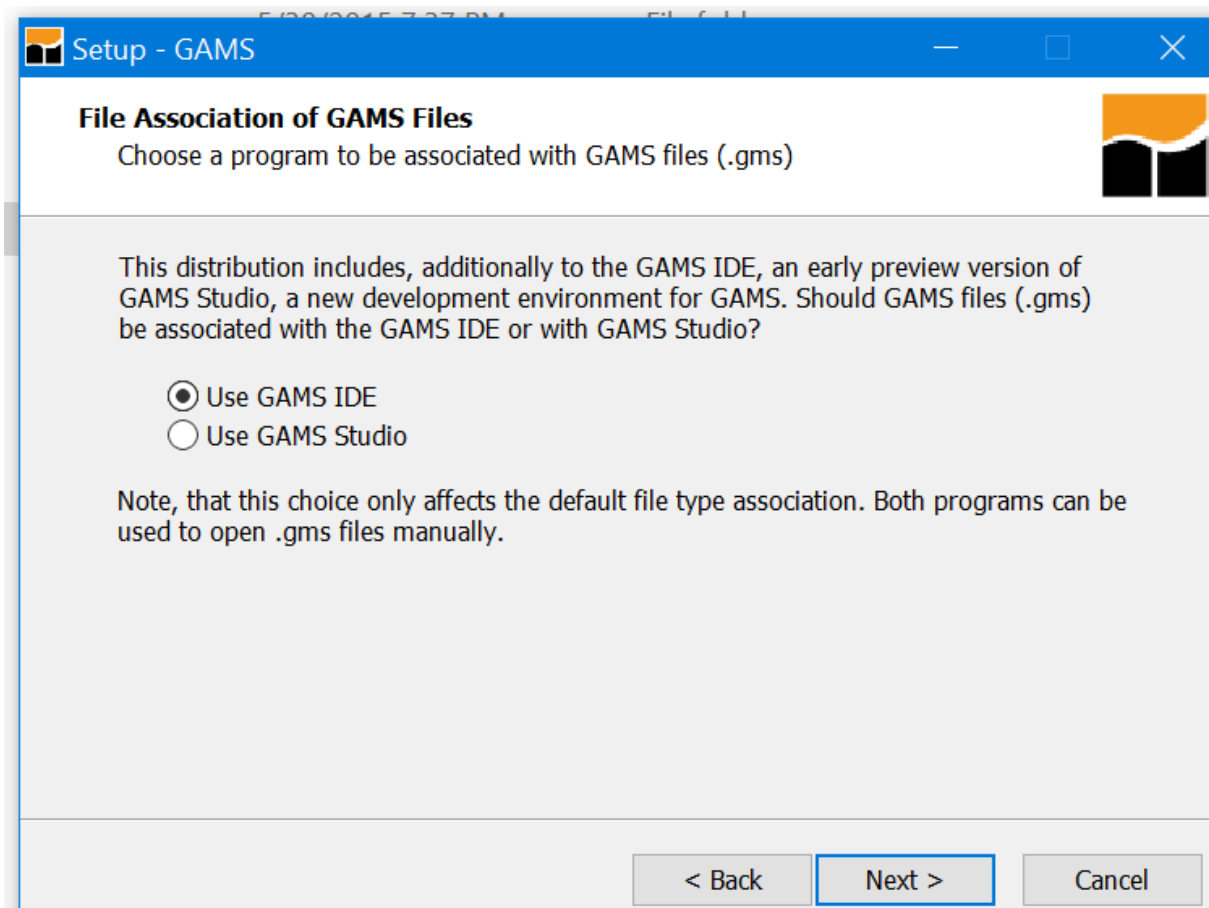

2. Start the installation

Installer should place an icon on the desktop yielding

4.20.3 Using STUDIO after Installation

During the install you will find

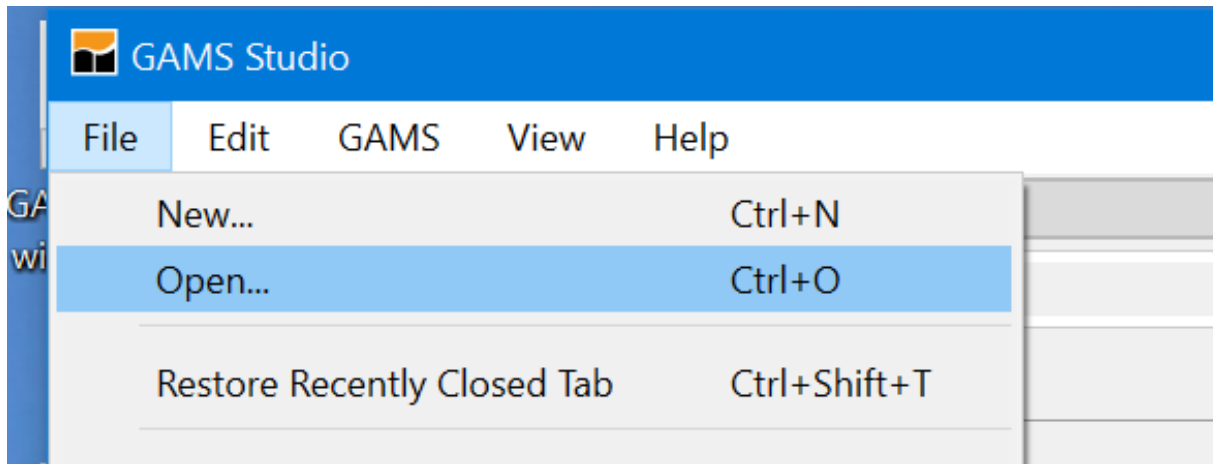

Which allows you to choose which graphical interface to use as the default. For now choose STUDIO.

Open STUDIO through the icon

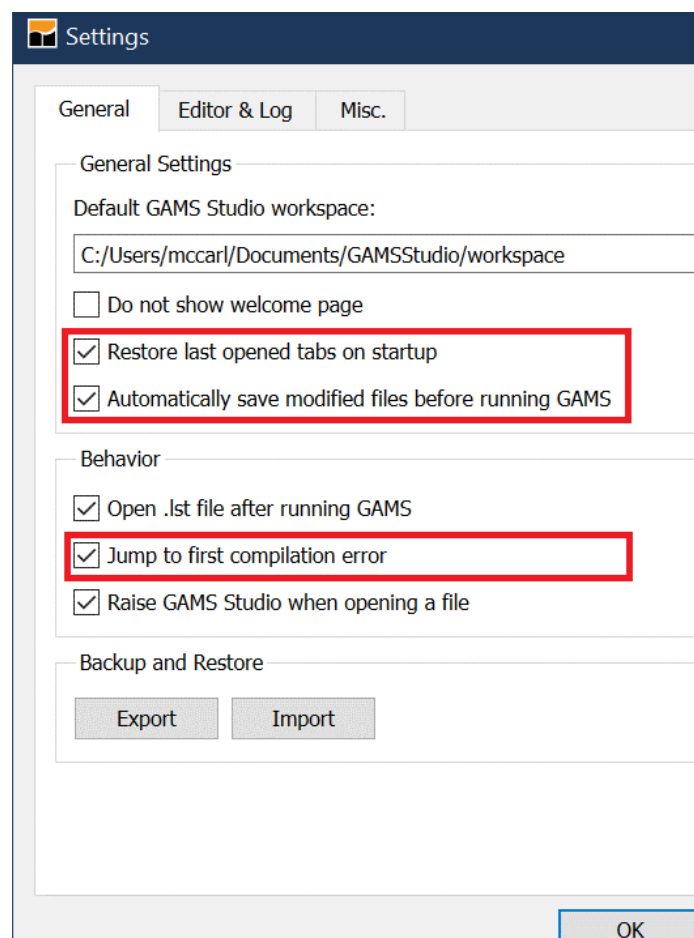

Open the File menu choice. Select a file.

Note, the file location determines where all generated files are placed (to place files elsewhere use the save as dialogue) and where GAMS looks for files when executing. *I recommend that you make sure your file is in a place where you want it also making sure that place contains all associated files ie this is the file storage directory for this endeavor.*

Fix defaults and suppress cursor driven object highlighting. When first opening Studio go to settings and I would make sure check marks are as follows especially the checked ones in the red boxes and the unchecked green one

General Editor & Log Misc.

Editor Settings

Font: Courier New Font Size: 10

Enable auto-indentation Auto close opening brackets and quotes

Enable line wrapping in editor Highlight current line

Show line numbers Highlight word under cursor without selection

Tab stop size: 4

Log Settings

Enable line wrapping in process log

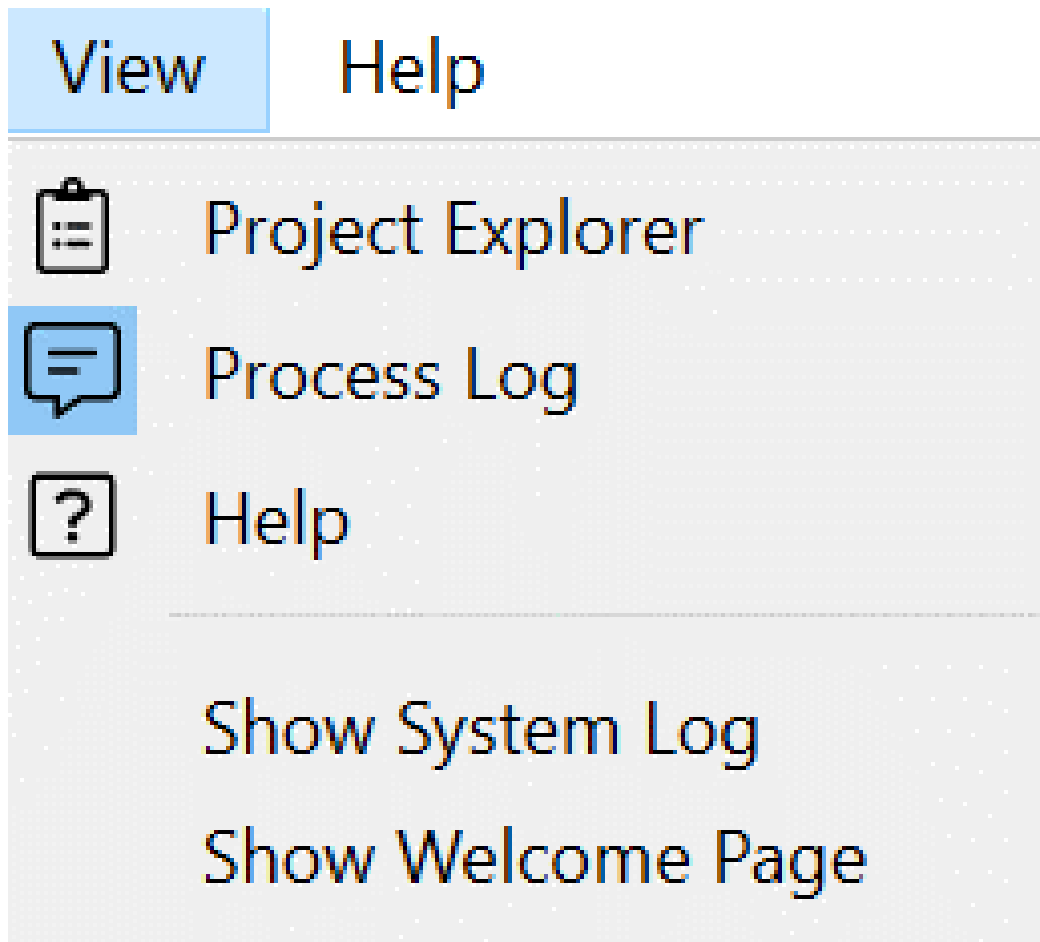

Clear process log before GAMS execution

Always write log to disk

Number of log backup files: 3

OK Cancel Apply

Here selecting the **Process Log** and possibly the **Explorer** are of interest.

The Explorer will open automatically when a file is opened and the **Process Log** will open when a solve is done. I usually hide the Explorer and sometimes want to get rid of the Process window.

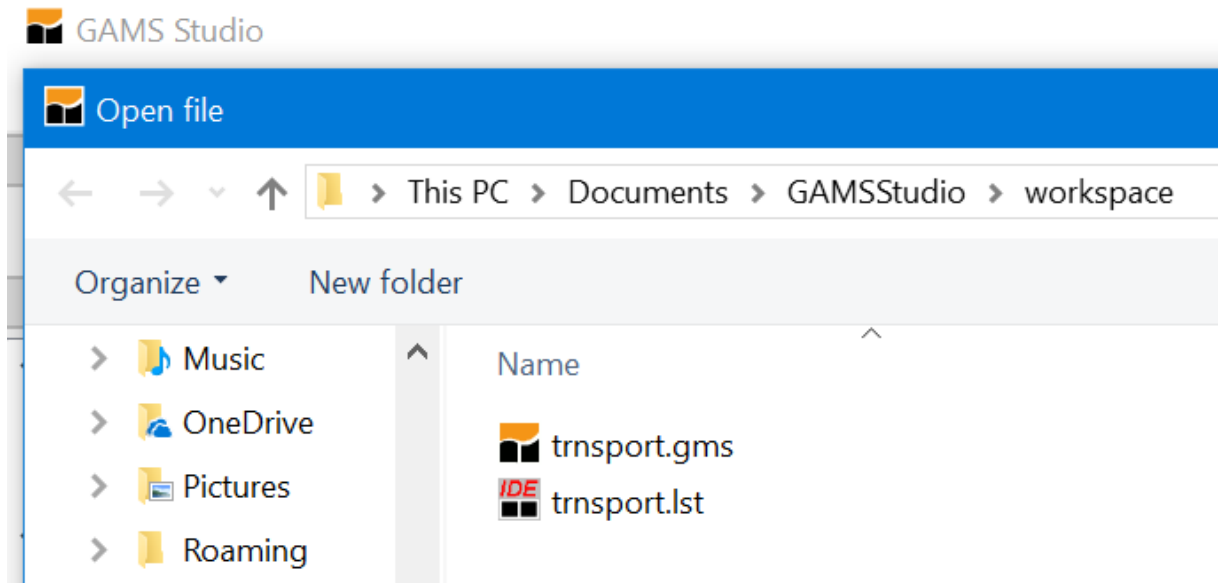

4.20.3.1 Getting Started

4.20.3.1.1 Create or open an existing GMS file Several cases are possible

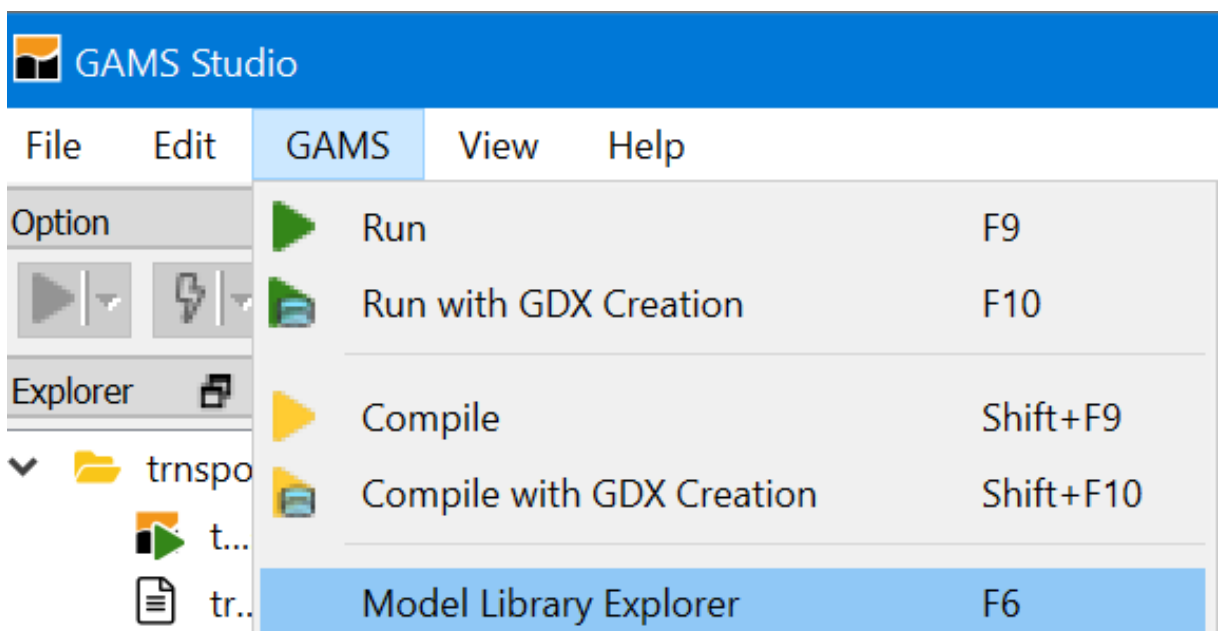

1. Create a new file (covered later)
2. Open an existing file – at first this will be in

› This PC › Documents › GAMSStudio › workspace

then you see something like

3. Open the GAMS model library explorer under the GAMS tab or press F6 (this is the simplest for first time users and the one we will use)

Select a model like *trnsport.gms*

SeqNr	Lic	Name	Application Area	Type	Contributor	
001	G	TRANSPORT	Management Science and OR	LP	Dantzig, G B	A Transportation Problem
002	G	BLEND	Management Science and OR	LP	Dantzig, G B	Blending Problem I
003	G	PRODMIX	Management Science and OR	LP	Dantzig, G B	A Production Mix Problem
004	D	WHOUSE	Management Science and OR	LP	Dantzig, G B	Simple Warehouse Problem
005	D	JOBT	Management Science and OR	LP	Dantzig, G B	On-the-Job Training

It will be automatically saved in the last directory you used or in the STUDIO default Workspace directory.

4.20.3.1.2 Prepare file for execution When using model library *transport.gms* should now appear as part of your STUDIO screen.

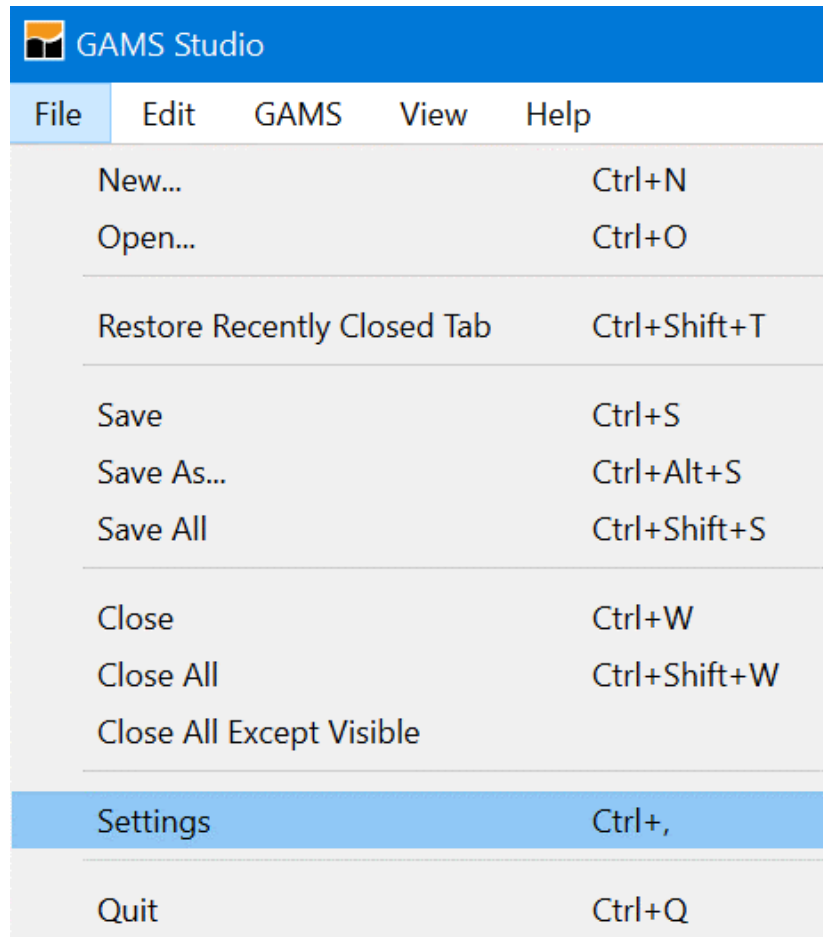

```

21 Set
22   i 'canning plants' / seattle, san-diego /
23   j 'markets' / new-york, chicago, topeka /;
24
25 Parameter
26   a(i) 'capacity of plant i in cases'
27       / seattle 350
28       san-diego 600 /;
29
30   b(j) 'demand at market j in cases'
31       / new-york 325
32       chicago 300
33       topeka 275 /;
34

```

The STUDIO contains a full-featured editor. Go through the file and change what you want.

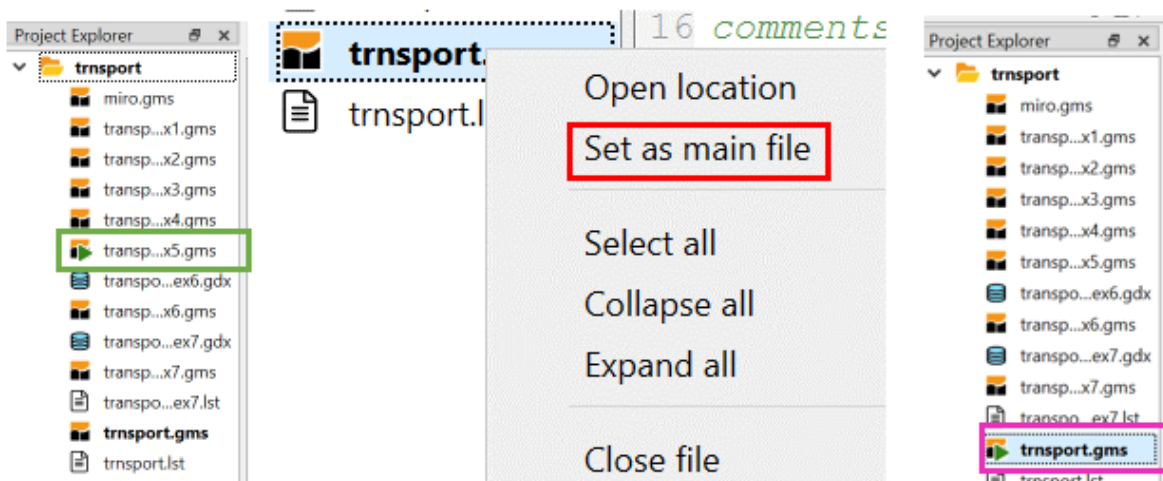

You can also customize the appearance somewhat through the settings choice under the File menu.

There you can change font size (under editor), tabs, default file location (called workspace) and some other features on how GAMS runs. For now leave it alone.

4.20.3.1.3 Make sure right file is executed Unlike a lot of other programs, STUDIO does not necessarily execute the file you have been working on rather executing what it calls the "main" file.

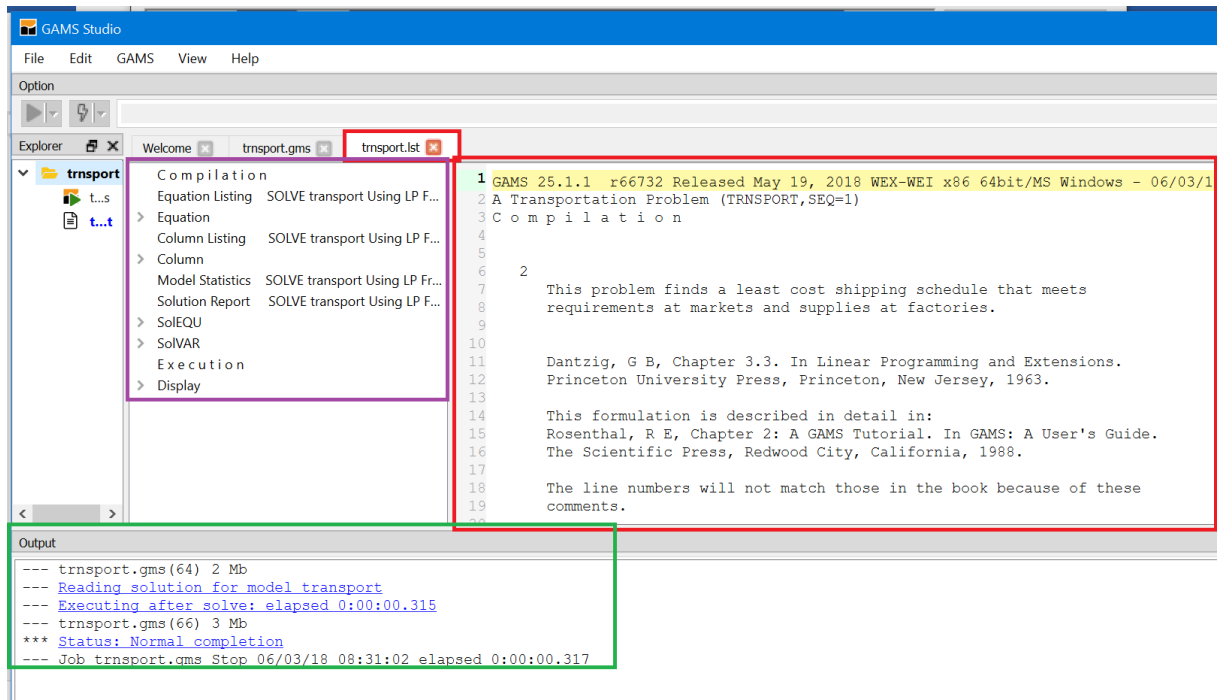

In particular, if you activate the explorer view then the main file is the one marked with a **green triangle** as below. If the triangle is not marking the file to be run you need to right click on that file and then choose **Set as main file**. In turn the triangle will move.

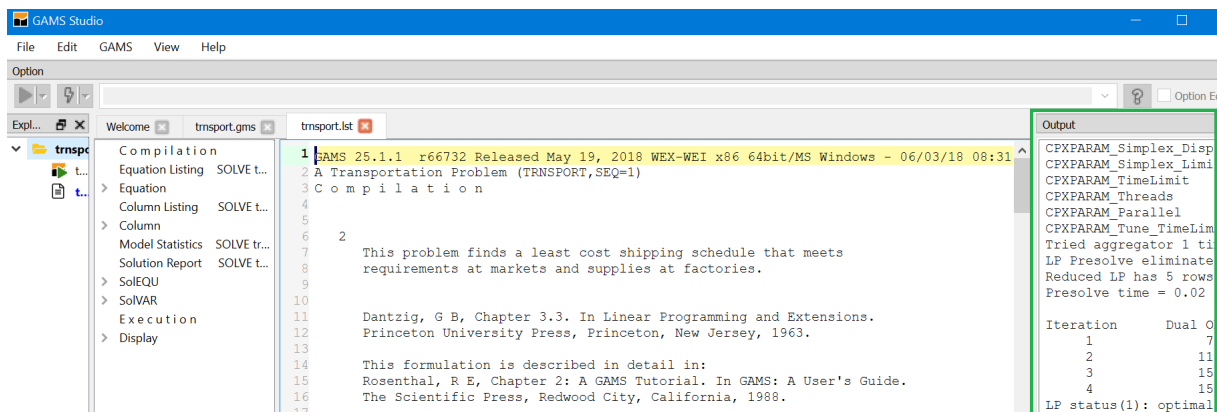

4.20.3.1.4 Run GAMS by clicking the run button

The **Process Log** window (green) will then appear which logs the steps executed in running the model. The **LST file** (red) and the **navigation window** (magenta) also appear. Note to save space I would close the Explorer window and drag the **Process Log** window (green) to the bottom or the right hand side. The process window on the bottom is illustrated here and it is on the right side on the following picture.

Here it is after reconfiguring by dragging the *Process Log* up and to the right then resizing and repositioning.

Now use the *process window* (green) to navigate the LST file or open created files. By double clicking on lines in that window you access the LST file at particular locations or open created files. What and where you access is determined by the color of the line you click on.

```

Output

```

Color of Line	Function and Destination When Double Clicked
Blue line	Opens LST file and jumps to corresponding place.
Non-bolded black line	Control click on this takes you to LST file. Double click on error message takes you to spot in LST file.
Red line	Marks errors encountered. Cursor is positioned at first red line. When clicked on cursor jumps to Source (GMS) file location of error. Control click takes you to error location in LST file. Error description text is in execution process log and in LST file. You can use a little red icon in source to jump to error message in LST file or a green arrow in the LST to go to error location in source.
Green line	Causes studio to open a file that was created during the run like a GDX, PUT or REF file

4.20.3.1.5 Navigate with process window After double-clicking on any non-red line, or if we used the automatically open list file option our main editing window is augmented by the **LST file** (green) (see the magenta tabs)

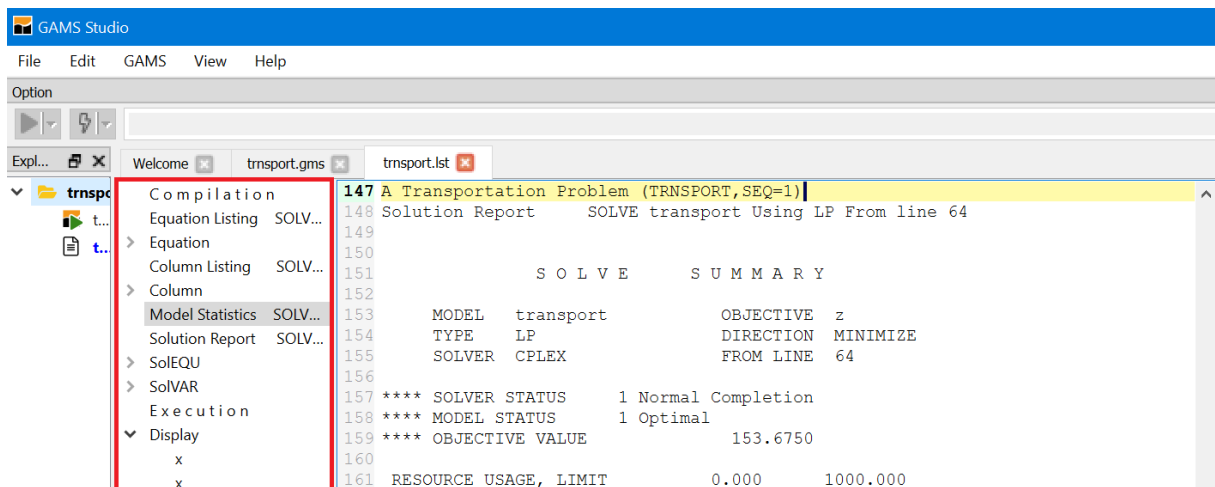

We can navigate as we would with an editor or word processor, as we are automatically in STUDIO text editor.

Sometimes I want to get the process window and explorer out of the way. I can do this through the view window and also through the icons (red) on the right side of the top bar

Clicking on these opens and closes the explorer and the process window.

4.20.3.1.6 Navigate with LXI window

Navig. Line	Function and Destination When Clicked.
Compilation	Jumps to top of echo print in LST file
Error Mess.	Jumps to list of error messages when errors present

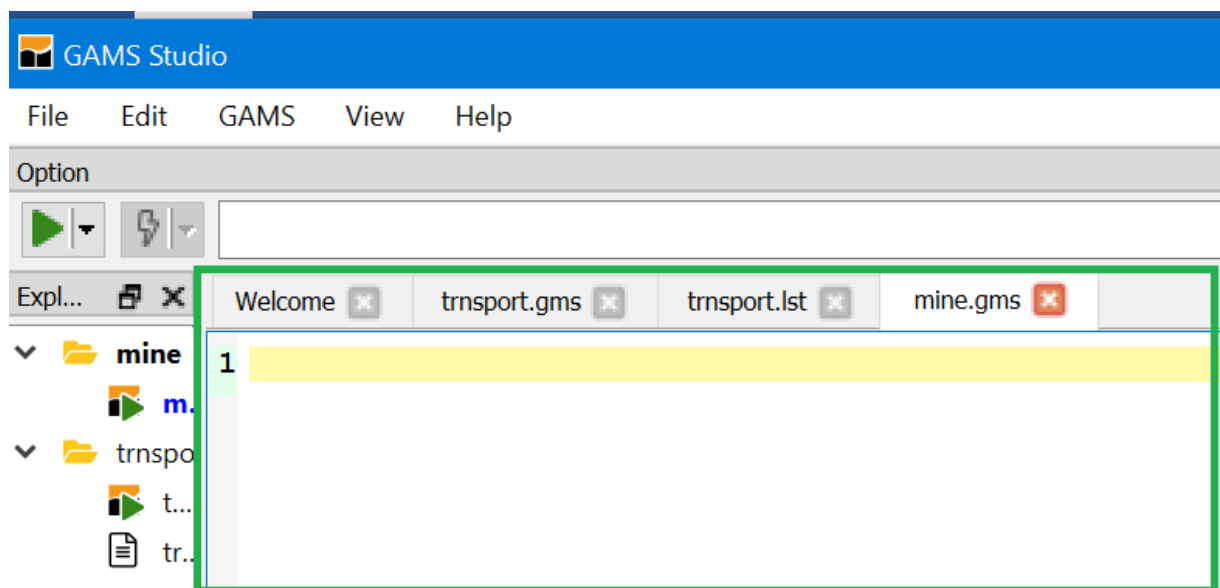

Navig. Line	Function and Destination When Clicked.
Equat. listing	Jumps to list of equation contents
Equation	Expandable allowing jump list of equation contents
Variab. listing	Jumps to list of variable
Variable	Expandable allowing jump to list of variable contents
Model stat.	Jumps to model statistics part of LST file
Solut.Report	Jumps to model summary solution report
SolEQU	Expandable allowing jump solution for each equation
SolVAR	Expandable allowing jump to solution for variable
Execution	Jumps to beginning of post solve execution
Display	Jump to displays of specific parameters and other items

4.20.3.2 Working with your own files

Now you are ready to work with your own files. You may already have a file or you may need to create one.

Creating a new file - Two principal ways

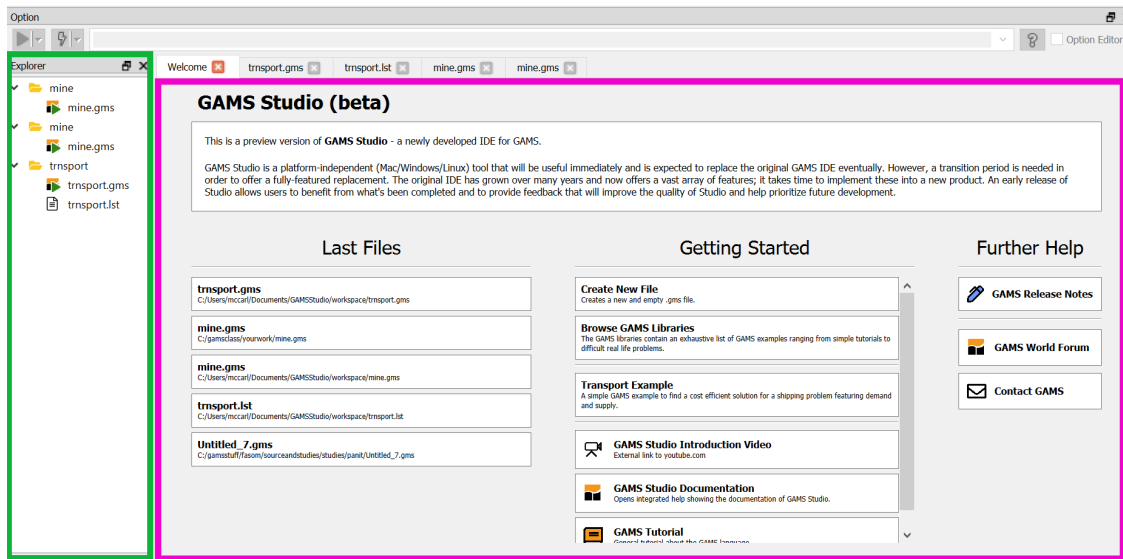

1. Open an existing file through the library or from a location on your hard disk. Then use the **save as** dialogue from the **file** menu to change its name. Now modify contents to what you want. You may cut and paste as in other Windows programs.
2. Open the **file** menu and use the **new** option. You will then be prompted for a name (I called it mine) with the extension .gms and then have a *blank screen* (green) into which you may type GAMS instructions

Save that file wherever you want and reopen it that will become the new default directory (**this only occurs upon an open not a save as**) and any subsequent non library opens, simple includes or saves will go there. Imports from the library go to the default workspace.

4.20.4 The Welcome and Explorer Windows

As you have worked with STUDIO you will find it shows a **Welcome** (magenta) window (*unless you told it not to in settings*), that remembers previous files plus gives access to documentation.

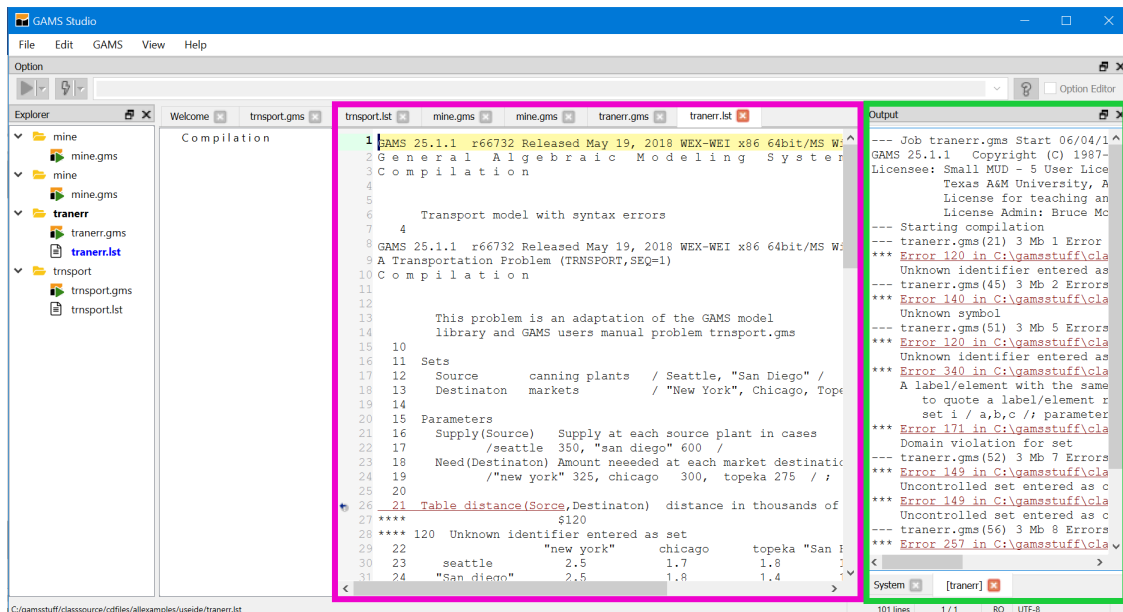

There as of now you get links to files recently used, and links to some documentation.

Also on the left hand side is an **Explorer** (green) window that shows recent files and allows you to open by double clicking. This remains whether you are in the welcome page or editing files unless it is not checked in the View dialogue.

4.20.5 Fixing Compilation Errors

No one is perfect, errors always occur. The STUDIO can help you in finding and fixing those errors.

Let's look at an example with a small typo to illustrate (note: **source** vs. **sorce**). A run yields the windows below where the right part is the **process window** (green) positioned to show the first error and the center is the **lst file** (magenta) positioned to show the first error.

The red lines in the process window mark errors with error messages just below. To see where the errors occurred click on the very first red line which opens the source file or look at the LST file where the marking \$ appears

A click on the red line takes you to the place in the source where the error was made. The tip here is always start at the top of the process file when doing this.

The screenshot shows the GAMS Studio interface. The source file window displays the following code:

```

1 $ontext
2 Transport model with syntax errors
3 $offtext
4
5 $Title A Transportation Problem (TRANSPORT,SEQ=1)
6 $ontext
7 This problem is an adaptation of the GAMS model
8 library and GAMS users manual problem trnsport.gms
9 $offtext
10
11 Sets
12 Source      canning plants / Seattle, "San Diego" /
13 Destinaton  markets      / "New York", Chicago, Topeka ,"San Francisco"/ ;
14
15 Parameters
16 Supply(Source)  Supply at each source plant in cases
17 /seattle 350, "san diego" 600 /
18 Need(Destinaton) Amount needed at each market destination in cases
19 /"new york" 325, chicago 300, topeka 275 / ;
20
21 Table distance(Source, Destinaton) distance in thousands of miles
22      "new york"      chicago      topeka      "San Francisco"
23 seattle      2.5      1.7      1.8      1.0
24 "San diego"    2.5      1.8      1.4      1.5;
25
26 Scalar
27 prmlcst      freight cost in $ per case per 1000 miles /90/
28 loadcost     freight loading cost in $ per case /25/ ;
29
30 Parameter trancost(Source, Destinaton) transport cost in dollars per case ;
31 trancost(Source, Destinaton)=loadcost + prmlcst * distance(Source, Destinaton) ;

```

The Output window shows the following error messages:

```

--- Job tranerr.gms Start 06/04/1

```

A double click on a black line takes you to the error location in the LST file.

Also in the source file window note the small red circle that appears on the line with the error

The close-up shows line 21 of the source file: `Table distance (Sorcel, Destinaton)`. A small red circle with a white arrow points to the word "Sorcel" in the code.

Clicking on that transfers you to the LST file where the error message appears.

The LST file shows the following error messages for line 21:

```

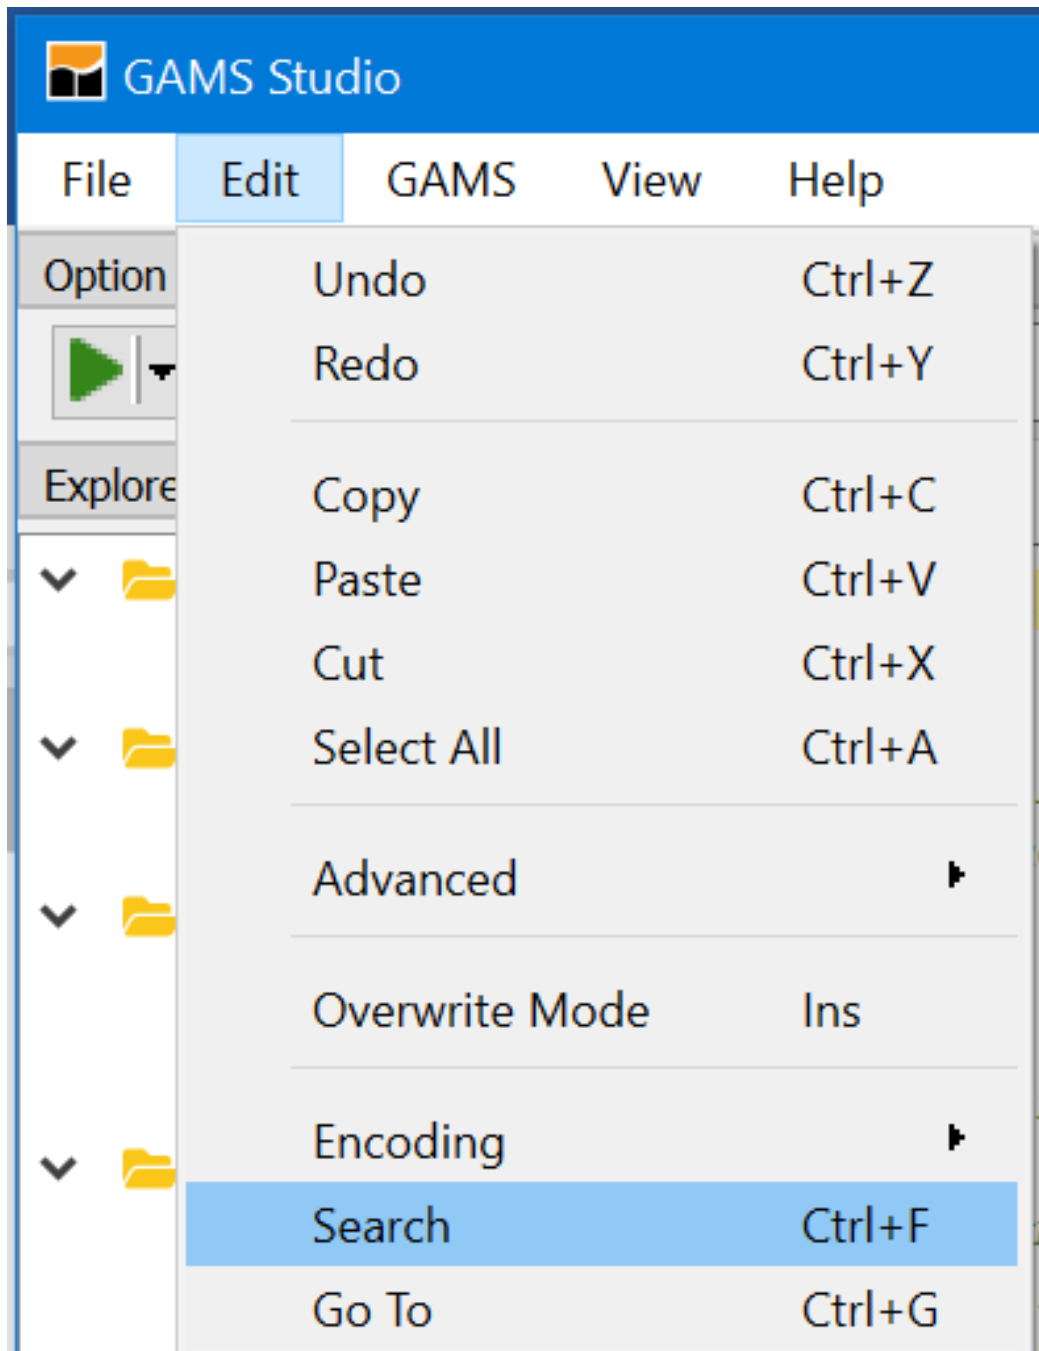

26 21 Table distance (Sorcel, Destinaton) dis
27 ****                               $120
28 **** 120 Unknown identifier entered as set

```

And there a small gray circle with an arrow in it that when clicked on will transfer you back to the source file

4.20.6 Ways to find and/or replace text strings

For finding you can use the search menu under the Edit tab or control F

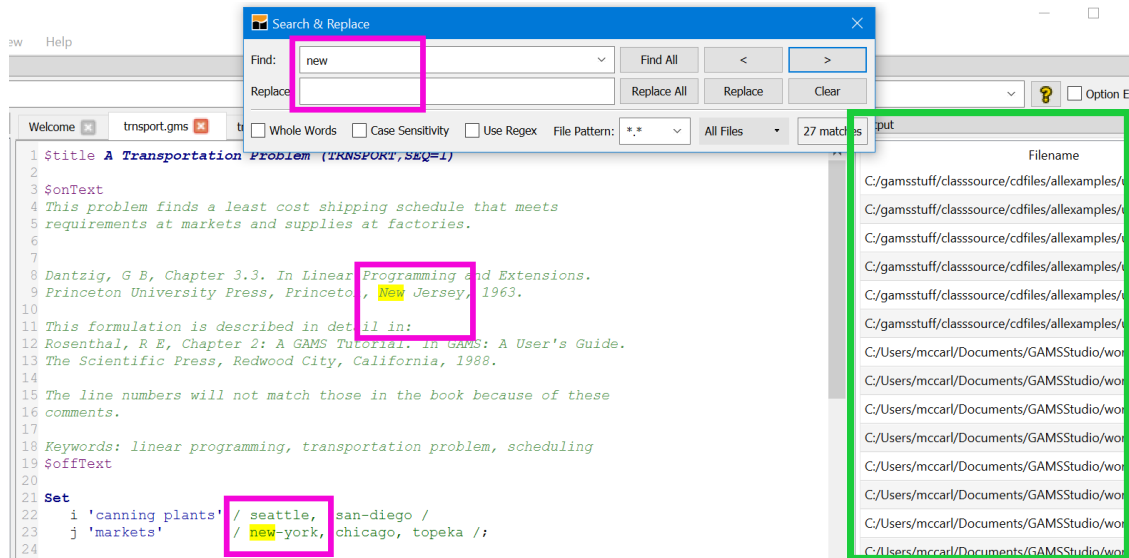

Subsequently you get

Which allows both search and replace. As of now this opens with the last option you used and may start with initially with an all files setting.

After the search you find

Where all occurrences of the **search term** in the current file are highlighted in yellow and to the right there is a **list of all files that contain that search term** (green) in all of the **directories corresponding to files opened in the explorer**.

The search dialogue is straight forward with arrow keys to jump to next (F3 also works for forward and shift F3 for backward) and the **all files can be manipulated as shown** (in yellow).

4.20.7 Matching Parentheses

The STUDIO provides you with a way of checking on how the **parentheses match up** in your GAMS code. This involves positioning your cursor just before an open parentheses or just after a close (Just after also works if there are not multiple parentheses). In either case the corresponding close or open is highlighted in **green**. Additionally positioning the cursor right before the beginning parentheses and tapping **Ctrl + b** will lead you to the matching ending parentheses whether it be 1, 100, or 1000+ lines away and vice versa.

```

54 demand(j) satisfy demand at market j ;
55
56 cost.. z =e= sum((i,j), c(i,j)*x(i,j));
57

```

When the expression in parentheses carries on the several lines the marking is in multiple lines and **Ctrl + b** will transfer position back and forth

```

55
56 cost..          z =e= (sum((i,j),
57                  c(i,j)*x(i,j)
58                  ));

```

This feature will also match up { } or [] with a red marking if the types don't match.

4.20.8 Moving Blocks

The STUDIO allows one to move text blocks through standard Cut and Paste Operations in two fashions.

1. One can identify a continuous block of text with the mouse or the keyboard (the latter involves putting the cursor at a beginning point then hold the shift key down and use the arrow keys).
2. One can identify a **column block of text** (blue) with the mouse or the keyboard (these involve holding **alt and shift down** then moving the mouse or the cursor with the arrow keys).

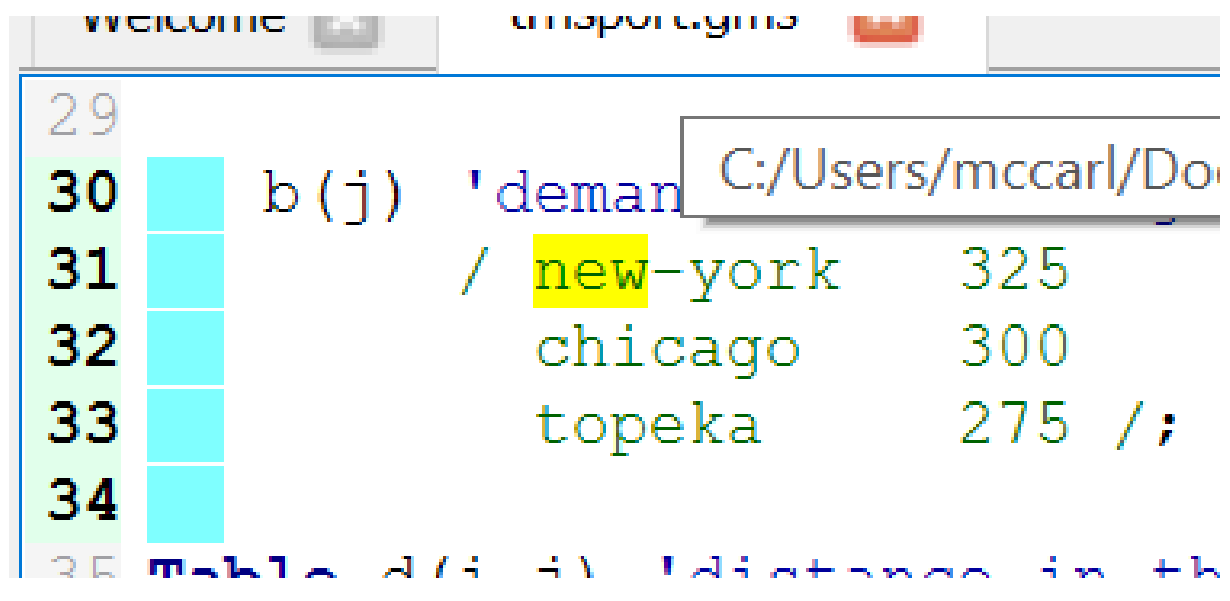

```

34
35 Table d(i,j) 'distance in thousands of miles'
36         new-york   chicago   topeka
37   seattle         2.5         1.7         1.8
38   san-diego       2.5         1.8         1.4;

```

In turn copy, cut, and paste can be done with the Edit menu or with control c, x and v respectively as in normal windows. Control insert also pastes.

Also if one types with a column block highlighted than the character goes in all rows of the block and replaces what was there before

```

29
30 b(j) 'deman C:/Users/mccarl/Do
31 / new-york 325
32   chicago 300
33   topeka 275 /;
34
35 Table d(i,j) 'distance in th

```

with an * typed becomes

```

29
30 * | b(j) 'demand at market j in cases'
31 * |   / new-york    325
32 * |   chicago      300
33 * |   topeka       275 /;
34 * |

```

4.20.9 Syntax Coloring

A feature in the STUDIO is syntax coloring. The STUDIO recognizes a subset of the GAMS syntax and reflects this in the display colors. Note in the display below that commands, explanatory text and set elements are differentially colored.

```

25 Parameter
26   a(i) 'capacity of plant i in cases'
27     / seattle    350
28     san-diego   600 /
29
30 b(j) 'demand at market j in cases'
31   / new-york    325
32   chicago      300
33   topeka       275 /;
34
35 Table d(i,j) 'distance in thousands of miles'
36     new-york  chicago  topeka
37   seattle    2.5      1.7      1.8
38   san-diego  2.5      1.8      1.4;
39
40 Scalar f 'freight in dollars per case per thousand miles' / 90 /;
41
42 Parameter c(i,j) 'transport cost in thousands of dollars per case';
43 c(i,j) = f*d(i,j)/1000;
44
45 Variable
46   x(i,j) 'shipment quantities in cases'
47   z      'total transportation costs in thousands of dollars';
48
49 Positive Variable x;
50
51 Equation
52   cost      'define objective function'
53   supply(i) 'observe supply limit at plant i'
54   demand(j) 'satisfy demand at market j';
55
56 cost..      z =e= [sum((i,j),

```

For now unlike in the IDE one cannot alter these syntax colors.

4.20.10 Showing where a symbol appears

Studio has a feature that identifies where a symbol is used. Taking the library file *agreste.gms* and positioning the cursor over a symbol like **c** (blue) then double clicking places a (gray) highlight over all visible instances of that symbol

```
$sTitle Model Definition
```

Variable

```
xcrop(p,s) 'cropping activities (ha) '
xliver(r) 'livestock activity defined on feed techniques (head) '
xlive 'livestock production (head) '
lswitch(s) 'land downgrading (ha) '
xprod(c) 'crop production (ton) '
cons(dr) 'on-farm consumption (ton) '
sales(c) 'crop sales (ton) '
flab(tm) 'family labor (man-days) '
tlab(tm) 'temporary labor (man-days) '
plab 'permanent labor (workers) '
rationr 'livestock ration requirements (cr) '
pdev(ty) 'positive price deviations (cr) '
ndev(ty) 'negative price deviations (cr) '
yfarm 'farm income (cr) '
revenue 'from crop and livestock sales (cr) '
cropcost 'accounting: cropping activities cost (cr) '
labcost 'accounting: labor costs - including family (cr) '
vetcost 'accounting: veterinary services cost (cr)';
```

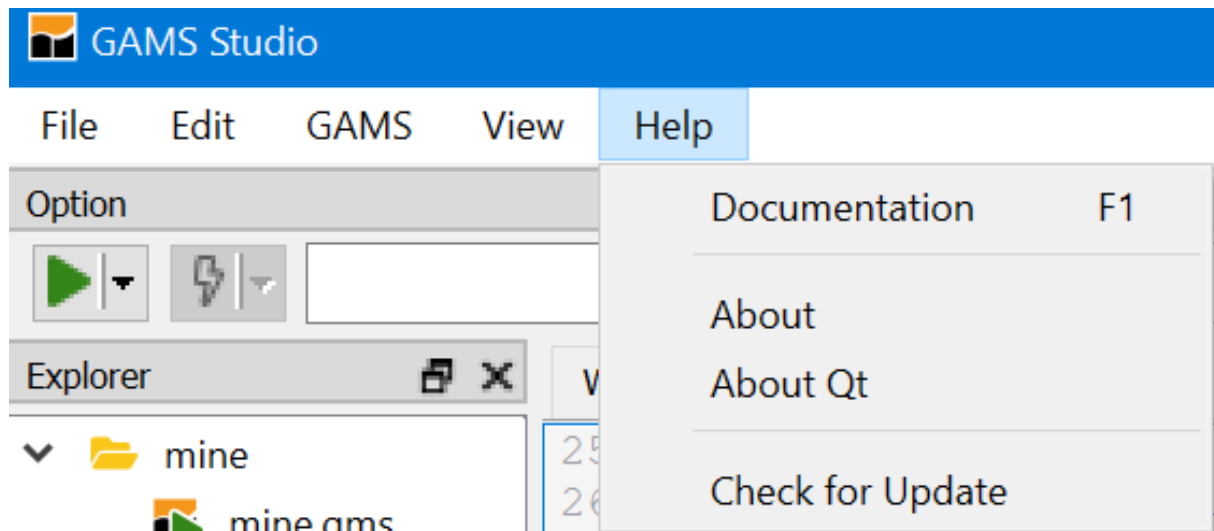

```
Positive Variable xcrop, xliver, lswitch, sales, cons, flab, tlab, plab,
```

Equation

```
landb(s) 'land balance'
lbal 'livestock balance ( )'
rliv 'livestock ration requirements definition ( )'
mbalc(c) 'material balance: crops ( )'
dprod(c) 'crop production definition ( )'
cond 'on farm consumption definition ( )'
labc(tm) 'labor supply-demand relation ( )'
ddev(ty) 'crop price deviation definition ( )'
```

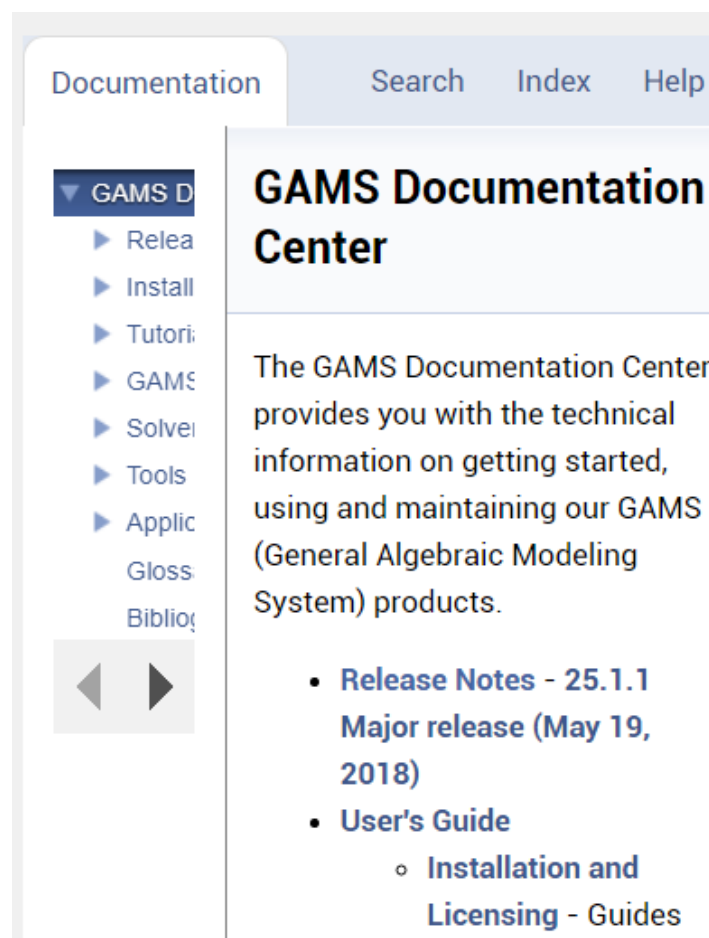

4.20.11 Accessing Documentation Via the Help

To access GAMS documentation choose help or F1

And if you choose documentation you get access through a window in lower right corner as shown. Therein you can navigate, search, and look at the index. Also if you get on the documentation page and go to the bottom you find the McCarl guide.

If your cursor is on a reserved word in the source file and you press F1 an index opens to all treatments of that word although in some strange places.

There is a [document](#) that explains features in the STUDIO and a [YouTube video](#) that can be accessed through the welcome page or in the general GAMS documentation under [Tools](#).

4.20.12 Making GDx files

STUDIO can create and show GDx files. To create in STUDIO use the GAMS tab and choose a GDx creating choice. Alternatively use one of the other ways in the language as we will discuss elsewhere.

To browse a GDx file open it with the file open dialogue or click on green lines for ones created during a run in the process window and then for the transport example

Entry	Name	Type	Dim	Records		i	j	Value
3	a	Parameter	1	2	capac	seattle	new-york	2.5
4	b	Parameter	1	3	dema	seattle	chicago	1.7
7	c	Parameter	2	0	trans	seattle	Please say that again	1.8
10	cost	Equation	0	1	defin	san-diego	new-york	2.5
12	demand	Equation	1	0	satisf	san-diego	chicago	1.8
5	di	Parameter	2	6	dista	san-diego	topeka	1.4
6	f	Parameter	0	1	freigh			
1	i	Set	1	2	canni			
2	j	Set	1	3	mark			
11	supply	Equation	1	0	obse			
8	x	Variable	2	0	shipr			
9	z	Variable	0	1	total			

Here in the left-hand panel one gets an alphabetical listing of the items in the GDx file and their characteristics. Then clicking on a left-hand panel item leads to the item contents being revealed in the right hand panel. As of now you can reorder columns and filter values then in table mode can move things in rows into columns and vice versa.

4.20.13 Examining GDX files

When you have opened a GDX file and selected an item then you get a window like that on the previous page

Entry	Name	Type	Dim	Records	Text	i	j	Value
3	a	Parameter	1	2	capacity of pla...	seattle	new-york	2.5
4	b	Parameter	1	3	demand at mar..	seattle	chicago	1.7
7	c	Parameter	2	0	transport cost i..	seattle	topeka	1.8
10	cost	Equation	0	1	define objectiv..	san-diego	new-york	2.5
12	demand	Equation	1	0	satisfy demand..	san-diego	chicago	1.8
5	di	Parameter	2	6	distance in tho..	san-diego	topeka	1.4

If in the right-hand panel you dragged **i to the right of value** (brown below) you get

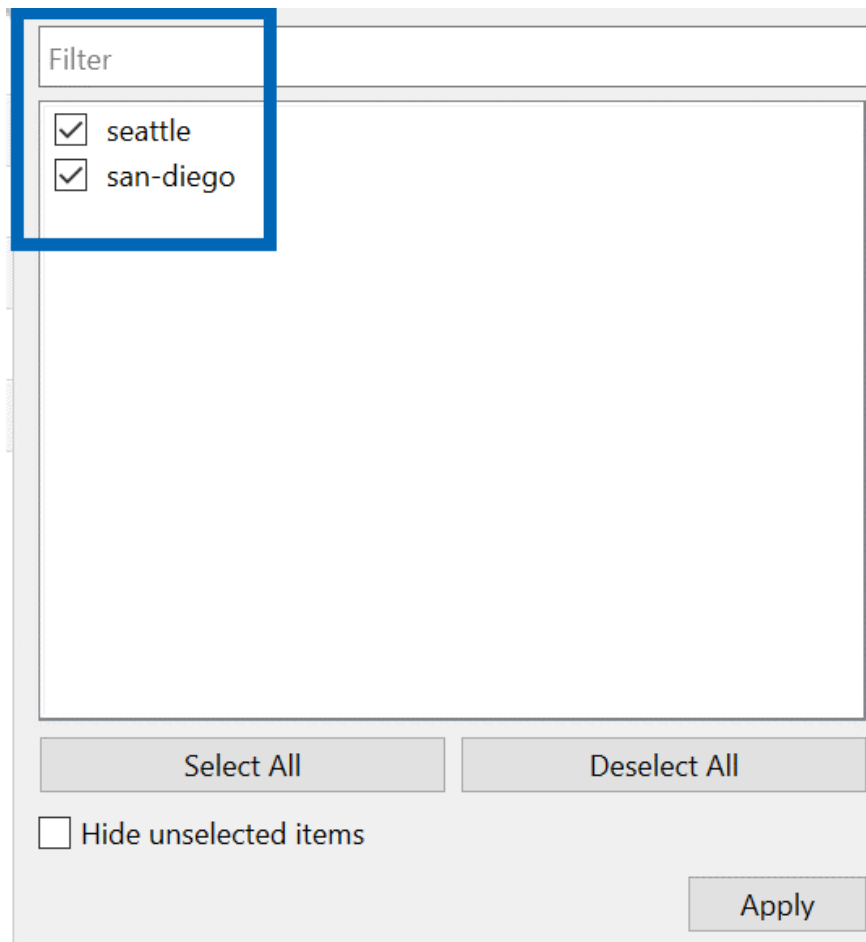

j	Value	i
new-york	2.5	seattle
chicago	1.7	seattle
topeka	1.8	seattle
new-york	2.5	san-diego
chicago	1.8	san-diego
topeka	1.4	san-diego

Also by clicking on the header you cause the array to be sorted with a \wedge marking the sort order and by clicking on

you can **establish a filter** (green above and brown below) and **choose what elements to display** (blue below).

\hat{j}	Value	i
chicago	1.7	seattle
chicago	1.8	san-diego
new-york	2.5	seattle
new-york	2.5	san-diego
topeka	1.8	seattle
topeka	1.4	san-diego

4.20.14 A difficulty you will have

When using and teaching both the IDE and STUDIO, I find that file locations sometimes gives me fits. I have a rule of thumb to avoid problems, but you will most likely inadvertently not follow it.

When working with a model with multiple files make sure they are located in the same directory location.

You do not have to follow this rule but deviations are the same as asking for trouble. When you are actively working on a file that you have opened from a directory then STUDIO will look for files in **the directory where active file is located**.

Also when you run a file which contains includes GAMS will look **in the directory where the active file is located**.

4.20.15 Command Line Parameters

Experienced DOS or UNIX based GAMS users are used to having command line parameters associated with their GAMS execution commands. In STUDIO a **command line parameter entry box** (magenta) is available just to the right of the execute button. The parameters are associated with a file and STUDIO will remember these whenever the file is opened.

This is particularly useful for save, restart, limrow, limcol, pw and rf parameters as once they are defined they are associated with every subsequent use of the file.

As of now there is no way to provide command line parameters for use in every run (like a wide page width) as there was in the IDE.

GAMS provides assistance with command line parameters through the command line parameter editor. To activate it **check the**

symbol at the far right (red) up top. Then part of the screen becomes as below. In the left hand part **existing command line parameters** (purple) **in use** (magenta) **are listed along with their values**. On the right all possible **command line parameters** are listed with definitions (green) and a **search dialogue** is provided (blue).

The search dialogue looks for text in any of the fields, thus typing in **wid** brings up page width as does **pw** and **maxi** brings up those with maximum in the description.

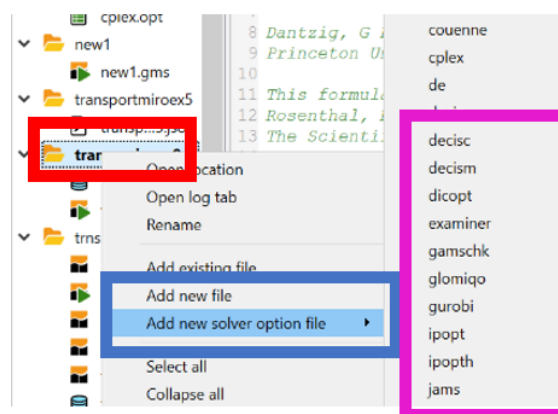

Note pressing F1 while the cursor is on a command line entry opens help to a place with a detailed description of that parameter.

4.20.16 Solver Option Files

STUDIO allows you to edit or create a solver option file. When using the solver **Conopt** you create **conopt.opt** or with **Cplex** use **cplex.opt** (or **.op1** or **.o10** or **.111**) and more generally **solvename.opt**. Specifying such a file allows you to manipulate the way the solver works on the model. For example, you can alter scaling, tolerances, iteration limits, solver algorithm, and branch and bound strategy along with many other things.

Now in Studio the option file editor is accessed by either

- Right clicking on the **group name** (red) for a group where you want an option file then choosing **add new solver option file** (blue) and picking the **appropriate solver name** (magenta)

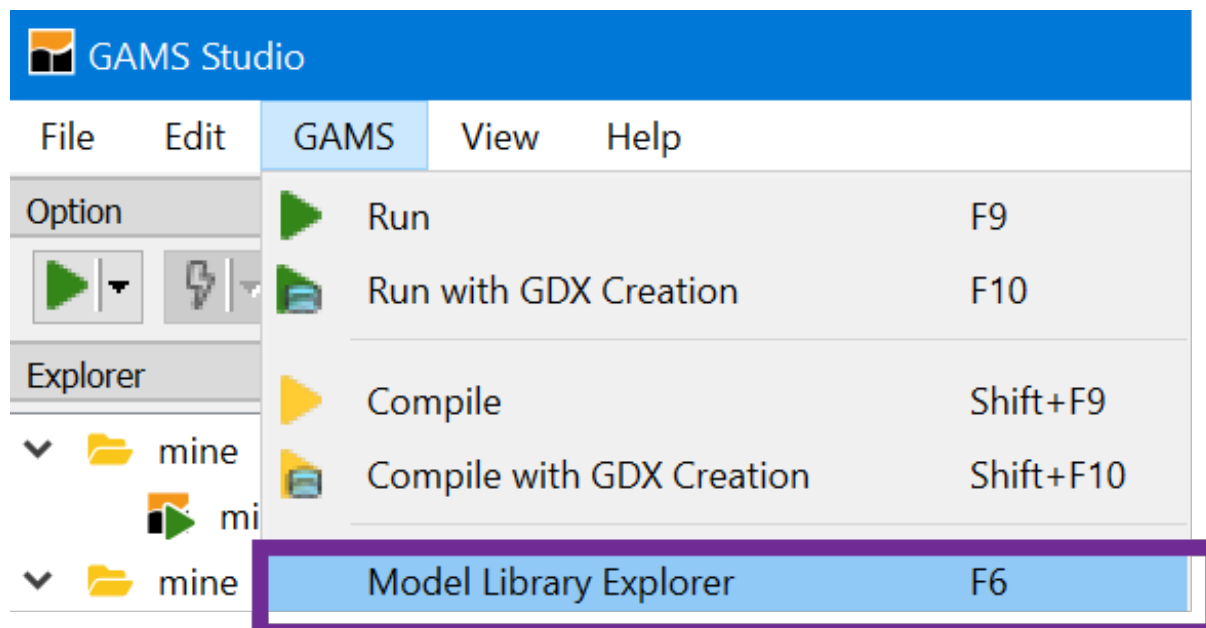

- Creating a file like **baron.opt** then when you bring that up in the editor the option file editor appears. In the editor you see **options in use** (blue), **possibilities and definitions** (red)

4.20.17 Using Libraries

STUDIO allows one to access libraries under the GAMS menu item and choosing the **Model Library Explorer** (purple).

In turn this opens a screen which identifies names of the libraries in tabs with a count of included files and, for the tab selected, the **library contents**. Furthermore across the top are tabs that when clicked on cause sorts. The picture below came after I clicked on the tab name with the model library active

SeqNr	Lic	Name	Application Area	Type	Contributor	Description
064	D	ABEL	Macro Economics	NLP	Kendrick, D	Linear Quadratic Control Problem
208	G	ABSMIP	Mathematics	MIP	GAMS Develop	Discontinuous functions abs() min() max() sign() as MIPs
088	D	AGRESTE	Agricultural Economics	LP	Kutcher, G P	Agricultural Farm Level Model of NE Brazil
008	D	AIRCRAFT	Management Science and OR	LP	Dantzig, G B	Aircraft Allocation Under Uncertain Demand
189	L	AIRSP	Stochastic Programming	LP	Dantzig, G B	Aircraft Allocation
196	L	AIRSP2	Stochastic Programming	DECIS	Dantzig, G B	Aircraft Allocation - stochastic optimization with DECIS

Users can define their own libraries. They have to define what's called a GLB file and the formatting creation of this is discussed in my newsletter in the second issue: <https://www.gams.com/mccarl/newsletter/news2.htm>.

4.20.18 Using reference files - Listing and Unraveling Data items

GAMS has a command line parameter to create reference files (aka. **.ref** files) called **reference (short: rf)**. These files give information on where things are defined and used.

Why? GAMS Modelers sometimes have to deal with complex implementations that

- Use include statements to incorporate numerous files.
- Have been developed by others.
- Have a complex structure with definitions and uses of items widely spread in a file or files.
- Contain items that are defined but never used.
- Were developed some time ago but are not extensively documented.

When faced with such cases one often asks

- Are there items defined in the program that are not used and if so what are they and where are they?
- In what files is an item defined, declared and used?

To resolve these questions some years ago I wrote a Fortran program called GAMSMAP but never made it widely available. Subsequently it was included into the GAMSIDE and then STUDIO.

When a .ref file is opened it creates a window as follows

Entry	Name	Type	Dim	Domain	Location	Line	Column
15	abs	Function	0				
392	ADJUST	Parameter	4	(ALLI,subreg,C			
234	AGPRODUCT	Set	1				
236	AGPRODUCT	Parameter	4	(REGIONS,ALI			
242	ALLCOM	Set	1	(ALLI)			
138	ALLI	Set	1				
152	ANIMAL	Set	1				
325	ARTIF	Variable	1	(ALLI)			
353	ARTIFICIAL	Equation	1	(CROP)			
327	ARTS	Variable	1	(ALLI)			
384	ascale	Parameter	1				

The **column on the left** (red) gives tags that can be clicked on and the key ones are

Column	Description
All Symbols	a list of items that are declared and a count of them
Set	a list of the sets that exist in the program and a count
Variable	a list of the variables in the program and a count
Parameter	a list of the parameters (items defined in scalar, parameter or table statements) and a count.
Equation	a list of the equations in the program and the names of files in which they appear
Model	a list of the models that exist in the program and the names of files in which they appear
Unused	a list of items that are declared or that are not used anywhere in the model
File used	a list of the files included into the model

4.20.18.1 All Symbols Tab

The all symbols tab causes the output to appear as follows:

Entry	Name	Type	Dim	Domain	Text
15	abs	Function	0		
392	ADJUST	Parameter	4	(ALLI,subreg,CR...	
234	AGPRODC	Set	1		
236	AGPRODUCT	Parameter	4	(REGIONS,ALLI,...	
242	ALLCOM	Set	1	(ALLI)	
138	ALLI	Set	1		ALL BUDGET ITEMS
152	ANIMAL	Set	1		NAMES OF LIVESTOCK BUDGETS
325	ARTIF	Variable	1	(ALLI)	ARTIFICIAL PRODUCTION
353	ARTIFICIAL	Equation	1	(CROP)	ARTIFICIAL FARM PROGRAM PRODUCTION
327	ARTS	Variable	1	(ALLI)	ARTIFICIAL SUPPLY
384	ascale	Parameter	1		
394	ATRAZINE	Parameter	2	(subreg,CHAN...	
280	AUMPS	Parameter	1	(REGIONS)	PRODUCER'S SURPLUS FOR AUMS BY REGION
372	AUMSCONVEX	Equation	1	(subreg)	AUMS CONVEXITY
362	AUMSIDENT	Equation	1	(subreg)	AUMS IDENTITY

Symbol Search: All Columns

This shows all symbols used. The columns give

- the symbol name (Name),
- it's type(Type),
- its dimension (Dim),
- the sets over which it is dimensioned (Domain)
- the explanatory text used in it's declaration (Text).

Things can be sorted by clicking on the column headings.

One can search for symbols using the box at the bottom

Symbol Search: All Columns

4.20.18.2 Sets, Parameters etc. Tabs

The display contains 5 lines that when activated give information for sets, parameters etc. The resultant display lists all items falling in a class (for all things that are sets or parameters etc.) and information on their characteristics and use. Specifically one gets output as follows (for the sets in this case)

Entry	Name	Dim	Domain	Text
234	AGPRODC	1		
242	ALLCOM	1	(ALLI)	
138	ALLI	1		ALL BUDGET ITEMS
152	ANIMAL	1		NAMES OF LIVESTOCK BUDGETS
216	AUMSIT	1		AUMS ITEMS FOR REPORTS
151	AUMSITEM	1		AUMS SUPPLY PARAMETERS
203	BALITEM	1		ITEMS IN SUPPLY DEMAND BALANCE TARI F
141	C	1	(CROP)	FARM PROGRAM CROPS
393	CHANGEITEM	1		
403	COMITEM	1		
144	COST	1	(ALLI)	BUDGET COST ITEMS
140	CROP	1	(PRIMARY)	CROPS

Location | Line | Column

- (1) Declared in
 - asmsurep.gms | 120 | 14
- (1) Defined in
 - asmsurep.gms | 121 | 7
- (0) Assigned
- (0) Implicitly Assigned
- (0) Controlled
- (1) Referenced in
 - asmsurep.gms | 126 | 48

In this output once clicked on the entries tell the names of the files in which certain things happen relative to the identified items. The categories of things include the file name, line and column where items are declared, defined and used as discussed below.

Clicking on a line takes you to the file and place where the item appears.

Clicking on a column name causes it to be sorted.

After clicking on an item one gets

Location	Line	Column
▼ (1) Declared in		
asmourep.gms	120	14
▼ (1) Defined in		
asmourep.gms	121	7
(0) Assigned		
(0) Implicitly Assigned		
(0) Controlled		
▼ (1) Referenced in		
asmourep.gms	126	48

Entries in location columns identify files where items are

Column	Description
Declared	places where the named item is declared in a Set, Parameter, Table, Scalar, Variable, Equation, Acronym, File or Model command. This will be the first appearance.
Defined	places set elements or data are explicitly entered. For equations this tells where the .. specification begins.
Assigned	places where items appear on left hand side of an assignment statement
Implicitly-Assigned	places where an equation or variable has data put into it by the results of a solve statement.
Controlled	places where set is used in controlling a sum or defining an equation
Ref	places where item is on left hand side of assignment statement or in a model equation

Clicking on lines here opens the subject file in the specific place

4.20.18.3 File used Tab

The file used tab causes the output to appear as follows:

	File Location
All Symbols (275)	
Set (59)	C:\GAMS\win64\27.1\mccar\asmcalrn.gms
Acronym (0)	C:\GAMS\win64\27.1\mccar\asmcalrsu.gms
Variable (40)	C:\GAMS\win64\27.1\mccar\asmcompr.gms
Parameter (131)	C:\GAMS\win64\27.1\mccar\asmcrop10.gms
Equation (41)	C:\GAMS\win64\27.1\mccar\asmcropmix10.gms
Model (1)	C:\GAMS\win64\27.1\mccar\asmdef.gms
File (0)	C:\GAMS\win64\27.1\mccar\asmdemand10.gms
Function (3)	C:\GAMS\win64\27.1\mccar\asmerosion.gms
Unused (46)	C:\GAMS\win64\27.1\mccar\asmfarmpro10.gms
File Used (21)	C:\GAMS\win64\27.1\mccar\asmfinal.gms
	C:\GAMS\win64\27.1\mccar\asmlive10.gms
	C:\GAMS\win64\27.1\mccar\asmlivemix10.gms
	C:\GAMS\win64\27.1\mccar\asmloop.gms

This gives the names of the files included in the program with their full path references.

4.20.18.4 Unused Tab

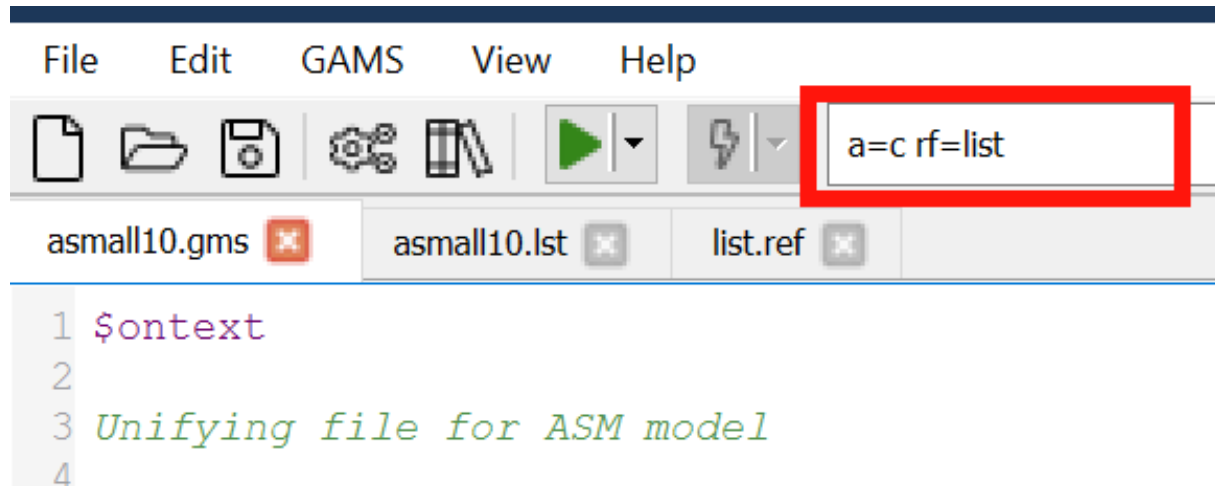

The unused tab identifies items that are declared (in set parameter etc. statements) but are never used on the right hand side of an assignment (=) statement or in a model equation:

Entry	Name	Type	Dim	Domain	Text	Location	Line	Column
236	AGPRODUCT	Parameter	4	(REGIONS,ALLI...		(1) Declared in		
219	AUMSSUM	Parameter	2	(REGIONS,AUM...	AUMS USE SUMMARY	asmurep.gms	126	20
202	BASEOUTPUT	Parameter	0			(0) Defined		
261	commodc	Parameter	4	(REGIONS,type...		(0) Assigned		
240	CROPREG	Parameter	2	(REGIONS,CROP)	REGIONAL CROP PRODUCTION REPORT	(0) Implicitly Assigned		
198	EROSION	Parameter	3	(REGIONS,CRO...	EROSION DATA	(0) Controlled		
249	EROSIONd	Parameter	2	(REGIONS)	EROSION	(0) Referenced		
266	fprevbal	Parameter	0					
229	FWELFARE	Parameter	2	(ALLI,ITEMFOR)	FOREIGN WELFARE			
270	grossrv	Parameter	2	(REGIONS,PRI...				

which shows the same information as in the All Symbols tab except when an item is clicked on one gets information on the files where it is declared.

4.20.18.5 Steps to use the Reference File Viewer

The [Reference File Viewer](#) will only work after a particular “reference file” has been created by a GAMS run. The file is generated by adding the `rf` option to the command line call entering a command in the command line box of Studio as follows (a=c cause compilation only)

Once the file has been run with the `rf` option the logfile is augmented with the (green) line identifying the `.ref` file name as below

```

Output
--- . asmloop.gms (171) 4 Mb
--- asmall10.gms (24) 4 Mb
--- . asmfinal.gms (52) 4 Mb
--- asmall10.gms (34) 4 Mb
--- RefFile C:\GAMS\win64\27.1\mccarl\list.ref
*** Status: Normal completion
--- Job asmall10.gms Stop 06/11/19 19:28:24 elap

```

Double clicking on this opens the Reference File Viewer window.

The run of GAMS with the `rf` option places the name of the `.ref` file in green in the GAMS log file and double clicking on that line causes the Reference File Viewer to be opened.

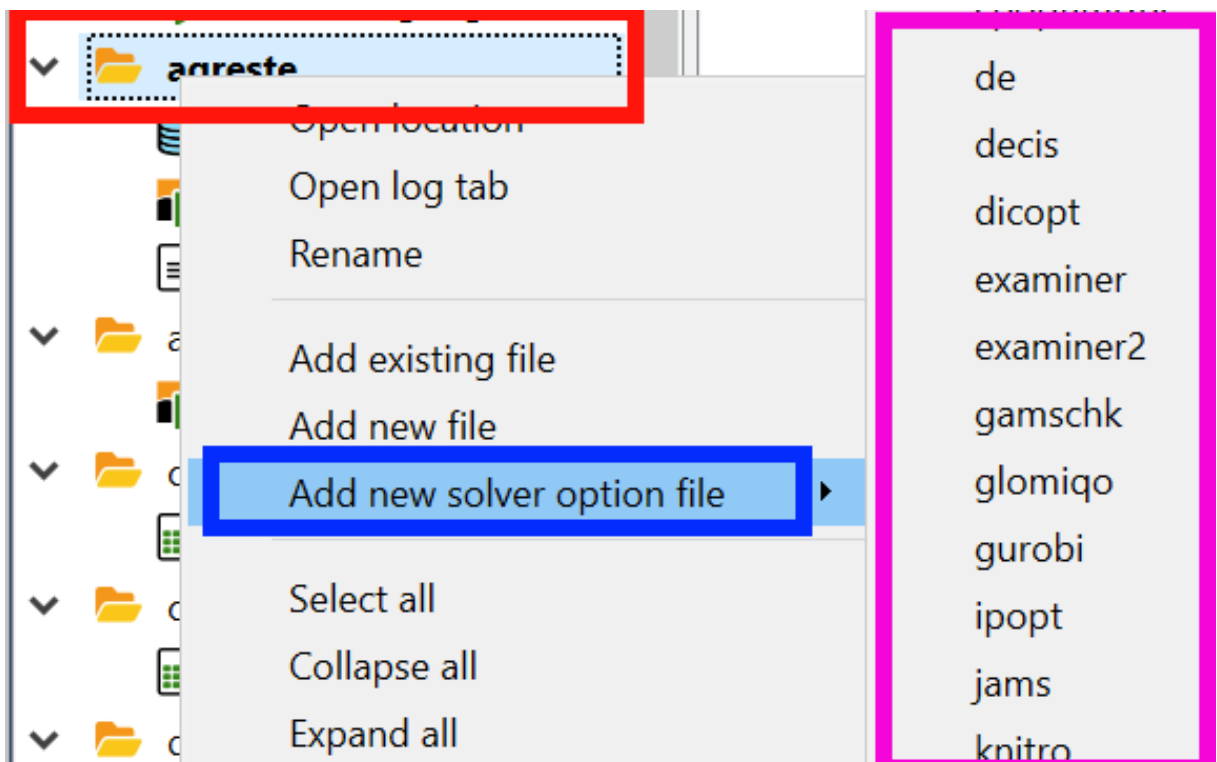

Several notes about the run

- The `rf=` command specifies the name of the file the Reference File Viewer will use. Generally, the Reference File Viewer expects it to have the extension `.ref`.
- The `.ref` file only covers the program components in a run and does not include any information from restart files. In general it is best to explicitly use all the files in one program without use of save and restart.
- It is often useful to just generate the reference file without any execution on behalf of the GAMS program. This is done by including the `a=c` option on the command line or in the command parameter IDE box.

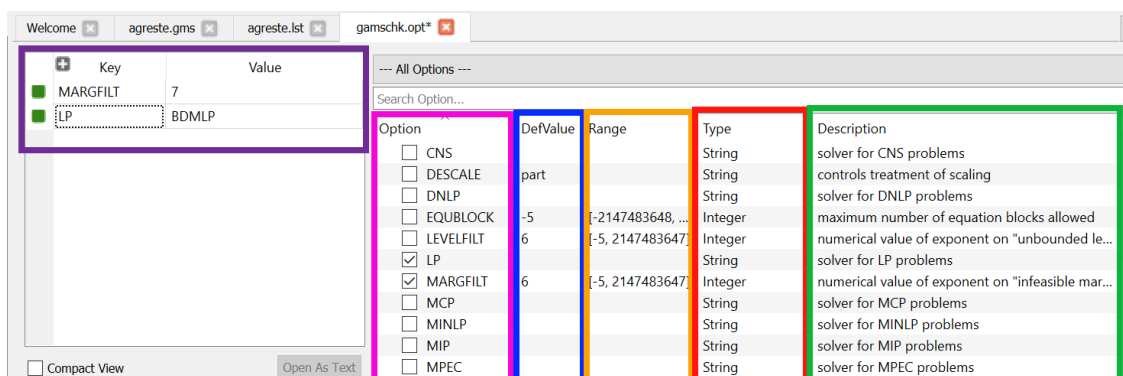

4.20.19 Editing Solver Option Files

Sometimes it is desirable to change solver specific options. This includes modifying things like branch and bound strategy, degree of scaling, barrier versus simplex solution approach, solution tolerances etc. The specific options allowed are described in the [solver manuals](#). In addition Studio contains a solver option file editor that presents a solver specific menu of all possible options, default values and ones that have been altered. This is activated by either

- Opening or saving a file with solversname.opt (Like MINOS.opt)
- Right clicking on a **group file name** (red) in the Studio Explorer then selecting **add new solver option file** (blue) and subsequently selecting one of the many available **solver names** (magenta and only a few shown). This will create a file you then need to save.

Once it opens the general format of the solve option editor is as follows. Note the specific content depends on the solver chosen and in this case I use GAMSCHK.

Here in the right part we see a list of all **possible options** (magenta) for this solver with boxes checked for those that are in the option file. A brief description of **default values** (blue), **entry type** (red), if relevant **allowable settings** (yellow) and a **one sentence description of the option** (green). In the left part we see the **current entries** (purple) in the option file and **their settings** (purple).

Subsequently when this file is opened or its tab activated then this solver option editor appears.

Note, pressing F1 while on an option opens help to a place with a detailed description of that option.

4.20.20 When is it Not Worth Using?

There are costs and benefits of these approaches.

The STUDIO is much easier for simple models and can run across platforms.

The DOS/command line approach is generally better for models in customized environments.

A **development strategy** for more complex implementations

1. Use the STUDIO to get it right
2. Debug components of large models using save and restart
3. Then use script files or DOS/UNIX with batch files such as

- GAMS mymodel -lo 0 -s ./t/save1
- call myprogram.exe
- GAMS moremod -lo 0 -r ./t/save1

4.20.21 What does it not do?

A number of IDE features are currently missing. Just to inventory (note the last three are pretty unimportant to me.)

- The ability to do tiled windows and look at multiple cases of a file
- Ability to save output from the reference files
- Ability to change the file associations when clicking on them in Windows Explorer (you get more than I like at the moment and sometimes I want more)
- Project files (mixed blessing)
- Text file differencing (can use other programs)
- Spell checking

4.20.22 What does it not do so well?

Here are also some difficulties with it as of today

- Washed out colors – on my machine the syntax and error coloring is not very prominent.
 - Excessive library choices and no way to put the ones you have no interest in somewhere out of the way. Plus any user defined libraries are at the end and there is no way to reorder.
-

4.21 Introduction

4.21.1 Summary

Today, algebraic modeling languages are widely accepted as the best way to represent and solve mathematical programming problems. Their main distinguishing features are the use of relational algebra and the ability to provide partial derivatives on multidimensional, very large and sparse structures. In this chapter we will briefly describe some of the origins of GAMS and provide background information that shaped early design decisions.

4.21.2 The Origins of GAMS

The initial Research and Development of GAMS was funded by the International Bank for Reconstruction and Development, usually referred to as The World Bank. Since 1987, further Research and Development has been funded by GAMS Development Corporation. GAMS was developed in close cooperation of mathematical economists who were and still are an important group of GAMS users. The synergy between economics, computer science and operations research was the most important success factor in the development of the system. Mathematical Programming and economics theory are closely intertwined. The Nobel Prize in Economics awarded to Leonid Kantorovich and Tjalling Koopmans in 1975 for their “contribution to the theory of optimal allocation of resources” was really a prize in mathematical programming. Other Nobel laureates like Kenneth Arrow in 1972, Wassily Leontief in 1973, and Harry Markowitz in 1990 are well known names in math programming. Another early example of this synergy is the use of LP in refining operations, which was started by Alan Manne, an economist, with his book on Scheduling of Petroleum Refinery Operations in 1956.

The origins of linear programming algorithms all go back to George Dantzig’s early work in the 1940s and 1950s. Computing technology and algorithmic theory had developed at a rapid pace. Thirty years later, we could solve problems of practical size and complexity that allowed us to test of the economic theory on real life problems. The research agenda at the World Bank in the 1970s and 1980s created the perfect environment to bring different disciplines together to apply mathematical programming to research and operational questions in Economic Development.

4.21.3 Background and Motivation

From the very beginning, the driving force behind the development of the General Algebraic Modeling System (GAMS) has been the users of mathematical programming who believed in optimization as a the powerful and elegant framework for solving real life problems in the sciences and engineering. At the same time, these users were frustrated with the high cost, skill requirements, and overall low reliability of applying optimization tools. Most of our initiatives and support for new development came from the worlds of economics, finance, and chemical engineering. These disciplines find it natural to view and understand the world and its behavior as a mathematical program.

GAMS’s impetus for development arose out of the frustrating experiences of a large economic modeling group at the World Bank. In hindsight, one may call it a historical accident that in the 1970s mathematical economists and statisticians were assembled to address problems of development. They used the best techniques available at the time to solve multisectoral economy-wide models and large simulation and optimization models in agriculture, steel, fertilizer, power, water use, and other sectors. Although the group produced impressive research, initial successes were difficult to reproduce outside their well functioning research environment. The existing techniques to construct, manipulate, and solve such models required several manual, time-consuming, and error-prone translations into the different, problem-specific representations required by each solution method. During seminar presentations, modelers had to defend the existing versions of their models, sometimes quite irrationally, because the time and money needed to make proposed changes were prohibitive. Their models just could not be moved to other environments,

because special programming knowledge was needed, and data formats and solution methods were not portable.

The idea of an algebraic approach to represent, manipulate, and solve largescale mathematical models fused old and new paradigms into a consistent and computationally tractable system. Using matrix generators (see appendix GAMS versus Fortran Matrix Generators) for linear programs taught us the importance of naming rows and columns in a consistent manner. The connection to the emerging relational data model became evident. Painful experience using traditional programming languages to manage those name spaces naturally lead one to think in terms of sets and tuples, and this led to the relational data model. Combining multidimensional algebraic notation with the relational data model was the obvious answer. Compiler writing techniques were by now widespread, and languages like GAMS could be implemented relatively quickly. However, translating this rigorous mathematical representation into the algorithm specific format required the computation of partial derivatives on very large systems. In the 1970s, TRW developed a system called PROSE that took the ideas of chemical engineers to compute point derivatives that were exact derivatives at a given point, and to embed them in a consistent, Fortran-style calculus modeling language. The resulting system allowed the user to use automatically generated exact first and second order derivatives. This was a pioneering system and an important demonstration of a concept. However, in our opinion PROSE had a number of shortcomings: it could not handle large systems, problem representation was tied to an array-type data structure that required address calculations, and the system did not provide access to state-of-the-art solution methods. From linear programming, we learned that exploitation of sparsity was the key to solve large problems. Thus, the final piece of the puzzle was the use of sparse data structures.

With all pieces in place, all we had to do was adopt the techniques to fit into one consistent framework and make it work for large problems

4.21.4 Design Goals and Changing Focus

The original and still valid goal is to improve the model builder's productivity, reduce costs, and improve reliability and overall credibility of the modeling process. To achieve this, we established the following key principles to guide the GAMS development:

- The problem representation is independent of the solution method.
- The data representation follows the relational data model.
- The problem and data representations are independent of computing platforms.
- The problem and data representations are independent of user interfaces.
- Optimization methods will fail, and systems have to be designed to be fail-safe.

Another way to express these principles is to think in terms of layers of representations and capabilities that have clearly defined interfaces and functions. The oldest and most basic layer is the solver layer or implementation of a specific algorithm. Above the solver is the model layer, expressed in an algebraic modeling language. The modeling layer translates the mathematical representation into a computational structure required by a specific solution method and provides various services such as function and derivative evaluations and error recovery. Above the modeling layer is the application or domain layer, which is highly context sensitive and has knowledge about the problem to be solved and the kind of user interacting with the system.

The representation of the model in GAMS is in a form that can be easily read by humans and by machines. This means that the GAMS program itself is the documentation of the model, and that the separate description required in the past (which was a burden to maintain, and which was seldom up-to-date) is no longer needed. Moreover, the design of GAMS incorporates the following features that specifically address the user's documentation needs:

- A GAMS model representation is concise, and makes full use of the elegance of the mathematical representation.
- All data transformations are specified concisely and algebraically. This means that all data can be entered in their most elemental form and that all transformations made in constructing the model and in reporting are available for inspection.
- Explanatory text can be made part of the definition of all symbols and is reproduced whenever associated values are displayed.
- All information needed to understand the model is in one document.

Of course some discipline is needed to take full advantage of these design features, but the aim is to make models more accessible, more understandable, more verifiable, and hence more credible.

It is instructive to put the development of modeling systems into some historic perspective and see how the focus and technical constraints have changed in the last 30 years. We can observe three major phases that shift the emphasis from computational issues to modeling issues and finally the application or the real problems. Each phase defined one of the main system layers discussed above. The dominant constraints in the first phase were the computational limits of our algorithms. Problem representation had to abide by algorithmic convenience, centralized expert groups managed large, expensive and long lasting projects and end users were effectively left out. The second phase has the model in focus. Applications are limited by modeling skill, project groups are much smaller and decentralized, the computational cost are low and the users are involved in the design of the application. Applications are designed to be independent of computing platforms and frequently operate in a client-server environment.

We believe that we are entering a third phase which has the application as its focus and the optimization model is just one of many analytic tools that help making better decisions. The users are often completely unaware of any optimization model or use a mental model that is different from the actual model to solved by optimization techniques. User interfaces are build with off-the-shelf components and frequently change to adjust to evolving environments and new computing technologies. As with databases, modeling components have a much longer life than user interfaces. We have observed cases where the model has remained basically unchanged over many years, whereas the computing environments and user interfaces have changed several times. The solvers used to solve the models have changed, the computing platforms have changed, the user interfaces have changed and the overall performance of the model has changed without any change in the model representation.

4.22 GAMS Programs

4.22.1 Introduction

This chapter provides a look at the structure of the GAMS language and its components. It should be emphasized again that GAMS is a programming language, and that programs must be written in the language to use it. A GAMS program is contained in a disk file, which is usually constructed with a text editor of choice (e.g. the **GAMS IDE**). When GAMS is 'run', the file containing the program (the input file) is submitted to be processed. After this processing has finished, the results, which are in the **output file(s)**, can be inspected. By default the GAMS log appears on the screen while GAMS runs, keeping the user informed about progress and error detection. It is the responsibility of the user to inspect the output file(s) carefully to see the results and to diagnose any errors.

4.22.2 The Structure of GAMS Programs

GAMS programs consist of one or more statements (sentences) that define data structures, initial values, data modifications, and symbolic relationships (equations). While there is no fixed order in which statements have to be arranged, the order in which data modifications are carried out is important. Symbols must be declared as to type before they are used, and must have values assigned before they can be referenced in assignment statements. Each statement is followed by a semicolon except the last statement, where a semicolon is optional.

Note

The semicolon at the end of a statement can be omitted if a new [GAMS keyword](#) follows. However, to improve readability of the code, it is recommended to use the semicolon at the end of a statement anyway.

4.22.2.1 Format of GAMS Input

GAMS input is free format. A statement may be placed anywhere on a line, multiple statements may appear on a line, or a statement may be continued over any number of lines as follows:

```
statement;  
statement;  
statement; statement; statement;  
the words that you are now reading is an example of a very  
long statement which is stretched over two lines;
```

Blanks and end-of-lines may generally be used freely between individual symbols or words. GAMS is not case sensitive. This means that lower and upper case letters may be mixed freely but are treated identically. Up to 80,000 characters may be placed on a line and completely blank lines may be inserted for easier reading.

Not all lines are a part of the GAMS language. Two special symbols, the asterisk '*' and the dollar symbol '\$' may be used in the first position on a line to indicate a non-language input line. An asterisk in column one means that the line will not be processed, but treated as a comment. For more on comments, see section [Comments](#). A dollar symbol in the first position indicates that compiler options or directives are contained in the rest of the line (see chapter [Dollar Control Options](#) for more information).

For example, multiple files may be used as input through the use of the [\\$include](#) facility. In short, the statement

```
$include file1
```

inserts the contents of the specified file (`file1` in this case) at the location of the call. A more complex versions of this is the option [\\$batinclude](#). Both options are introduced and discussed in details in chapter [Dollar Control Options](#).

4.22.2.2 Classification of GAMS Statements

Each statement in GAMS is classified into one of two groups:

1. Declaration and definition statements.
2. Execution statements.

A declaration statement describes the class of a [symbol](#). Often initial values are provided in a declaration, then it may be called a definition. The specification of symbolic relationships for an equation is a definition. The declaration and definition statements are:

- [acronym](#)
- [alias](#)
- [equation declaration](#)
- [equation definition](#)
- [file](#)
- [function](#)
- [model](#)
- [parameter](#)
- [scalar](#)
- [set](#)
- [table](#)
- [variable](#)

Execution statements are instructions to carry out actions such as data transformation, model solution, and report generation. The execution statements are:

- [abort](#)
 - [assignment](#)
 - [break](#)
 - [continue](#)
 - [display](#)
 - [execute](#)
 - [for](#)
 - [if](#)
 - [loop](#)
 - [option](#)
 - [put](#)
 - [put_utility](#)
-

- [putclear](#)
- [putclose](#)
- [puthd](#)
- [putpage](#)
- [puttl](#)
- [repeat](#)
- [solve](#)
- [while](#)

Note

While an assignment is an execution statement, it also defines the symbol on the left hand side of the assignment.

Although there is great freedom about the order in which statements may be placed in a GAMS program, certain arrangements are commonly used. The two most common are discussed next.

4.22.2.3 Organization of GAMS Programs

One common style of organizing GAMS statements places the data first, followed by the model and the solution statements.

Style 1:

Data:

Set declarations and definitions

Parameter declarations and definitions

Assignments

Displays

Model:

Variable declarations

Equation declarations

Equation definitions

Model definition(s)

Solution:

Solve(s)

Displays

In this style of organization, the sets are placed first. Then the data is specified with parameter, scalar, and table statements. Next, the model is defined with the variable declarations, equation declarations, equation definitions and one or more model statements. Finally, the model is / models are solved and the results are displayed. One can refer to the model **transport** as an example for this style.

A second style emphasizes the model by placing it before the data. This is a particularly useful order when the model is to be solved repeatedly with different data sets.

Style 2:

Model:

Set declarations
 Parameter declarations
 Variable declarations
 Equation declaration
 Equation definition
 Model definition

Data:

Set definitions
 Parameter definitions
 Assignments
 Displays

Solution:

Solve
 Displays

Here, there is a separation between declaration and definition. For example, sets and parameters may be declared first with the following statements:

```
Set      c      "crops" ;
Parameter yield(c) "crop yield" ;
```

Later they may be defined with the statements:

```
Set      c      / wheat, clover, beans / ;
Parameter yield(c) / wheat    1.5
                    clover    6.5
                    beans     1.0 / ;
```

The first statement declares that the identifier *c* is a set and the later statement defines the elements in this set. Similarly, in the second statement *yield* is declared to be a parameter and later the corresponding data is given.

Note

Sets and parameters that are used in equations must be *declared* before the equations are specified. However, they may be *defined* after the equation specifications but before the specific equation is used in a solve statement. This gives GAMS programs substantial organizational flexibility.

4.22.3 Data Types and Definitions

Each symbol or identifier has exactly one of the following basic GAMS data types:

- [acronyms](#)
- [equations](#)
- [files](#)
- [functions](#)
- [models](#)
- [parameters](#)
- [sets](#)
- [variables](#)

Note

- **Scalars** and **tables** are not separate data types but convenient input formats for the data type **parameter**. For details see the overview [Parameters, Scalars and Tables](#).
- GAMS uses shorthand symbols for each data type in the **output**. For details see the overview [GAMS Data Types and their Shorthand Symbols](#).

Declarations have common characteristics. The following example has a typical structure:

```
Parameter    a(i,j)          "input-output matrix" ;
```

The structure is:

```
Keyword for data type - identifier (with index list) - explanatory text ;.
```

Note that the index list (or domain list) and the explanatory text are always optional characteristics. However, we recommend to specify the index list if the data type is defined over a domain; the advantages of this practice are outlined in section [Domain Checking](#).

Note

Variables, sets, parameters and equations may be declared and defined over one or more indices or dimensions. Currently the maximum number of dimensions for all these data types is 20.

It is also recommend to add an explanatory text for reasons of clarity. For more on explanatory texts, see section [Text](#) below. Other examples for declarations follow:

```
Set          time          "time periods" ;
Model        turkey        "turkish fertilizer model" ;
Variables    x,y,z ;
```

Observe that in the last example a number of identifiers (separated by commas) is declared in one statement.

4.22.4 Language Items

Before proceeding with more language details, a few basic symbols need to be defined and the rules for recognizing and writing them in GAMS established. These basic symbols are often called lexical elements and form the building blocks of the language. They are:

- [characters](#)
- [comments](#)
- [delimiters](#)
- [identifiers \(idents\)](#)
- [labels](#)
- [numbers](#)
- [reserved words and tokens](#)
- [text](#)

Each of these items is discussed in detail in the following subsections.

Attention

As noted previously, GAMS is not case sensitive, so we may use any mix of lower and upper case.

4.22.4.1 Characters

A few characters are not allowed in a GAMS program, because they are illegal or ambiguous on some machines. Generally, all unprintable and control characters are illegal. The only place where any character is legal, is in an `$ontext-$offtext` block as illustrated in section [Block Comments](#) below. For completeness, the full set of legal characters are listed in [Table 1](#). Note that most of the uncommon punctuation characters are not part of the language, but they may be used freely in the context of explanatory texts, comments, and labels (if quoted). Similarly, special language specific characters (e.g. ä, ß, à, é, ç, ð, ñ) may also be used freely in explanatory texts, comments, and labels (if quoted).

Table 1: Legal Characters

Legal Characters	Description
A to Z	alphabet
a to z	alphabet
0 to 9	numerals
+	plus
-	minus
=	equals
<	less than
>	greater than
()	parenthesis
[]	square brackets
{ }	braces
'	single quote
"	double quote

Legal Characters	Description
\	back slash
/	slash
,	comma
:	colon
;	semicolon
.	dot
?	question mark
!	exclamation mark
	space
_	underscore
&	ampersand
^	circumflex
#	pound sign
*	asterisk
%	percent
@	at
\$	dollar

Note

Not every character listed above is allowed to be used in every place (for example, [identifiers](#) have certain limitations).

4.22.4.2 Reserved Words

GAMS, like other programming languages such as C and Java, uses reserved words (often also called keywords) that have predefined meanings. Users are in general not permitted to use these for their own definitions, neither as identifiers nor labels. The complete list of reserved words is given below. In addition, a small number of symbols constructed from non-alphanumeric characters have a meaning in GAMS.

Note

While it is not allowed to use reserved words as identifiers and labels in general, it is still possible (put not recommended) in certain cases which are explained in more detail further below.

- [abort](#)
 - [acronym\[s\]](#)
 - [alias](#)
 - [all](#)
 - [and](#)
 - [binary](#)
 - [break](#)
 - [card](#)
 - [continue](#)
 - [diag](#)
-

-
- display
 - do*
 - else
 - elseif
 - endfor*
 - endif*
 - endloop*
 - endwhile*
 - eps
 - equation[s]
 - execute
 - execute_load
 - execute_loaddc
 - execute_loadhandle
 - execute_loadpoint
 - execute_unload
 - execute_unloaddi
 - execute_unloadidx
 - file[s]
 - for
 - free
 - function[s]
 - if
 - inf
 - integer
 - logic
 - loop
 - model[s]
 - na
 - negative
 - nonnegative
 - no
 - not
 - option[s]
 - or
 - ord
-

-
- [parameter\[s\]](#)
 - [positive](#)
 - [procedure\[s\]](#) (deprecated)
 - [prod](#)
 - [put](#)
 - [put_utility/put_utilities](#)
 - [putclear](#)
 - [putclose](#)
 - [putfncl](#)
 - [puthd](#)
 - [putheader](#)
 - [putpage](#)
 - [puttitle](#)
 - [puttl](#)
 - [repeat](#)
 - [sameas](#)
 - [scalar\[s\]](#)
 - [semicont](#)
 - [semiint](#)
 - [set\[s\]](#)
 - [singleton](#)
 - [smax](#)
 - [smin](#)
 - [solve](#)
 - [sos1](#)
 - [sos2](#)
 - [sum](#)
 - [system](#)
 - [table\[s\]](#)
 - [then*](#)
 - [undf](#)
 - [until](#)
 - [variable\[s\]](#)
 - [while](#)
 - [xor](#)
 - [yes](#)
-

Attention

Some of the keywords above can actually be used as an identifier (e.g. `sameas`). But if they get used as identifier, their built-in meaning as part of the GAMS language can not be accessed anymore.

Note

The words marked with * in the list above are no reserved words by default. However, they get a special meaning if the dollar control option `$onEnd` is set.

The following list shows words which have a special meaning in GAMS (e.g. they are part of the solve statement), but can be used as identifiers anyway:

- `eq`
- `eqv`
- `ge`
- `gt`
- `imp`
- `le`
- `lt`
- `maximizing`
- `minimizing`
- `ne`
- `scenario`
- `using`

The reserved non-alphanumeric symbols are:

- `..`
 - `=|=`
 - `=g=`
 - `=e=`
 - `=n=`
 - `=x=`
 - `=c=`
 - `=b=`
 - `--`
 - `++`
 - `**`
 - `->`
 - `<=>`
-

4.22.4.3 Identifiers

Identifiers are the names given to sets, parameters, variables, models, etc. GAMS requires an identifier to start with a letter followed by more letters or digits. The length of an identifier is currently limited to 63 characters. Identifiers may only contain alphanumeric characters (letters or numbers) or underscores (_). Examples of legal identifiers are:

```
a   a15   revenue   x0051
```

Note that the following identifiers are incorrect:

```
15  $casg      milk&meat
```

Attention

A name used for one data type cannot be reused for another.

4.22.4.4 Labels

Labels are set elements. They may be up to 63 characters long and may be used in quoted or unquoted form.

The unquoted form is simpler to use but places restrictions on characters allowed, in that any unquoted label must start with a letter or digit and can only be followed by letters, digits, underscores (_) or the sign characters + and -. Examples of valid unquoted labels are:

```
Phos-Acid      1986      1952-53   A
September      H2S04      Line-1
```

Quotes can be used to delimit labels. Quoted labels may begin with and include *any* legal character. Either single or double quotes may be used but the closing quote has to match the opening quote. A label quoted with double quotes may contain a single quote (and vice versa). Most experienced users avoid quoted labels because they can be tedious to enter and confusing to read. There are a couple of special circumstances though. If we want to make a label stand out, we could put asterisks in it and indent it. A more subtle example is that GAMS keywords may be used as labels if they are quoted. So labels like `parameter`, `put` or `while` may be used if they are quoted. Some examples of quoted labels follow:

```
' *TOTAL*'   "MATCH"   '10%-INCR'   '12" / FOOT'   "line 1"
```

Note

- Labels do not have any numerical value. The label '1986' does not have the numerical value 1986 and the label '01' is different from the label '1'. One can access the numerical value of a label with the [Set Attributes](#) `.val` attribute.
- Leading blanks in a label are significant and preserved while trailing blanks are trimmed. So 'label11' is different from 'label11', but 'label12 ' is identical to 'label12'.

To summarize, set names are identifiers and set elements are labels. An overview of the rules for constructing identifiers and labels is given in the following table.

	Identifiers	Unquoted Labels	Quoted Labels
Number of characters	63	63	63
Must begin with	A letter	A letter or a number	Any character
Permitted special characters	Underscore (-)	Underscore (-) and the characters + and -	Any but the starting quote

Table 2: Rules for constructing identifiers and labels

4.22.4.5 Text

Identifiers and set elements may also be associated with a line of descriptive text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the identifier.

Text may be quoted or unquoted. Quoted text may contain any character except the quote character used. Single or double quotes may be used but they must match. Text has to fit on one line and cannot exceed 255 characters in length. Text used in unquoted form must follow a number of mild restrictions. Unquoted text cannot start with a reserved word, '..' or '=' and must not include semicolons ';', commas ',', or slashes '/'. End of lines terminate a text. These restrictions are a direct consequence of the GAMS syntax and are usually followed naturally by the user. Some examples are:

```
this is text
final product shipment (tpy)
"quoted text containing otherwise illegal characters ; /,"
'use single quotes to put a "double" quote in text'
```

4.22.4.6 Numbers

Numeric values are entered in a style similar to that used in other computer languages

Attention

- Blanks cannot be used in a number: GAMS treats a blank as a separator.
- The common distinction between real and integer data types does not exist in GAMS. If a number is used without a decimal point it is still stored as a real number.

In addition, GAMS uses an extended range arithmetic that contains special symbols for infinity (INF), negative infinity (-INF), undefined (UNDF), epsilon (EPS), and not available (NA). The user cannot enter UNDF; it is only produced by an operation that does not have a proper result, such as division by zero. All the other special symbols may be entered and used as if they were ordinary numbers. For more details, see section [Extended Range Arithmetic](#).

The following example shows various legal ways of entering numbers:

```
0      156.70  -135      .095      1.
2e10   2e+10   15.e+10   .314e5   +1.7
0.0    .0      0.        INF      -INF
EPS    NA
```

The letter e denotes the well-known scientific notation allowing convenient representation of very large or small numbers. For example,

```
1e-5 = 1 * 10^{-5} = 0.00001;
3.56e6 = 3.56 * 10^6 = 3,560,000;
```

Note

- GAMS uses a smaller range of numbers than many computers are able to handle. This has been done to ensure that GAMS programs will behave in the same way on a wide variety of machines, including personal computers. GAMS will create an error if a number with an absolute value greater or equal to $1.0e+300$ is used.
- A number may be entered with up to 16 significant digits. The dollar control option [\\$offDigit](#) can be used to control the behavior if this number is exceeded.

4.22.4.7 Delimiters

As mentioned before, statements are separated by a semicolon ';'. However, if the next statement begins with a reserved word (often called keyword in succeeding chapters), then GAMS does not require that the semicolon is used.

The characters comma ',' and slash '/' are used as delimiters in data lists, to be introduced later. The comma terminates a data element (as does an end-of-line) and the slash terminates a data list.

4.22.4.8 Comments

A comment is an explanatory text that is not processed or retained by the computer. There are several ways to include comments in a GAMS program.

4.22.4.8.1 Blank Lines The user may freely enter blank lines to set off certain sections and enhance readability. For example, in **transport** there are blank lines between the different parameters:

```
Sets
  i  "canning plants"   / seattle, san-diego /
  j  "markets"          / new-york, chicago, topeka / ;

Parameters

  a(i) "capacity of plant i in cases"
      /  seattle      350
        san-diego    600 /

  b(j) "demand at market j in cases"
      /  new-york     325
        chicago      300
        topeka       275 / ;
```

4.22.4.8.2 Single Line Comments Users may insert a single line comment on any line by placing an asterisk * in column 1. The text that follows the asterisk is the comment and may contain GAMS reserved words, messages or any other content. It is completely ignored by the GAMS compiler. Note that several successive lines may be single line comments as in the example below.

The default asterisk * may be replaced by other symbols. GAMS provides the dollar control option [\\$comment](#) to customize the comment character (for more on dollar control options, see chapter [Dollar Control Options](#)). The new comment character cannot be used in column 1 as before, since now it has a special meaning. The change of comment character should be used with great care. An example can be seen here:

```
*normal comment
*next line is a deactivated GAMS statement
* x=sum(I,z(i));
$comment !
!comment with new character
$comment *
*now we are back to how it should be
```

In the fourth line, the new comment character ! replaces the GAMS default * as the comment delimiter. Note that single line comments appear in the echo print of the GAMS output as numbered lines. For details see section [The Echo Print of the Input File](#).

4.22.4.8.3 Block Comments For longer comments special 'block' delimiters may be used that cause GAMS to ignore an entire section of the program. The dollar control option `$ontext` marks the beginning of the comment block and the option `$offtext` marks the end. Note that the \$ symbol must be in the first character position. The example below illustrates the use of the block comment and also contains some useful information. For more on dollar control options, see chapter [Dollar Control Options](#).

```
$ontext
Following a $ontext directive in column 1 all lines are
ignored by GAMS but printed on the output file until the matching $offtext is encountered, also
in column 1. This facility is often used to logically remove parts of programs
that are not used every time, such as statements producing voluminous reports.
Every $ontext must have a matching $offtext in the same file
$offtext
```

Note that block comments appear in the echo print without line numbers. For details see section [The Echo Print of the Input File](#).

4.22.4.8.4 End-of-Line Comments Comments may also be placed at the end of a line that contains GAMS code. The dollar control option `$onEolCom` activates end-of-line comments. The default symbol to indicate that the comment begins is a double exclamation mark !!. This symbol may be reset with the option `$eolCom` followed by the desired symbol which may be one character or a two-character sequence. The following example serves as illustration. For more on dollar control options, see chapter [Dollar Control Options](#).

```
Scalar x /0/;
$onEolCom
x=x+1;      !! eol comment
x = x      !! eol comment in line of GAMS statement, where the GAMS statement continues to the ne
+1;
$eolCom &&
x=x+1;      && eol comment with new symbol
```

Note that the option to add end-of-line comments may be deactivated with the dollar control option `$offEolCom`. End-of-line comments appear in the echo print on the appropriate lines. For details see section [The Echo Print of the Input File](#).

4.22.4.8.5 In-Line Comments Comments may also appear *in* a line of GAMS code. The dollar control option `$onInline` activates in-line comments. By default, the in-line comment symbols are set to the two character pairs `'/*'` and `'*/'`, where `'/*'` indicates that the in-line comment begins and `'*/'` indicates that the in-line comment ends. The comment may span lines till the end-of-comment characters are encountered. The in-line comment symbols may be reset with the option `$inLineCom` followed by the desired pair of characters. The following example serves as illustration. For more on dollar control options, see chapter [Dollar Control Options](#).

```
Scalar x /0/;
$onInline
x=x      /* in-line comment*/ +1;
x=x      /* in-line comment in line
          that continues to next line */
          +1;
$inLineCom /& &/
x=x      /& in-line comment with new character &/ +1;
```

Note that the option to add in-line comments may be deactivated with the dollar control option `$offInline`. In-line comments appear in the echo print on the appropriate lines. For details see section [The Echo Print of the Input File](#). Note that in-line comments may be allowed to be nested using the dollar control option `$onNestCom`.

4.22.4.8.6 Outside Margin Comments GAMS provides the facility to define margins. The active code is within the margins, everything outside the set margins is ignored by the compiler and treated as comment. The dollar control option `$onMargin` activates margin marking and `$offMargin` deactivates it. The option `$minCol` is used to specify the first column, where GAMS code that is to be compiled may appear. Similarly, the option `$maxCol` is used to specify the last column for GAMS code. The following example shows how this works. For more on dollar control options, see chapter [Dollar Control Options](#).

```
$ontext
      1           2           3           4           5           6
123456789012345678901234567890123456789012345678901234567890
$offtext

$onMargin minCol 20 maxCol 45
Now I have          Set i plant /US, UK/          This defines i
turned on the       Scalar x / 3.145 /           A scalar example.
margin marking.     Parameter a, b;                Define some
                                                           parameters.
$offMargin
```

The text before column 20 and after column 45 is treated as a comment. Note that the full content of the lines is copied to the echo print, including everything outside the margins. For details see section [The Echo Print of the Input File](#).

4.22.4.8.7 Hidden Comments Finally, GAMS also allows hidden comments, that are not copied to the echo print of the GAMS output file. These comments contain information that is only relevant for the person manipulating the file. They are single line comments starting with the dollar control option `$hidden`. An example follows. For more on dollar control options, see chapter [Dollar Control Options](#).

```
$hidden a comment I do not want in LST file
set a /a1,a2/;
set b /a2,c2/;
set c /a3,d3/;
```

4.22.5 Summary

This completes the discussion of the components of the GAMS language. Many unfamiliar terms used in this chapter are further explained in the [Glossary](#).

4.23 Set Definition

4.23.1 Introduction

Sets are fundamental building blocks in any GAMS model. They allow the model to be succinctly stated and easily read. In this chapter we will introduce how sets are declared and initialized. More advanced set concepts, such as assignments to sets, and lag and lead operations are covered in the chapters [Dynamic Sets](#) and [Sets as Sequences](#). The topics discussed in this chapter will be enough to provide a good start on most models. We will introduce [simple sets](#), [subsets](#), [multi-dimensional sets](#), [singleton sets](#) and the [universal set](#). The chapter will be concluded by a topic on [domain checking](#), a very important feature of GAMS, and a section about [Domain Defining Symbol Declarations](#).

4.23.2 Simple Sets

Using common mathematical notation, a set S that contains the elements a , b and c is written as:

$$S = \{a, b, c\}$$

Using GAMS notation, the same set is defined in the following way:

```
Set S / a, b, c /;
```

The set statement begins with the keyword `set`, `S` is the name of the set, and its members are `a`, `b`, and `c`. They are labels, but are often referred to as elements or members.

4.23.2.1 Defining a Simple Set: The Syntax

In general, the syntax for *simple* sets in GAMS is as follows:

```
set[s] set_name ["text"] [/element [text] {,element [text]} /]
      {,set_name ["text"] [/element [text] {,element [text]} /] } ;
```

`Set[s]` is the keyword that indicates that this is a set statement. `Set_name` is the internal name of the set in GAMS, it is an [identifier](#). The optional [explanatory text](#) may be used to describe the set or a specific set element for future reference and to ease readability. The list of set elements is delimited by forward slashes. `Element` is the name of the set element(s). Note that each element in a set must be separated from other elements by a comma or by an end-of-line, and each element is separated from any associated text by a blank.

Consider the following example from the Egyptian fertilizer model [[FERTS](#)], where the set of fertilizer nutrients could be written as

```
Set cq "nutrients" / N, P205 /;
```

or as

```
Set cq "nutrients" / N
          P205 /;
```

The order in which the set members are listed is usually not important. However, if the members represent, for example, time periods, then it may be useful to refer to the *next* or *previous* member. There are special operations to do this, and they are discussed in chapter [Sets as Sequences: Ordered Sets](#). For now, it is enough to remember that the order in which set elements are specified is not relevant, unless and until some operation implying order is used. At that time, the rules change, and the set becomes what we will later call an *ordered set*.

Note

- The data statement, i.e. specification of set elements in forward slashes can be omitted. In such cases a set is declared without being defined.
- More than one set may be declared and defined in one set statement. Examples are given in subsection [Declaring Multiple Sets](#) below.

4.23.2.2 Illustrative Examples

Consider the following example based on the model [\[SHALE\]](#):

```
Set cf "final products" / syncrude "refined crude (mil bbls)"
          lpg      "liquefied petroleum gas (million bbls)"
          ammonia "ammonia (mil tons)"
          coke     "coke (mil tons)"
          sulfur  "sulfur (mil tons)" /;
```

The set statement is introduced with the keyword `set`, the name of the set is `cf` and the explanatory text `"final products"` describes the set. The set has five elements with explanatory texts that contain details of the units of measurement.

Usually sets are declared and defined once and then referenced in the model. There are two exceptions: the dollar control option `onMulti` allows adding more elements later, and dynamic sets. For details on dynamic sets, see chapter [Dynamic Sets](#). The following code slightly varies the previous example to demonstrate the option `$onMulti`:

```
Set cf "final products" / syncrude "refined crude (mil bbls)"
          lpg      "liquefied petroleum gas (million bbls)"
          ammonia "ammonia (mil tons)" /
$onmulti
Set cf "more final products" / coke     "coke (mil tons)"
          sulfur  "sulfur (mil tons)" /;
```

After `$onmulti` additional elements are added to the set `cf`. Note that without the [dollar control option](#) `$onMulti` that would generate an error as per default a symbol can have at most one data statement.

4.23.2.3 Sequences as Set Elements

The asterisk '*' plays a special role in set definitions. It is used to relieve the tedium of typing a sequence of elements for a set, and to make intent clearer. For example, in a simulation model there might be ten annual time periods from 1991 to 2000. Instead of typing ten years, the elements of this set can be written as:

```
Set t "time" / 1991 * 2000 /;
```

This means that the set includes the ten elements 1991, 1992, ..., 2000. GAMS builds up these label lists by looking at the differences between the two labels. If the only characters that differ are digits, with the number L formed by these digits in the left and R in the right, then a label is constructed for every integer in the sequence L to R. Any non-numeric differences or other inconsistencies cause errors.

The following example illustrates the most general form of the '*asterisked*' definition:

```
Set g1 / a1bc * a20bc /;
```

Note that this is not the same as:

```
Set g2 / a01bc * a20bc /;
```

Both sets have 20 members, but they have only 11 members in common.

Lists in decreasing order are also possible:

```
Set y "years in decreasing order" / 2000 * 1991 /;
```

As a last example, the following set definitions are both illegal because they are not consistent with the rule given above for making lists:

```
Set illegal1 / a1x1 * a9x9 /
    illegal2 / a1 * b9 /;
```

4.23.2.4 Declaring Multiple Sets

The keyword set does not need to be used for each set, rather only at the beginning of a group of sets. It is often convenient to put a group of set declarations (and definitions) together at the beginning of the program. When this is done the set keyword needs only be used once. Those who prefer to intermingle set declarations with other statements, have to use a new set statement for each additional group of sets. Note that the keywords `set` and `sets` are equivalent. The following example below shows how two sets can be declared together. Note that the semicolon is used only after the last set is declared.

```
Sets s "Sectors" / manuf, agri, services, government /
    r "Regions" / north, eastcoast, midwest, sunbelt / ;
```

4.23.2.5 Using Previously Defined Sets in Set Definitions

The following notation allows previously defined sets to be used in a new set definition:

```
Set i / i1 * i4 /
    j / j6 * j9 /
    k / #i, set.j /;
```

The set `k` contains all elements of the sets `i` and `j`. Note that the hash sign '#' followed by a set name is a shorthand for referring to all the elements in a set. The notation `set.set_name` works identically and is just a different way to refer to all elements in a previously defined set.

4.23.3 The Alias Statement: Multiple Names for a Set

Sometimes it is necessary to have more than one name for the same set. In input-output models for example, each commodity may be used in the production of all other commodities and it is necessary to have two names for the set of commodities to specify the problem without ambiguity. In the general equilibrium model [ORANI], the set of commodities `c` is written as

```
Set c "Commodities" / food, clothing /;
```

A second name for the set `c` is established with either of the following statements:

```
Alias (c, cp) ;
Alias (cp, c) ;
```

Here `cp` is the new set name that can be used instead of the original set name `c`.

Note

The newly introduced set name may be used as an alternative name for the original set; the associated set will always contain the same elements as the original set.

With the `alias` statement more than one new name may be introduced for the original set:

```
Alias (c,cp, cpp, cppp);
```

Here `cp`, `cpp`, `cppp` are all new names for the original set `c`.

Note

The order of the set names in the alias statement does not matter. The only restriction is that exactly one of the sets in the statement must be defined earlier. All the other sets are introduced by the alias statement.

Typical examples for the usage of aliases are problems where transportation costs between members of one set have to be modeled. The following code snippet is adapted from the Andean fertilizer model [ANDEAN]:

```
Set i "plant locations" / palmasola, pto-suarez, potosi, baranquill, cartagena /;
Alias(i,ip);
```

```
Table tran(i,i) "transport cost for interplant shipments (us$ per ton)"
```

	palmasola	pto-suarez	potosi	baranquill
pto-suarez	87.22			
potosi	31.25	55.97		
baranquill	89.80	114.56	70.68	
cartagena	89.80	114.56	70.68	5.00

```
;
Parameter mui(i,ip) "transport cost: interplant shipments (us$ per ton)";
mui(i,ip) = (tran(i,ip) + tran(ip,i));
```

The alias statement introduces `ip` as another name for the set `i`. The table `tran` is two-dimensional and both indices are the set `i`. The data for the transport cost between the plants is given in this table; note that the transport costs are given only for one direction here, i.e. the costs from `pto-suarez` to `palmasola` are explicitly specified in the table while the costs in the opposite direction are not given at all. The parameter `mui` is also two-dimensional and both indices refer to the set `i`, but this time the alias `ip` is used in the second position. The parameter `mui` is defined with the assignment statement in the next line: `mui` contains the transport costs from one plant location to the other, in both directions. Note that if `mui` were defined without the alias, then all its entries would have been zero. For other examples where aliases are used, see sections [The Universal Set](#) and [Finding Sets from Data](#) below.

4.23.4 Subsets

It is often necessary to define sets whose members must all be members of some larger set. The syntax is:

```
set set_ident1(set_ident2) ;
```

Here `set` is the keyword indicating that this is a set statement, and `set_ident1` is a subset of the larger set `set_ident2`. The larger set is also called superset.

For instance, we may wish to define the sectors in an economic model following the style in [CHENERY].

```
Set i    "all sectors"          / light-ind, food+agr, heavy-ind, services /
t(i)    "traded sectors"       / light-ind, food+agr, heavy-ind /
nt      "non-traded sectors"   / services /;
```

Some types of economic activity, for example exporting and importing, may be logically restricted to a subset of all sectors. In order to model the trade balance we need to know which sectors are traded, and one obvious way is to list them explicitly, as in the definition of the set `t` above. The specification `t(i)` means that each member of the set `t` must also be a member of the set `i`. GAMS will enforce this relationship, which is called [domain checking](#). Obviously, the order of declaration and definition is important: the membership of `i` must be known before `t` is defined, otherwise checking cannot be done.

Note

All elements of the subset must also be elements of the superset.

It is legal but unwise to define a subset without reference to the larger set, as is done above for the set `nt`. In this case domain checking cannot be performed: if `services` were misspelled no error would be marked, but the model may give incorrect results. Hence, it is recommended to use domain checking whenever possible. It catches errors and allows to write models that are conceptually cleaner because logical relationships are made explicit.

An alternative way to define elements of a subset is with [assignments](#):

```
Set i    "all sectors"    / light-ind, food+agr, heavy-ind, services /
      t(i) "traded sectors" / light-ind, heavy-ind /;
t('food+agr') = yes;
```

In the last line the element `food+agr` of the set `i` is assigned to the subset `t`. Assignments may also be used to *remove* an element from a subset:

```
t('light-ind') = no;
```

Note that `yes` and `no` are [reserved words](#) in GAMS. Note further that if a subset is assigned to, it then becomes a [dynamic set](#). For more on assignments in GAMS in general, see section [The Assignment Statement](#).

Attention

A subset can be used as a domain in the declaration of other sets, variables, parameters and in equations as long as it is no [dynamic set](#).

This completes the discussion of sets in which the elements are simple. This is sufficient for many GAMS applications. However, there are a variety of problems for which it is useful to have sets that are defined in terms of two or more other sets.

4.23.5 Multi-Dimensional Sets

It is often necessary to provide mappings between elements of different sets. For this purpose, GAMS allows the use of multi-dimensional sets. For the current maximum number of permitted dimensions, see [Dimensions](#). The next two subsections explain how to express one-to-one and many-to-many mappings between sets.

4.23.5.1 One-to-one Mapping

Consider a set whose elements are pairs: $A = \{(b, d), (a, c), (c, e)\}$. In this set there are three elements and each element consists of a pair of letters. This kind of set is useful in many types of modeling. For example, in the world aluminum model [**ALUM**] a port has to be associated with a nearby mining region

```
Set i      "mining regions"    / china, ghana, ee+ussr, s-leone /
    n      "ports"            / accra, freetown, leningrad, shanghai /
    in(i,n) "mines to ports map" / china .shanghai
                                       ghana .accra
                                       ee+ussr.leningrad
                                       s-leone.freetown /;
```

Here `i` is the set of mining regions, `n` is the set of ports and `in` is a two dimensional set that associates each port with a mining region. The dot between `china` and `shanghai` is used to create one such pair. Blanks may be used freely around the dot for readability. The set `in` has four elements, and each element consists of a region-port pair. The notation `(i,n)` after the set name `in` indicates that the first member of each pair must be a member of the set `i` of mining regions, and that the second must be in the set `n` of ports. GAMS will [domain check](#) the set elements to ensure that all members belong to the appropriate sets.

4.23.5.2 Many-to-Many Mapping

A many-to-many mapping is needed in certain cases. Consider the following sets:

```
Set  i          / a, b /
     j          / c, d, e /
     ij1(i,j)  / a.c, a.d /
     ij2(i,j)  / a.c, b.c /
     ij3(i,j)  / a.c, b.c, a.d, b.d /;
```

Here the set `ij1` presents a *one-to-many* mapping where one element of the set `i` maps onto many elements of the set `j`. The set `ij2` represents a *many-to-one* mapping where many elements of the set `i` map onto one element of the set `j`. The set `ij3` is the most general case: a *many-to-many* mapping where many elements of the set `i` map to many elements of the set `j`.

These sets may be written compactly as:

```
Set  i          / a, b /
     j          / c, d, e /
     ij1(i,j)  / a.(c,d) /
     ij2(i,j)  / (a,b).c /
     ij3(I,j)  / (a,b).(c,d) /;
```

The parenthesis provides a list of elements that is expanded when creating pairs. Note that the dot '.', if used like above, acts as *product operator* and supports building the Cartesian product of sets.

Attention

When complex sets like this are created, it is important to check that the desired set has been obtained. The checking can for example be done by using a [display statement](#).

GAMS provides more notation to define multi-dimensional sets in a succinct way. As introduced [above](#) the hash sign '#' followed by a set name is a shorthand for referring to all the elements in a set. The matching operator ':' may be used to map [ordered sets](#). This operator is similar to the product operator '.'. However, in this case elements are matched pairwise by mapping elements with the same order number. The examples below demonstrate these concepts.

```
Set
i          / a, b /
j          / c, d, e /

ij4a(i,j) / a.#j /
ij4b(i,j) / a.c, a.d, a.e /

ij5a(i,j) / #i.#j /
ij5b(i,j) / a.c, a.d, a.e, b.c, b.d, b.e /

ij6a(i,j) / #i:#j /
ij6b(i,j) / a.c, b.d /;
```

Note that set names that differ only by the last letter denote identical sets. For example, set `ij4a` is identical to set `ij4b`. Observe that set `i` has two elements and set `j` has three elements, where `e` is the element with the highest order. Set `ij6a` is an ordered mapping of all elements of set `i` to all elements of set `j`. However, since there is a mismatch in the number of elements, element `e` is not mapped to.

These concepts may be generalized to sets with higher dimensions. Mathematically, these are called 3-tuples, 4-tuples, or more generally, *n*-tuples. Some examples for the compact representation of sets of *n*-tuples using combinations of dots, parentheses, and commas are shown in [Table 1](#).

Compact Notation	Result
$(a,b).c.d$	$a.c.d, b.c.d$
$(a,b).(c,d).e$	$a.c.e, b.c.e, a.d.e, b.d.e$
$(a.1*3).c$	$(a.1, a.2, a.3).c$ or $a.1.c, a.2.c, a.3.c$
$1*3. 1*3. 1*3$	$1.1.1, 1.1.2, 1.1.3, \dots, 3.3.3$

Table 1: Examples for compact representation of multi-dimensional sets

Note that the asterisk may also be used in conjunction with the dot. Recall that the elements of the list $1*4$ are $\{1, 2, 3, 4\}$.

A powerful and very compact way to define multi-dimensional sets is with a [special option](#) that takes an identifier as value and carries out [identifier operations](#) like [index matching](#) using the matching operator `'`. The following example illustrates the method.

```
Set i / i1*i4 /
    j / j1*j5 /
    k / k1,k2 /
    h / h1*h3 /;
```

```
Set b(i,j,k), c(i,j,k,h);
```

```
Option b(i:j,k), c(b:h);
display b, c;
```

The set `b` is a three-dimensional set, the option statement specifies which permutations of the elements of `i`, `j`, and `k` are elements of `b`. The matching operator `'` is between `i` and `j`, so we must first match the elements of the sets `i` and `j`. That gives us the the first two positions. For the third position we cycle through all elements of the set `k`. This results in the following elements for the set `b`:

```
i1.j1.k1, i1.j1.k2, i2.j2.k1, ... , i4.j4.k2
```

The set `c` is a four-dimensional set. Note that the first three dimensions are identical to the domain of the set `b`. The option statement specifies that in the first three positions we will have elements of the set `b` and and these are matched with the elements of the set `h` which are in the fourth position. Now, the set `h` has only three elements, so only the first three elements of the set `b` are matched with the members of the set `h`. This results in the following set:

```
i1.j1.k1.h1, i1.j1.k2.h2, i2.j2.k1.h3
```

As recommended above, it is important to always check whether the multi-dimensional sets generated with compact statement like these are indeed the sets that were intended.

For more sophisticated examples of how to use the matching operator within an [option](#) statement please see section [Index Matching](#) .

4.23.5.3 The Table Format for Multi-Dimensional Sets

An alternative way to declare multi-dimensional sets is with [tables](#). We show by example how tables may be used in the context of set definitions:

```
Set origins      / Berlin, Paris /
  destinations / London, Chicago, Budapest /
  linked_1(origins,destinations) "cities linked by railways"
      / Berlin.London, Berlin.Budapest,
      Paris .London, Paris .Budapest /;
```

```
Set Table linked_2(origins,destinations)
      London      Chicago      Budapest
Berlin      yes      no      yes
Paris      yes      yes      ;
```

The set `linked_1` is a two-dimensional set that is defined with the dot notation introduced above. The set `linked_2` is the same set defined using the table notation: the keyword `set` is followed by the keyword `table` and the name of the set with its domain. The table itself consists of the elements of the first index in the first column, the elements of the second index in the first row, and the data in the grid positions. Note that the keyword `yes` indicates that a label combination is part of the two-dimensional set and the keyword `no` or a blank indicates that the label combination is not contained in the new set. Please see section [Tables](#) for detailed requirements for inputting data in the table format.

Alternatively, the multi-dimensional set may be declared first without any elements, and the elements are added later in a separate [table statement](#):

```
Set  origins      / Berlin, Paris /
  destinations / London, Chicago, Budapest /
  linked_2(origins,destinations) "cities linked by railways";
Table linked_2(origins,destinations)
      London      Chicago      Budapest
Berlin      yes      no      yes
Paris      yes      yes      ;
```

Instead of the keywords `yes` and `no` users may also use numbers to specify membership in the two-dimensional set: nonzero numeric entries mean that a label combination is part of the set and zero or a blank indicates that the label combination is not contained in the set.

4.23.5.4 Projection and Aggregation of Sets

In GAMS, projection and aggregation operations on sets can be performed in two different ways: with an option statement and with an assignment. For a detailed discussion, see section [Projection and Aggregation of Sets and Parameters](#).

4.23.6 Singleton Sets

A *singleton set* in GAMS is a special set that has at most one element (zero elements are allowed as well). Like other sets, singleton sets may have a domain with several dimensions. For the current maximum number of permitted dimensions, see [Dimensions](#). Singleton sets are declared and defined with the keyword `singleton` that acts as a modifier to the keyword `set`:

```
Set          i          / a, b, c /;
Singleton Set j          / d      /
              k(i)      / b      /
              l(i,i)    / b.c    /;
```

The sets `j`, `k` and `l` are declared as singleton sets, each of them has just one element. The set `k` is a subset of the set `i` and the set `l` is a two-dimensional set.

Note that a data statement for a singleton set with more than one element will create a compilation error:

```
1 Singleton Set s / s1*s3 /;
****                               $844
2 display s;
```

Error Messages

844 Singleton with more than one entry (see \$onStrictSingleton)

It is also possible to assign an element to a singleton set. In this case the singleton set is automatically cleared of the previous element first. For example, adding the following line to the code above will result in set `k` containing only element `a` after execution:

```
k('a') = yes;
```

The dollar control option [offStrictSingleton](#) may be used to allow sets that are declared as singleton sets to have more than one element in compile time definitions. However, in this case only the first listed element is a valid element of the set. Note that the value of zero for the command line parameter [strictSingleton](#) has the same effect for execution time definitions of singleton sets via assignment statements.

For more on dollar control options, see chapter [Dollar Control Options](#). For more on GAMS command line parameters, see chapter [The GAMS Call and Command Line Parameters](#). For more on compilation errors, see section [Compilation Errors](#).

Singleton sets can be especially useful in [assignment statements](#) since they do not need to be controlled by a controlling index or an indexed operator like other sets. Consider the following examples:

```
Set          i          / a, b, c /;
Singleton Set k(i)      / b      /
              h(i)      / a      /;
Parameter    n(i)      / a 2, b 3, c 5 /;
Scalar z1, z2;
```

```
z1 = n(k);
z2 = n(k) + 100*n(h);
```

The singleton sets `k` and `h` are both subsets of the set `i`. The [parameter](#) `n` is defined over the set `i`. The [scalar](#) `z1` is assigned a value of the parameter `n` without naming the respective label explicitly in the assignment. It is already specified in the definition of the singleton set `k`. The assignment statement for the scalar `z2` contains an expression where the singleton sets `k` and `h` are referenced without a controlling index or an indexed operation.

Note

Singleton sets cannot be used as domains.

4.23.7 The Universal Set: * as Set Identifier

GAMS provides the *universal set* denoted by '*' for cases where the user wishes not to specify an index but have only a placeholder for it. The following examples show two ways how the universal set is introduced in a model. We will discuss the advantages and disadvantages of using the universal set later. The first example is from the production and inventory model [ROBERT]:

```
Sets  r          "raw materials" / scrap, new /;
Table misc(*,r) "other data"
        scrap  new
max-stock  400  275
storage-c   .5   2
res-value   15  25;
```

A `table` is an input format for the data type `parameter` and has at least two dimensions. For details see section [Tables](#). In our example, the first index is the universal set '*' and the second index is the previously defined set `r`. Since the first index is the universal set any entry whatsoever is allowed in this position. In the second position elements of the set `r` must appear, they are [domain checked](#), as usual.

The second example illustrates how the universal set is introduced in a model with an [alias](#) statement.

```
Alias (new_universe,*);
Set k(new_universe) / Chicago / ;
```

The alias statement links the universal set with the set name `new_universe`. Set `k` is a subset of the universal set and `Chicago` is declared to be an element of `k`. Any item may be added freely to `k`.

The universal set is particularly useful for generating reports, since it allows the use of any labels without having to define special sets for them. For an example, see section [Set Attributes](#) below. For more on report writing, see chapter [The Put Writing Facility](#).

Attention

It is recommended to not use the universal set for data input, since there is no [domain checking](#) and thus typos will not be detected and data that the user intends to be in the model might actually not be part of it.

Observe that in GAMS a simple set is always regarded as a subset of the universal set. Thus the set definition

```
Set i / i1*i10 /;
```

is the same as

```
Set i(*) / i1*i10 /;
```

GAMS follows the concept of a domain tree for domains in GAMS. It is assumed that a set and its subset are connected by an arc where the two sets are nodes. Now consider the following one dimensional subsets:

```
Set i, ii(i), j(i), jj(j), jjj(jj);
```

These subsets are connected with arcs to the set `i` and thus form a *domain tree* that is rooted in the universe node '*'. This particular domain tree may be represented as follows:

```
* - i - ii
    |
    - j - jj - jjj
```

Note that with the construct `i(jjj)` we may access `ii` iterating through the members of `jjj`. For an example, see [domain tree in the loop statement](#).

Observe that the universal set is assumed to be *ordered* and operators for ordered sets such [ord](#), [lag](#) and [lead](#) may be applied to any sets aliased with the universal set.

4.23.8 Set and Set Element Referencing

Sets or set elements are referenced in many contexts, including assignments, calculations, equation definitions and loops. Usually GAMS statements refer to the whole set or a single set element. In addition, GAMS provides several ways to refer to more than one, but not all elements of a set. In the following subsections we will show by example how this is done. GAMS also has [set functions](#) that specifically reference sets and are introduced in the chapter about [logical conditions](#).

4.23.8.1 Referencing the Whole Set

Most commonly whole sets are referenced as in the following examples:

```
Set i / i1*i100 /;
Parameter k(i);
k(i) = 4;
Scalar z;
z = sum(i, k(i));
```

The [parameter](#) `k` is declared over the set `i`, in the [assignment statement](#) in the next line *all* elements of the set `i` are assigned the value 4. The [scalar](#) `z` is defined to be the [sum](#) of *all* values of the parameter `k(i)`.

4.23.8.2 Referencing a Single Element

Sometimes it is necessary to refer to specific set elements. This is done by using single or double quotes around the [label\(s\)](#). We may add the following line to the example above:

```
k('i77') = 15;
```

This statement changes the value of `k('i77')` to 15, all the other values of `k` remain 4.

4.23.8.3 Referencing a Part of a Set

There are multiple ways to restrict the domain to more than one element, e.g. subsets, conditionals and tuples. Suppose we want the parameter `k` from the example above to be assigned the value 10 for the first 8 elements of the set `i`. The following two lines of code illustrate how easily this may be accomplished with a subset:

```
Set j(i) / i1*i8 /;
k(j) = 10;
```

First we define the set `j` to be a subset of the set `i` with exactly the elements we are interested in. Then we assign the new value to the elements of this subset. The other values of the parameter `k` remain unchanged. For examples using conditionals and tuples, see sections [Restricting the Domain: Conditionals](#) and [Restricting the Domain: Tuples](#) respectively.

4.23.9 Set Attributes

A GAMS set element has several numbers attached to it. These values are called *attributes*; they may be recovered during execution. The attributes are listed in [Table 3](#).

Set Attribute	Symbol	Description
Position	.pos	Element position in the current set (set does not have to be ordered), starting with 1.
Ord	.ord	Same as .pos but for ordered sets only.
Offset	.off	Element position in the current set minus 1. So .off = .pos - 1 (set does not have to be ordered).
Reverse	.rev	Reverse element position in the current set, so the value for the last element is 0, the value for the penultimate is 1, etc. (set does not have to be ordered)
Unique Element List	.uel	Element position in the unique element list. For details see section Ordered and Unordered Sets
Length	.len	Length of the set element name (a count of the number of characters).
Value	.val	If a set element is a number, this attributes gives the value of the number. For extended range arithmetic symbols, the symbols are reproduced. If a set element is a string that is not a number, then this attribute is not defined and trying to use it results in an error.
First set element	.first	Returns 1 for the first set element, otherwise 0.
Last set element	.last	Returns 1 for the last set element, otherwise 0.

Table 3: Set Attributes

The attributes may be accessed with an assignment statement:

```
data(set_name) = set_name.attribute ;
```

Here data is a [parameter](#), set_name is the name of the set and .attribute is one of the attributes listed above. The following example serves as illustration:

```
Set      id          "example set"          / Madison, tea-time, '-inf', '-7', '13.14'/;
Parameter report(id,*) "set attribute values";
```

```
report(id,'position') = id.pos ;
report(id,'reverse')  = id.rev ;
report(id,'offset')   = id.off ;
report(id,'length')   = id.len ;
report(id,'first')    = id.first;
report(id,'last')     = id.last ;
```

```
display report;
```

The parameter `report` is declared to have two dimensions with the set `id` in the first position and the [universal set](#) in the second position. In the following six statements the values of `report` are defined for six entries of the universal set. Note how the flexibility of the universal set is used here to make reporting easy. The [display statement](#) generates the output that follows.

```
----- 11 PARAMETER report set attribute values

           position      reverse      offset      length      first      last
Madison      1.000        4.000                7.000        1.000
tea-time     2.000        3.000        1.000        8.000
-inf         3.000        2.000        2.000        4.000
-7           4.000        1.000        3.000        2.000
13.14       5.000                4.000        5.000                1.000
```

4.23.10 Finding Sets from Data

Sometimes it is desirable to find a set from the available data in order to use it later in the model. We will show by example how this may be accomplished using the alias statement, the [universal set](#) and [conditionals](#). Suppose we have only the data related to the transportation model [TRANSPORT] and we want to identify the sets. We can tell from the data that there are two sets that we are interested in. First, we define these two sets as [aliases](#) of the universal set, which means that no elements are specified:

```
Alias(sources, places, *);
```

Then we enter the data that contain an indicator of which set elements are valid entries in the sets to be computed. We use the [table](#) format.

```
Table trandata (sources,places)    "data from spreadsheet"
      Newyork      Chicago      totalsupply
Seattle          2.5          1.7          350
Sandiego         2.5          1.8          300
totalneed       325          75
```

Next we define subsets that we will need in the calculations that follow:

```
Set source(sources)      "sources in spreadsheet data"
   destination(places)  "destination in spreadsheet data";
```

Now we have everything that we need to do the calculation using the data on hand. In our case, a label qualifies as an element of the set `source` if it has an entry for `totalsupply` in the table above, and a label is an element of the set `destination` if it has an entry for `totalneed` in the table `trandata`:

```
source(sources)$(trandata(sources,"totalsupply")) = yes;
destination(places)$(trandata("totalneed", places )) = yes;
```

These conditional assignments define the elements of the sets `source` and `destination`. From this point on these sets may be used in the model. However, note that the resulting sets are [dynamic sets](#). Hence they cannot be used as domains in *declaration* statements of other sets, parameters, variables and equations. But they may be referenced and used in equation *definitions*.

Such computations may for example be useful if the user gets a data table from elsewhere and needs to specify the sets. Alternatively, if the data is available in gdx format, the dollar control option [load](#) provides functionality to project sets from data contained in a GDX file.

See also section [Implicit Set Definition \(or: Domain Defining Symbol Declarations\)](#).

4.23.11 Domain Checking

The GAMS compiler performs a check to ensure that each label quoted as a member of a set is indeed an element of the respective set, and each element defined in a subset is in fact a member of the superset. This screening for consistency is called *domain checking*. It is done whenever a domain is referenced, be it in set, variable, parameter or equation declarations and definitions, or in assignments. The following examples serve as illustration.

```
Set  i      "all cities"      / Lima, Toronto, Wuhan, Shanghai /
     as(i)  "Asian cities"    / Wuhan, Shanhai, Calcutta /
     am     "American cities" / Lima, Toront /;
```

The set `as` is declared to be a subset of the set `i`, therefore domain checking will test every label for inconsistencies. It will catch two errors: there is a typo in `Shanhai` and `Calcutta` is not a member of the set `i`, so it cannot legally be a member of a subset.

```
1 Set  i      "all cities"      / Lima, Toronto, Wuhan, Shanghai /
2      as(i)  "Asian cities"    / Wuhan, Shanhai, Calcutta /
****                                     $170      $170
**** 170 Domain violation for element
3      am     "American cities" / Lima, Toront /;
```

The user can rectify the spelling error, and either delete `Calcutta` from the subset `as` or add it to the superset `i`. The following line will pass domain checking:

```
Set  as(i)  "Asian cities"    / Wuhan, Shanghai /;
```

Note that `am` is not declared as a subset of the set `i` even though it apparently should contain cities contained in `i`. Hence, `am` cannot be domain checked and the typo in `Toront` will go undetected. This has consequences for the next line:

```
Parameter pam(am) "population in millions" / Lima 8.9, Toronto 5.6 /;
```

In this [parameter](#) definition the domain of the parameter `pam` is the set `am`. GAMS will report an error here, since domain checking does not recognize the label `Toronto`. `Toront`, as specified in the definition of the set `am` above would be accepted.

A further example for domain checking concerns multi-dimensional domains where the user accidentally switches the positions of the indices:

```
Parameter h(as,am) / Wuhan.Lima 10, Wuhan.Toronto 12, Shanghai.Lima 7/;
Parameter d(as,am);
d(as,am) = 5*h(am,as) + 78;
```

Observe that we assume that the typo in the label `Toronto` has been rectified. The parameter `h` is defined over the domain `(as,am)`. However, in the [assignment statement](#) in the last line above, it is referenced with the domain `(am,as)`. This mistake is caught by domain checking and an error is reported.

As we have seen in the definition of the set `am` above, domain checking is not compulsory. If the following statement is entered, GAMS makes no assumptions about `rho` until further information is provided.

```
set      t   years      / 1988 * 1995 /;
Parameter rho discount rate ;
```

The modeler may later choose to domain check `rho` by continuing the definition with the following line:

```
Parameter rho(t) / 1988 0.07, 1989*1994 0.10, 1995 0.09 /;
```

Alternatively, the modeler may choose not to domain check the parameter `rho`, as is shown in the deliberately nonsensical (but legal) statement that follows:

```
Parameter rho / 1988.January 0.07, strategy-1.cost 44, cat.capacity 99 /;
```

If a parameter is not domain-checked, the only restriction is that the dimensionality must be constant. Once the number of labels per data item has been established it is frozen; to refer to the parameter differently is an error.

Note

Domain checking is automatic; it is only suppressed in two cases:

1. The index is the [universal set](#) or a set aliased to the universal set, see the examples above.
2. The dollar control option [\\$onWarning](#) is used. It has the effect that warnings rather than errors are reported for domain violations.

We urge modelers to use domain checking whenever possible. It catches errors and allows users to write models that are conceptually cleaner because logical relationships are made explicit.

Note that the dollar control option [\\$load](#) is available in several variations to enable domain checking when loading data from a GDX file. For details, see [\\$loadDC](#), [\\$loadDCM](#) and [\\$loadDCR](#) and chapter [GAMS Data eXchange \(GDX\)](#).

4.23.12 Implicit Set Definition (or: Domain Defining Symbol Declarations)

As seen above, sets can be defined through data statements in the declaration. Alternatively, sets can be defined implicitly through data statements of other symbols which use these sets as domains. This is illustrated in the following example, which is derived from the `[TRANSPORT]` model:

```
Set
  i 'canning plants'
  j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
      new-york  chicago  topeka
seattle      2.5      1.7      1.8
san-diego    2.5      1.8      1.4;

Display i,j;
```

Note the `<` signs in the domain list of the declaration of `d` (`d(i<,j<)`). These signal, that the set `i` will contain all elements which define the first dimension of symbol `d` and that the set `j` will contain all elements which define the second dimension of symbol `d`, respectively. So, this is the output of the `Display` statement at the end:

```
----      10 SET i  canning plants
seattle  ,    san-diego
```

```
----      10 SET j  markets
new-york,    chicago ,    topeka
```

This syntax is not limited to the table statement, but can be used with any symbol declaration. Also, one domain set can be defined through multiple symbols using the same domain, when using the dollar control option [onMulti](#):

```
Set
  food
  fruits(food<) / apple, orange /
$onMulti
  vegetable(food<) / carrot, cauliflower /
  meat(food<) / beef, pork /;
```

Display food;

This is the output of the Display statement:

```
----      8 SET food
apple    ,    orange    ,    carrot    ,    cauliflower,    beef    ,    pork
```

Note

If the < sign is used to mark a declaration as "domain defining", this attribute is not limited to the data statement following this declaration, but also influences other ways to define data at compile time like the dollar control option [load](#), as shown in the following example:

```
Set
  i 'canning plants'
  j 'markets';

Parameter d(i<,j<) 'distance in thousands of miles';

$gdxIn data.gdx
$load d
```

Attention

Only non-zero elements in a symbol will add elements to an implicitly defined set. This is illustrated in the following two examples.

```
Set
  i 'canning plants'
  j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
      new-york  chicago  topeka
seattle      2.5      1.8
san-diego    2.5      1.4;

Display i,j;
```

Note the empty column for `chicago`. Since there is no data, `chicago` will not end up in the set `j`, which can be seen in the output of the `Display` statement:

```
----      10 SET j  markets
new-york,   topeka
```

Also, an explicit 0 in a data statement does not add elements to an an implicitly defined set (in contrast to an `eps`). This is shown in the following GAMS code and output:

```
Set
  j 'markets';

Parameter
  b(j<) 'demand at market j in cases'
    / new-york   325
      chicago    0
      topeka     eps /;

Display j;

----      10 SET j  markets
new-york,   topeka
```

See also section [Finding Sets from Data](#).

4.23.13 Summary

In GAMS, a simple set consists of a set name and the elements of the set. Both the name and the elements may have associated text that explains the name or the elements in more detail. More complex sets have elements that are pairs or even n -tuples. These sets with pairs and n -tuples are ideal for establishing relationships between the elements in different sets. GAMS also uses a domain checking capability to help catch labeling inconsistencies and typographical errors made during the definition of related sets.

The discussion here has been limited to sets whose members are all specified as the set is being declared. For many models this is all the user needs to know about sets. Later we will discuss more complicated concepts, such as sets whose membership changes in different parts of the model (assignment to sets) and other set operations such as unions, complements and intersections.

4.24 Dynamic Sets

4.24.1 Introduction

Sets in general are covered in chapter [Set Definition](#). In this chapter we introduce a special type of sets: *dynamic sets*. The sets that we discuss in detail in chapter [Set Definition](#) have their elements stated at compile time (e.g. enclosed in slashes at the [set declaration](#) or when loading a set from `gdx` via [\\$load](#)) and during execution time the membership is never changed. Therefore they are called *static sets*. In contrast, the elements of *dynamic sets* are not fixed, but may be added and removed during execution of the program. Dynamic sets are most often used as *controlling indices* in assignments or equation definitions and as the conditional set in a dollar-controlled indexed operation. We will first show how assignments are used to change set membership in dynamic sets. Then we will introduce set operations and the last part of this chapter covers dynamic sets in the context of dollar conditions.

4.24.2 Assigning Membership to Dynamic Sets

Dynamic Sets may be assigned to in a similar way as other data types. There are only two possible values: **yes** and **no**. Note that arithmetic operations *cannot* be performed on sets in the same way as on *value typed* identifiers (parameters, variables and equations subtypes). However, there are special [set operations](#).

4.24.2.1 The Syntax

Like any other set, a dynamic set has to be declared before it may be used in the model. Often, a dynamic set is declared as [subset](#) of a static set. Dynamic sets in GAMS may also be multi-dimensional like static sets. The maximum number of permitted dimensions follows the rules of the basic [Data Types and Definitions](#). For multi-dimensional dynamic sets the index sets can also be specified explicitly at declaration. That way dynamic sets are [domain checked](#). Of course it is also possible to use dynamic sets that are not domain checked. This provides additional power and flexibility but also a lack of intelligibility and danger. Any label is legal as long as such a set's dimension, once established, is preserved.

In general, the syntax for assigning membership to dynamic sets in GAMS is:

```
set_name(index_list | label) = yes | no ;
```

Set_name is the internal name of the set in GAMS, **index_list** refers to the domain of the dynamic set and **label** is one specific element of the domain. An assignment statement may assign membership to the dynamic set either to the whole domain or to a subset of the domain or to one specific element. Note that, as usual, a label must appear in double or single quotes. **Yes** and **no** are [keywords](#) in GAMS. They are used to add members to or remove them from the dynamic set. Examples are given in the following subsections.

4.24.2.2 Illustrative Example

Throughout this chapter we will use examples adapted from the database model **[ZLOOF]** to illustrate the introduced concepts. Here we start with assignments of membership to dynamic sets.

```
Set  item          "all items"          / dish, ink, lipstick, pen, pencil, perfume /
     subitem1(item) "first subset of item" / pen, pencil /
     subitem2(item) "second subset of item";

subitem1('ink')    = yes ;
subitem1('lipstick') = yes ;
subitem2(item)     = yes ;
subitem2('perfume') = no ;
display subitem1, subitem2;
```

Note that the sets **subitem1** and **subitem2** are declared like any other set. The two sets become dynamic as soon as they are assigned to a few lines later. They are also domain checked: the only members they will ever be able to have must also be members of the set **item**. The first assignment not only makes the set **subitem1** dynamic, it also has the effect that its superset **item** becomes a static set and from then on its membership is frozen. The first two assignments each add one new element to **subitem1**. Note that both are also elements of **item**, as required. The third assignment is an example of the familiar indexed assignment: **subitem2** is assigned all the members of **item**. The last assignment removes the label **'perfume'** from the dynamic set **subitem2**. The output generated by the [display statement](#) is shown below:

```

----      9 SET subitem1  first subset of item
ink      ,   lipstick,   pen      ,   pencil

----      9 SET subitem2  second subset of item
dish     ,   ink       ,   lipstick,   pen      ,   pencil

```

Note that even though the labels 'pen' and 'pencil' were declared to be members of the set `subitem1` before the assignment statements that added the labels 'ink' and 'lipstick' to the set, they appear in the listing above at the end. The reason is that elements are displayed in the internal order, which in this case is the order specified in the declaration of the set `item`.

Alternatively, the elements of the set `subitem2` could be assigned in the following way:

```

subitem2(item)      = no;
subitem2(subitem1) = yes;
subitem2('dish')   = yes;

```

The first statement removes all elements from the set `subitem2`. The second statement adds all elements of the set `subitem1`. Note that this assignment is permitted since the set `subitem1` is a proper subset of the set `item` (which is the domain of `subitem2`). The third statement adds one additional element.

4.24.2.3 Dynamic Sets with Multiple Indices

As mentioned earlier, dynamic sets may be multi-dimensional. The following lines continue the example above and illustrate assignments for multi-dimensional sets.

```

Sets sold(item)      "items sold" / pencil, pen /
  sup                "suppliers" / bic, parker, waterman /
  supply(sold,sup) ;

supply('pencil','bic') = yes ;
supply('pen',sup)      = yes ;

```

Note that `supply` is a two-dimensional dynamic set. It links sold items with their respective suppliers. Other examples with multi-dimensional dynamic sets are in subsections [Dynamic Sets in Conditional Assignments](#) and [Conditional Indexed Operations with Dynamic Sets](#) below.

All the mechanisms using asterisks and [parenthesized lists](#) that were introduced in section [Multi-Dimensional Sets](#) in chapter [Set Definition](#) are available for dynamic sets as well.

4.24.2.4 Equations Defined over the Domain of Dynamic Sets

Generally, dynamic sets are not permitted as domains in *declarations* of sets, variables, parameters and equations. However, they may be *referenced* and sometimes it is necessary to *define* an equation over a dynamic set.

Note

The trick is to *declare* the equation over the entire domain but *define* it over the dynamic set.

For example, defining an equation over a dynamic set can be necessary in models that will be solved for arbitrary groupings of regions simultaneously. We assume there are no explicit links between regions, but that we have a number of independent models with a common data definition and common logic. We illustrate with an artificial example, leaving out lots of details.

```

Set      allr      "all regions" / N, S, W, E, N-E, S-W /
        r(allr)   "region subset for particular solution"
        type      "set for various types of data" ;

Scalar   price                /10/ ;
Parameter revenue(allr);
Table    data(allr,type) "all other data ..." ;

Variables activity1(allr) "first activity"
          activity2(allr) "second activity"
          revenue(allr)   "revenue"      ;

Equations resource1(allr) "first resource constraint ..."
          prodbal1(allr)  "first production balance ..." ;

resource1(r).. activity1(r)      =l= data(r,'resource-1');
prodbal1(r)..  activity2(r)*price =e= revenue(r) ;

```

To repeat the important point: the equation is *declared* over the set `allr`, but *defined* over `r`, a subset. Note that the variables and data are *declared* over `allr` but *referenced* over `r`. Then the set `r` may be assigned arbitrary combinations of elements of the set `allr`, and the model may be solved any number of times for the chosen groupings of regions.

4.24.2.5 Assigning Membership to Singleton Sets

[Singleton sets](#) have only one element. Hence any assignment to a singleton set first clears or empties the set, no explicit action to clear the set is necessary. This is illustrated with the following example:

```

Set      i      "Static Set"          / a, b, c /
        ii(i)   "Dynamic Set"         /  b   /;
Singleton Set si(i) "Dynamic Singleton Set" /  b   /;

ii('c') = yes;
si('c') = yes;
display ii, si;

```

Note that both `ii` and `si` are subsets of the set `i`, but only `si` is declared as a singleton set. The assignment statements assign to both sets the element `'c'`. While `'c'` is *added* to the set `ii`, it *replaces* the original element in the singleton set `si`. The output from the [display statement](#) confirms this:

```

----      8 SET ii  Dynamic Set
b,      c

----      8 SET si  Dynamic Singleton Set
c

```

For more information on singleton sets in GAMS, see section [Singleton Sets](#).

Attention

That an assignment to a `singleton set` first clears the set always, means that it is even cleared if there would be no change at all for a regular set:

```

Singleton Set s / 1 /;
s(s)$0 = yes;
display s;

```

Here is the output from the `display` statement in the listing file:

```

----      3 SET s

                                     ( EMPTY )

```

The assignment behavior can be changed with the option and command line parameter `strictSingleton` which affects the behavior of a membership assignment to a Singleton Set. With `strictSingleton=0` GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With `strictSingleton=1` (default), such an assignment raises an error. Consider the following example:

```

Set          i      "Static Set"          / a, b, c /
Singleton Set si(i) "Dynamic Singleton Set";
si(i) = ord(i) > 1;
display si;

```

By default, the above code will trigger an error as an assignment to a singleton set with more than one element on the right hand side is forbidden:

```

*** Error at line 3: Multiple assignment to Singleton Set not allowed (see option strictSingleton)

```

However, with option (or command line parameter) `strictSingleton=0` GAMS does not complain about such an assignment with more than one element on the right hand side but takes the first one:

```

Set          i      "Static Set"          / a, b, c /
Singleton Set si(i) "Dynamic Singleton Set";
option strictSingleton = 0;
si(i) = ord(i) > 1;
display si;

```

The output from the `display statement` confirms this:

```

----      5 SET si  Dynamic Singleton Set

b

```

4.24.3 Set Operations

GAMS provides symbols for arithmetic set operations that may be used with dynamic sets. An overview of the set operations in GAMS is given in [Table 1](#). Examples and alternative formulations for each operation follow. Note that in the table below the set `i` is the static superset and the sets `j` and `k` are dynamic sets.

Set Operation	Operator	Description
Set Union	$j(i) + k(i)$	Returns a subset of i that contains all the elements of the sets j and k .
Set Intersection	$j(i) * k(i)$	Returns a subset of i that contains the elements of the set j that are also elements of the set k .
Set Complement	<code>not j(i)</code>	Returns a subset of i that contains all the elements of the set i that are <i>not</i> elements of the set j .
Set Difference	$j(i) - k(i)$	Returns a subset of i that contains all the elements of the set j that are <i>not</i> elements of the set k .

Table 1: Set Operations with Dynamic Sets

The following examples draw on the database model [ZLOOF] that we introduced above. Recall that the set `item` is the superset of the dynamic sets `subitem1` and `subitem2`. We add new dynamic sets for the results of the respective set operations. The following example illustrates that the dynamic set operations are equivalent to the following alternative ways of representation.

```
Sets union1(item), intersection1(item), complement1(item), difference1(item)
      union2(item), intersection2(item), complement2(item), difference2(item);
```

```
union1(item) = subitem1(item) + subitem2(item); display union1;
union2(subitem1) = yes; union2(subitem2) = yes; display union2;
```

```
intersection1(item) = subitem1(item) * subitem2(item);          display intersection1;
intersection2(item) = yes$(subitem1(item) and subitem2(item));  display intersection2;
```

```
complement1(item) = not subitem1(item);                          display complement1;
complement2(item) = yes; complement2(subitem1) = no; display complement2;
```

```
difference1(item) = subitem2(item) - subitem1(item);            display difference1;
difference2(item) = yes$(subitem2(item)); difference2(subitem1) = no; display difference2;
```

The display statements will show that the above assignment statements for each operation result in the same dynamic set like using the set operator. Observe that the alternative formulations for the set intersection and set difference involve conditional assignments. Conditional assignments in the context of dynamic sets are discussed in depth in the next section.

Note

The indexed operation `sum` may be used for set unions. Similarly, the indexed operation `prod` may be used for set intersections. For examples see section [Conditional Indexed Operations with Dynamic Sets](#) below.

4.24.4 Using Dollar Controls with Dynamic Sets

The remainder of this chapter assumes familiarity with the [dollar condition](#) that is introduced in chapter [Conditional Expressions, Assignments and Equations](#). All the dollar control machinery is available for use with dynamic sets. In fact, the full power of dynamic sets can be exploited using these dollar controls.

Recall that set membership of subsets and dynamic sets may be used as a logical condition; see subsection [Logical Conditions: Set Membership and Set Functions](#) for details. Set membership may also be a building block in complex logical conditions that are constructed using the logical operators `not`, `and`, `or`, `xor`, `imp` and `eqv`. Moreover, the set operations introduced in the previous section may also be used in logical conditions. Like other dollar conditions, dollar conditions with dynamic sets are used in the context of assignments, indexed operations and equations. We will discuss in detail each of these in the following subsections.

Apart from being part of logical conditions, dynamic sets may be assigned members with conditional assignments. Examples are given in the next subsection.

4.24.4.1 Dynamic Sets in Conditional Assignments

Dynamic sets may be used in two ways in conditional assignments: they may be the item on the left-hand side that is assigned to and they may be part of the [logical condition](#). Below we present examples for both. The examples are again based on the database model [\[ZLOOF\]](#) that we introduced above.

```
Set  item          "all items"          / dish, ink, lipstick, pen, pencil, perfume /
     subitem1(item) "first subset of item" /      ink, lipstick, pen, pencil      /
     subitem2(item) "second subset of item";

subitem2(item)$subitem1(item) = yes;
display subitem2;
```

The conditional assignment adds the members of dynamic set `subitem1` to the dynamic set `subitem2`. Thus `subitem2` will have the following elements:

```
----      6 SET subitem2  second subset of item

ink      ,   lipstick,   pen      ,   pencil
```

Note that instead of using `subitem1` in a dollar condition we could also write:

```
subitem2(subitem1) = yes;
```

In the next example of a conditional assignment, a dynamic set features in the logical condition on the right-hand side. The first statement clears the set `subitem2` of any previously assigned members and the second statement assigns all members of `subitem1` to `subitem2`. The following conditional assignment will have the same result:

```
subitem2(item) = no;
subitem2(item) = yes$subitem1(item);
```

The logical condition in this assignment is `subitem1(item)`. It is satisfied for all members of the set `subitem1`. Hence the statement assigns all elements of the domain `item` that are members of the set `subitem1` to the dynamic set `subitem2`. Note that in this assignment the dollar operator is on the right. In the section [Dollar on the Right](#) we show that conditional assignments with the dollar operator on the right-hand side imply an `if-then-else` structure where the `else` case is automatically zero. Unlike parameters, dynamic sets cannot be assigned the value of zero, they are assigned the value `no` instead. Therefore a more explicit formulation of the conditional assignment above would be:

```
subitem2(item) = no;
subitem2(item) = yes$subitem1(item) + no$(not subitem1(item));
```

For more on sets in logical conditions, see section [Logical Conditions: Set Membership and Set Functions](#). For more on conditional assignments, see section [Conditional Assignments](#).

4.24.4.2 Conditional Indexed Operations with Dynamic Sets

Indexed operations in GAMS are introduced in section [Indexed Operations](#). They may be controlled by dollar conditions as discussed in section [Conditional Indexed Operations](#). The domain of conditional indexed operations is often restricted by a set, called the [conditional set](#). Dynamic sets may be used as conditional sets or they may be assigned to with a statement that features a conditional indexed operation on the right-hand side. We will illustrate both cases with examples.

Suppose we have a set of origins, a set of destinations and a table specifying the flight distance between them:

```
Set  i          "origins"          / Chicago, Philadelphia /
     j          "destinations"     / Vancouver, Bogota, Dublin, Rio, Marrakech / ;

Table d(i,j)    "distance (miles)"
              Vancouver  Bogota  Dublin  Rio  Marrakech
Chicago      1777      2691   3709   5202  4352
Philadelphia 2438      2419   3306   4695  3757      ;
```

We wish to find the longest distance that we can travel given that we have a limit of 3500 miles.

```
Set  can_do(i,j) "connections with less than 3500 miles";
can_do(i,j)$ (d(i,j) < 3500) = yes;
display can_do;
Scalar maxd "longest distance possible"
maxd = smax((i,j)$can_do(i,j), d(i,j));
display maxd;
```

The dynamic set `can_do` contains all connections that are less than 3500 miles. The scalar `maxd` is defined by a conditional assignment where the indexed operation `smax` scans all entries of the parameter `d` whose label combinations are members of the set `can_do` and chooses the largest value. The output generated by the [display statements](#) is shown below:

```
-----      11 SET can_do  connections with less than 3500 miles

              Vancouver      Bogota      Dublin
Chicago      YES            YES
Philadelphia YES            YES            YES

-----      15 PARAMETER maxd = 3306.000 longest distance possible
```

There is a shorter alternative formulation for this assignment; see subsection [Filtering through Dynamic Sets](#) below for details.

Finally, we also wish to know which flight connection is linked to the longest possible distance. Consider the following two lines:

```
Singleton set maxc(i,j) "maximum distance connection";
maxc(i,j) = yes$can_do(i,j) and (d(i,j) = maxd);
```

The dynamic singleton set is assigned the member of the dynamic set `can_do` whose distance equals the maximum distance.

The full power of indexed operators becomes apparent with multi-dimensional dynamic sets. As earlier in this chapter, we illustrate with fragments of code adapted from the relational database model [ZLOOF].

```
Set dep      "departments" / cosmetics, hardware, household, stationary, toy /
    sup      "suppliers"   / bic, dupont, parker, revlon /
    item     "items sold"  / dish, ink, lipstick, pen, pencil, perfume /

sales(dep,item) "departments and items sold" /
  cosmetics. (lipstick,perfume)
  hardware.  ink
  household. (dish,pen)
  stationary. (dish,ink,pen,pencil)
  toy.       (ink,pen,pencil) /

supply(item,sup) "items and suppliers" /
  dish.(bic,dupont) , ink.(bic,parker) , lipstick.revlon
  pen.(parker,revlon) , pencil.(bic,parker) , perfume.revlon /

Set g03(dep) "departments selling items supplied by Parker";

g03(dep) = sum(item$supply(item,'parker'), sales(dep,item));
display g03;
```

The assignment above is used to create the set of departments that sell items supplied by 'parker'. Note that the set `g03` is a subset of the set `dep`. Its members are specified by assignment, hence it is a dynamic set. Note that the assignment is made to a set, therefore the indexed operator `sum` refers to a [set union](#) (and not to an addition as would be the case if the assignment were made to a parameter). The indexed operation is controlled by the two-dimensional set `supply` with the label 'parker' in the second index position. This logical condition is TRUE for all members of the set `supply` where the second index is 'parker'. Hence the summation is over all items sold, provided that the supplier is 'parker'. Given the declaration of the set `supply`, this means 'ink', 'pen' and 'pencil'. The associated departments are thus all departments except for 'cosmetics':

```
----      19 SET g03  departments selling items supplied by Parker

hardware ,   household ,   stationary,   toy
```

Now suppose we are interested in the departments that are selling *only* items supplied by 'parker'. We introduce a new dynamic set `g11` and the following assignment adds the desired departments:

```
Set g11(dep) "departments only selling items supplied by parker";
g11(dep) = prod(sales(dep,item), supply(item,"parker"));
display g11;
```

Note that the indexed operation `prod` refers to [set intersections](#) in the context of assignments to dynamic sets. From all departments linked with items only those are included where *all* items sold are supplied by 'parker'. This means that departments that additionally sell items that are not supplied by 'parker' are excluded. Hence, only 'hardware' and 'toy' are added to `g11`.

4.24.4.3 Conditional Equations with Dynamic Sets

Recall that dollar conditions in the context of equations may restrict the domain of the equation and they may also feature in the algebraic formulation of the equation; see section [Conditional Equations](#) for more information. In both instances dynamic sets may be used as part of the logical condition. Dollar conditions with dynamic sets in the algebra of equations are similar to conditional assignments with dynamic sets; see section [Dynamic Sets in Conditional Assignments](#) above. The example that follows illustrates the use of a dynamic set to restrict the domain of definition of an equation. In section [Equations Defined over the Domain of Dynamic Sets](#) above we had the following equation definition:

```
prodball1(r) ..          activity2(r)*price    =e= revenue(r)    ;
```

Recall that `r` is a dynamic set and a subset of the set `allr`. Hence this equation may be rewritten in the following way:

```
prodball1(allr)$r(allr) .. activity2(allr)*price =e= revenue(allr) ;
```

Note that both formulations achieve the same result: restricting the domain of definition to those elements that belong to the dynamic set `r`. While in the second formulation the condition is specified explicitly, in the first formulation the domain is *filtered* through the dynamic set `r`. This is the topic of the next subsection.

4.24.4.4 Filtering through Dynamic Sets

The filtering process is introduced and explained in section [Filtering Sets](#) in chapter [Conditional Expressions, Assignments and Equations](#). In certain circumstances it is an alternative to the dollar condition to restrict the domain of equations, sets, variables, parameters and indexed operations. We already saw an example for restricting the domain of definition of an equation in the previous subsection. The next example refers to restricting the domain in an indexed operation. In section [Conditional Indexed Operations with Dynamic Sets](#) we had the following assignment:

```
maxd = smax((i,j)$can_do(i,j), d(i,j));
```

Recall that `maxd` is a scalar, `i` and `j` are sets, `can_do` is a dynamic set and `d` is a two-dimensional parameter. Note that the conditional set is the dynamic set `can_do`. The assignment may be rewritten in the following way:

```
maxd = smax(can_do(i,j), d(i,j));
```

Here the indexed operation is filtered through the dynamic set `can_do`, a dollar condition is not necessary.

4.25 Sets as Sequences: Ordered Sets

4.25.1 Introduction

Sets are introduced in chapter [Set Definition](#). There we state that in general, sets in GAMS are regarded as an unordered collection of labels. However, in some contexts, say, multi-period planning models, some sets need to be treated as if they were sequences. In this chapter we will establish the notion of *ordered sets* and we will cover their special features and the associated operations.

Examples where ordered sets are needed include economic models that explicitly represent conditions in different time periods that are linked, location problems where the formulation may require a representation of contiguous areas, as in a grid representation of a city, scheduling problems and programs that model stocks of capital with equations of the form '*stocks at the end of period n are equal to stocks at the end of period $n - 1$ plus net gains during period n* '.

Note

Models involving sequences of time periods are often called *dynamic models*, because they describe how conditions change over time. This use of the word *dynamic* unfortunately has a different meaning from that used in connection with [dynamic sets](#), but this is unavoidable.

4.25.2 Ordered and Unordered Sets

Certain one-dimensional sets may be treated as if they were a sequence. Those sets need to be ordered and [static](#). A one-dimensional set is ordered if the definition or initialization of the elements in the set corresponds to the order of the [labels](#) in the GAMS Entry order.

Note

- The GAMS entry order is the order in which the individual [labels](#) first appear in the GAMS program, either explicitly or as a result of using the shorthand [asterisk notation](#).
- For the sake of simplicity, sets that are static and ordered are often just referred to as *ordered sets*.

GAMS maintains a *unique element list* where all labels that are used as elements in one or more sets are listed. The order of the elements in any one set is the same as the order of those elements in the unique element list. This means that the order of a set may not be what it appears to be if some of the labels were used in an earlier definition. The internal GAMS order of the labels can be made visible with the dollar control option [\\$onUELList](#). This directive generates a map that is shown in the [compilation output](#) of the listing file. For details on the listing file and GAMS output in general, see chapter [GAMS Output](#). A good rule of thumb is that if the user wants a set to be ordered and the labels in the set have not been used already, then they will be ordered.

In the example below we show ordered and unordered sets and the map showing the order. The input is:

```
$onUELList
Set   t1 / 1987, 1988, 1989, 1990, 1991 /
      t2 / 1983, 1984, 1985, 1986, 1987 /
      t3 / 1987, 1989, 1991, 1983, 1985 / ;
```

Note that the label "1987" is the first label seen by GAMS. It appears again as the last label in the initialization list for the set `t2`. This means that the set `t2` is *not* ordered and any attempt to use `t2` in a context implying order, such as the operations introduced later in this chapter, will cause error messages. Observe that the set `t3` is ordered, as all the members of `t3` have appeared in the GAMS program before, and in the same order that they are listed in the definition of `t3`.

The [unique element listing map](#) below shows the entry order (the important one) and the sorted order, obtained by sorting the labels into dictionary order. The single digits on the left are the sequence numbers of the first label on that line.

```
General Algebraic Modeling System
Unique Element Listing
```

```
Unique Elements in Entry Order
```

```
 1 1987      1988      1989      1990      1991      1983
 7 1984      1985      1986
```

```
Unique Elements in Sorted Order
```

```
 1 1983      1984      1985      1986      1987      1988
 7 1989      1990      1991
```

A set can always be made ordered by moving its declaration closer to the beginning of the program. With these restrictions in mind, we will continue in the next section with the operations that may be used with ordered sets.

4.25.3 Sorting a Set

Note that besides the entry order of unique elements there is also a sorted (alphabetical) order. To obtain the sorted order (of an ordered or unordered set) the special predefined two-dimensional set `SortedUEls(*,*)` can be used. Consider the following example where set `j` is reported in an alphabetically sorted format:

```
set j / c, a, b, 1, 2, 11 /;
display j;
alias(*,u);
file ordered /ordered.txt/;
loop(SortedUEls(u,j), put ordered j.tl:0 ' ');
putclose ordered;
```

The output generated by the display statement follows:

```
----      2 SET j
c ,      a ,      b ,      1 ,      2 ,      11
```

Note that, as expected, the [display statement](#) shows the elements of set `j` in the entry order *not* in alphabetical order. However, the elements are listed in alphabetical order in the file `ordered.txt`. Note furthermore, that alphabetical sorting leads to an order where e.g. 11 precedes 2.

```
1 11 2 a b c
```

In the example above `u` is aliased with the [Universal Set](#). For an introduction to writing external files with `put`, see chapter [The Put Writing Facility](#).

4.25.4 Ord and Card Operators

As stated in section [Labels](#) in chapter [GAMS Programs](#), labels in GAMS do not have a numerical value. The examples used were that the label '1986' does not have a numerical value of 1986 and the label '01' is different from the label '1'. This section introduces two operators - `ord` and `card` - that return integer values when applied to sets. While the integer values returned do not represent the numerical value of the label, they can be used for the same purpose.

Note

GAMS provides some [string manipulation](#) capability by extending the `card` and `ord` operators to also work on strings.

4.25.4.1 The Ord Operator

The operator `ord` returns the relative position of a member in a set.

Attention

By default the operator `ord` may be used only with one-dimensional sets that are static and ordered.

Some examples show the usage.

```
Set      t      "time periods" / 1985*1995 / ;
Parameter val(t) ;
val(t) = ord(t);
```

Note that as a result of the statements above, the value of `val('1985')` will be 1, `val('1986')` will be 2 and so on.

A common use of `ord` is in setting up vectors that represent quantities growing in some analytically specified way. For example, suppose a country has 56 million people in the base period and the population is growing at the rate of 1.5 percent per year. Then the population in succeeding years can be calculated as follows:

```
population(t) = 56*(1.015**(ord(t) - 1)) ;
```

It is often useful to simulate general matrix operations in GAMS. The first index of a two dimensional parameter can conveniently represent the rows, the second the columns and order is necessary. The example below shows how to set the upper triangle of a matrix equal to the row index plus the column index, and the diagonal and lower triangle to zero.

```
Set      i      "row and column labels"      / x1*x10 /;
alias (i,j);
Parameter a(i,j) "a general square matrix";
a(i,j) $ (ord(i) < ord(j)) = ord(i) + ord(j);
```

Note that in the assignment statement the logical condition (`ord(i) < ord(j)`) restricts the assignment to the entries of the upper triangle. For more information on logical conditions and conditional assignments in GAMS, see sections [Logical Conditions](#) and [Conditional Assignments](#) respectively.

Note that the strict requirement that the set needs to be ordered for the operator `ord` to be used may be relaxed with a [dollar control option](#) called `offOrder`. Consider the following lines where we revisit the example from the previous section.

```
$offOrder
Set      t1      / 1987, 1988, 1989, 1990, 1991 /
         t2      / 1983, 1984, 1985, 1986, 1987 /;
Parameter p(t2);
p(t2) = ord(t2);
display p;
```

Note that, as we explained above, the set `t2` is *not* ordered. Therefore using `ord(t2)` somewhere in the model will usually cause the program to be terminated with an error message. However, with the dollar control option `offOrder` active, the set `t2` is treated as if it were ordered and the [display statement](#) will generate the following output:

```
----          6 PARAMETER p
1987 1.000,    1983 2.000,    1984 3.000,    1985 4.000,    1986 5.000
```

While this may be useful in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the `ord` operator can be turned on again via [onOrder](#).

4.25.4.2 The Card Operator

The operator `card` returns the number of elements in a set.

Note

The operator `card` may be used with any set: static and dynamic sets, ordered and unordered sets.

The following example illustrates its use:

```
Set      t  "time periods" / 1985*1995 /;
Scalar  s;
s = card(t);
Display s;
```

Note that `s` will be assigned the value 11 since the set `t` has 11 elements.

A common use of `card` is to specify some condition only for the final period, for example to fix a variable. Consider the following artificial example:

```
c.fx(t)$ (ord(t) = card(t)) = demand(t);
```

Note that the logical condition (`ord(t) = card(t)`) restricts the assignment to the last element of the set `t`: no assignment is made for other members of `t`. The advantage of this way of fixing the variable `c` is that the membership of `t` can be changed safely and this statement will always fix `c` for the last element. For more information on logical conditions and conditional assignments in GAMS, see sections [Logical Conditions](#) and [Conditional Assignments](#) respectively.

4.25.5 Lag and Lead Operators

Lag and lead operators are used to relate the *current* member of an ordered set to the *previous* or *next* member of the set. GAMS provides two forms of lag and lead operators (linear and circular), they are summarized in [Table 1](#). Note that in the table below `t` is a member of an ordered set and `n` is a positive integer.

Operation	Symbol	Description
Linear Lag	$t - n$	Refers to the element of the ordered set whose relative position in the set is $\text{ord}(t)-n$.
Linear Lead	$t + n$	Refers to the element of the ordered set whose relative position in the set is $\text{ord}(t)+n$.
Circular Lag	$t -- n$	Same as $t - n$, only here the first element of the set is assumed to be preceded by the last element of the set, thus forming a circle of elements.
Circular Lead	$t ++ n$	Same as $t + n$, only here the last element of the set is assumed to be followed by the first element of the set, thus forming a circle of elements.

Table 1: Linear and Circular Lag and Lead Operators

Note that the only difference between *linear* and *circular* lag and lead operators is how endpoints are treated. *Linear* operators assume that there are no members preceding the first and following the last member of the ordered set. This assumption may result in elements of the set being referenced that actually do not exist. Therefore the user must think carefully about the treatment of endpoints: models with linear lag and lead operators will need special exception handling logic to deal with them. The next two sections will describe how this issue is handled in GAMS in the context in which these operators are typically used: assignments and equations. Linear lag and lead operators are useful for modeling time periods that do not repeat, like a set of years (say 1990 to 1997).

Circular lag and lead operators assume that the first and last members of the set are adjacent, so as to form a circular sequence of members. This means that ' $\text{first}-1$ ' is a reference to ' last ' and ' $\text{last}++2$ ' is the same as ' $\text{first}++1$ '. All references and assignments are defined. The assumption of circularity is useful for modeling time periods that repeat, such as months of the year or hours in the day. It is quite natural to think of January as the month following December. Agricultural farm budget models and workforce scheduling models are examples of applications where circular leads occur naturally.

Note

- GAMS is able to distinguish the linear lag and lead operators '-' and '+' from [arithmetic operators](#) by context. To avoid ambiguity, GAMS does not allow to mix lag and lead operators with arithmetic operators. For example, $i+1+1$ is not allowed, but writing $i+(1+1)$ would work.
- Observe that the lag (or lead) value n does not have to be an explicit constant: it can be an arbitrary expression, provided that it evaluates to an integer. If it does not, error messages will be produced. A negative result causes a switch in sense (from lag to lead, for example).

Note that if lag and lead operators are used with an *unordered* set, the program will terminate with an error message. The strict requirement that the set be ordered may be relaxed with the dollar control option [offOrder](#). If the directive `$offOrder` is added, in the lines that follow unordered sets are treated as if they were ordered and therefore lag and lead operators may be used with them. While this may be advantageous in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the use of lag and lead operators can be turned on again via [onOrder](#).

The next two subsections will give some illustrative examples on the use of lag and lead operators in assignment statements and in equations respectively.

4.25.5.1 Lags and Leads in Assignments

Lag and lead operators may be used in [assignment statements](#). The use of a lag or lead operator on the right-hand side of an assignment is called a *reference*, while their use on the left-hand side is called an *assignment* and involves the definition of a domain of the assignment. The concepts behind reference and assignment are equally valid for the linear and circular forms of the lag and lead operators. However, the importance of the distinction between reference and assignment is not pronounced for circular lag and lead operators, because non-existent elements are not referred to in this case.

Note

A reference to a non-existent element causes the default value zero to be used, whereas an attempt to assign to a non-existent element results in no assignment being made.

We will first illustrate *linear* lag and lead operators for reference and assignment. Then we will turn to the *circular* form of the operators.

4.25.5.1.1 Linear Lag and Lead Operators in Assignments - Reference Consider the following example, where the lag operator is used on the right-hand side of an assignment statement:

```
Set      t          "time sequence" / y-1987*y-1991 /;
Parameter a(t), b(t);
a(t) = 1986 + ord(t);
b(t) = -1;
b(t) = a(t-1);
option decimals = 0;
display a, b;
```

Note that the [option statement](#) suppresses the decimal places from the [display statement](#).

```
----          7 PARAMETER a
y-1987 1987,   y-1988 1988,   y-1989 1989,   y-1990 1990,   y-1991 1991

----          7 PARAMETER b
y-1988 1987,   y-1989 1988,   y-1990 1989,   y-1991 1990
```

Note that, as expected, the values for the parameter **a** are 1987, 1988 up to 1991 corresponding to the labels "y-1987", "y-1988" and so on. Observe that the parameter **b** is initialized to -1 so that the result of the next assignment can be seen clearly. Note that in the last assignment the lag operator '-' is used on the right-hand side, resulting in the values for **b** to equal the values for **a** from the *previous* period. If there is no previous period, as with the first element, "y-1987", the value zero is assigned, replacing the previous value of -1 (values of zero for parameters are not displayed).

4.25.5.1.2 Linear Lag and Lead Operators in Assignments - Assignment Consider the following variation of the previous example. Here the lead operator is used on the left-hand side of an assignment statement:

```
Set      t          "time sequence" / y-1987*y-1991 / ;
Parameter a(t), c(t) ;
a(t)    = 1986 + ord(t) ;
c(t)    = -1;
c(t+2)  = a(t) ;
option decimals = 0;
display a, c ;
```

Note that, as before, the [option statement](#) suppresses the decimal places from the [display statement](#).

```
-----      7 PARAMETER a
y-1987 1987,   y-1988 1988,   y-1989 1989,   y-1990 1990,   y-1991 1991

-----      7 PARAMETER c
y-1987  -1,   y-1988  -1,   y-1989 1987,   y-1990 1988,   y-1991 1989
```

The assignment to `a` is explained in the previous subsection. Note that the parameter `c` is initialized to `-1`. The assignment to `c` involving the lead operator on the left-hand side needs special attention. It is best to spell out step by step how this assignment is made. For each member of `t` in sequence, find the member of `c` associated with `t+2`. If it exists, replace its value with the value of `a(t)`. If not (as with labels "y-1990" and "y-1991") make no assignment. The first member of the set `t` is "y-1987", therefore the first assignment is made to `c("y-1989")` which takes the value of `a("y-1987")`, that is 1987. No assignments at all are made to `c("y-1987")` and `c("y-1988")`: these two retain their previous values of `-1`.

4.25.5.1.3 Circular Lag and Lead Operators in Assignments The following example illustrates the use of circular lag and lead operators in assignment statements.

```
Set      s          "seasons" / spring, summer, autumn, winter /;
Parameter val(s)          / spring 10, summer 15, autumn 12, winter 8 /
      lagval(s)
      leadval(s);
lagval(s)    = -1 ;
lagval(s)    = val(s--2) ;
leadval(s)   = -1 ;
leadval(s++1) = val(s) ;
option decimals = 0;
display val, lagval, leadval;
```

Note that, as before, the [option statement](#) suppresses the decimal places from the [display statement](#). The results are shown below.

```
-----      10 PARAMETER val

spring 10,   summer 15,   autumn 12,   winter 8

-----      10 PARAMETER lagval
```

```
spring 12,    summer 8,    autumn 10,    winter 15
```

```
----      10 PARAMETER leadval
```

```
spring 8,    summer 10,    autumn 15,    winter 12
```

In the example parameter `lagval` is used for reference while `leadval` is used for assignment. Notice that the case of circular lag and lead operators does not refer to any non-existent elements. The difference between reference and assignment is therefore not important. Note that the following two statements from the example above,

```
lagval(s)      = val(s--2) ;
leadval(s++1) = val(s) ;
```

are equivalent to

```
lagval(s++2) = val(s) ;
leadval(s)   = val(s--1) ;
```

The use of reference and assignment have been reversed with no difference in effect.

4.25.5.2 Lags and Leads in Equations

The principles established in the previous section follow quite naturally into [equation definitions](#). A lag or lead to the left of the `'..'` symbol is a modification of the domain of definition of the equation. The linear form may cause one or more individual equations to be suppressed. A lag or lead operation in the body of an equation (to the right of the `'..'` symbol) is a reference. If the associated label is not defined, the term vanishes.

Note

All lag and lead operands must be *exogenous*. For more information, see section [Functions in Equation Definitions](#).

In the next two subsections we will provide examples illustrating the use of the *linear* form of the lag and lead operators in equations to modify the domain of definition and for reference respectively. In the last subsection we will turn to *circular* lag and lead operators in equations.

4.25.5.2.1 Linear Lag and Lead Operators in Equations - Domain Control Consider the following simple artificial multi-period example. We specify a complete [model](#) and encourage users to solve it and further explore it.

```

Sets      t          / t1*t5 /
          tfirst(t);
Parameter i(t)      / #t 1 /;
Scalar    k0        / 3.00 /;

tfirst(t) = yes$(ord(t) = 1);

Variables k(t), z;
k.fx(tfirst) = k0;

Equations kk(t), dummy;
dummy..      z =e= 0;
kk(t+1)..   k(t+1) =e= k(t) + i(t);

model m /all/;
option limrow = 10;
solve m using lp min z;

```

Note that the equation `kk` is declared over the set `t`, but it is defined over the domain `(t+1)`. Therefore the first equation that will be generated is the following:

```
k('t2') =e= k('t1') + i('t1');
```

Note that the value of the variable `k('t1')` is fixed at the value of scalar `k0`. Observe that for the last element of `t`, the term `k(t+1)` is not defined and therefore the equation will not be generated. If lag or lead operators are used in the domain of definition of an equation, the [equation listing](#) can be a useful tool to verify whether the equations that have been generated are those that were intended:

```

kk(t2).. - k(t1) + k(t2) =E= 1 ; (LHS = 0, INFES = 1 ****)
kk(t3).. - k(t2) + k(t3) =E= 1 ; (LHS = 0, INFES = 1 ****)
kk(t4).. - k(t3) + k(t4) =E= 1 ; (LHS = 0, INFES = 1 ****)
kk(t5).. - k(t4) + k(t5) =E= 1 ; (LHS = 0, INFES = 1 ****)

```

To summarize, the lead operator in the domain of definition has restricted the number of constraints generated so that there are no references to non-existent variables.

For a more realistic model that illustrates the usage of linear lag operators in equations, see for example the optimal economic growth model [[RAMSEY](#)].

4.25.5.2.2 Linear Lag and Lead Operators in Equations - Reference In the previous subsection we showed how to write the equation `kk` using the lead operator for domain control in combination with fixing the variable `k(tfirst)` to `k0`. An alternative formulation could neglect the fixing of `k(tfirst)` and use a lag operator and a dollar condition in the *body* of the equation while the *domain* of definition is unrestricted:

```
kk(t).. k(t) =e= k(t-1) + i(t-1) + k0$tfirst(t);
```

Note that for the first element of the set `t` the terms `k(t-1)` and `i(t-1)` are not defined and therefore vanish. Without the conditional term, the resulting equation would be:

```
k('t1') =e= 0;
```

However, this would lead to different results as `k('t1')` would not be set to the value of `k0` anymore. Therefore the [conditional expression](#) `k0$tfirst(t)` is added. Observe that in this formulation equations are generated for *all* time periods, no equation is suppressed.

In general, the choice between using lag and lead operators as reference like in the last example or in domain control is often a matter of taste.

4.25.5.2.3 Circular Lag and Lead Operators in Equations In the case of circular lag and lead operators, the difference between their use in domain control and as reference is not important because it does not lead to any equations or terms being suppressed. Consider the following artificial example.

```
Set      s      "seasons" / spring, summer, autumn, winter /;

Variable produ(s) "amount of goods produced in each season"
        avail(s) "amount of goods available in each season"
        sold(s)  "amount of goods sold in each season";

Equation matbal(s);

matbal(s).. avail(s+1) =e= avail(s) + produ(s) - sold(s);
```

In this example four individual equations are generated. They are listed below.

```
avail('summer') =e= avail('spring') + produ('spring') - sold('spring');
avail('autumn')  =e= avail('summer') + produ('summer') - sold('summer');
avail('winter')  =e= avail('autumn') + produ('autumn') - sold('autumn');
avail('spring')  =e= avail('winter') + produ('winter') - sold('winter');
```

Note that for the last element of the set `s` the term `avail(s+1)` is evaluated to `avail('spring')`. This term is well defined and therefore it does not vanish. Similarly, using the circular lead operator in the domain of definition like in the following line will result in the same four equations being generated as above and no equation being suppressed.

```
matbal(s+1).. avail(s+1) =e= avail(s) + produ(s) - sold(s);
```

4.25.6 Summary

This chapter introduced the concept of ordered sets. All the features in GAMS that dealt with this issue including the `ord` and `card` functions, as well as the linear and circular forms of the lag and lead operators were described in detail.

4.26 Data Manipulations with Parameters

4.26.1 Introduction

In this chapter we explicitly cover only *parameter* manipulation, including all aspects of data handling. Much of this material is relevant elsewhere (e.g. to sets), but for specifics related to assignment to sets, to conditions, and to assignments within flow control constructs such as the `loop` statement, see chapters [Dynamic Sets](#), [Conditional Expressions, Assignments and Equations](#) and [Programming Flow Control Features](#) respectively.

Once initialized, data often requires manipulation in order to bring it into a form most suitable for use in a model or an application. The assignment statement is the way to do this. All the possible components of the assignment statement except conditions are introduced and discussed in this chapter.

4.26.2 The Assignment Statement

The assignment statement is the fundamental data manipulation statement in GAMS. It may be used to define or alter values associated with sets, parameters, variables or equations.

A simple assignment is written in the style associated with many other computer languages. GAMS uses the traditional symbols for addition (+), subtraction (-), multiplication (*) and division (/). We will use them in the examples that follow, and give more details in section [Expressions](#).

4.26.2.1 Scalar Assignments

Consider the following artificial sequence:

```
scalar x / 1.5 /;  
x = 1.2;  
x = x + 2;
```

The scalar x is initialized to be 1.5. The second statement changes the value to 1.2, and the third changes it to 3.2. The second and third statements are assignments: each replaces the current value of x with a new one.

Note that the same symbol can be used on the left and right of the = sign. The new value is not available until the calculation is complete, and the operation gives the expected result.

Note

An assignment cannot start with a reserved word. A semicolon is therefore required as a delimiter before all assignments.

Note that extended range identifiers (e.g. INF) and acronyms may also be used in assignment statements. For specific details, see sections [Extended Range Arithmetic](#) and [Acronym Usage](#) respectively.

4.26.2.2 Indexed Assignments

The GAMS syntax for performing indexed assignments is extremely powerful. This operation offers what may be thought of as simultaneous or parallel assignments and provides a concise way of specifying large amounts of data. Consider the mathematical statement $DJ_d = 2.75 \cdot DA_d$ for all elements of d . This means that for every member of the set d , a value is assigned to DJ . This can be written in GAMS as follows:

```
dj(d) = 2.75*da(d) ;
```

This assignment is known technically as an *indexed assignment* and set d as the controlling index or controlling set.

Attention

The index set(s) on the left hand side of an indexed assignment are referred to synonymously as the controlling indices, controlling sets, or controlling domain of the assignment.

The extension to two or more controlling indices should be obvious. There will be an assignment made for each label combination that can be constructed using the indices inside the parentheses. Consider the following example of an assignment to all 100 data elements of the parameter `a`.

```
sets row          / r-1*r-10 /
     col          / c-1*c-10 /
     sro(row)     / r-7*r-10 / ;
parameters r(row) /r-1*r-7 4, r-8*r-10 5/
           c(col)  /c-1*c-5 3, c-6*c-10 2/;
parameters a(row,col);
a(row,col) = 13.2 + r(row)*c(col) ;
```

The calculation in the last statement is carried out for each of the 100 unique two-label combinations that can be formed from the elements of `row` and `col`. An explicit formulation of the first of these assignments follows:

```
a('r-1','c-1') = 13.2 + r('r-1')*c('c-1');
```

Note that for indexed assignments a copy of the symbols on the right hand side is installed before the assignment is carried out. That means it does not work "in-place" or recursively. Consider the following example where we compute the first ten Fibonacci numbers and store them in parameter `f` using a loop. The example also illustrates how such a recursive calculation does not work with a parallel assignment statement for parameter `g`.

```
set i / i1*i10 /
parameter
  f(i) / i1 1 /
  g(i) / i1 1 /;
loop(i$(ord(i)>=2),
  f(i) = f(i-2) + f(i-1);
);
g(i$(ord(i)>=2) = g(i-2) + g(i-1)
display f,g;
```

The display statement results in the following output.

```
-----          9 PARAMETER f
i1  1.000,    i2  1.000,    i3  2.000,    i4  3.000,    i5  5.000
i6  8.000,    i7 13.000,    i8 21.000,    i9 34.000,   i10 55.000

-----          9 PARAMETER g
i1 1.000,    i2 1.000,    i3 1.000
```

4.26.2.3 Restricting the Domain in Assignments

Sometimes it is necessary to make assignments over selected elements of a set instead of over the entire domain. There are several ways to accomplish this: using [explicit labels](#), [subsets](#), [conditionals](#) and [tuples](#).

4.26.2.3.1 Restricting the Domain: Explicit Labels The strongest restriction of the domain is assigning a value to just one element. Labels may be used explicitly in the context of assignments to accomplish this. The following example illustrates:

```
a('r-7', 'c-4') = -2.36 ;
```

This statement assigns a constant value to just one element of the parameter `a`. All other elements of `a` remain unchanged. Labels must be quoted when used in this way.

4.26.2.3.2 Restricting the Domain: Subsets In general, wherever a set name may occur in an indexed assignment, a subset may be used instead.

Consider the following example:

```
a(sro, 'col-10') = 2.44 -33*r(sro) ;
```

Since the set `sro` was declared as a subset of the set `row`, we can use `sro` as a controlling index in the assignment above to make the assignment only for the elements of `sro`.

4.26.2.3.3 Restricting the Domain: Conditionals Conditional assignments are discussed in detail in section [Conditional Assignments](#) in chapter [Conditional Expressions, Assignments and Equations](#). For details on the types of logical conditions, see section [Logical Conditions](#). Here we present a simple example to illustrate:

```
a(row,col)$[a(row,col) >= 100] = INF ;
```

This assignment has the following effect: all elements of the parameter `a` whose value was at least 100 are assigned the value `INF`, while all other elements of `a` remain unchanged.

4.26.2.3.4 Restricting the Domain: Tuples Tuples or multi-dimensional sets are introduced in section [Many-to-Many Mapping](#). In this simple example we show how they may be used to restrict the domain. The example builds on the first example in this section. We repeat the whole code here for clarity.

```
sets row          / r-1*r-10 /
    col          / c-1*c-10 /
    sro(row)     / r-7*r-10 / ;
set tuple(row,col) /r-1.c-1, r-1.c-10, r-10.c-1, r-10.c-10/;
parameters r(row) /r-1*r-7 4, r-8*r-10 5/
           c(col) /c-1*c-5 3, c-6*c-10 2/;
parameters a(row,col), b(row,row);
a(row,col) = 13.2 + r(row)*c(col) ;
a(tuple(row,col)) = 7 + r(row)*c(col) ;
a(tuple) = 0.25 * a(tuple) ;
```

Note that we have introduced the new set `tuple`. It is two-dimensional and contains just four elements. As before, the parameter `a` is first assigned values for all its 100 elements. We then change some of these values using the set `tuple` as domain. The values of the elements of the parameter `a` that are not elements of the set `tuple` remain unchanged.

For a more elaborate example involving tuples, see section [Filtering Sets in Assignments](#).

4.26.2.4 Issues with Controlling Indices

Attention

The number of controlling indices on the left of the = sign should be at least as large as the number of indices on the right. There should be no index on the right-hand side of the assignment that is not present on the left unless it is operated on by an indexed operator. For more on indexed operators, see section [Indexed Operations](#).

Consider the following statement:

```
a(row,'col-2') = 22 - c(col) ;
```

GAMS will flag this statement as an error since `col` is an index on the right-hand side of the equation but not on the left.

Note that there would be no error here if `col` were a **singleton set**. Since there is only one element in a singleton set, the intent and behavior is well-defined even when `col` is not under control.

Attention

Each set is counted only once to determine the number of controlling indices. If the intent is for a set to appear independently more than once within the controlling domain, the second and subsequent occurrences of the set should be **aliases** of the original set, so that the number of controlling indices is equal to the number of indices. For details on aliases, see section [The Alias Statement: Multiple Names for a Set](#).

Consider the following statement as an illustration:

```
b(row,row) = 7.7 - r(row) ;
```

This statement has only one controlling index, namely `row`. One element (on the diagonal of `b`) is assigned for each element of `row`, for a total of 10 assigned values. None of the off-diagonal elements of `b` will be changed!

If the intent is to assign values to each element of `b`, this can be done by introducing an alias `rowp` for `row` and using this alias in the second index position. There will then be two controlling indices and GAMS will make assignments over all 100 values of the full Cartesian product. The following example illustrates this method:

```
alias(row,rowp) ;
b(row,rowp) = 7.7 - (r(row) + r(rowp))/2 ;
```

4.26.3 Expressions

An expression is an arbitrarily complicated specification for a calculation, with parentheses nested as needed for clarity and intent. In this section the discussion of parameter assignments will continue by showing in more detail the expressions that may be used on the right of the = sign. We will cover standard arithmetic operations and indexed operations here, and [functions](#) and [extended range arithmetic](#) in the next two sections.

4.26.3.1 Standard Arithmetic Operations

The standard arithmetic symbols and operations and their order of precedence are given in [Table 1](#). Note that 1 denotes the highest order of precedence and 3 denotes the lowest order of precedence. Parentheses can be used to override the default precedence order in the usual way. Operators (including exponentiation) on the same level are evaluated from left to right.

Operation	Symbol	Order of Precedence
Exponentiation	**	1
Multiplication	*	2
Division	/	2
Addition	+	3
Subtraction	-	3

Table 1: Standard Arithmetic Operations

Note that the full GAMS operator precedence hierarchy also includes logical operators; it is given in section [Mixed Logical Conditions](#). Note further that the symbols for addition, subtraction and multiplication have a different meaning if they are used in the context of sets. For details see sections [Set Operations](#) and [Lag and Lead Operators](#).

Attention

The operation `x**y` is equivalent to the function `rPower(x,y)` and is calculated internally as $e^{y \times \log(x)}$. This operation is not defined if x is negative; an error will result in this case. If the possibility of negative values for x is to be admitted *and* the exponent is known to be an integer, then the function `power(x,n)` may be used.

Like many [GAMS intrinsic functions](#), the operation `x**y` is not defined for all possible input values. When evaluating nonlinear functions and operators GAMS guards against evaluating at or very near singular points and in such cases signals an error or returns an appropriate function value.

Note

As usual, operations within parentheses or brackets are evaluated before other numerical calculations, where the innermost parentheses are resolved first. Any of the pairs `()`, `[]` and `{}` are allowed.

Consider for example:

```
x = 5 + 4*3**2;
```

For clarity, this could have been written as follows:

```
x = 5 + (4*[3**2]) ;
```

In both cases the result is 41.

Note

It is often better to use parentheses than to rely on the order of precedence of operators, since this prevents errors and clarifies intentions.

Note that expressions may be freely continued over many lines: an end of line is permissible at any point where a blank may be used. Blanks may be used for readability around identifiers, parentheses and operation symbols. Blanks are not allowed within identifiers or numbers, and are significant inside the quotes used to delimit labels.

4.26.3.2 Indexed Operations

In addition to the simple operations in [Table 1](#), GAMS also provides the following four indexed operations.

Operation	Keyword
Summation	sum
Product	prod
Minimum value	smin
Maximum value	smax

Table 2: Indexed Operations

These four operations are performed over one or more controlling indices. The syntax in GAMS for these operations is:

```
indexed_op( (index_list), expression);
```

`Indexed_op` is one of the four keywords for indexed operations, `index_list` is the list of the controlling indices and `expression` is the expression to be evaluated. If there is only one controlling index, the parentheses around it may be removed. Consider the following simple example adapted from [ANDEAN]:

```
sets i  plants / cartagena, callao, moron /
      m  product / nitr-acid, sulf-acid, amm-sulf /;

parameter capacity(i,m) capacity in tons per day
           totcap(m)    total capacity by process ;

totcap(m) = sum(i, capacity(i,m));
```

The index over which the summation is done, `i`, is separated from the reserved word `sum` by a left parenthesis and from the data term `capacity(i,m)` by a comma. The set `i` is called the controlling index for this operation. The scope of the control is the pair of parentheses () that start immediately after the sum. Note that using normal mathematical representation the last line could be written as: $totC_m = \sum_i C_{im}$.

It is also possible to sum simultaneously over the domain of two or more sets as in the first assignment that follows. The second assignment demonstrates the use of a less trivial expression than an identifier within the indexed operation.

```
count = sum((i,j), a(i,j)) ;
emp = sum(t, l(t)*m(t)) ;
```

The equivalent mathematical forms are:

$$count = \sum_i \sum_j A_{ij} \quad \text{and} \quad emp = \sum_t L_t M_t.$$

Note that the following alternative notation may be used for the first assignment above:

```
count = sum(i, sum(j, a(i,j)));
```

In the context of sets the `sum` operator may be used to compute the number of elements in a set and for projections. For details see section [Projection and Aggregation of Sets](#).

The `smin` and `smax` operations are used to find the largest and smallest values over the domain of the index set or sets. The index for the `smin` and `smax` operators is specified in the same manner as in the index for the `sum` operator. In the following example we want to find the largest capacity:

```
lrgunit = smax((i,m), capacity(i,m));
```

Attention

The indexed operations `smin` and `smax` may be used in equation definitions only if the corresponding model is of type [DNLP](#). For more on GAMS model types, see [GAMS Model Types](#).

Note

- In the context of assignment statements, the attributes of variables and equations (e.g. `x.up(i, j)`) may be used in indexed operations just as scalars and parameters are used. For more on variable and equations attributes, see sections [Variable Attributes](#) and [Equation Attributes](#) respectively.
- In the context of equation definitions, scalars, parameters and variables may appear freely in indexed operations. For more on equation definitions, see section [Defining Equations](#).

Sometimes it is necessary to restrict the domain of indexed operations. This may be done with the same techniques as in indexed assignments, see section [Restricting the Domain in Assignments](#) for details. See also section [Conditional Indexed Operations](#) for more details on conditions in the context of indexed operations.

We now turn to two additional capabilities that are available in GAMS to add power and flexibility to expression calculations: [functions](#) and [extended range arithmetic](#).

4.26.4 Functions

Functions play an important role in the GAMS language, especially for nonlinear models. Like other programming languages, GAMS provides a number of built-in or intrinsic functions. GAMS is used in an extremely diverse set of application areas and this creates frequent requests for the addition of new and quite sophisticated or specialized functions. There is a trade-off between satisfying these requests and avoiding a complexity not needed by most users. The GAMS Function Library Facility provides the means for managing this trade-off, see subsection [Extrinsic Functions](#) below.

4.26.4.1 Intrinsic Functions

GAMS provides many functions, ranging from commonly used standard functions like exponentiation, logarithms, and trigonometric functions to utility functions for controlling and querying the running GAMS job or process. The complete list of available functions is given in the following tables: [Mathematical Functions](#), [String Manipulation Functions](#), [Logical Functions](#), [Time and Calendar Functions](#), and [GAMS Utility and Performance Functions](#). For details specific to using these functions in equations, see the section on [Expressions in Equation Definitions](#).

Some of the tables that follow contain an endogenous classification column "End. Classif." that specifies in which models the function may legally appear. In order of least to most restrictive, the choices are *DNLP*, *NLP*, *any*, *none*. See section [Classification of Models](#) for details on model types in GAMS. Note well: functions classified as *any* are only permitted with exogenous (constant) arguments.

Functions are typically used in assignment statements and equations. In these cases, they are only evaluated at execution time. Some functions can also be used at compile time, e.g. to compute the factorial or square root of a scalar. Some of the tables below contain a column "Compile Time" indicating which functions can be used at compile time.

A word on the notation in the tables below: for function arguments, lower case indicates that an endogenous variable is allowed. For details on endogenous variables, see section [Functions in Equation Definitions](#). Upper case function arguments indicate that a constant is required. Arguments in square brackets may be omitted: the default values used in such cases are specified in the function description provided.

4.26.4.1.1 Mathematical Functions Mathematical functions may be used as expressions in assignment statements and in equation definitions. We start with some simple examples to illustrate. A list with all mathematical functions available in GAMS is given in [Table 3](#).

Exp(x)

```
a = exp(t);
b = exp(t+2);
```

The GAMS function `exp(x)` returns the exponential e^x of its argument. The assignments above set $a = e^t$ and $b = e^{t+2}$ respectively.

Log(x)

```
z(j) = log(y(j));
```

The GAMS function `log(x)` returns the natural logarithm of its argument. The assignment above evaluates the logarithm once for each element of the controlling domain j .

Max(x1,x2,x3,...)

```
x = max(y+2, t, t*t);
```

The function `max` returns the maximum of a set of expressions or terms. In the assignment above, x will be assigned the maximum of $y + 2$, t , and $t \cdot t$.

Round(x[,DECPL])

The function `round` rounds its argument x to the specified number `DECPL` of places, where positive values of `DECPL` indicating rounding to the right of the decimal point. If the argument `DECPL` is not specified, it defaults to zero, and the function rounds its argument to the nearest integer value. For example,

```
x = round(q);
y = round(q,d);
z = round(12.432,2);
h = round(515.5,-1);
```

In the first assignment q is rounded to the nearest integer value, while in the second q is rounded to the number of decimals specified by d . The result of the third assignment is 12.43, while the final assignment results in a value of 520.

Table 3: Mathematical Functions

Function	Description	End. Classif.	Compile Time
<code>abs(x)</code>	Absolute value of the argument x .	DNLP	yes
<code>arccos(x)</code>	Inverse cosine of the argument x , where x is a real number between -1 and 1 and the output is in radians, see MathWorld	NLP	no

Function	Description	End. Classif.	Compile Time
<code>arcsin(x)</code>	Inverse sine of the argument x , where x is a real number between -1 and 1 and the output is in radians, see MathWorld	NLP	no
<code>arctan(x)</code>	Inverse tangent of the argument x , where x is a real number and the output is in radians, see MathWorld	NLP	no
<code>arctan2(y,x)</code>	Four-quadrant arctan function yielding $\arctan(\frac{y}{x})$ which is the angle the vector (x,y) makes with $(1,0)$ in radians.	NLP	no
<code>beta(x,y)</code>	Beta function: $B(x,y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}$, see MathWorld	DNLP	no
<code>betaReg(x,y,z)</code>	Regularized beta function , see MathWorld	NLP	no
<code>binomial(n,k)</code>	(Generalized) Binomial coefficient for $n > -1$, $-1 < k < n + 1$.	NLP	no
<code>ceil(x)</code>	Ceiling: returns the smallest integer greater than or equal to x .	DNLP	yes
<code>centropy(x,y[,Z])</code>	Cross-entropy: $x \cdot \ln(\frac{x+Z}{y+Z})$, where $Z \geq 0$. Default Z : $1e-20$.	NLP	no
<code>cos(x)</code>	Cosine of the argument x , where x must be in radians, see MathWorld	NLP	yes
<code>cosh(x)</code>	Hyperbolic Cosine of x , where x must be in radians, see MathWorld	NLP	no
<code>cvPower(X,y)</code>	Real power: returns X^y for $X \geq 0$.	NLP	no
<code>div(dividend,divisor)</code>	Returns $\frac{\text{dividend}}{\text{divisor}}$, undefined for $\text{divisor} = 0$.	NLP	no
<code>div0(dividend,divisor)</code>	Returns $\frac{\text{dividend}}{\text{divisor}}$, returns 10^{299} for $\text{divisor} = 0$.	NLP	no
<code>eDist(x1[,x2,x3,...])</code>	Euclidean or L-2 Norm: $\sqrt{x_1^2 + x_2^2 + \dots}$	NLP	no
<code>entropy(x)</code>	Entropy: $-x \cdot \ln(x)$.	NLP	no
<code>erf(x)</code>	Integral of the standard normal distribution from negative infinity to x : $\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt.$	NLP	no

Function	Description	End. Classif.	Compile Time
execSeed	Reads or resets the seed for the random number generator (RNG). Note that the state of the RNG cannot typically be captured in one seed value; in such cases "reading" the seed involves harvesting a seed from the RNG, resetting the RNG with this seed, and returning the seed.	none	no
exp(x)	Exponential of x : e^x , see MathWorld	NLP	yes
fact(N)	Factorial of N , where $N \geq 0$ is an integer.	any	yes
floor(x)	Floor : greatest integer less than or equal to x .	DNLP	yes
frac(x)	Returns the fractional part of x , s.t. $x = \text{trunc}(x) + \text{frac}(x)$	DNLP	yes
gamma(x)	Gamma function : $\Gamma(x) = \int_0^{\infty} t^{x-1} e^{-t} dt$, see MathWorld	NLP	no
gammaReg(x,a)	Lower Incomplete Regularized Gamma function , see <code>GammaRegularized[a,0,x]</code> in MathWorld	NLP	no
log(x)	Natural logarithm : logarithm base e , see MathWorld	NLP	yes
logBeta(x,y)	Log Beta function : $\log(B(x,y))$.	NLP	no
logGamma(x)	Log Gamma function as discussed in MathWorld	NLP	no
logit(x)	Logit Transformation : $\log(x/(1-x))$, see MathWorld	NLP	yes
log10(x)	Common logarithm : logarithm base 10, see MathWorld	NLP	yes
log2(x)	Binary logarithm : logarithm base 2, see MathWorld	NLP	yes
max(x1,x2,x3,...)	Maximum value of the arguments, where the number of arguments may vary.	DNLP	yes
min(x1,x2,x3,...)	Minimum value of the arguments, where the number of arguments may vary.	DNLP	yes
mod(x,y)	Remainder of x divided by y .	DNLP	yes
ncpCM(x,y,Z)	Chen-Mangasarian smoothing : $x - Z \cdot \ln(1 + e^{\frac{x-y}{Z}})$.	NLP	no
ncpF(x,y[,Z])	Fisher-Burmeister smoothing : $\sqrt{(x^2 + y^2 + 2 \cdot Z)} - x - y$, $Z \geq 0$. Default $Z = 0$.	NLP	no

Function	Description	End. Classif.	Compile Time
<code>ncpVUpow(r,s[,MU])</code>	NCP Veelken-Ulbrich: smoothed $\min(r,s)$ result $=$ $\begin{cases} \frac{(r+s- t)}{2} & \text{if } t \geq \mu \geq 0 \\ \frac{(r+s-\frac{\mu}{8} \cdot (-\frac{t}{\mu})^4 + 6(\frac{t}{\mu})^2 + 3)}{2} & \text{otherwise} \end{cases}$ where $t = r - s$. Default $MU = 0$.	NLP	no
<code>ncpVUsin(r,s[,MU])</code>	NCP Veelken-Ulbrich: smoothed $\min(r,s)$ result $=$ $\begin{cases} \frac{(r+s- t)}{2} & \text{if } t \geq \mu \geq 0 \\ \frac{(r+s-(\frac{2\mu}{\pi} \sin(\frac{\pi}{2\mu} + \frac{3\pi}{2}) + \mu))}{2} & \text{otherwise} \end{cases}$ where $t = r - s$. Default $MU = 0$.	NLP	no
<code>normal(MEAN,STDDEV)</code>	Generate a random number from the normal distribution with mean MEAN and standard deviation STDDEV, see MathWorld	none	no
<code>pi</code>	Value of $\pi = 3.141593\dots$	any	yes
<code>poly(x,A0,A1,A2[,A3,...])</code>	Returns $p(x)$, where the polynomial $p(x) = A_0 + A_1x + A_2x^2 + A_3x^3 + \dots + A_{20}x^{20}$. By default $A_3, \dots, A_{20} = 0$.	NLP	no
<code>power(x,Y)</code>	Returns x^Y , where Y must be an integer.	NLP	no
<code>randBinomial(N,P)</code>	Generate a random number from the binomial distribution , where N is the number of trials and P the probability of success for each trial, see MathWorld	none	no
<code>randLinear(LOW,SLOPE,HIGH)</code>	Generate a random number between LOW and HIGH with linear distribution , SLOPE must be greater than $\frac{2}{\text{HIGH}-\text{LOW}}$	none	no
<code>randTriangle(LOW,MID,HIGH)</code>	Generate a random number between LOW and HIGH with triangular distribution , MID is the most probable number, see MathWorld	none	no
<code>round(x[,DECPL])</code>	Round x to DECPL decimal places. Default DECPL=0	DNLP	yes
<code>rPower(x,y)</code>	Returns x^y for $x > 0$ and also for $x = 0$ and restricted values of y . This function is equivalent to the operation ' $x**y$ ', see Standard Arithmetic Operations .	NLP	no
<code>sigmoid(x)</code>	Sigmoid: $\frac{1}{1+e^{-x}}$, see MathWorld	NLP	no

Function	Description	End. Classif.	Compile Time
<code>sign(x)</code>	Sign of x : returns 1 if $x > 0$, -1 if $x < 0$, and 0 if $x = 0$.	DNLP	yes
<code>signPower(x,Y)</code>	Signed power : for $Y > 0$, returns x^Y if $x \geq 0$ and $-1 \cdot x ^Y$ if $x < 0$.	NLP	no
<code>sin(x)</code>	Sine of the argument x , where x must be in radians, see MathWorld	NLP	yes
<code>sinh(x)</code>	Hyperbolic sine of x , where x must be in radians, see MathWorld	NLP	no
<code>slexp(x[,S])</code>	Smooth (linear) exponential : result = $\begin{cases} e^x & \text{if } x \leq S \\ e^x \cdot (1 + (x - S)) & \text{otherwise} \end{cases}$ where $S \leq 150$, default $S = 150$.	NLP	no
<code>slllog10(x[,S])</code>	Smooth (linear) logarithm base 10 : result = $\begin{cases} \log_{10}(x) & \text{if } x \geq S \\ \frac{1}{\ln(10)} \cdot (\ln S + \frac{x-S}{S}) & \text{otherwise} \end{cases}$ where $S \geq -150$, default $S = -150$.	NLP	no
<code>slrec(x[,S])</code>	Smooth (linear) reciprocal : result = $\begin{cases} \frac{1}{x} & \text{if } x \geq S \\ \frac{1}{S} - \frac{x-S}{S^2} & \text{otherwise} \end{cases}$ where $S \geq 10^{-10}$, default $S = 10^{-10}$.	NLP	no
<code>sqexp(x[,S])</code>	Smooth (quadratic) exponential : result = $\begin{cases} e^x & \text{if } x \leq S \\ e^x \cdot (1 + (x - S) + \frac{(x-S)^2}{2}) & \text{otherwise} \end{cases}$ where $S \leq 150$, default $S = 150$.	NLP	no
<code>sqlog10(x[,S])</code>	Smooth (quadratic) logarithm base 10 : result = $\begin{cases} \log_{10}(x) & \text{if } x \geq S \\ \frac{1}{\ln(10)} \cdot (\ln S + \frac{x-S}{S} - \frac{(x-S)^2}{2S^2}) & \text{otherwise} \end{cases}$ where $S \geq -150$, default $S = -150$.	NLP	no
<code>sqr(x)</code>	Square of argument x .	NLP	yes
<code>sqrec(x[,S])</code>	Smooth (quadratic) reciprocal : result = $\begin{cases} \frac{1}{x} & \text{if } x \geq S \\ \frac{1}{S} - \frac{x-S}{S^2} + \frac{(x-S)^2}{S^3} & \text{otherwise} \end{cases}$ where $S \geq 10^{-10}$, default $S = 10^{-10}$.	NLP	no
<code>sqrt(x)</code>	Square root of x , see MathWorld	NLP	yes
<code>tan(x)</code>	Tangent of the argument x , where x must be in radians, see MathWorld	NLP	yes

Function	Description	End. Classif.	Compile Time
<code>tanh(x)</code>	Hyperbolic tangent of x , where x must be in radians, see MathWorld	NLP	no
<code>trunc(x)</code>	Truncation: returns the integer part of x , truncating towards zero.	DNLP	yes
<code>uniform(LOW,HIGH)</code>	Generates a random number from the uniform distribution between LOW and HIGH, see MathWorld	none	no
<code>uniformInt(LOW,HIGH)</code>	Generates an integer random number from the discrete uniform distribution whose outcomes are the integers between LOW and HIGH, inclusive, see MathWorld	none	no
<code>vcPower(x,Y)</code>	Returns x^Y for $x \geq 0$.	NLP	no

4.26.4.1.2 String Manipulation Functions GAMS provides some string manipulation capability by extending the [card](#) and [ord](#) functions to work on strings as well as sets. In [Table 4](#) the extended behavior is described. In this context, the functions take *strings* and *places* as arguments, and the numeric *places* argument must be a constant. This behavior only applies to execution-time usage of these functions.

Table 4: String Manipulation Functions

Function	Description
<code>card(String)</code>	Returns the number of characters in the string.
<code>ord(String[,PLACE])</code>	Returns the ASCII code number of a character in a position in a string. The optional <code>place</code> entry defaults to 1 if omitted and identifies the character position within the string to be examined (1 for the first, 2 for the second, etc.)

There are four types or sources of strings in this context. A string may be a string literal, i.e. a concatenation of letters and blanks as in "drink it" in the example that follows. It may be the symbol text (aka the explanatory text) associated with any symbol. Or it may be the labels or text associated with the elements of a set. The following table gives an overview:

Table 5: String Types

Notation	Description	Comments
<code>characters</code>	A concatenation of characters and blanks: all legal GAMS characters are allowed, see section Characters for details.	The characters must be surrounded by double or single quotes.
<code>symbol_name.ts</code>	The string is the explanatory text associated with a symbol name.	If the explanatory text is missing, the value of <code>card</code> is 0.
<code>set_name.tl</code>	The string is the label for a set element.	This string type may be used only when <code>set_name</code> is part of the controlling domain.
<code>set_name.te</code>	The string is the explanatory text associated with a set element.	This string type may be used only when <code>set_name</code> is part of the controlling domain. If the explanatory text is missing, the value of <code>card</code> is 0.

The string types are illustrated in the following example. Note that the directive in the first line activates the end-of-line comment option, see [eolCom](#).

```
$oneolcom
variable z 'any symbol can have explanatory text';
set teas "teas available to order" / black "English Breakfast", green, peppermint /;
scalar p;

p = card("drink it");          !! result: p=8
p = card(z.ts);                !! result: p=36
p = card(teas.ts);             !! result: p=23

loop{teas,
  p = card(teas.tl)            !! length of set element label from the set "teas": "teas" is the control.
  display "length of set element label", p;
  p = card(teas.te)            !! length of set element explanatory text: "teas" is the controlling set
  display "length of set element explanatory text", p;
};
```

Note that the strings `teas.tl` and `teas.te` are used in the context of a loop statement (see section [The Loop Statement](#)). This is a typical usage pattern.

4.26.4.1.3 Logical Functions Logical functions may be used as expressions in assignment statements as in the following example.

```
x = ifthen(tt=2, 3, 4+y);
```

Here $x = 3$ if $tt = 2$, otherwise $x = 4 + y$.

The logical functions available in GAMS are given in [Table 6](#). Note that logical functions may also be used in conditions and logic equations, see sections [Logical Conditions](#) and [Logic Equations](#) respectively. Most of the logical functions can also be indicated using the familiar operator notation, e.g. $(x \text{ and } y)$, $(x \geq y)$, etc. In such cases, the operator notation is allowed at compile time. The last column in [Table 6](#) indicates if a logical function can be used at compile time (yes) or if only its alternative notation is available (alt). Further, note that the inputs and outputs of these functions are often logical/Boolean values, so GAMS does implicit conversions as necessary. As expected, false becomes 0 and true becomes 1 when converting logical values to numeric, and 0 becomes false and nonzero becomes true when numeric values are converted to logicals. For details on behavior when the inputs are special values, see sections [Extended Range Arithmetic](#) and [Acronym Usage](#), but note that EPS, +INF, -INF, and acronyms become true when converted to logicals.

Table 6: Logical Functions

Function	Alternative Notation 1	Alternative Notation 2	Description	Return Values	End. Classif.	Compile Time
<code>bool_and(x,y)</code>	$x \text{ and } y$		Boolean AND	Returns true iff both x and y are true	DNLP	alt
<code>bool_eqv(x,y)</code>	$x \text{ eqv } y$	$x \lt;=> y$	Boolean equivalence	Returns false iff <i>exactly</i> one argument is false	DNLP	alt

Function	Alternative Notation 1	Alternative Notation 2	Description	Return Values	End. Classif.	Compile Time
<code>bool_imp(x,y)</code>	<code>x imp y</code>	<code>x -> y</code>	Boolean implication	Returns true iff x is false or y is true	DNLP	alt
<code>bool_not(x)</code>	<code>not x</code>		Boolean NOT	Returns true iff x is false	DNLP	alt
<code>bool_or(x,y)</code>	<code>x or y</code>		Boolean OR	Returns true iff x is true or y is true	DNLP	alt
<code>bool_xor(x,y)</code>	<code>x xor y</code>		Boolean XOR	Returns true iff <i>exactly</i> one argument is false	DNLP	alt
<code>ifThen(cond, iftrue, else)</code>			Condition	If the logical condition (first argument) is true, the function returns <code>iftrue</code> , else it returns <code>else</code> . See example above.	DNLP	yes
<code>rel_eq(x,y)</code>	<code>x eq y</code>	<code>x = y</code>	Numeric Relation: Equal	Returns true iff $x = y$	DNLP	alt
<code>rel_ge(x,y)</code>	<code>x ge y</code>	<code>x >= y</code>	Numeric Relation: Greater Equal	Returns true iff $x \geq y$	DNLP	alt
<code>rel_gt(x,y)</code>	<code>x gt y</code>	<code>x > y</code>	Numeric Relation: Greater Than	Returns true iff $x > y$	DNLP	alt
<code>rel_le(x,y)</code>	<code>x le y</code>	<code>x <= y</code>	Numeric Relation: Less Equal	Returns true iff $x \leq y$	DNLP	alt
<code>rel_lt(x,y)</code>	<code>x lt y</code>	<code>x < y</code>	Numeric Relation: Less Than	Returns true iff $x < y$	DNLP	alt
<code>rel_ne(x,y)</code>	<code>x ne y</code>	<code>x <> y</code>	Numeric Relation: Not Equal	Returns true iff $x \neq y$	DNLP	alt

4.26.4.1.4 Time and Calendar Functions GAMS offers several functions that relate to time and dates. The fundamental measurement of time in GAMS is the serial day number beginning with January 1, 1900. This serial day number is a real number whose integer part contains a unique number for each day and whose fractional part contains information about hours, minutes, and seconds. We can think of

the serial day number as being a `date.time` pair. The day information extracted from serial day numbers is based on the Gregorian calendar.

Note

In all functions given in [Table 7](#), *serial day 1* is *January 1, 1900*.

All of the functions in [Table 7](#) can be used at compile time.

Table 7: Time and Calendar Functions

Function	Description	End. Classif.
<code>gday(SDAY)</code>	Returns Gregorian day from a serial day number <code>date.time</code> .	any
<code>gdow(SDAY)</code>	Returns Gregorian day of week from a serial day number <code>date.time</code> .	any
<code>ghour(SDAY)</code>	Returns Gregorian hour of day from a serial day number <code>date.time</code> .	any
<code>gleap(SDAY)</code>	Returns 1 if the year that corresponds to a serial day number <code>date.time</code> , is a leap year , else returns 0.	any
<code>gmillisec(SDAY)</code>	Returns Gregorian milli second from a serial day number <code>date.time</code> .	any
<code>gminute(SDAY)</code>	Returns Gregorian minute of hour from a serial day number <code>date.time</code> .	any
<code>gmonth(SDAY)</code>	Returns Gregorian month from a serial day number <code>date.time</code> .	any
<code>gsecond(SDAY)</code>	Returns Gregorian second of minute from a serial day number <code>date.time</code> .	any
<code>gyear(SDAY)</code>	Returns Gregorian year from a serial day number <code>date.time</code> .	any
<code>jdate(YEAR,MONTH,DAY)</code>	Returns a serial day number .	any
<code>jnow</code>	Returns the current time as a serial day number.	none
<code>jstart</code>	Returns the time of the start of the GAMS job as a serial day number.	none
<code>jtime(HOUR,MIN,SEC)</code>	Returns fraction of a day that corresponds to hour, minute and second.	any

4.26.4.1.5 GAMS Utility and Performance Functions GAMS provides several functions that may be used to get (and in some cases set) GAMS system information, for example:

```
scalar o;
o = heapLimit;
heapLimit = 1024;
```

Table 8: GAMS Utility and Performance Functions

Function	Description	End. Classif.	Compile Time
<code>embeddedHandle</code>	Returns the handle for the last embedded code section executed, see section Syntax in chapter Embedded Code Facility for details.	none	no
<code>errorLevel</code>	Return code of the most recently used command.	none	yes
<code>execError</code>	Get or set the number of execution errors .	none	no
<code>gamsRelease</code>	Returns the release number of the running GAMS system, for example 24.7.	none	yes
<code>gamsVersion</code>	Returns the version number of the running GAMS system, for example 247.	none	yes
<code>handleCollect(HANDLE)</code>	Tests if the solve of the model instance identified by the calling argument <code>HANDLE</code> is done: if so, it loads the solution into GAMS. For details, see Table 1 in section Grid Computing .	none	no
<code>handleDelete(HANDLE)</code>	Deletes the model instance identified by <code>HANDLE</code> . For details, see Table 1 in section Grid Computing .	none	no
<code>handleStatus(HANDLE)</code>	Tests if the solve of the model instance identified by <code>HANDLE</code> is done: if so, it loads the solution into a GDX file . For details, see Table 1 in section Grid Computing .	none	no
<code>handleSubmit(HANDLE)</code>	Resubmits the model instance identified by <code>HANDLE</code> for solution. For details, see Table 1 in section Grid Computing .	none	no
<code>heapFree</code>	Get the amount of free memory in the heap in MB, i.e. memory allocated to the process and available for future use by GAMS.	none	no
<code>heapLimit</code>	Get or set the current heap limit (maximum allowable dynamic memory usage) in Mb.	none	no
<code>heapSize</code>	Get the current heap size in Mb.	none	no
<code>jobHandle</code>	Returns the process ID (PID) of the last job started.	none	yes
<code>jobKill(PID)</code>	Sends a kill signal to the job with process ID <code>PID</code> . The return value is 1 if this was successful, 0 otherwise.	none	yes

Function	Description	End. Classif.	Compile Time
<code>jobStatus(PID)</code>	Get the status of the job with process ID PID. Possible return values are: 0: error (input is not a valid PID or access is denied) 1: process is still running 2: process is finished with return code which could be accessed by errorlevel 3: process not running anymore or was never running, no return code available	none	yes
<code>jobTerminate(PID)</code>	Sends an interrupt signal to the job with process ID PID. The return value is 1 if this was successful, 0 otherwise.	none	yes
<code>licenseLevel</code>	Get an indicator for the type of license : 0: demo license, limited to small models 1: full unlimited developer license 2: run time license, no new variables or equations can be introduced besides those inherited from a work file 3: application license, only works with a specific work file which is locked to the license file 5: community license, limited to somewhat bigger models compared to demo license.	any	no
<code>licenseStatus</code>	Returns non-zero if a license error has occurred.	any	no
<code>mapVal(x)</code>	Returns an integer value that indicates what special value (if any) is stored in the input x . Possible results: 0: x is not a special value 4: x is UNDF (undefined) 5: x is NA (not available) 6: x is INF (∞) 7: x is -INF ($-\infty$) 8: x is EPS >8: x is an acronym	any	no
<code>maxExecError</code>	Get or set the maximum number of execution errors . See also <code>maxExecError</code> .	none	no
<code>numCores</code>	Get the number of logical CPU cores in the system	any	yes
<code>platformCode</code>	Returns an integer indicating the current platform. Possible return values can be seen here .	any	yes

Function	Description	End. Classif.	Compile Time
<code>readyCollect(HANDLES[,MAXWAIT])</code>	Waits until a model solution is ready to be collected. For details, see Table 1 in section Grid Computing .	none	no
<code>sleep(SEC)</code>	Pause or sleep execution for SEC seconds.	none	yes
<code>timeClose</code>	Returns the accumulated closedown time , i.e. the time GAMS uses to save its state to disk prior to a solve.	none	no
<code>timeComp</code>	Returns the compilation time in seconds.	none	no
<code>timeElapsed</code>	Returns the elapsed time since the start of a GAMS run in seconds.	none	no
<code>timeExec</code>	Returns the execution time in seconds.	none	no
<code>timeStart</code>	Returns the accumulated startup time , i.e. the time GAMS uses to restore its state from disk after a solve.	none	no

4.26.4.2 Extrinsic Functions

Using the GAMS Function Library Facility, functions may be imported from an external library into a GAMS model. Apart from the import syntax, the imported functions may be used in the same way as intrinsic functions. In particular, they may be used in equation definitions. Some function libraries are included with the standard GAMS software distribution, but GAMS users can also create their own libraries using an open programming interface. The GAMS Test Library instances [\[TRILIB01\]](#), [\[TRILIB02\]](#), [\[TRILIB03\]](#), and [\[CPPLIB00\]](#) are simple examples (in the programming languages C, Delphi, Fortran and C++, respectively) that come with every GAMS system.

For details on using and creating extrinsic function libraries, and on the extrinsic function libraries that are provided with GAMS, see the chapter on [Extrinsic Functions](#).

4.26.4.3 Function Suffixes

Up to this point, this section has described and discussed functions without mentioning their derivatives. These derivatives are very important, though: most of the nonlinear solvers integrated with GAMS will require first derivatives to solve models, and many will also use or require second derivatives as well. It is sometimes useful (e.g. when testing an extrinsic function) to evaluate the derivatives of GAMS functions instead of the functions themselves. This can be done via function suffixes.

Function suffixes can specify the evaluation of a gradient (i.e. first derivative), a Hessian (i.e. second derivative), a minimum or maximum value of the function over a given range, or the minimum or maximum value of the gradient over a given range. A full list of function suffixes is given in [Table 9](#). For functions whose arguments are constant, the derivatives are zero, so typically `func` is a mathematical function listed in [Table 3](#) above. Note that function suffixes are *not* defined for functions without arguments (for example, `pi`), so specifying something like `pi.grad` results in a compilation error.

Table 9: *Function Suffixes*

Function Suffix	Description
<code>func.value(x)</code>	Value of the function <code>func</code> at <code>x</code> , equals <code>func(x)</code> .
<code>func.grad(x)</code>	Value of the gradient of the function <code>func</code> at <code>x</code> .
<code>func.gradn(x)</code>	Value of the gradient of the function <code>func</code> at <code>x</code> , computed numerically.
<code>func.hess(x)</code>	Value of the Hessian of the function <code>func</code> at <code>x</code> .
<code>func.hessn(x)</code>	Value of the Hessian of the function <code>func</code> at <code>x</code> , computed numerically.
<code>func.low(x1:x2)</code>	Lower bound of the function <code>func(x)</code> on the interval <code>[x1,x2]</code> .
<code>func.high(x1:x2)</code>	Upper bound of the function <code>func(x)</code> on the interval <code>[x1,x2]</code> .
<code>func.gradL(x1:x2)</code>	Lower bound of the gradient of the function <code>func(x)</code> on the interval <code>[x1,x2]</code> .
<code>func.gradH(x1:x2)</code>	Upper bound of the gradient of the function <code>func(x)</code> on the interval <code>[x1,x2]</code> .

Consider the following simple example:

```

scalars g, l, h, gl, gh;

g = sin.grad(0);
l = sin.low(pi/3:pi/2);
h = sin.high(pi/3:pi/2);
gl = sin.gradL(pi/3:pi/2);
gh = sin.gradH(pi/3:pi/2);

display g, l, h, gl, gh;

```

For univariate functions like sine or cosine, there is no need to specify a variable index when evaluating derivatives. For multivariate functions, the default is to take partial derivatives w.r.t. the first variable. To specify other variables, the colon syntax in the example below is used.

```

scalars
  x / 1 /
  ylo / -1 /
  yup / 2 /
  e0, e1, elo, ehi
  e_1, e_2
  e_11, e_22, e_21
;
e0 = edist(x,ylo);
e1 = edist(x,yup);
elo = edist.low(x,ylo:x,yup);
ehi = edist.high(x,ylo:x,yup);

e_1 = edist.grad(x,yup);
* e_1 = edist.grad(1:x,yup); same as above
e_2 = edist.grad(2:x,yup);

e_11 = edist.hess(x,yup);
* e_11 = edist.hess(1:1:x,yup); same as above
e_22 = edist.hess(2:2:x,yup);
e_21 = edist.hess(2:1:x,yup);

display x, ylo, yup, e0, e1, elo, ehi, e_1, e_2, e_11, e_22, e_21;

```

For more examples, see model [FUNCS4] in the GAMS Test Library.

Note

- The function suffixes `value`, `grad`, `gradn`, `hess` and `hessn` are also defined for [extrinsic functions](#). When implementing an extrinsic function, be aware that missing derivatives will be computed numerically: see model [TRILIB01] for an example.

To compute derivatives numerically, GAMS uses finite difference approximations. This computation can be controlled with two options: the `FDOpt` option controls which variant of the finite difference method is used, while the `FDDelta` option controls the step size.

4.26.5 Extended Range Arithmetic and Error Handling

GAMS uses an *extended range* arithmetic to handle missing data, the results of undefined operations, infinite values, and zeros that are stored explicitly. The *special values* used in this arithmetic are listed and described in [Table 10](#) below, along with the value of the `mapVal` function that corresponds to these values. We can think of special values as any value for which `mapVal` does not return 0.

Special value	Description	mapVal
INF	Plus infinity. Similar to IEEE plus infinity. Behaves in the expected way in computations, so that e.g. $\min(x, \text{INF}) = x$ unless x is also special.	6
-INF	Minus infinity. Similar to IEEE minus infinity. Behaves in the expected way in computations, so that e.g. $\max(x, \text{INF}) = x$ unless x is also special.	7
NA	Not available - used to indicate missing data. It is a sticky value: e.g. $\max(x, \text{NA}) = \text{NA}$ even for $x = \text{INF}$	5
UNDF	Undefined - indicates the result of an undefined or illegal operation. Similar to IEEE NaN. A user cannot directly set a value to UNDF unless the dollar control option <code>onUNDF</code> is active. For details, see the chapter on Dollar Control Options .	4
EPS	A <i>stored</i> zero value. If the dollar control option <code>onEPS</code> is active, zeros in a parameter or table statement are treated as EPS. For details on dollar control options, see chapter Dollar Control Options .	8

Table 10: Special Values for Extended Range Arithmetic

Attention

Avoid creating or using numbers with very large ($1.0\text{e}299$ or above) or very small ($1.0\text{e}-299$ or below) magnitudes. Large numbers may be treated by GAMS as undefined (UNDF) or other special values, leading to unpredictable and unusable results. Always use INF (or -INF) explicitly for arbitrarily large (or small) numbers.

GAMS has defined the results of all arithmetic operations and all function evaluations that use these special values. The behavior is designed to both maximize utility and minimize surprise, and is illustrated in the library model [CRAZY]. For example: $1 + \text{INF}$ evaluates to INF, $1 - \text{EPS}$ to 1, $\text{NA} * 2$ to NA, and $\text{EPS} * \text{INF}$ to UNDF.

The following table shows a selection of results for exponentiation and division for a variety of input parameters including NA and INF.

a	b	a**b	power(a,b)	a/b
2	2	4	4	1
-2	2	UNDF	4	-1
2	2.1	4.28	UNDF	.952
NA	2.5	NA	NA	NA
3	0	1	1	UNDF
INF	2	INF	INF	INF
2	INF	UNDF	UNDF	0

Table 11: Extended Range Arithmetic in Exponentiation and Division

Note that most extended range identifiers may be used in assignment statements, as illustrated below.

```
a(row,'col-3') = NA;
a(row,'col-4') = INF;
a(row,'col-5') = -INF;
```

The values most often used in assignments are **NA** in incomplete tables and **INF** for variable bounds.

The special value **EPS** is numerically equal to zero, so when used in the context of numerical comparisons, it behaves as zero. For example, the logical expressions $x > 0$ and $x > \text{EPS}$ have the same result. However, **EPS** is a *stored* zero, so setting a parameter to zero (e.g. `a(row,col)=0`) results in no values being stored for **a**, while setting a parameter to **EPS** (e.g. `a(row,col)=EPS`) results in the value **EPS** being stored for every `(row,col)` tuple. This is sometimes useful, especially if **a** is used later in loops (see [Programming Flow Control Features](#)) or dollar conditions (see [Conditional Expressions, Assignments and Equations](#)). For example, consider the statement

```
a(row,col)$[a(row,col)] = INF ;
```

In the case where **a** was originally assigned to be zero, the dollar-condition is always false so no infinities are assigned. If **a** was originally assigned the value **EPS**, the dollar-condition is always true and every tuple in **a** will be set to infinity.

When an attempted arithmetic operation is illegal or has undefined results because of the value of arguments (division by zero is the normal example), an error is reported and the result is set to undefined (**UNDF**). The error is marked on the output file with a row of four asterisks '****' making this sequence a good search target in the editor. GAMS will also report the line number of the offending statement and give as much detail as possible about the cause. From there on, the resulting **UNDF** is treated as a proper data value and does not trigger additional error messages. For more on error messages, see chapter [GAMS Output](#).

Note

GAMS will not solve a model if an error has been detected, and it will terminate with an error condition.

It is therefore wise to anticipate and avoid operations like division by zero that will cause errors. This is most easily done with the dollar control, and is discussed in section [The Dollar Condition](#).

4.26.6 Predefined Symbols

GAMS offers several *predefined* symbols including: `sameAs`, `diag`, `sortedUels`, `solvers`, `licenseCodes`, `solverCapabilities`, `componentEDate`, `componentMDate`, and `ComponentLicenseOptions`. With the exception of `sameAs`, `diag`, and `sortedUels` these predefined symbols are for very special (and mostly internal) purposes, but the way they work is identical.

These symbols can be used in a GAMS program without being declared but work in an idiosyncratic way. For example, the complete program

```
display solvers, sameAs;
```

compiles and executes without error and produces the following result in the listing file:

```
----          1 SET Solvers  Available Solvers
                                                    ( EMPTY )

----          1 SET SameAs  Set Element Comparison Without Checking
                                                    ( EMPTY )
```

However, if labels have been declared (in any set) that corresponds to a solver name, then set `solvers` will contain this label. Consider the following example:

```
Set titles / Lord, Baron, Duke /;
Set greeks / Euclid, Pythagoras, Antigone /;
display solvers, sameAs;
```

Note that `Antigone` and `Baron` are the names of solvers in GAMS and therefore they will be displayed as a member of the set `solvers`. Also note that the set `sameAs` contains the diagonal elements for both sets:

```
----          3 SET Solvers  Available Solvers
Baron      ,      Antigone

----          3 SET SameAs  Set Element Comparison Without Checking
                Lord      Baron      Duke      Euclid  Pythagoras      Antigone
Lord                YES
Baron                YES
Duke                  YES
Euclid                YES
Pythagoras                YES
Antigone                YES
```

User defined symbols can have the same name as a predefined symbol. In this case the user symbol *hides* the predefined symbols as demonstrated in the following example:

```
Set diag / 1*3 /;
$if setType diag $log diag is a set
$if preType diag $log diag is a predefined type
```

The log will only contain the line `diag is a set`. The test `$if preType diag` fails.

The list of all predefined symbols can be retrieved by declaring and displaying a set using some [system data](#) `set pre /system.predefinedSymbols/; display pre;` which results in

```
----          1 SET pre
SameAs      ,      Diag      ,      Solvers
LicenseCodes ,      SolverCapabilities ,      SortedUels
ComponentEDate ,      ComponentMDate ,      ComponentLicenseOptions
```

4.26.7 Summary

GAMS provides powerful facilities for data manipulation with parallel assignment statements, built-in functions and extended range arithmetic.

4.27 Data Entry: Parameters, Scalars and Tables

4.27.1 Introduction

Data handling is of crucial importance in all modeling applications. The quality of the numbers and the intelligence with which they are used is likely to be at least as important as the logic of the model in determining if an application is successful or not. GAMS has been designed to have a complete set of facilities for entering information, manipulating it and reporting on the results. In this chapter we will concentrate on data entry. Chapter [Data Manipulations with Parameters](#) introduces and discusses data manipulations. For details on reporting, see chapters [GAMS Output](#), [The Display Statement](#), [The Put Writing Facility](#), and [GAMS Data eXchange \(GDX\)](#).

One very important principle will motivate all our discussions on data:

Note

Data should be entered in its most basic form and each data item should be entered only once.

There are two reasons for adopting this principle. Numbers are almost certain to change, and when they do we want to be able to make the process of changing them as easy and safe as possible. We also want to make our model easy for others to read and understand. Keeping the amount of data as small as possible will certainly help. All the data transformations are shown explicitly in the GAMS representation, which makes it possible to reproduce the results of a study and shows the reader all the assumptions made during data manipulation. Another advantage is that everything needed to run or change the model is included in one program that can easily be moved from place to place or from one machine to another.

This chapter deals with the data type *parameter*. For other data types, see section [Data Types and Definitions](#). Data for *parameters* can be entered in three basic formats: scalar, list oriented, or tables of two or more dimensions. For each of these formats, GAMS offers a separate keyword:

Keyword	Description
Scalar	Single (scalar) data entry.
Parameter	List oriented data, defined over one or more sets.
Table	Table oriented data, must involve two or more dimensions.

Table 1: Parameters, Scalars and Tables

Note that the term *parameter* is used in two ways: as data type and as keyword, so one could also see **scalars** and **tables** as special formats of *parameters*. Each of the data input formats will be introduced and discussed in the following sections. At the end of the chapter the special data type [acronym](#) is introduced.

Note

- By default, parameters in all input formats may only be initialized once, thereafter data must be modified with assignment statements. This can be changed using the dollar control option [\\$onMulti](#).

- This chapters explains the complete syntax to declare *parameters* which includes the optional initialization. So, while it is possible to initialize the data at declaration, often the data is read from other sources like databases or spreadsheets. More information about this can be found in the chapter [Data Exchange with Other Applications](#).

4.27.2 Scalars

The `scalar` statement is used to declare and (optionally) initialize a GAMS parameter of dimensionality zero. This means that there are no associated sets, so there is exactly one number associated with the parameter.

4.27.2.1 The Syntax

In general, the syntax for a `scalar` declaration in GAMS is as follows:

```
scalar[s] scalar_name [text] [/numerical_value/]
      { scalar_name [text] [/numerical_value/]} ;
```

The keyword `scalar[s]` indicates that this is a `scalar` statement and `scalar_name` is the internal name of the scalar in GAMS, it is an [identifier](#). The optional [explanatory text](#) is used to describe the scalar and the optional `numerical_value` is assigned to be the value of `scalar_name`. `Numerical_value` can be given as fixed number or as [constant evaluation](#). Alternatively, the special data type acronym may be used as value. For details on acronyms, see section [Acronyms](#).

Note that more than one scalar may be declared in one scalar statement. The entries have to be separated by commas or by end of line. For advice on explanatory text and how to choose a `scalar_name`, see the tutorial [Good Coding Practices](#).

Note that scalars may be declared but not initialized in the scalar statement. A value can also be assigned later as illustrated in the example that follows.

4.27.2.2 An Illustrative Example

An example of a `scalar` definition in GAMS is shown below.

```
Scalar
  rho "discount rate" / .15 /
  irr "internal rate of return"
  life "financial lifetime of productive units" / 20 /;
```

The statement above initializes `rho` and `life`, but not `irr`. Later on another scalar statement can be used to initialize `irr` or an assignment statement could be used to provide the value:

```
irr = 0.07;
```

For more on scalar assignments and parameter assignments in general, see section [Data Entry by Assignment](#).

4.27.3 Parameters

The parameter format is used to enter list oriented data which can be indexed over one or several sets.

4.27.3.1 The Syntax

In general, the syntax for a `parameter` declaration in GAMS is as follows:

```
parameter[s] param_name[(index_list)] [text] [/ element [=] numerical_value
                                     {,element [=] numerical_value} /]
      {,param_name[(index_list)] [text] [/ element [=] numerical_value
                                     {,element [=] numerical_value} /]} ;
```

The keyword `parameter[s]` indicates that this is a parameter statement and `param_name` is the internal name of the parameter in GAMS, it is an [identifier](#). A parameter may be defined over one or more sets that may be specified in the `index_list`. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section [Domain Checking](#). The optional [explanatory text](#) is used to describe the parameter.

Parameter initialization requires a list of data elements, each consisting of a label or label-tuple and a value. `Element` is an element of the defining set or - if there is more than one defining set - a combination of the elements of the defining sets. The referenced set elements must belong to the set that the parameter is indexed over. Finally, `numerical_value` is the value assigned to the record defined by the set element or element tuple. It can be given as fixed number or as [constant evaluation](#). Alternatively, the special data type [acronym](#) may be entered as value. For details on acronyms, see section [Acronyms](#).

Note

The default value of a `parameter` is 0.

Slashes must be used at the beginning and end of the list, and commas must be used if several data elements are listed in one line. An equals sign or a blank separates the label tuple from its associated value. A parameter can be defined in a similar syntax to that used for a [set](#). For advice on explanatory text and how to choose a parameter name, see the tutorial [Good Coding Practices](#).

Note

Several parameters may be declared in one parameter statement.

4.27.3.2 Illustrative Examples

The following example illustrates the parameter statement. It is adapted from [\[MEXSS\]](#). We also show the set definitions because they make the example clearer. For more on sets definitions, see chapter [Set Definition](#).

```
Set i      "steel plants"  / hylsa      monterrey
      j      "markets"    / hylsap     puebla /
      / mexico-df, monterrey, guadalaja /;

Parameter
  dd(j) "distribution of demand"
      / mexico-df  55,
      guadalaja   15 /;
```

The index specification for the parameter `dd` means that there will be a vector of data associated with it, one number corresponding to every member of the set `j`. The numbers are specified along with the declaration in a format very reminiscent of the way we specify sets: in this simple case a label followed by a blank separator and then a value. Any of the legal number entry formats are allowable for the value. For details on number formats in GAMS, see subsection [Numbers](#). The default data value is zero. Since `monterrey` has been left out of the data list, the value associated with `dd('monterrey')` is zero. As with sets, commas are optional at end of line.

We may also list several data elements on a line, separated by commas as in the following example:

```
Parameter
  a(i) / seattle = 350, san-diego = 600 /
  b(i) / seattle 2000, san-diego 4500 /;
```

If a parameter is defined over a set and all elements of the set are assigned the same value, then the following notation may be used as a shortcut:

```
parameter param_name[(set_name)] [text] /(#|set.)set_name numerical_value/;
```

Here `set` is a reserved word and `set_name` is the name of the set as it has been declared in a previous set declaration statement. Instead of `set.` one could also use the `#` sign. The following artificial example illustrates this notation:

```
Set      j      /j1, j2/;
Parameter hh(j) /set.j 10/
         gg      /#j 10/;
```

This resolves in `hh('j1') = hh('j2') = gg('j1') = gg('j2') = 10`.

Note

By default it is not possible to define an empty parameter at declaration. This may be changed using the dollar control option [\\$onEmpty](#), as shown in the following example:

```
Set i      / seattle, san-diego /;
$onEmpty
Parameter
  a(i) / /;
```

That initializes `a('seattle')` and `a('san-diego')` to 0. So it is not the same as this:

```
Set i      / seattle, san-diego /;
Parameter
  a(i);
```

Here, `a` is declared, but not initialized (so, it is not defined yet) and one would get an error when trying to read it.

4.27.3.3 Parameter Data for Higher Dimensions

A parameter may have several dimensions. For the current maximum number of permitted dimensions, see [Dimensions](#). The list oriented data initialization through the parameter statement can be easily extended to data of higher dimensionality. The label that appears on each line in the one-dimensional case is replaced by a label tuple for higher dimensions. The elements in the n -tuple are separated by dots (.) just like in the case of multi-dimensional sets.

The following example illustrates the use of parameter data for higher dimensions:

```
Parameter
  salaries(employee,manager,department)
  / anderson .murphy .toy          = 6000
    hendry   .smith  .toy          = 9000
    hoffman  .morgan .cosmetics    = 8000 /;
```

All the mechanisms using asterisks and parenthesized lists that we introduced in our discussion of sets are available here as well. For details see section [Multi-Dimensional Sets](#). Below is an artificial example, in which a very small fraction of the total data points are initialized. GAMS will mark an error if the same label combination (or label-tuple) appears more than once in a data list.

```
Set row / row1*row10 /
    col / col1*col10 /;
Parameter
  a(row, col)
  / (row1,row4) . col2*col7      12
    row10      . col10           17
    row1*row7  . col10           33 /;
```

In this example the twelve elements `row1.col2` to `row1.col7` and `row4.col2` to `row4.col7` are all initialized at 12, the single element `row10.col10` at 17, and the seven elements `row1.col10` to `row7.col10` at 33. The other 80 elements (out of a total of 100) remain at their default value, which is 0. This example shows the ability of GAMS to provide a concise initialization or definition for a sparse data structure.

4.27.4 Tables

Tabular data can be declared and initialized in GAMS using a table statement. For two and higher-dimensional parameters this provides an easier and more concise method of data entry than the list based approach, since - at least in smaller tables - each label appears only once.

4.27.4.1 The Syntax

In general, the syntax for a table declaration in GAMS is as follows:

```
table table_name[(index_list)] [text] [EOL
  element          { element }      EOL
  element          numerical_value  { numerical_value} EOL
  {element         numerical_value  { numerical_value} EOL}] ;
```

The keyword `table` indicates that this is a `table` declaration and `table_name` is the internal name of the table in GAMS, it is an [identifier](#). The name of the parameter can be followed by the `index_list`. In the `index_list` the sets are specified over which the table is defined. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section [Domain Checking](#). The optional [explanatory text](#) is used to describe the table, followed by `EOL` which means "end of line", a line break. `Element` is an element of one of the driving sets. More details follow below. `Numerical_value` is the value of the entry associated with the corresponding element combination. It can be given as fixed number or as [constant evaluation](#). Alternatively, the special data type `acronym` may be used as value. For details on acronyms, see section [Acronyms](#). For advice on explanatory text and how to choose a `table_name`, see the tutorial [Good Coding Practices](#).

Attention

By default, the table statement is the only statement in the GAMS language that is not free format. This may be changed using the dollar control option `$onDelim`.

The following rules apply:

- The relative positions of all entries in a table are significant. This is the only statement where end of line (EOL) has meaning. The character positions of the numeric table entries must overlap the character positions of the column headings.
- The column section has to fit on one line.
- The sequence of values forming a row must be on the same line.
- The element definition of a row can span more than one line.
- A specific column can appear only once in the entire table.

The rules for building simple tables are straightforward. The components of the header line are

```
keyword - identifier - index_list - text
```

Note that the `index_list` and the `text` are optional. Labels are used on the top and the left to map out a rectangular grid that contains the data values. The order of labels is unimportant, but if domain checking has been specified (i.e. the `index_list` has been given in the first line of the table declaration) each label must match one in the associated set. Labels must not be repeated, but can be left out if the corresponding numbers are all zero or not needed. At least one blank must separate all labels and data entries. Blank entries imply that the default value (zero) will be associated with that label combination.

Note

- Tables must have at least two dimensions. For the current maximum number of permitted dimensions, see [Dimensions](#).
- The `table` statement can also be terminated with a `;` in the first line, so without entering data. In this case the parameter `table_name` would be declared but not initialized.
- In contrast to the `set`, `scalar`, and `parameter` statements, only one identifier may be initialized in a `table` statement, though multiple ones could be declared.

4.27.4.2 An Illustrative Example

In the following example a simple table is presented. It is adapted from [KORPET], the relevant set definitions are also given.

```
Set i  "plants"
      /  inchon, ulsan, yosu /
m     "productive units"
      /  atmos-dist  "atmospheric distillation unit"
        steam-cr    "steam cracker"
        aromatics   "aromatics unit"
        hydrodeal   "hydrodealkylator"  /;
```

Table ka(m,i) "initial cap. of productive units (100 tons per yr)"

	inchon	ulsan	yosu
atmos-dist	3702	12910	9875
steam-cr		517	1207
aromatics		181	148
hydrodeal		180	

;

In this example the row labels are drawn from the set *m* and those on the column from the set *i*. Note that the data for each row is aligned under the corresponding column headings. Entries that are not specified are assigned the default value zero.

Note

If there is any uncertainty about which column a number belongs to, GAMS will protest with an error message and mark the ambiguous entry.

Attention

Special care has to be taken, if tabs are used. The GAMS command line option `TabIn` controls the tab spacing. Note that this spacing might be different from the spacing that the editor is showing, hence the visible alignment might be different from the alignment that GAMS is actually using.

4.27.4.3 Continued Tables

If a table has too many columns to fit nicely on a single line, then the columns that don't fit may be continued on additional lines. We use the same example to illustrate:

Table ka(m,i) "initial cap. of productive units (100 tons per yr)"

	inchon	ulsan
atmos-dist	3702	12910
steam-cr		517
aromatics		181
hydrodeal		180

+	yosu
atmos-dist	9875
steam-cr	1207
aromatics	148

;

The crucial item is the plus '+' sign above the row labels and to the left of the column labels in the continued part of the table. The row labels have been duplicated, except that `hydrodeal` has been left out, since it does not have any associated data. Tables may be continued as many times as necessary.

4.27.4.4 Tables with more than Two Dimensions

Tables may have more than two dimensions. For the current maximum number of permitted dimensions, see [Dimensions](#). As usual, dots are used to separate adjacent labels and may be used in the row or column position. The label on the left of the row corresponds to the first set in the index list, and that on the right of each column header to the last. Obviously, there must be the same number of labels associated with each number in the table, as there are sets in the index list.

The best layout depends on the size of the defining sets and the amount of data. It should provide the most intuitively satisfactory way of organizing and inspecting the data. For most people it is easier to look down a column of numbers than across a row. However, putting extra labels on the row has the advantage of greater density of information.

The following example, adapted from [\[MARCO\]](#), illustrates the use of tables with more than two dimensions.

```
Set ci  "commodities : intermediate"
      / naphtha  "naphtha"
        dist    "distillate"
        gas-oil "gas-oil" /
cr     "commodities : crude oils"
      / mid-c    "mid-continent"
        w-tex   "west-texas" /
q     "attributes of intermediate products"
      / density, sulfur /;
```

```
Table attrib(ci, cr, q) "blending attributes"
      density  sulfur
naphtha. mid-c  272    .283
naphtha. w-tex  272    1.48
dist . mid-c    292    .526
dist . w-tex    297    2.83
gas-oil. mid-c  295    .98
gas-oil. w-tex  303    5.05
;
```

The table `attrib` could also be laid out as shown below:

```
Table attrib (ci,cr,q) "blending attributes"
      w-tex.density mid-c.density w-tex.sulfur mid-c.sulfur
naphtha  272          272          1.48          .283
dist     297          292          2.83          .526
gas-oil  303          295          5.05          .98
;
```

4.27.4.5 Condensing Tables

All the mechanisms using asterisks and parenthesized lists that were introduced in the discussion of sets are available here as well. For details on these mechanisms, see section [Multi-Dimensional Sets](#). The following example shows how repeated columns or rows can be condensed with asterisks and lists in parentheses. The set membership is not shown, but can easily be inferred.

```
Table upgrade(strat,size,tech)
      small.tech1  small.tech2  medium.tech1  medium.tech2
strategy-1      .05      .05      .05      .05
strategy-2      .2      .2      .2      .2
strategy-3      .2      .2      .2      .2
strategy-4      .2      .2      .2      .2
```

```
Table upgradex(strat,size,tech) "alternative way of writing table"
      tech1*tech2
strategy-1.(small,medium)      .05
strategy-2*strategy-3.(small,medium)      .2
strategy-4.medium      .2;
```

4.27.4.6 Handling Long Row Labels

It is possible to continue the row labels in a table on a second, or even third line in order to accommodate a reasonable number of columns. The break must come after a dot, and the rest of each line containing an incomplete row label-tuple must be blank.

The following example, adapted from [INDUS], is used to illustrate. This table actually has nine columns and many rows, here we have reproduced just a small part to show continued row label-tuples.

```
Table yield (c,t,s,w,z) "crop yield (metric tons per acre)"
      nwfp      pmw
wheat.(bullock, semi-mech).la-plant.
      (heavy, january)      .385      .338
wheat.(bullock, semi-mech).la-plant. light      .506      .446
wheat.(bullock, semi-mech).la-plant. standard      .592      .524
wheat.(bullock, semi-mech).(qk-harv, standard).
      (heavy, january)      .439      .387
```

4.27.5 Constant Evaluation

Instead of fixed numerical values, one can also use constant expressions to assign values to parameters in a data statement. The syntax of constant expressions used in data statements follows the GAMS syntax as described in [Data Manipulations with Parameters](#), but is restricted to scalar values and a subset of the GAMS intrinsic functions, as summarized below:

- Real numbers only
- Evaluation left to right
- Operator precedence:
 - ^ **
 - * /
 - + - binary and unary
 - < <= = <> >= > LE LE EQ NE GE GT
 - NOT
 - AND
 - OR XOR EQV IMP

- See [Functions](#) for list of supported functions

When used in a data statement, the constant expressions have to be enclosed in a pair of square brackets `[]` or curly brackets `{ }`. Spaces can be used freely inside those brackets. Here is a little example:

```
Scalars x "PI half"      / [pi/2] /
        e "famous number" / [ exp( 1 ) ] /;

Parameter y "demo" / USA.(high,low) [1/3]
            USA.medium {1/4}      /;
```

4.27.6 Data Entry by Assignment

Data may also be entered using assignment statements. Assignments are introduced and discussed in detail in section [The Assignment Statement](#). This section here is a short outlook and shows how parameters that have already been declared may be assigned values. The general assignment statement has the following form:

```
parameter_name[(index_list)] = expression;
```

Here `parameter_name` is the name of a parameter that has been declared previously in a scalar, parameter or table statement, `index_list` indicates the controlling indices and may either contain a set or sets, a label or label tuple or a combination of those, and `expression` may be a number, a numerical expression or an acronym. For details on numerical expressions, see section [Expressions](#).

The following examples illustrate how assignments may be used for data entry.

```
Set      j      /j1, j2, j3/;
Scalar   a1;
Scalars  a2      /11/;
Parameter cc(j),
         bc(j)  /j2 22/;

a1 = 10;
a2 = 5;
cc(j) = bc(j)+10;
cc("j1") = 1;
```

The scalar `a1` is declared but not initialized in the first scalar statement. It is assigned the value of 10 in the first assignment. The scalar `a2` is initialized in the second scalar statement and this value is changed to 5 in the second assignment. Note that the original data is not retained. In the parameter statement the parameter `cc(j)` is declared but not initialized and the parameter `bc(j)` is only initialized for `j2`. This means that `bc('j2') = 22` and `bc('j1') = bc('j3') = 0`, the default value. Now, the third assignment sets the parameter `cc(j)` and assigns to all elements of the set `j` the value of the parameter `bc(j)` plus 10. So we have `cc('j2') = 32` and `cc('j1') = cc('j2') = 10`. Note that in this example the set `j` has only three elements so only 3 assignments are made simultaneously. However, suppose that the number of set elements is large, say 100,000, then to each element a value is assigned with just one assignment statement. Finally, the value of `cc('j1')` is changed to 1.

Observe that in the examples above assignments either refer to one specific set element or to the whole set. It is also possible to make assignments to only a part of the set. The mechanisms for partial set references are discussed in section [Restricting the Domain in Assignments](#). Set elements that are not assigned new values in an assignment with a partial set reference retain their previous values. Recall that these may be the default value, values from the parameter or table statement, or values resulting from previous calculations.

4.27.7 Acronyms

An acronym is a special data type that allows the use of strings as values. Note that acronyms have *no numeric values* and are treated as character strings only.

4.27.7.1 The Syntax

The declaration for an acronym is similar to a set or parameter declaration. The basic format is as follows:

```
Acronym[s] acronym_name [text] {, acronym_name [text]};
```

The keyword `acronym[s]` indicates that this is an acronym statement and `acronym_name` is the internal name of the acronym in GAMS, it is an [identifier](#). The optional [explanatory text](#) is used to describe the acronym. For advice on explanatory text and how to choose an `acronym_name`, see the tutorial [Good Coding Practices](#).

Note that more than one acronym may be declared in one acronym statement. The entries have to be separated by commas or by end of line. A simple example illustrates this:

```
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
```

4.27.7.2 Acronym Usage

Acronyms may be used as data in scalar, parameter and table statements. An example for acronyms in a parameter statement follows.

```
Set machines / m-1*m-5 / ;
Acronym
    Monday, Tuesday, Wednesday, Thursday, Friday;
Parameter
    shutdown(machines)
    /   m-1  Tuesday
      m-2  Wednesday
      m-3  Friday
      m-4  Monday
      m-5  Thursday /;
```

Acronyms may also be used in assignments as in the example below. For more on assignments, see section [The Assignment Statement](#).

```
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
Scalar dayOfWeek;
dayOfWeek = Wednesday;
```

Note that *numerical* operations like addition or subtraction are not allowed with acronyms. Such operations would be meaningless since acronyms do not have numeric values.

Another context where acronyms may be used is in logical conditions. For more on logical conditions, see chapter [Conditional Expressions, Assignments and Equations](#). This is shown in the following example:

```

Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
Scalar dayOfWeek
    workHours /6/;
dayOfWeek = Wednesday;
workHours$(dayOfWeek <> Friday) = 8;

```

Note that only the equality and inequality operators may be used with acronyms. Other operations like addition and division are meaningless since acronyms do not have numeric values.

Acronyms are specific to GAMS and hence difficult to deal with when exchanging data with other systems. Users often replace parameters that contain acronyms with dynamic sets that have an additional index whose values correspond to the acronyms found in the original parameter. The machine shutdown data from above can be represented via a two-dimensional set as follows:

```

Set machines / m-1*m-5 /
    weekdays / Monday, Tuesday, Wednesday, Thursday, Friday /
    shutdown(machines,weekdays)
    /   m-1.Tuesday
      m-2.Wednesday
      m-3.Friday
      m-4.Monday
      m-5.Thursday /;

```

4.27.8 Summary

In this chapter, the declaration and initialization of parameters with the [Scalar](#), [Parameter](#), and [Table](#) statement have been discussed. Chapter [Data Manipulations with Parameters](#) will describe how this data can be changed with assignment statements.

4.28 Variables

4.28.1 Introduction

This chapter covers the declaration and manipulation of GAMS **variables**. Many of the concepts covered in the previous chapters are directly applicable here.

A **variable** is the GAMS name for what are called *endogenous variables* by economists, *columns* or *activities* by linear programming experts, and *decision variables* by industrial Operations Research practitioners. They are the entities whose values are generally unknown until after a model has been solved. A crucial difference between GAMS variables and columns in traditional mathematical programming terminology is that one GAMS variable is likely to be associated with many columns in the traditional formulation.

4.28.2 Variable Declarations

A GAMS variable, like all other identifiers, must be declared before it may be referenced.

4.28.2.1 The Syntax

The declaration of a **variable** is similar to a **set** or **parameter** declaration, in that domain lists and explanatory text are allowed and recommended, and several variables may be declared in one statement. The syntax is given below.

```
[var_type] variable[s] var_name [(index_list)] [text] [/var_data/] {, var_name [(index_list)] [text]}
```

The keyword `var_type` denotes the optional variable type that is explained in detail in the next subsection. `Variable[s]` is the keyword that indicates that this is a variable statement. `Var_name` is the internal name of the variable in GAMS, it is an [identifier](#). In the optional `index_list` the set or sets may be specified over which an indexed variable is declared. The optional [explanatory text](#) may be used to describe the variable for future reference and to ease readability. Specifying variable data is another optional element in the variable statement. Variable data allows to initialize variable attributes at compile time. For an example and details on variable attributes, see section [Variable Attributes](#).

A typical variable statement adapted from the model `[RAMSEY]` is shown below for illustration:

```
Variables
  k(t)      capital stock (trillion rupees)
  c(t)      consumption (trillion rupees per year)
  i(t)      investment (trillion rupees per year)
  utility   utility measure;
```

The declaration of `k` above implies, as usual, that references to `k` are restricted to the domain of the set `t`. A model that includes `k` will probably have several corresponding variables in the associated mathematical programming problem: most likely one for each member of `t`. In this way, very large models can be constructed using a small number of variables. (It is quite unusual for a model to have as many as 50 distinct variables.) It is still unclear from the declaration whether `utility` is not domain checked or whether it is a scalar variable, i.e., one without associated sets. Later references will be used to settle the issue. For more details on domain checking, see section [Domain Checking](#).

As the syntax indicates, the explanatory text is optional. However, it is important that variable declarations include explanatory text and that this be as descriptive as possible, since the text is used to annotate the solution output. Note the use of 'per' instead of '/' in the text above: slashes are illegal in all unquoted text.

Note

- Variable names, the contained set element names plus the explanatory text must obey the general [rules for language items](#).
- Variables can be defined over from 0 up to 20 sets
- The sets over which variables are declared indicate that these variables are potentially defined for every element of the defining sets. However the actual definition of variables does not occur until variables appear in an [equation definition](#) where the equation needs to be part of a [model](#) that in turn occurs in a [solve statement](#).

4.28.2.2 Variable Types

There are nine basic types of variables that may be used in variable statements. These are shown in [table 1](#).

Keyword	Description	Default Lower Bound	Default Upper Bound
free (default)	No bounds on variable. Both bounds may be changed from the default values by the user.	-inf	+inf
positive nonnegative	or No negative values are allowed for variable. The user may change both bounds from the default value.	0	+inf
negative	No positive values are allowed for variables. The user may change both bounds from the default value.	-inf	0
binary	Discrete variable that can only take values of 0 or 1. For details see section Types of Discrete Variables . In relaxed Model types the integrality requirement is relaxed.	0	1
integer	Discrete variable that can only take integer values between the bounds. The user may change both bounds from the default value. The default upper bound inside GAMS is +inf but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default +inf) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed.	0	+inf
sos1	A set of variables, such that at most one variable within a group may have a non-zero value. For details see section Types of Discrete Variables .	0	+inf

Keyword	Description	Default Lower Bound	Default Upper Bound
sos2	A set of variables, such that at most two variables within a group may have non-zero values and the two non-zero values are adjacent. For details see section Types of Discrete Variables .	0	+inf
semicont	Semi-continuous, must be zero or above a given minimum level. For details see section Types of Discrete Variables .	1	+inf
semiint	Semi-integer, must be zero or above a given minimum level and integer. For details see section Types of Discrete Variables . The default upper bound inside GAMS is +inf but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default +inf) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed.	1	+inf

Table 1: Variable types and default bounds

The default type is **free**, which means that if the type of the variable is not specified, it will not be bounded at all. The most frequently used types are **free** and **positive**. The type **positive variables** is used for variables for which negative values are meaningless, such as capacities, quantities or prices. Note that bounds may be changed using variable attributes and assignment statements, see section [Variable Attributes](#).

Note

- Every optimization model must contain at least one unrestricted named variable (i.e. one declared with the keywords **Variable** or **Free Variable**). This variable is the objective variable. Even an objective variable can have lower and upper bounds assigned via the **.lo** and **.up** variable attribute.
- If a model is unbounded, a frequent cause for the unboundedness is that the modeler forgot to make a variable positive.

4.28.2.3 Styles for Variable Declaration

Two styles are commonly used to declare variable types. The first is to list all variables with domain specifications and explanatory text as a group, and later to group them separately as to type. The example shown below is adapted from [MEXSS]. The default type is `free`, so `phi` and `phipsi` will be `free` variables in the example below. Note the use of variable names derived from the original mathematical representation.

```
Variables
  u(c,i) "purchase of domestic materials (mill units per yr)"
  v(c,j) "imports          (mill tpy)"
  e(c,i) "exports          (mill tpy)"
  phi    "total cost       (mill us$)"
  phipsi "raw material cost (mill us$)";
Positive Variables u, v, e;
```

The commas in the list of positive variables are required separators.

Attention

It is possible to declare an identifier more than once. However, the second and any subsequent declarations should only add new information that does not contradict what has already been entered.

The second popular way of declaring variables is to list them in groups by type. We rewrite the example above using this second method:

```
Free Variables
  phi    "total cost       (mill us$)"
  phipsi "raw material cost (mill us$)"
```

```
Positive Variables
  u(c,i) "purchase of domestic materials (mill units per yr)"
  v(c,j) "imports          (mill tpy)"
  e(c,i) "exports          (mill tpy)";
```

The choice between the two approaches is best based on clarity.

4.28.3 Variable Attributes

While a GAMS parameter has one number associated with each unique label combination, a variable has several. They represent:

Variable Attribute	Symbol	Description
Lower bound	.lo	Lower bound for the variable. Set by the user either explicitly or through default values associated with the variable type.
Upper bound	.up	Upper bound for the variable. Set by the user either explicitly or through default values associated with the variable type.
Fixed value	.fx	A fixed value for the variable. If set it results in the upper and lower bounds of the variable to be set to the value of the .fx attribute.

Variable Attribute	Symbol	Description
Activity level	.l	Activity level for the variable, also the current value or starting point. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.
Marginal	.m	The marginal value (or reduced cost) for the variable. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.
Scale factor	.scale	Numerical scaling factor for all coefficients associated with the variable if the model attribute <code>scaleopt</code> is set to 1. For more on scaling, see section Model Scaling - The Scale Option . Only applicable for continuous variables.
Branching priority	.prior	Branching priority value used in mixed integer programming models if the model attribute <code>prioropt</code> is set to 1. For details see section Setting Priorities for Branching . It can also be used to relax discrete restrictions by setting <code>.prior = +inf</code> regardless of the <code>prioropt</code> setting. Only applicable for discrete variables.
Stage	.stage	This attribute allows to assign variables to stages in a stochastic program or other block structured model. Thus, among other places, it is used for 2-stage stochastic programs solved with DECIS or the Benders partition in Cplex .

Table 2: Variable Attributes

Users distinguish between these values when necessary by appending the suffix to the variable name. Examples are given below.

It is possible to specify initial values for these variable attributes at compile time. This can be done within the variable declaration statement as illustrated in the following example or during execution time as explained in section [Assigning Values to Variable Attributes](#).

```
Variable x1(j) my first / j1.up 10 , j1.lo 5, j1.l 7, j1.m 0, j1.scale 20 /;
```

The upper bound of the variable `x1("j1")` is set to 10, the lower bound is set to 5, the starting value for the activity level is set to 7 and the starting value for the marginal is set to 0. The variable is also scaled by the factor 20, which means it is *multiplied* by 20.

Note that it is also possible to use a table structure to assign values to variable attributes. The following example is adapted from model `[TRANSPORT]`.

```
Variable Table x(i,j) initial values
                1      m
seattle.  new-york    50
seattle.  chicago    300
san-diego.new-york   275
san-diego.chicago   0.009;
```

Note

- `.fx` and attributes `.lo` and `.up` on the same variable cannot be in a data statement. `.fx` sets both `.lo` and `.up` and hence we would have a double definition of the same attribute. Since attribute `.scale` is applicable for continuous variables and attribute `.prior` for discrete variables, they share the same internal space in a GAMS variable. Some solvers can make use of priorities even for continuous variables (e.g. [BARON](#)). Such priorities need to be supplied via a solver option file.
- The attribute `.stage` uses the same internal space as `.scale` and `.prior`. So a model cannot specify scale factor and branching priorities together with stages.
- Fixing a [semi-continuous](#) or [semi-integer](#) variable to a non-zero value like `x.fx = 4` does not result in a truly fixed variable. The domain of the variable remains $\{0,4\}$. To really fix a semi-continuous or semi-integer variable, the discrete restriction could be relaxed by setting the [branching priority](#) to infinity (`x.prior=inf`).
- For variables in discrete models (such as MIP, MINLP), the `.m` attribute provides the marginals obtained by fixing all the discrete variables and solving the resulting continuous problem (such as LP, NLP). Many solvers allow to enable/disable solving such a fixed problem. When disabled, no marginals will be provided for discrete models.

In addition to the variable attributes introduced above, there are a number of variable attributes that cannot be assigned but may be used in computations. They are given in [Table 3](#).

Variable Attribute	Symbol	Description
Range	<code>.range</code>	The difference between the lower and upper bounds for a variable. It becomes zero if the lower equals the upper bound, e.g. if the <code>fx</code> attribute is set.
Slack upper bound	<code>.slackup</code>	Slack from variable upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of a variable.
Slack lower bound	<code>.slacklo</code>	Slack from variable lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of a variable.
Slack	<code>.slack</code>	Minimum slack from variable bound. This is defined as the minimum of two values: the slack from the variable lower bound and the slack from the variable upper bound.
Infeasibility	<code>.infeas</code>	Amount by which a variable is infeasible falling below its lower bound or above its upper bound. This is defined as the smallest of three values: zero, the difference between the lower bound and the level value, the difference between the level value and the upper bound of a variable, i.e. $\max(0, \text{lower-level}, \text{level-upper})$.

Table 3: Additional Variable Attributes that Cannot Be Assigned but May Be Used in Computations.

4.28.3.1 Bounds on Variables

All default bounds set at declaration time may be changed using assignment statements.

Attention

For discrete variable types, the consequences of the type declaration cannot be completely undone (e.g. the `scale` attribute is not available) but their value domain can be changed to continuous by setting attribute `prior` to infinity.

Bounds on variables are the responsibility of the user. After variables have been declared, default bounds have already been assigned: for many purposes, especially in linear models, the default bounds are sufficient. In nonlinear models, however, bounds play a far more important role. It may be necessary to provide bounds to prevent undefined operations, such as division by zero. In nonlinear programming it is often necessary to define a 'reasonable' solution space that will assist in efficiently finding a solution.

Attention

The lower bound cannot be greater than the upper bound: if you happen to impose such a condition, GAMS will generate an execution error, namely `**** Matrix error - lower bound > upper bound` when executing a solve statement.

Note that the upper bound on integer and semi-integer variables needs special consideration. The default upper bound is `+inf` and the option or command line parameter `IntVarUp` controls what upper bound is sent to the solver. With the current default value (0) of `IntVarUp`, an upper bound of `+inf` is sent to the solver. Setting `IntVarUp` to one will pass 100 as the default upper bound to the solver. The other available values for `IntVarUp` work like zero, but enable special reports/execution errors in case the solution reports a level value greater than 100 for any integer variable with a default bound of `+inf`.

4.28.3.2 Fixing Variables

GAMS allows the user to fix variables through the `.fx` variable suffix. This is almost equivalent to setting the lower bound and upper bound equal to the fixed value. The attribute `.fx` also resets the activity level `.l` to the fixed value. When setting `.lo` and `.up` the activity level remains unchanged. A `solve` statement will project the activity level within the active bounds. Fixed variables can subsequently be freed by changing the lower and upper bounds.

4.28.3.3 Activity Levels of Variables

GAMS allows the user to set the activity levels of variables through the `.l` variable suffix. These activity levels of the variables prior to the solve statement serve as initial value for the solver. This is particularly important for nonlinear programming problems. For discrete models in many cases the solver needs an additional indicator to interpret the activity levels as a feasible integer solution via a solver option (e.g. Cplex' `mipstart`).

Attention

- GAMS only stores variables with non-default values (similar to storing only non-zero values of parameters). Non-default variables can be accidentally created by using harmlessly looking assignments like

```
x.up(i,j,k,l) = 0;
```

Even if the equations only reference such variables over a small subset of (i,j,k,l) this statement creates `card(i)*card(j)*card(k)*card(l)` variable records in the GAMS database. Such fixings of `x(i,j,k,l)` to 0 can be avoided by using dynamic sets or dollar conditions in the equation algebra to only reference tuples of (i,j,k,l) for which `x(i,j,k,l)` can possibly have a non-zero value.

- In order to filter only necessary tuples for an equation the filtering conditions needs to be provided only once when defining the equation (`equ(i,j,k)`). This is different for variables because they appear in many equations and the filtering condition needs to be potentially repeated many time. Therefore it is good practice and reduces GAMS model generation time if the filtering of the variables is governed by a dynamic set:

```
sum((i,j)$ (ord(i)>ord(j) and cap(i,j)>0), x(i,j))
```

versus

```
set net(i,j); net(i,j) = ord(i)>ord(j) and cap(i,j)>0;
sum(net(i,j), x(i,j))
```

4.28.4 Variables in Display and Assignment Statements

GAMS allows the modeler to use the values associated with the various attributes of each variable in assignment and `display` statements. The next two subsections explain the use of variables on the left and right-hand sides of assignment statements respectively. Then we will explain the use of variables in `display` statements.

4.28.4.1 Assigning Values to Variable Attributes

Assignment statements operate on one variable attribute at a time, and require the suffix to specify which attribute is being used. Any index list comes after the suffix.

The following code snippets are from models `[MEXSS]` and `[RAMSEY]`. The first example illustrates the use of assignment statements to set upper and lower bounds on variables.

```
x.up(c,i,j) = 1000 ; phi.lo = inf ;
```

A very common use is to bound one particular entry individually:

```
p.up('pellets', 'ahmsa', 'mexico-df') = 200 ;
```

Or to put small lower bounds on a variable identifier used as a divisor in a nonlinear program:

```
c.lo(t) = 0.01 ;
```

Or to provide initial values for a nonlinear problem:

```
c.l(t) = 4*cinit(t) ;
```

Remember that the order is important in assignments, and notice that the two pairs of statements below produce very different results. In the first case, the lower bound for `c('1985')` will be 0.01, but in the second, the lower bound is 1.

```
c.fx('1985') = 1;           c.lo(t) = 0.01 ;
c.lo(t) = 0.01 ;         c.fx('1985') = 1 ;
```

Everything works as described in the previous chapter, including the various mechanisms described there of indexed operations, dollar operations, subset assignments and so on. An example from model `LOCATION` follows.

```
ship_sm.lo(s1,m)$(ord(s1) = 1 and ord(m) = 1) = 1;
```

The lower bound of the variable `ship_sm(s1,m)` is set to 1 and this assignment is only valid for `ship_sm('s1','d1')`, the realization of the variable where both indices are the first members of their respective sets.

4.28.4.2 Variable Attributes in Assignments

Using variable attributes on the right-hand side of assignment statements is important for a variety of reasons. Two common uses are for generating reports and for generating initial values for some variables based on the values of other variables. For more on variable attributes in report writing, see section [Displaying Variable Attributes](#) below and especially chapter [The Put Writing Facility](#).

The following examples adapted from model [\[CHENERY\]](#) illustrate the use of variable attributes on the right-hand side of assignment statements:

```
* initial values for variables

y.l(i) = 250 ; x.l(i) = 200 ;
e.l(t) = 0 ; m.l(t) = 0 ;

g.l(t) = mew(t) + xsi(t)*m.l(t) ;
h.l(t) = gam(t) - alp(t)*e.l(t) ;

[...]

* generating report after solve

Scalar
    cva  "total value added at current prices"
    rva  "real value added"
    cli  "cost of living index" ;

cva = sum (i, v.l(i)*x.l(i)) ;
cli = sum(i, p.l(i)*ynot(i))/sum(i, ynot(i)) ;
rva = cva/cli ;

Display cli, cva, rva ;
```

As with parameters, a variable must have some non-default data values associated with it before it can be used in a `display` statement or on the right-hand side of an assignment statement. After a `solve` statement has been processed or if non-default values have been set with an assignment statement, this condition is satisfied. `Solve` statements are introduced and discussed in chapter [Model and Solve Statements](#).

Attention

The `.fx` suffix is mostly just a shorthand for `.lo` and `.up` and can therefore only be used only on the left-hand side of an assignment statement.

Note

- In general, the variable level needs to be specified via the attribute `.l` for assignment statements. However, the dollar control option [\\$on/offDotL](#) allows the implicit use of the attribute `.l` in assignment statements, thus it facilitates using the same algebra in model definitions and assignment statements. This is especially useful in the context of [macros](#).

4.28.4.3 Displaying Variable Attributes

The `display` statement is introduced and discussed in detail in chapter [The Display Statement](#). Here we demonstrate how variable attributes are used in `display` statements.

Since several values are associated with each variable, the user must specify which attribute should be displayed when using variables in `display` statements. As before, appending the appropriate suffix to the variable name does this and no domain specification may appear. As an example, we show how to `display` the level of `phi` and the level and the marginal values of `v` from `[MEXSS]`:

```
display phi.l, v.l, v.m;
```

The output looks similar, except that (of course) the listing shows which of the values is being displayed. Because zeroes, and especially all zero rows or columns, are suppressed, the patterns seen in the level and marginal displays will be quite different, since non-zero marginal values are often associated with activity levels of zero.

```
Mexico Steel - Small Static   (MEXSS,SEQ=15)
E x e c u t i o n

----   203 VARIABLE  PHI.L           =      538.811 total cost
                                           (mill us$)
----   203 VARIABLE  V.L             imports
                                           (mill tpy)
           ( ALL      0.000 )

----   203 VARIABLE  V.M             imports
                                           (mill tpy)
           mexico-df  monterrey  guadalaja
steel      7.018      18.822      6.606
```

We should mention here a clarification of our previous discussion of displays. It is actually the default values that are suppressed on display output. For parameters and variable levels and marginals, the default is zero, and so zero entries are not shown. For bounds, however, the defaults can be non-zero. The default value for the upper bound of a positive variable is `+INF`, and if we would also display `v.up` above, for example, we would see:

```
----   203 VARIABLE  V.UP             imports
                                           (mill tpy)
           ( ALL      +INF )
```

If any of the bounds have been changed from the default value, then only the entries for the changed elements will be shown. This may sound confusing, but since few users display bounds it has not proved troublesome in practice.

Note

The attribute `.range` may be used in `display` statements. It provides a convenient way to check whether a variable is fixed as it lists the 0 values explicate because the default for range (which won't be displayed) is `+inf`.

4.28.5 Summary

Remember that wherever a parameter may appear in a display or an assignment statement, a variable may also appear - provided that it is qualified with one of the suffixes. The only places where a variable name may appear without a suffix is in a variable declaration, as has been shown in this chapter, in an equation definition, which is discussed in chapter [Equations](#), or in a `$on/offDotL` block.

4.29 Equations

4.29.1 Introduction

The keyword `equation` defines GAMS names that may be used in the `model statement`. A GAMS equation name is associated with the symbolic algebraic relationships that will be used to generate the constraints in a model. The algebraic relationships are defined by using constants, mathematical operators, functions, [sets](#), [parameters](#) and [variables](#). As with variables, one GAMS equation may be defined over a group of sets and in turn map into several individual constraints associated with the elements of those sets. Most of the example code in this chapter is from the model `location`.

This chapter is organized as follows. First, we introduce how equations are declared and defined, then we discuss expressions in equation definitions, followed by a section on equation attributes. A summary and quick reference conclude the chapter.

4.29.2 Declaring Equations

An `equation` must be declared before it can be defined and used in a model.

4.29.2.1 The Syntax

The declaration of an `equation` is similar to a `set` or `parameter` declaration. The syntax is given below.

```
Equation[s] eqn_name [(index_list)] [explanatory text] [/eqn_data/] {, eqn_name [(index_list)] [expl
```

`Equation[s]` is the reserved word that indicates that one or more blocks of equations are about to be declared. A block of equations may initiate one or more individual constraints. `Eqn_name` is the internal name of the equation, an [identifier](#) in GAMS. In the optional `index_list` the set or sets are specified over which an indexed equation is declared. The optional [explanatory text](#) may be used to describe the equation for future reference and to ease readability. Specifying equation data is another optional element in the equation declaration. Equation data allows to initialize equation attributes at compile time. For an example see the next section. For more on equation attributes see section [Equation Attributes](#).

One or more equations may be declared in one `equation` statement. The equation names have to be separated by commas or by a line break as in the example that follows. The end of the declaration statement is indicated by a semicolon.

Note

It is good practice to end the equation declaration with a semicolon, even though it is not mandatory if the next statement starts with a GAMS [keyword](#).

For advice on choosing equation names and phrasing the explanatory text see chapter [Good Modeling Practices](#).

4.29.2.2 An Illustrative Example

The following example is from the model `location`. In addition to the equation declarations the relevant set definitions are given.

```
Sets
  sl          'supply locations'          /s1, s2/
  wh          'warehouse locations'       /a, b, c/;

Equations
  tcost_eq    'total cost accounting equation'
  supply_eq(sl) 'limit on supply available at supply location'
  capacity_eq(wh) 'warehouse capacity' /a.scale 50, a.l 10, b.m 20/;
```

The keyword `Equations` marks the beginning of the equation declaration. Each equation name is optionally followed by its domain (associated set or sets) unless it is a *scalar equation*. It is possible but not good practice to declare indexed equations without their domains. The name of the first equation is `tcost_eq` and it is followed by the explanatory text `'total cost accounting equation'`. The name of the equation `tcost_eq` is not followed by any associated sets. Since we follow good practice here we assume that `tcost_eq` is a scalar equation. Scalar equations do not have any associated sets and will generally produce one equation in the model. For more on scalar equations see subsection [Scalar Equations](#).

The other two equations are *indexed equations*, they are declared over a set. The equation `supply_eq` is declared over the set `sl` and the equation `capacity_eq` is declared over the set `wh`. In typical circumstances an indexed equation declaration implies that a block of constraints will be generated. For example, equation `supply_eq(sl)` implies that two constraints will be generated, one for each element of the set `sl`. For more on indexed equations see subsection [Indexed Equations](#).

The declaration of the equation `capacity_eq` specifies some equation attributes. The first entry indicates that the equation `capacity_eq('a')` is scaled by a factor of 50, which means division of all entries in that equation by 50 upon model passage to the solver. For more on scaling see section [Model Scaling - The Scale Option](#). The second entry sets the initial value of the equation `capacity_eq('a')` to 10 and `b.m` means that the initial marginal value of the equation `capacity_eq('b')` is set to 20. Alternatively, a table structure may be used to specify the values of equation attributes. The following table may replace the notation above.

```
Equation Table capacity_eq(wh) 'warehouse capacity'
  scale    l      m
  a    50    10
  b                      20 ;
```

For more on equation attributes see section [Equation Attributes](#).

Note

An equation may be declared over more than one set.

4.29.3 Defining Equations

After declaring equations they have to be defined. The definition of an equation specifies the algebraic structure of the equation in GAMS. The syntax is given first, an illustrative example follows and in the remainder of this section some of the key components of equation definitions are discussed.

4.29.3.1 The Syntax

The syntax for defining an equation is as follows:

```
eqn_name(index_list)[$logical_condition(s)].. expression eqn_type expression ;
```

Eqn_name is the name of the equation as introduced in the equation declaration, that may be followed by an **index_list** for indexed equations. In the **index_list** the set or sets are specified over which an indexed equation is defined. These sets are also called *domain of definition* of the equation. One or more logical conditions are optional. For an example see [Indexed Equations](#). For more on logical conditions in equation definitions see [Dollar Control over the Domain of Definition](#). The two dots '..' are mandatory and indicate the start of the algebra. It is good practice to end the definition of an equation with a semicolon, even though it is not mandatory if the next statement starts with a GAMS keyword.

Attention

An equation must be declared before it is defined.

Expression refers to an algebraic expression which may include variables, parameters, functions, and constants among other items. For details on expressions in GAMS, see section [Expressions](#).

Attention

Only variables that appear at least once with a nonzero coefficient in an equation definition will appear in a model.

Eqn_type refers to the equation type denoted by the symbol between the right-hand side and left-hand side expressions that form the equation. The symbols that are allowed are given in [Table 1](#).

Type	Description
=e=	Equality: right-hand side must equal left-hand side.
=g=	Greater than: left-hand side must be greater than or equal to right-hand side.
=l=	Less than: left-hand side must be less than or equal to right-hand side.
=n=	No relationship implied between left-hand side and right-hand side. This equation type is ideally suited for use in MCP models and in variational inequalities .
=x=	Equation is defined by external programs. See External Equations .
=c=	Conic constraint. See Conic Programming in GAMS .
=b=	Boolean equations. See Logic Equations .

Table 1: Equation Types

Equation definitions may be carried over as many lines of input as needed. Blanks may be inserted to improve readability, and expressions may be arbitrarily complicated.

Note that an equation can only be defined once. By using logical conditions it is possible to control which constraints are generated. In addition, the components of an equation may be modified by changing the data it uses. However, if the logic of the equation needs to be changed then a new equation with a new name has to be declared and defined.

4.29.3.2 An Illustrative Example

Consider the following example adapted from the model `[mexss]`. The associated variable and equation declarations are also included.

```
Variables phi, phipsi, philam, phipi, phieps ;
Equations obj ;
obj.. phi =e= phipsi + philam + phipi - phieps ;
```

The name of the equation being defined is `obj` and the symbol `=e=` indicates that this is an equality. Any of the following forms of the equation are mathematically equivalent.

```
obj.. phipsi + philam + phipi - phieps =e= phi ;
obj.. phieps - phipsi =e= philam - phi + phipi ;
obj.. phi + phieps - phipsi - philam - phipi =e= 0 ;
obj.. 0 =e= phi + phieps - phipsi - philam - phipi ;
```

Note

The arrangement of the terms in the equation is a matter of choice, but often a particular one is chosen because it makes the model easier to understand.

4.29.3.3 Scalar Equations

A scalar equation will produce one equation in the associated optimization problem. The equation `obj` defined above is an example of a scalar equation which contains only scalar variables. Note that scalar equations may contain indexed variables. However, they must occur with an indexed operator such as `sum` or `prod`, unless the indexed variables refer to a singleton set (a set with only one element). Consider the following example from the model `location`. Note that the set `wh` has three elements.

```
configure_eq.. sum(wh,build(wh)) =l= 1;
```

The variable `build` is defined over the set `wh`, it is an indexed variable. It may be used in the scalar equation `configure_eq` since it occurs in conjunction with the indexed operator `sum`.

4.29.3.4 Indexed Equations

All the set references in scalar equations are within the scope of indexed operators or they refer to singleton sets; thus many variable, set and parameter references can be included in one equation. In addition, GAMS also allows for equations to be defined over a domain, thereby developing a compact representation for constraints. The index sets to the left of `..` are called the *domain of definition* of the equation.

Note

- Domain checking ensures that the domain over which an equation is defined is the set (or the sets) or a subset of the set (or the sets) over which the equation was declared.
- As a corollary, domain checking also catches the error of the indices being listed in an inconsistent order. For example, declaring an equation as `myequation(s,t)` and then naming it in the definition as `myequation(t,s)` causes an error (unless `s` and `t` are aliases of the same set). For more information, see section [Domain Checking](#).

The following indexed equation with a single index generates a separate constraint for each member of the driving (or controlling) set. It is taken from the model `[chenery]`. In this example, `t` is a set with three members, `mew` and `xsi` are parameters and `m` and `g` are variables.

```
dg(t).. g(t) =e= mew(t) + xsi(t)*m(t) ;
```

As the set `t` has three members, three constraints will be generated, one for each member of `t` specifying the dependence of `g` on `m`. The data associated with the parameters `mew` and `xsi` are used to build the individual constraints. This data does not have to be known when the equation is defined, but it has to be populated before a model containing the equation is solved.

The extension to two or more indices on the left of `..` is obvious. There will be one constraint generated for each combination of set elements that can be constructed using the indices inside the parenthesis. Here are two examples from the model `[aircraft]`, a scheduling model.

```
bd(j,h).. b(j,h) =e= dd(j,h) - y(j,h) ;
yd(j,h).. y(j,h) =l= sum(i, p(i,j)*x(i,j)) ;
```

The domain of definition of both equations is the Cartesian product of `j` and `h`: constraints will be generated for every set element pair that can be constructed from the members of these two sets.

The next example illustrates the use of the optional logical conditions in the definition of equations. It is taken from the production and distribution model `[ferts]`.

```
CC(m,i)$mpos(m,i).. sum(p$ppos(p,i), b(m,p)*z(p,i)) =l= util*k(m,i) ;
```

`CC` is a capacity constraint defined for elements of the sets `m` and `i`. However, in this case not all cases of `m` exist at each location `i`, and the mapping set `mpos(m,i)` tells the cases where `m` exists at `i` and thus is used to restrict the domain cases for which the constraints are actually generated. The control of the summation over `p` with `ppos(p,i)` is an additional logical condition, and is required because not all processes `p` are possible at all locations `i`.

The equation may alternatively written in the following way:

```
CC(mpos(m,i)).. sum(ppos(p,i), b(m,p)*z(p,i)) =l= util*k(m,i) ;
```

Instead of defining the equation over the indices `(m,i)` the equation is defined over the set `mpos` that is itself defined over the indices `(m,i)`. A similar logic applies to restricting the summation.

Conditional expressions are introduced and discussed in the section [Conditional Expressions, Assignments and Equations](#). See specifically [Dollar Control over the Domain of Definition](#) for logical conditions in equation definitions.

4.29.3.5 Using Labels Explicitly in Equations

Sometimes it can be necessary to refer to specific set elements in equations. This can be done as with parameters - by using quotes or double quotes around the `label`. Consider the following example from the model `location`:

```
sum(m, ship_wm(wh,m)) =l= build(wh)*data(wh,"capacity") ;
```

4.29.3.6 Logic Equations

Logic equations use Boolean algebra and have to evaluate to `TRUE` (or 1) to be feasible. The Boolean functions available in GAMS and the default order of precedence of the operators are given in [Table 2](#). Note that 1 denotes the highest order of precedence or the most binding operator and 3 denotes the lowest order of precedence or the least binding operators. As usual, the default order of precedence holds only in the absence of parentheses and operators on the same level are evaluated from left to right.

Function	Operator	Alternative Notation	Return Values	Order of precedence
Negation	<code>not x</code>	<code>bool_not(x)</code>	returns 1 if $x = 0$, else returns 0	1
Logical conjunction	<code>x and y</code>	<code>bool_and(x,y)</code>	returns 1 if $x = y = 1$, else returns 0	2
Logical disjunction	<code>x or y</code>	<code>bool_or(x,y)</code>	returns 0 if $x = y = 0$, else returns 1	3
Exclusive disjunction	<code>x xor y</code>	<code>bool_xor(x,y)</code>	returns 1 if <i>exactly</i> one argument is 1, else returns 0	3
Material implication	<code>x imp y</code> or <code>x -> y</code>	<code>bool_imp(x,y)</code>	returns 0 if $x = 1$ and $y = 0$, else returns 1	3
Material equivalence	<code>x eqv y</code> or <code>x <=> y</code>	<code>bool_eqv(x,y)</code>	returns 0 if <i>exactly</i> one argument is 0, else returns 1	3

Table 2: Boolean Functions and Operator Precedence

Note that in the table above x and y are binary variables.

There are three ways to declare and define logic equations:

1. The logic equation is declared using the keyword `Logic Equation` and the definition contains only Boolean algebra symbols.
2. The logic equation is declared like any other equation using the keyword `Equation` and in the definition the symbol `=b=` appears indicating that it is a logic equation.
3. This is a combination of the first two options: the equation is declared with the keyword `Logic Equation` and defined using the symbol `=b=`.

The following example demonstrates the first way to declare and define a logic equation. It is adapted from the food manufacturing problem `[foodemp]`. In this problem the blending of oils is modeled.

Sets

```

m          "planning period (month)"    / m1*m6 /
p          "raw oils"                   / v1*v2, o1*o3 /

```

Variables

```

induse(m,p) "indicator for usage of raw oil per month" ;
Binary variable induse;

```

Logic Equation

```

deflogic(m) "if some vegetable raw oil is used we also need to use the non-vegetable oil o3" ;

deflogic(m).. induse(m,'v1') or induse(m,'v2') -> induse(m,'o3');

```

The variable `induse` is a binary variable, it can only take the values 0 and 1. The equation ensures that in an optimal solution if either vegetable oil `v1` or vegetable oil `v2` is blended in a product, then non-vegetable oil `o3` is also blended in that product.

An alternative formulation of the equation `deflogic` using the `=b=` notation is given below.

```

deflogic(m).. induse(m,'v1') or induse(m,'v2') -> induse(m,'o3') =b= 1;

```

Note that the value of 1 on the right-hand side means that the logic expression on the left-hand side must evaluate to `TRUE` in a feasible solution. To illustrate further, we could negate the left-hand side expression using the logic operator `not` and then the right-hand side would have to evaluate to zero or `FALSE` to yield the same result as above. The respective equation definition follows.

```

deflogic(m).. not (induse(m,'v1') or induse(m,'v2') -> induse(m,'o3')) =b= 0;

```

Note that currently logic equations are allowed only in models of the GAMS model type `EMP`. For more on GAMS model types see section [Classification of Models](#).

4.29.4 Expressions in Equation Definitions

The arithmetic operators and some of the functions that are described in section [Expressions](#) may be used in equation definitions.

Consider the following example adapted from the model [`chenery`] demonstrating the use of parentheses and exponentiation.

```

dem(i) .. y(i) =e= ynot(i)*(pd*p(i))**thet(i) ;

```

A list of arithmetic operators is given in subsections [Standard Arithmetic Operations](#) and [Indexed Operations](#).

4.29.4.1 Functions in Equation Definitions

All available GAMS functions are listed in the section [Functions](#). Some functions are not allowed at all in equation definitions. They include random distribution functions and are marked with *none* in the third column of the tables listing all functions.

Attention

Some functions like `uniform` and `normal` are not allowed in equation definitions.

The use of the other functions is determined by the type of arguments in the model. There are two types of arguments:

1. *Exogenous arguments*: The arguments are known. Parameters and variable attributes (for example, `.l` and `.m` attributes) are used as arguments. The expression is evaluated once when the model is being set up and most mathematical functions as well as time and calendar functions are allowed.
2. *Endogenous arguments*: The arguments are variables and therefore unknown at the time of model setup. The function will be evaluated many times at intermediate points while the model is being solved. Note that the occurrence of any function with endogenous arguments implies that the model is not linear.

Functions that are allowed only with exogenous arguments are marked with *any* in the tables listing all functions.

There are two types of functions allowing endogenous arguments: *smooth* functions and *discontinuous* functions. Smooth functions are continuous functions with continuous derivatives (like `sin`, `exp`, `log`). Discontinuous functions include continuous functions with discontinuous derivatives (like `max`, `min`, `abs`) and discontinuous functions (like `ceil`, `sign`). Smooth functions may be used routinely in nonlinear models. However, discontinuous functions may cause numerical problems and should be used only if unavoidable, and only in a special model type called DNLP. For more details on model types see section [Classification of Models](#).

Attention

The best way to model discontinuous functions is with binary variables. The result is a model of the type MINLP. The model `[ABSMIP]` demonstrates this formulation technique for the functions `abs`, `min`, `max` and `sign`. See also section [Reformulating DNLP Models](#). We strongly discourage the use of the DNLP model type.

In [Table 3](#) the use of functions in equation definitions is summarized.

Functions are allowed ...	Description of Functions
not at all	Functions that are marked <i>none</i> in the third column of the tables listing all functions in section Functions .
only with exogenous arguments	Functions that are marked <i>any</i> in the third column of the tables listing all functions in section Functions .
with endogenous arguments	Smooth functions. They are marked <i>NLP</i> in the third column of the tables listing all functions in section Functions .
with endogenous arguments	Discontinuous functions. They are marked <i>DNLP</i> in the third column of the tables listing all functions in section Functions .

Table 3: Functions in Equation Definitions**4.29.4.2 Preventing Undefined Operations in Equations**

Some operations are not defined at particular values of the arguments. Two examples are division by 0 and the \log - of 0. While this can easily be identified at model setup for exogenous functions and expressions, it is a lot more difficult when the terms involve variables. The expression may be evaluated many times when the problem is being solved and the undefined result may arise only under certain cases. One way to avoid an expression becoming undefined is adding bounds to the respective variables. Consider the following example from the model `[ramsey]`:

```
c.lo(t) = 0.01 ;
util .. utility =e= sum(t, beta(t)*log(c(t))) ;
```

Specifying a lower bound for $c(t)$ that is slightly larger than 0 prevents the \log -function from becoming undefined.

4.29.5 Equation Attributes

Equation attributes may be specified in a similar way as variable attributes. Five values are associated with each unique label combination of every equation. They are denoted by the suffixes `.l`, `.m`, `.lo`, `.up` and `.scale`. A list of the attributes and their description is given in [Table 4](#).

Equation Attribute	Symbol	Description
Lower bound	<code>.lo</code>	Negative infinity for <code>=l=</code> equations. Right hand side value for <code>=g=</code> , <code>=e=</code> , and <code>=b=</code> equations. Zero for <code>=c=</code> equations.
Upper bound	<code>.up</code>	Positive infinity for <code>=g=</code> and <code>=c=</code> equations. Right hand side value for <code>=l=</code> , <code>=e=</code> , and <code>=b=</code> equations.
Equation level	<code>.l</code>	Level of the equation in the current solution, equal to the level of all terms involving variables.
Marginal	<code>.m</code>	Marginal value for equation. This attribute is reset to a new value when a model containing the equation is solved. The marginal value for an equation is also known as the shadow price for the equation and in general not defined before solution but if present it can help to provide a basis for the model
Scale factor	<code>.scale</code>	Numerical scaling factor that scales all coefficients in the equation. This is only used when the model attribute <code>scaleopt</code> is set to 1. For more on scaling, see section Model Scaling - The Scale Option .
Stage	<code>.stage</code>	This attribute allows to assign equations to stages in a stochastic program or other block structured model. Its current use is limited to 2-stage stochastic programs solved with DECIS.

Table 4: Equation Attributes

Note that all attributes except for `.scale` and `.stage` contain the attribute values of equations *after* a solution of the model has been obtained. For some solvers it can be useful to specify marginal values `.m` and level values `.l` on input to provide starting information. Also note that the marginal value is also known as the *dual* or *shadow price*. Roughly speaking, the marginal value `.m` of an equation is the amount by which the value of the objective variable would change if the equation level were moved one unit.

Equation attributes may be referenced in expressions and can be used to specify starting values (see section [Declaring Equations](#)). In addition, they serve for scaling purposes and for reporting after a model was solved. For example, they may be displayed using the `display` statement. The following example is from the model `location`.

```
Model warehouse 'warehouse location model' /all/;
solve warehouse using mip min tcost;
display supply_eq.l;
```

The `display` statement generates the following output at the end of the listing file:

```
----      108 EQUATION supply_eq.L  limit on supply available at supply location

s1 50.000,      s2 75.000
```

The level values of the equation `supply_eq` are displayed. As expected, there are two level values, one for each member of the set `s1` over which the equation `supply_eq` was defined.

Note

By default, all equation attributes introduced above except for `.scale` are echoed to the solution report that is part of the listing file.

In addition to the equation attributes introduced above, there are a number of equation attributes that cannot be assigned but may be used in computations. They are given in [Table 5](#).

Equation Attribute	Symbol	Description
Range	<code>.range</code>	The difference between the lower and upper bounds of an equation.
Slack lower bound	<code>.slacklo</code>	Slack from equation lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of an equation.
Slack upper bound	<code>.slackup</code>	Slack from equation upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of an equation.
Slack	<code>.slack</code>	Minimum slack from equation bound. This is defined as the minimum of two values: the slack from equation lower bound and the slack from equation upper bound.
Infeasibility	<code>.infeas</code>	Amount by which an equation is infeasible falling below its lower bound or above its upper bound. This is defined as $\max(0, \text{lower bound} - \text{level}, \text{level} - \text{upper bound})$.

Table 5: Additional Equation Attributes that Cannot Be Assigned but May Be Used in Computations.

4.29.6 Summary and Quick Reference

In this chapter we have covered the declaration and definition of `equations` in GAMS, arithmetic operations and functions that may be used in equations and equation attributes. A list summarizing the main points to keep in mind follows.

- Equations must be declared before they may be defined. [1]
- It is good practice to add an explanatory text to the declaration. [2]
- More than one equation may be declared at once. The equation names have to be separated by commas or by a line break. [3]
- Equations may be declared and defined over sets which are called the domain of definition of the equation. [4]
- One indexed equation may generate many constraints depending on the size of the set(s) over which it is defined. [5]
- Equations may be defined over subsets. The dollar condition may be used to filter the members of a set so that only a subset of the members are considered. [6]
- The set(s) over which an equation is defined must be consistent with the set(s) over which the equation was declared, being the set(s) themselves or a subset of the set(s). [7]
- The arrangement of terms in an equation is up to the other. Variables can appear on both sides of an equation. [8]
- Labels of specific set elements may be used explicitly in equations. [9]
- All arithmetic operations that may be used to evaluate expressions are also allowed in equations. [10]
- Many functions that are defined in GAMS may be used in equations. [11]
- It is good practice to set bounds for variables to avoid undefined operations if equations contain operations that are undefined at certain values. [12]
- Equations have attributes similar to variables (`.l`, `.m`, `.lo`, `.up` and `.scale`). [13]

4.30 Model and Solve Statements

4.30.1 Introduction

This chapter brings together all the concepts discussed in previous chapters by explaining how to specify a model and solve it.

4.30.2 The Model Statement

The model statement is used to collect equations into groups and to label them so that they can be solved. The simplest form of the model statement uses the keyword `all`: the model consists of all equations declared before the model statement is entered. For most simple applications this is all the user needs to know about the model statement.

4.30.2.1 The Syntax

In general, the syntax for a model declaration in GAMS is as follows:

```
model[s] model_name [text] [/ (all | eqn_name {, eqn_name}) {, var_name(set_name)} /]
      {,model_name [text] [/ (all | eqn_name {, eqn_name}) {, var_name(set_name)} /]} ;
```

The keyword `model[s]` indicates that this is a `model` statement and `model_name` is the internal name of the model in GAMS, it is an [identifier](#). The optional [explanatory text](#) is used to describe the model, `all` is a keyword as introduced above and `eqn_name` is the name of an equation that has been declared prior to the model statement. `Var_name(set_name)` is a couple of previous declared variable and and set to limit the domain of variables in the model. More details about this are described in the following [subsection](#). For advice on explanatory text and how to choose a `model_name`, see the tutorial [Good Coding Practices](#).

Note

Model statements for Mixed Complementarity Problem (MCP) and Mathematical Program with Equilibrium Constraints (MPEC) models require a slightly different notation, since complementarity relationships need to be included. For details see subsections [Mixed Complementarity Problem \(MCP\)](#) and [Mathematical Program with Equilibrium Constraints \(MPEC\)](#).

An example of a model definition in GAMS is shown below.

```
Model transport "a transportation model" / all /;
```

The `model` is called `transport` and the keyword `all` is a shorthand for all known (declared) equations.

Several models may be declared (and defined) in one model statement. This is useful when experimenting with different ways of writing a model, or if one has different models that draw on the same data. Consider the following example, adapted from [\[PROLOG\]](#), in which different groups of the equations are used in alternative versions of the problem. Three versions are solved: the linear, nonlinear, and 'expenditure' versions. The model statement to define all three is:

```
Model nortonl "linear version" / cb,rc,df1,bc,obj /
      nortonn "nonlinear version" / cb,rc,dfn,bc,obj /
      nortone "expenditure version" / cb,rc,dfe,bc,obj / ;
```

Here `cb`, `rc`, etc. are the names of the equations. We will describe below how to obtain the solution to each of the three models.

Note

If several models are declared and defined with one model statement, the models have to be separated by commas or linefeeds and a semicolon terminates the entire statement.

If several models are declared then it is possible to use one previously declared model in the declaration of another. The following examples illustrate this:

```
Model one "first model" / tcost_eq, supply_eq, demand_eq /
      two "second model that nests first" / one, balance_eq /
      three "third model that nests first and second" / two, capacity_eq, configure_eq /;
```

Model `one` is declared and defined using the general syntax, model `two` contains all the equations of model `one` and the equation `balance_eq`, and model `three` contains all of model `two` and the equations `capacity_eq` and `configure_eq`.

In addition to nesting models as illustrated above, it is also possible to use the symbols `+` and `-` to augment or remove items relative to models that were previously defined. The following examples serve as illustration:

```
Model four "fourth model: model three minus model one"      / three-one /
      five "fifth model: model three without eqn configure_eq" / three-configure_eq /
      six  "sixth model: model four plus model two"          / four+two /;
```

Model `four` contains the equations from model `three` except for those that belong to model `one`. Model `five` contains all equations from model `three` except for equation `configure_eq`. Model `six` contains the union of the equations in model `four` and `two`. Note that both model names and equation names may be used in association with the symbols `+` and `-`.

4.30.2.1.1 Limited domain for variables As mentioned [above](#), it is possible to limit the domain of variables used in a model in the model statement. This allows to restrict the generation of blocks of variables in a single place instead of using, e.g., [dollar conditions](#) at every place where this variable block is used in equations (which might be required for an [efficient model generation](#)).

The following examples is based on the basic transportation model `[TRANSPORT]`. To limit the transportation network in that model to certain links (e.g. because some are blocked because of some reason) one could introduce a [subset](#) of the free links and use that with dollar conditions in the equations like this:

```
* Initialize whole network as free
Set freeLinks(i,j) Useable links in the network / #i.#j /;

cost..      z =e= sum((i,j), c(i,j)*x(i,j)$freeLinks(i,j));

supply(i).. sum(j, x(i,j)$freeLinks(i,j)) =l= a(i);

demand(j).. sum(i, x(i,j)$freeLinks(i,j)) =g= b(j);

* Block a particular link
freeLinks('san-diego','topeka') = no;

Model transport / all /;
solve transport using lp minimizing z;
```

Now, instead of adding the dollar condition to each appearance of `x` in the model, one could simply add a domain restriction for that variable to the model statement directly by specifying a variable and the set that limits its domain. Using this approach, the previous example looks like this:

```
* Initialize whole network as free
Set freeLinks(i,j) Useable links in the network / #i.#j /;

cost..      z =e= sum((i,j), c(i,j)*x(i,j));

supply(i).. sum(j, x(i,j)) =l= a(i);

demand(j).. sum(i, x(i,j)) =g= b(j);

* Block a particular link
freeLinks('san-diego','topeka') = no;

Model transport / all, x(freeLinks) /;
solve transport using lp minimizing z;
```

Note

If one adds the domain restriction to the model statement, internally GAMS inserts a dollar condition to every appearance of the restricted variables in equations of the model. When doing this, the indices are copied as they appear with the variable. So, in the example above, $x(i,j)$ becomes $x(i,j)\$freeLinks(i,j)$. In the same way $x(i-1,j+1)$ becomes $x(i-1,j+1)\$freeLinks(i-1,j+1)$ and $x('seattle','chicago')$ becomes $x('seattle','chicago')\$freeLinks('seattle','chicago')$.

Attention

As a consequence of above's note one could see some unexpected results, like "division by zero errors", if it is not done carefully. For example, the following dummy model, will trigger such an error, since we sum over all i , but some x were excluded leaving a 0 as divisor:

```
Set i          / i1*i3 /
    sub(i) / i2    /;

Positive Variable x(i);
Variable          z;
Equation          obj;

obj.. z =e= sum(i, 1/x(i));
x.lo(i) = 1;
Model m / obj, x(sub) /;
solve m min z use nlp;
```

4.30.2.2 Classification of Models

Various types of problems can be solved with GAMS. Note that the type of the model must be known before it may be solved. The model types are briefly discussed in this section. GAMS checks that the model is in fact the type the user thinks it is, and issues explanatory error messages if it discovers a mismatch - for instance, that a supposedly linear model contains nonlinear terms. Some problems may be solved in more than one way, and the user has to choose which way to use. For instance, if there are binary or integer variables in the model, it can be solved either as a MIP or as a RMIP.

The model types and their identifiers, which are needed in the a solve statement, are given in [Table 1](#). For details on the solve statement, see section [The Solve Statement](#).

GAMS Model Type	Model Type Description	Requirements and Comments
LP	Linear Program	Model with no nonlinear terms or discrete (i.e. binary, integer, etc) variables.
NLP	Nonlinear Program	Model with general nonlinear terms involving only <i>smooth</i> functions, but no discrete variables. For a classification of functions as to smoothness, see section Functions .
QCP	Quadratically Constrained Program	Model with linear and quadratic terms, but no general nonlinear terms or discrete variables.
DNLP	Discontinuous Nonlinear Program	Model with <i>non-smooth</i> nonlinear terms with discontinuous derivatives, but no discrete variables. This is the same as NLP, except that non-smooth functions may appear as well. These models are more difficult to solve than normal NLP models and we strongly advise not to use this model type.

GAMS Model Type	Model Type Description	Requirements and Comments
MIP	Mixed Integer Program	Model with binary, integer, SOS and/or semi variables, but no nonlinear terms.
RMIP	Relaxed Mixed Integer Program	Like MIP, except that the discrete variable requirement is relaxed. See the note below on relaxed model types.
MINLP	Mixed Integer Nonlinear Program	Model with both nonlinear terms <i>and</i> discrete variables.
RMINLP	Relaxed Mixed Integer Nonlinear Program	Like MINLP except that the discrete variable requirement is relaxed. See the note below on relaxed model types.
MIQCP	Mixed Integer Quadratically Constrained Program	Model with both quadratic terms <i>and</i> discrete variables, but no general nonlinear term.
RMIQCP	Relaxed Mixed Integer Quadratically Constrained Program	Like MIQCP except that the discrete variable requirement is relaxed. See the note below on relaxed model types.
MCP	Mixed Complementarity Problem	A square, possibly nonlinear, model that generalizes a system of equations. Rows and columns are matched in one-to-one complementary relationships.
CNS	Constrained Nonlinear System	Model solving a square, possibly nonlinear system of equations, with an equal number of variables and constraints.
MPEC	Mathematical Programs with Equilibrium Constraints	A difficult model type for which solvers and reformulations are currently being developed.
RMPEC	Relaxed Mathematical Program with Equilibrium Constraints	A difficult model type for which solvers and reformulations are currently being developed. See the note below on relaxed model types.
EMP	Extended Mathematical Program	A family of mathematical programming extensions.
MPSGE	General Equilibrium	Not actually a model type but mentioned for completeness, see MPSGE .

Table 1: GAMS Model Types

Note

- The relaxed model types RMIP, RMINLP, RMIQCP, and RMPEC solve the problem as the corresponding model type (e.g. MIP for RMIP) but *relax* the discrete requirement of the discrete variables. This means that [integer](#) and [binary](#) variables may assume any values between their bounds. [SemiInteger](#) and [SemiCont](#) variables may assume any values between 0 and their upper bound. For [SOS1](#) and [SOS2](#) variables the restriction of the number of non-zero values is removed.
- Many "LP" solvers like [Cplex](#) offer the functionality of solving *convex* quadratic models. So the Q matrices in the model need to be positive semidefinite. An extension to this are the

second-order cone programs (SOCP) with either symmetric or rotated cones. See the solver manuals (e.g. on [MOSEK](#)) for details.

- Unlike other checks on the model algebra (e.g. existence of discrete variables or general non-linear terms), the GAMS *compiler* does not enforce a quadratic model to only consist of quadratic and linear terms. This requirement is enforced at *runtime* for a particular model instance.

4.30.2.2.1 Linear Programming (LP) Mathematically, the Linear Programming (LP) problem looks like:

$$\begin{array}{ll} \text{Minimize or maximize} & cx \\ \text{subject to} & Ax \alpha b \\ & L \leq x \leq U, \end{array}$$

where x is a vector of variables that are continuous real numbers, cx is the objective function, and $Ax \alpha b$ represents the set of constraints. Here, α is an equation operator. For details on the equation types allowed in GAMS, see [Equation Types](#). L and U are vectors of lower and upper bounds on the variables.

GAMS supports free (unrestricted) variables, positive variables, and negative variables. Note that users may customize lower and upper bounds, for details see section [Bounds on Variables](#).

For information on LP solvers that can be used through GAMS see the [Solver/Model type Matrix](#).

4.30.2.2.2 Nonlinear Programming (NLP) Mathematically, the Nonlinear Programming (NLP) problem looks like:

$$\begin{array}{ll} \text{Minimize or Maximize} & f(x) \\ \text{subject to} & g(x) \alpha 0 \\ & L \leq x \leq U, \end{array}$$

where x is a vector of variables that are continuous real numbers, $f(x)$ is the objective function, and $g(x) \alpha 0$ represents the set of constraints. For details on the equation types allowed in GAMS, see [Equation Types](#). Note that the functions $f(x)$ and $g(x)$ have to be differentiable. L and U are vectors of lower and upper bounds on the variables.

For information on NLP solvers that can be used through GAMS see the [Solver/Model type Matrix](#). See also the tutorial [Good NLP Formulations](#).

Note

NLP models may have the nonlinear terms inactive. In this case setting the model attribute [TryLinear](#) to 1 causes GAMS to check the model and use the default LP solver if possible. For details on model attributes, see subsection [Model Attributes](#).

4.30.2.2.3 Quadratically Constrained Programs (QCP) Mathematically, the Quadratically Constrained Programming (QCP) problem looks like:

$$\begin{array}{ll} \text{Maximize or Minimize} & cx + x'Qx \\ \text{subject to} & A_i x + x'R_i x \leq b_i \quad \text{for all } i \\ & L \leq x \leq U, \end{array}$$

where x denotes a vector of variables that are continuous real numbers, cx is the linear part of the objective function, $x'Qx$ is the quadratic part of the objective function, $A_i x$ represents the linear part of the i th constraint, $x'R_i x$ its quadratic part and b_i its right-hand side. For details on the equation types allowed in GAMS, see [Equation Types](#). Further, L and U are vectors of lower and upper bounds on the variables.

Note that a QCP is a special case of the [NLP](#) in which all the nonlinearities are required to be quadratic. As such, any QCP model can also be solved as an NLP. However, most "LP" vendors provide routines to solve LP models with a quadratic objective. Some allow quadratic constraints as well. Solving a model using the QCP model type allows these "LP" solvers to be used to solve quadratic models as well as linear ones. Some NLP solvers may also take advantage of the special (quadratic) form when solving QCP models.

Attention

In case a model with quadratic *constraints* is passed to a QCP solver that only allows a quadratic *objective*, a capability error will be returned (`solver status 6 CAPABILITY PROBLEMS`). Some solvers will fail when asked to solve a non-convex quadratic problems as described [above](#).

Note

Using the model attribute [TryLinear](#) causes GAMS to see if the problem can be solved as an LP problem. For details on model attributes, see subsection [Model Attributes](#).

For information on QCP solvers that can be used through GAMS see the [Solver/Model type Matrix](#).

4.30.2.2.4 Nonlinear Programming with Discontinuous Derivatives (DNLP) Mathematically, the Nonlinear Programming with Discontinuous Derivatives (DNLP) problem looks like:

$$\begin{array}{ll} \text{Maximize or Minimize} & f(x) \\ \text{subject to} & g(x) \leq 0 \\ & L \leq x \leq U, \end{array}$$

where x is a vector of variables that are continuous real numbers, $f(x)$ is the objective function, $g(x) \leq 0$ represents the set of constraints, and L and U are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see [Equation Types](#). Note that this is the same as [NLP](#), except that non-smooth functions, like `abs`, `min`, `max` may appear in $f(x)$ and $g(x)$.

For information on DNLP solvers that can be used through GAMS see the [Solver/Model type Matrix](#).

Attention

- We strongly advise against using the model type DNLP. The best way to model discontinuous functions is with binary variables, which results in a model of the type [MINLP](#). The model [\[ABSMIP\]](#) demonstrates this formulation technique for the functions `abs`, `min`, `max` and `sign`. See also section [Reformulating DNLP Models](#).
- Solvers may have difficulties when dealing with the discontinuities, since they are really NLP solvers and the optimality conditions and the reliance on derivatives may be problematic. Using a [global solver](#) may alleviate this problem.

4.30.2.2.5 Mixed Integer Programming (MIP) Mathematically, the Mixed Integer Linear Programming (MIP) problem looks like:

$$\begin{array}{ll}
 \text{Maximize or Minimize} & c_1t + c_2u + c_3v + c_4w + c_5x + c_6y + c_7z \\
 \text{subject to} & A_1t + A_2u + A_3v + A_4w + A_5x + A_6y + A_7z \quad \alpha \quad b \\
 & t \in \mathbb{R} \\
 & u \geq 0 \quad \text{and } u \leq L_2 \quad \text{and } u \in \mathbb{Z} \\
 & v \in (0, 1) \\
 & w \in \text{SOS1} \\
 & x \in \text{SOS2} \\
 & y = 0 \quad \text{or } L_6 \leq y \\
 & z = 0 \quad \text{or } L_7 \leq z \quad \text{and } z \in \mathbb{Z},
 \end{array}$$

where

- $c_1t + c_2u + c_3v + c_4w + c_5x + c_6y + c_7z$ is the objective function,
- $A_1t + A_2u + A_3v + A_4w + A_5x + A_6y + A_7z \quad \alpha \quad b$ represents the set of constraints of various equality and inequality forms,
- t is a vector of variables that are continuous real numbers,
- u is a vector of variables that can only take integer values smaller than L_2 ,
- v is a vector of binary variables,
- w is a vector of variables that belong to SOS1 sets; this means that at most one variable in the set is nonzero,
- x is a vector of variables that belong to SOS2 sets; this means that at most two adjacent variables in the set are nonzero,
- y is a vector of variables that are semi-continuous; they are either zero or larger than L_6 ,
- z is a vector of variables that are semi-integer; they are integer and either zero or larger than L_7 .

For details on the equation types allowed in GAMS, see [Equation Types](#). For more details on MIPs in GAMS, especially the use of SOS and semi variables, see section [Special Mixed Integer Programming \(MIP\) Features](#).

For information on MIP solvers that can be used through GAMS, see the [Solver/Model type Matrix](#).

Attention

Not all MIP solvers cover all the cases associated with SOS and semi variables. Please consult the solver manuals for details on capabilities.

4.30.2.2.6 Mixed Integer Nonlinear Programming (MINLP) Mathematically, the Mixed Integer Nonlinear Programming (MINLP) problem looks like:

$$\begin{array}{ll}
 \text{Maximize or Minimize} & f(x) + Dy \\
 \text{subject to} & g(x) + Hy \quad \alpha \quad 0 \\
 & L \leq x \leq U \\
 & y = \{0, 1, 2, \dots\},
 \end{array}$$

where x is a vector of variables that are continuous real numbers, y denotes a vector of variables that can only take integer values, $f(x) + Dy$ is the objective function, $g(x) + Hy \quad \alpha \quad 0$ represents the set of constraints, and L and U are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see [Equation Types](#). Further, $y = \{0, 1, 2, \dots\}$ is the integrality restriction on y .

For information on MINLP solvers that can be used through GAMS see the [Solver/Model type Matrix](#).

Note

- SOS and semi variables can also be accommodated by some solvers. Please consult the solver manuals for details on capabilities.
- The model attribute `TryLinear` causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection [Model Attributes](#).

4.30.2.2.7 Mixed Integer Quadratically Constrained Programs (MIQCP) A Mixed Integer Quadratically Constrained Program (MIQCP) is a special case of the [MINLP](#) in which all the nonlinearities are required to be quadratic. For details see the description of the [QCP](#), a special case of the [NLP](#).

For information on MIQCP solvers that can be used through GAMS, see the [Solver/Model type Matrix](#).

Note

The model attribute `TryLinear` causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection [Model Attributes](#).

4.30.2.2.8 Mixed Complementarity Problem (MCP) Unlike the other model types we have introduced so far, the Mixed Complementarity Problem (MCP) does not have an objective function. An MCP is specified by three pieces of data: a function $F(z) : \mathbb{R}^n \mapsto \mathbb{R}^n$, lower bounds $l \in \{\mathbb{R} \cup \{-\infty\}\}^n$ and upper bounds $u \in \{\mathbb{R} \cup \{\infty\}\}^n$. A solution is a vector $z \in \mathbb{R}^n$ such that for each $i \in \{1, \dots, n\}$, one of the following three conditions hold:

$$\begin{aligned} F_i(z) = 0 & \quad \text{and} \quad \ell_i \leq z_i \leq u_i \quad \text{or} \\ F_i(z) > 0 & \quad \text{and} \quad z_i = \ell_i \quad \text{or} \\ F_i(z) < 0 & \quad \text{and} \quad z_i = u_i. \end{aligned}$$

This problem can be written compactly as

$$F(z) \perp L \leq z \leq U,$$

where the symbol \perp (which means "perpendicular to", shortened to "perp to") indicates pair-wise complementarity between the function F and the variable z and its bounds.

The following special case is an important and illustrative example:

$$F(z) \perp z \geq 0.$$

In this example, the unstated but implied upper bound u is infinity. Since z is finite, we cannot have $z_i = u_i$ and the third condition above cannot hold: this implies $F(z) \geq 0$. The remaining two conditions imply pair-wise complementarity between $z \geq 0$ and $F(z) \geq 0$. This is exactly the Nonlinear Complementarity Problem, often written as

$$F(z) \geq 0, \quad z \geq 0, \quad \langle F(z), z \rangle = 0.$$

None of this rules out the degenerate case (i.e. $F_i(z)$ and z_i both zero). In practice, these can be difficult models to solve.

Another special case arises when the bounds L and U are infinite. In this case, the second and third conditions above cannot hold, so we are left with $F(z) = 0$, a square system of nonlinear equations. And finally, we should mention a special case that occurs frequently in practice: if $\ell_i = u_i$ (i.e. z_i is fixed) then we have a complementary pair: one of the three conditions will hold as long as $F_i(z)$ is defined. Essentially, fixing a variable removes or obviates the matching equation. This is often useful when modeling with MCP.

The definition above describes the canonical MCP model as it exists when GAMS passes it to an MCP solver. Some models have exactly this form even in the GAMS code, but usually some processing is done by the GAMS system to arrive at a model in this form. Here we'll describe the steps of this process and illustrate with an example from the model library.

1. The process starts with the list of rows (aka single equations) and columns (aka single variables) that make up the MCP model, and potentially some matching information.
 - The usual rules apply: rows are part of the model because their associated equations are included in the model statement, but columns only become part of the model by use: a column enters the model only if it is used in some row of the model. Therefore including a variable symbol as part of a match in the model statement will not influence the set of columns belonging to the model.
 - Matches (where they exist) are pointers from rows to columns.
 - Technically, the MCP is defined via a function F while a model contains constraints. Given a constraint, we define an associated function as LHS - RHS, so e.g. $F_i \geq 0$ is consistent with a =G= constraint.
2. The explicit matches are processed: each match creates a complementary pair. What remains after the explicit matches are consumed are the unmatched rows and unmatched columns.
 - It is an error for any column to be matched to multiple rows, so the row-column matching is one-to-one.
 - For each match some consistency checks between the column bounds and the row type are made. For details, see [Table 2](#).
 - For example, matching an =N= row with any column is good, matching an =E= row with a free column is good, matching an =E= row with a lower-bounded column is allowed, and matching a =G= row with an upper-bounded column results in an error.
3. Any fixed columns remaining are ignored: these columns can be treated like exogenous variables or parameters.
4. If what remains is a set of =E= rows and an *equal number* of unbounded columns, these can be matched up in any order and we have a well-defined MCP. If this is not what remains, an error is triggered.

To illustrate how this works, consider the spatial equilibrium model [SPATEQU] with the following model statement:

```
Model P2R3_MCP          / dem, sup, in_out.p, dom_trad.x /;
```

1. The model P2R3_MCP includes the rows from equations `dem`, `sup`, `in_out` and `dom_trad` and exactly the columns used by these rows. Checking the listing file, we see columns for `Qd`, `Qs`, `x`, and `p`. In addition, the model statement specifies two matches: `in_out.p` and `dom_trad.x`. These matches always take the form of an `equation.variable` pair, with no indices or domains included.
2. In this example, the rows corresponding to the equation `in_out` match up perfectly with the columns from the variable `p`: there are no holes in the set of rows or columns because of some dollar conditions in the equation definition. We have a one-to-one match so all the rows of `in_out` and columns of `p` are consumed by the match in the model statement. The same holds for the `dom_trad.x` pair, so what is left are the rows of `dem` and `sup` and the columns of `Qd` and `Qs`, all of which are unmatched.
3. There are no fixed variables to remove.
4. Since `dem` and `sup` are =E= constraints and `Qd` and `Qs` are free variables, we can match them in any order without changing the solution set for this model. The counts of these unmatched equality rows and unmatched free variables are equal, so we get a well-defined MCP.

When rows are matched explicitly to columns, some care must be taken to match them consistently. For example, consider a row-column match $g.y$. The row g can be of several types: =N=, =E=, =G=, or =L=. An =N= row can be matched to any sort of variable: the =N= doesn't imply any sort of relationship, which works perfectly with our definition of \perp above: the allowed sign or direction of g is determined completely

by the bounds on the complementary variable y . If g is an =E= row, this is consistent with a free variable y , but what if y has an active lower bound? By definition we allow g to be positive at solution, but this violates the declaration as an =E= row. Such cases can be handled by marking the row with a *redef*. The total number of redefs for a given model is available via the `NumRedef` model attribute and is shown in the report summary. Note that the set of rows marked depends on the solution: in the example above, if g is zero at solution it will not be marked as a redef, regardless of what the bounds are on y . Finally, some combinations are simply not allowed: they will result in a model generation error. The table below lists the outcome for all possible combinations.

Table 2: MCP Matching

Column Bounds	=N=	=E=	=G=	=L=
lower	OK	redef	OK	ERROR
upper	OK	redef	ERROR	OK
free	OK	OK	OK	OK
double	OK	redef	redef	redef
fixed	OK	redef	redef	redef

The definition, process, and rules above have several implications for valid MCP models:

- It is always acceptable to use the =N= notation when defining the equations in an MCP model, *provided these equations are matched explicitly*. In this case the bounds on $F(\mathbf{z})$ are implied by the bounds on the matching columns, and redefs will never occur.
- Variables that are known to be lower-bounded (no upper bound) will match consistently with =G= equations.
- Variables that are known to be upper-bounded (no lower bound) will match consistently with =L= equations.
- Variables that are known to be unbounded will match consistently with =E= equations.
- Where the bound structure is not known in advance, or both upper and lower bounds exist, a match with an =N= equation will always be consistent. Other equation types will result in errors or redefs.
- The model may initially have fewer rows than columns, as long as the "extra" columns are unmatched fixed columns that ultimately get removed from the MCP passed to the solver.
- Any bounded-but-not-fixed column must be matched explicitly to a row.
- The only rows that may be unmatched are =E= rows.
- It is customary to re-use the constraints of an LP or NLP model when formulating the MCP corresponding to the Karush-Kuhn-Tucker (KKT) conditions. If the original model is a *minimization*, the LP/NLP marginals `.m` and the variables for these marginals in the MCP will use the same sign convention, and the orientation for the constraints will be consistent between the two models, making re-use easier.

As mentioned above, it is typical to use the same equations in both NLP and MCP models. Sometimes, it is not the original equation that is wanted for the MCP, but rather the reoriented (aka negated or flipped) equation. For example, the flipped version of $x**1.5 =L= y$ is $y =G= x**1.5$, while $\text{sqr}(u) - \text{sqr}(v) =E= 5$ becomes $-\text{sqr}(u) + \text{sqr}(v) =E= -5$. Instead of re-implementing the equation in flipped form, the same result can be achieved by prefixing the equation name with a `-` in the model statement. See the `[mcp10]` model for an example of such usage. When equations are used in flipped form, they are marked with a *redir* in the listing file's solution listing.

An example of complementarity that should be familiar to many is the relationship between a constraint and its associated dual multiplier: if the constraint is non-binding, its dual multiplier must be zero (i.e. at

bound) while if a dual multiplier is nonzero the associated constraint must be binding. In fact, the KKT or first-order optimality conditions for LP and NLP models can be expressed and solved as an MCP.

These complementarity relationships found in optimization problems are useful in understanding the marginal values assigned to rows and columns in the GAMS solution for MCP. With no objective function, the usual definition for marginal values and their interpretation isn't useful. Instead, the GAMS MCP convention for the marginal values of columns is to return the slack of the associated row (i.e. its value when interpreted and evaluated as a function). For the marginal values of rows, the level value (*not* the slack) of the associated column is returned. When we apply this convention to the NCP ($F(z) \geq 0, z \geq 0, \langle F(z), z \rangle = 0$) we see pairwise complementarity between the levels and marginals returned for each of the rows and columns in the model. This is also the case if we take the KKT conditions of an LP in a suitable standard form: minimization, $x \geq 0, Ax \geq b$.

MCPs arise in many application areas including applied economics, game theory, structural engineering and chemical engineering. For further details on this class of problems, see <http://www.neos-guide.org/content/complementarity-problems>.

For information on MCP solvers that can be used through GAMS, see [Solver/Model type Matrix](#).

4.30.2.2.9 Constrained Nonlinear System (CNS) The Constrained Nonlinear System (CNS) is the second GAMS model type that does not have an objective function. Mathematically, a CNS model looks like:

$$\begin{aligned} &\text{Find} && x \\ &\text{subject to} && F(x) = 0 \\ & && L \leq x \leq U \\ & && G(x) \alpha b, \end{aligned} \tag{4.1}$$

where x is a set of continuous variables and F is a set of nonlinear equations of the same dimension as x . This is a key property of this model type: the number of equations equals the number of variables, so we have a square system. The (possibly empty) constraints $L \leq x \leq U$ are not intended to be binding at the solution, but instead are included to constrain the solution to a particular domain, to avoid regions where $F(x)$ is undefined, or perhaps just to give the solver a push in the right direction. The (possibly empty) constraints $G(x) \alpha b$ are intended to serve the same purpose as the variable bounds and are silently converted to equations with bounded slacks.

Note that since there is no objective in a CNS model, there are no marginal values for variables and equations. Any marginal values already stored in the GAMS database will remain untouched. CNS models also make use of some [model status](#) values that allow a solver to indicate if the solution is unique (e.g. for a non-singular linear system) or if the linearization is singular at the solution. For singular models (solved or otherwise), the solver can mark one or more dependent rows with a *depnd*. The total number of rows so marked for a given model is available via the [NumDepnd](#) model attribute and is shown in the report summary.

The CNS model is a generalization of a square system of equations $F(x) = 0$. Such a system could also be modeled as an NLP with a dummy objective. However, there are a number of advantages to using the CNS model type, including:

- A check by GAMS that the model is really square,
- solution/model diagnostics by the solver (e.g. singular at solution, (locally) unique solution),
- CNS-specific warnings if the side constraints $L \leq x \leq U$ or $G(x) \alpha b$ are active at a solution,
- and potential improvement in solution times, by taking better advantage of the model properties.

For information on CNS solvers that can be used through GAMS, see the [Solver/Model type Matrix](#).

4.30.2.2.10 Mathematical Program with Equilibrium Constraints (MPEC) Mathematically, the Mathematical Program with Equilibrium Constraints (MPEC) problem looks like:

$$\begin{array}{ll} \text{Maximize or Minimize} & f(x, y) \\ \text{subject to} & g(x, y) \alpha 0 \\ & L_x \leq x \leq U_x \\ & F(x, y) \perp L_y \leq y \leq U_y, \end{array}$$

where x and y are vectors of continuous real variables. The variables x are often called the *control* or *upper-level* variables, while the variables y are called the *state* or *lower-level* variables. $f(x, y)$ is the objective function. $g(x, y) \alpha 0$ represents the set of traditional (i.e. NLP-type) constraints; some solvers may require that these constraints only involve the control variables x . The function $F(x, y)$ and the bounds L_y and U_y define the equilibrium constraints. If x is fixed, then $F(x, y)$ and the bounds L_y and U_y define an **MCP**; the discussion of the "perp to" symbol \perp in that section applies here as well. From this definition, we see that the MPEC model type contains **NLP** and **MCP** models as special cases of MPEC.

A simple example of an entire MPEC model is given below.

```
variable z, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up = 1;

equations cost, g, h1, h2;

cost.. z =E= x1 + x2;
g..    sqr(x1) + sqr(x2) =L= 1;
h1..   x1 =G= y1 - y2 + 1;
h2..   x2 + y2 =N= 0;

model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min z;
```

Note that as in the **MCP**, the complementarity relationships in an MPEC are specified in the model statement via equation-variable pairs: the `h1.y1` specifies that the equation `h1` is perpendicular to the variable `y1` and the `h2.y2` specifies that the equation `h2` is perpendicular to the variable `y2`. For details on the solve statement, see section [The Solve Statement](#).

While the MPEC model formulation is very general, it also results in problems that can be very difficult to solve. The state-of-the-art for MPEC solvers is not nearly as advanced as that for other model types. As a result, you should expect the MPEC solvers to be more limited by problem size and/or robustness issues than solvers for other model types.

For information on MPEC solvers that can be used through GAMS, see the [Solver/Model type Matrix](#). For more details on MPECs and solver development, see <http://gamsworld.org/mpec/index.htm> and <http://www.neos-guide.org/content/complementarity-problems>.

4.30.2.2.11 Extended Mathematical Programs (EMP) Extended Mathematical Programming (EMP) is an (experimental) framework for automated mathematical programming reformulations. Using EMP, model formulations that GAMS cannot currently handle directly or for which no robust and mature solver technology exists can be automatically and reliably reformulated or transformed into models for which robust and mature solver technology does exist within the GAMS system. For more details, see the chapter on **EMP**. Currently EMP supports:

- Equilibrium problems including variational inequalities, Nash games, and Multiple Optimization Problems with Equilibrium Constraints (MOPECs).

- Hierarchical optimization problems such as bilevel programs.
- Disjunctive programs for modeling discrete choices with binary variables.
- Stochastic programs including two-stage and multi-stage stochastic programs, chance constraints and risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR).

Apart from the disjunctive and stochastic programming models mentioned above, EMP models are typically processed (aka solved) via the [JAMS](#) solver: this solver does the work of reformulation/transformation, calling GAMS to solve this reformulation, and post-processing the solution that results to bring it back in terms of the original EMP model.

Examples demonstrating how to use the EMP framework and the [JAMS](#) and [DE](#) solvers are available in the GAMS **EMP Library**. These solvers require no license of their own to run but can and do call subsolvers that *do* require a license.

4.30.2.3 Model Attributes

Models have attributes that hold a variety of information, including

- information about the results of a solve performed, a solve statement, the solution of a model,
- information about certain features to be used by GAMS or the solver,
- information passed to GAMS or the solver specifying various settings that are also subject to option statements.

Model attributes are accessed in the following way:

```
model_name.attribute
```

Here `model_name` is the name of the model in GAMS and `.attribute` is the specific attribute that is to be accessed. Model attributes may be used on the left-hand side and the right-hand side of assignments. Consider the following example:

```
transport.resLim = 600;  
x = transport.modelStat;
```

In the first line the attribute `.resLim` of the model `transport` is specified to be 600 (seconds). In the second line the value of the attribute `.modelStat` of the model `transport` is assigned to the scalar `x`. Note that model attributes may also be used in [display](#) statements”.

Some of the attributes are mainly used before the solve statement to provide information to GAMS or the solver link. Others are set by GAMS or the solver link and hence are mainly used after a solve statement.

Moreover, some of the attributes used before the solve may also be set via an option statement or the command line. Consider the following example:

```
option ResLim=10;
```

This line is an option statement and applies to all models. One can set the model attribute `.ResLim` to overwrite the global `ResLim` option. In order to revert the individual `.ResLim` to the global `ResLim` option, one needs to set the model attribute to `NA`. For more on option statements, see chapter [The Option Statement](#).

```
gams mymodel ResLim=10
```

This sets the global `ResLim` option when invoking the `gams` run (e.g. from the command line). For more on command line parameters, see chapter [The GAMS Call and Command Line Parameters](#).

Note that a model-specific option takes precedence over the global setting specified with an option statement and that a setting via an option statement takes precedence over a setting via the command line parameter.

The complete list of model attributes is given below. Observe that each entry is linked to a detailed description of the respective attribute, including information of whether the attribute is also available as command line parameter or option statement. Note that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section [Detailed Descriptions of All Options](#).

Attribute	Description
bRatio	Basis detection threshold
cheat	Cheat value, i.e. minimum solution improvement threshold
cutOff	Cutoff value for branch and bound
defPoint	Indicator for passing on default point
dictFile	Force writing of a dictionary file if <code>dictfile > 0</code>
domLim	Domain violation limit solver default
fdDelta	Step size for finite differences
fdOpt	Options for finite differences
holdFixed	Treat fixed variables as constants
integer1..5	Integer communication cells
iterLim	Iteration limit of solver
limCol	Maximum number of columns listed in one variable block
limRow	Maximum number of rows listed in one equation block
MCPRHoldFx	Print list of rows that are perpendicular to variables removed due to the <code>holdfixed</code> setting
nodLim	Node limit in branch and bound tree
optCA	Absolute Optimality criterion solver default
optCR	Relative Optimality criterion solver default
optFile	Default option file
priorOpt	Priority option for variable attribute <code>.prior</code>
real1..5	Real communication cells
reform	Reformulation level
resLim	Wall-clock time limit for solver
savePoint	Save solver point in GDX file
scaleOpt	Employ user specified variable and equation scaling factors
solPrint	Solution report print option
solveLink	Solver link option
solveOpt	Multiple solve management
sysOut	Solver Status file reporting option
threads	Number of threads to be used by a solver
tolInfeas	Infeasibility tolerance for an empty row of the form <code>a.. 0*x =e= 0.0001</code> ;

Attribute	Description
tolInfRep	This attribute sets the tolerance for marking infeasible in the equation listing
tolProj	Tolerance for setting solution values to a nearby bound when reading a solution
tryInt	Whether solver should make use of a partial integer-feasible solution
tryLinear	Examine empirical NLP model to see if there are any NLP terms active. If there are none the default LP solver will be used
workFactor	Memory Estimate multiplier for some solvers
workSpace	Work space for some solvers in MB

4.30.2.3.1 Model Attributes Mainly Used Before Solve

Attribute	Description
domUsd	Number of domain violations
etAlg	Solver dependent timing information
etSolve	Elapsed time it took to execute a solve statement in total
etSolver	Elapsed time taken by the solver only
handle	Unique handle number of SOLVE statement
iterUsd	Number of iterations used
line	Line number of last solve of the corresponding model
linkUsed	Integer number that indicates the value of SolveLink used for the last solve
marginals	Indicator for marginals present
maxInfes	Maximum of infeasibilities
meanInfes	Mean of infeasibilities
modelStat	Integer number that indicates the model status
nodUsd	Number of nodes used by the MIP solver
number	Model instance serial number
numDepnd	Number of dependencies in a CNS model
numDVar	Number of discrete variables
numEqu	Number of equations
numInfes	Number of infeasibilities
numNLIns	Number of nonlinear instructions
numNLNZ	Number of nonlinear nonzeros
numNOpt	Number of nonoptimality
numNZ	Number of nonzero entries in the model coefficient matrix
numRedef	Number of MCP redefinitions
numVar	Number of variables
numVarProj	Number of bound projections during model generation
objEst	Estimate of the best possible solution for a mixed-integer model
objVal	Objective function value
procUsed	Integer number that indicates the used model type
resCalc	Time spent in function and derivative calculations (deprecated)
resDeriv	Time spent in derivative calculations (deprecated)
resGen	Time GAMS took to generate the model in CPU seconds(deprecated)
resIn	Time to import model (deprecated)
resOut	Time to export solution (deprecated)
resUsd	Time the solver used to solve the model in seconds
rObj	Objective function value from the relaxed solve of a mixed-integer model when the integer solver did not finish

Attribute	Description
<code>solveStat</code>	Indicates the solver termination condition
<code>sumInfes</code>	Sum of infeasibilities
<code>sysIdent</code>	Solver identification number
<code>sysVer</code>	Solver version

4.30.2.3.2 Model Attributes Mainly Used After Solve

4.30.3 The Solve Statement

Once a model has been defined using the model statement, the solve statement prompts GAMS to call one of the available solvers for the particular model type. This section introduces and discusses the solve statement in detail. For a list of GAMS model types, see [Table 1](#). For information on how to specify desired solvers, see section [Choosing a Solver](#).

Note

It is important to remember that GAMS does *not* solve the problem, but passes the problem definition to one of a number of separate solver programs that are integrated with the GAMS system.

4.30.3.1 The Syntax of the Solve Statement

In general, the syntax for a `solve` statement is as follows. Note that there are two alternatives that are equally valid:

```
solve model_name using model_type maximizing|minimizing var_name;
solve model_name maximizing|minimizing var_name using model_type ;
```

The keyword `solve` indicates that this is a `solve` statement. `Model_name` is the name of the model as defined by a `model` statement. Note that the `model` statement must be placed before the `solve` statement in the program. The keyword `using` is followed by `model_type`, which is one of the GAMS model types described above, see [Table 1](#). The keywords `maximizing` or `minimizing` indicate the direction of the optimization. `Var_name` is the name of the objective variable that is being optimized. An example of a `solve` statement in GAMS is shown below.

```
Solve transport using lp minimizing cost ;
```

`Solve` and `using` are reserved words, `transport` is the name of the model, `lp` is the model type, `minimizing` is the direction of optimization, and `cost` is the objective variable. Note that an objective variable is used instead of an objective row or function.

Attention

The objective variable must be scalar and of type **free**, and must appear in at least one of the equations in the model.

Recall that some model types (e.g. the Constrained Nonlinear System (**CNS**) or the Mixed Complementarity Problem (**MCP**)) do not have an objective variable. So their **solve** statement syntax is slightly different:

```
solve model_name using model_type;
```

As before, **solve** and **using** are keywords, **model_name** is the name of the model as defined by a **model** statement and **model_type** is the GAMS model type **CNS** or **MCP**. There is no objective variable and consequently no direction of optimization. An example from the spatial equilibrium model **[SPATEQU]** illustrates this **solve** statement:

```
Solve P2R3_MCP using mcp;
```

P2R3_MCP is the model name, the model type is **MCP** and as expected, there is no objective variable.

The **EMP** model type serves many purposes including some experimental ones. The **solve** statement with model type **EMP** can be with or without the objective variable and optimization direction. For more information, see chapter [Extended Mathematical Programming \(EMP\)](#).

4.30.3.2 Actions Triggered by the Solve Statement

When GAMS encounters a **solve** statement during compilation (the syntactic check of the input file) or execution (actual execution of the program), it initiates a number of special actions. The purpose is to prevent waste that would be caused by solving a model that has apparently been incorrectly specified. During compilation the following are verified:

1. All symbolic equations have been defined and the objective variable is used in at least one of the equations.
 2. The objective variable is scalar and of type **free** (even though lower and upper bounds may have been specified)
 3. **MCP** models are checked for appropriate complementarity and squareness.
 4. Each equation fits into the specified problem class (linearity for **LP**, continuous derivatives for **NLP**, as outlined above).
 5. All sets and parameters in the equations have values assigned.
-

Note

GAMS issues explanatory error messages if it discovers that the model is not according to type; for example, the presence of nonlinear terms in a supposedly LP model. For details on error messages, see chapter [GAMS Output](#).

At execution time the solve statement triggers the following sequence of steps:

1. The model is translated into the representation required by the solution system to be used.
2. Debugging and comprehension aids that the user wishes to see are produced and written to the output file (`EQUATION LISTING`, etc). For customizing options (e.g. `LimRow` and `LimCol`), see chapter [The Option Statement](#).
3. GAMS verifies that there are no inconsistent bounds or unacceptable values (for example, `NA` or `UNDF`) in the problem.
4. Any errors detected at this stage cause termination with as much explanation as possible, using the GAMS names for the identifiers causing the trouble.
5. GAMS designs a solution strategy based on the possible availability of level values or basis information from a previous solution: all available information is used to provide efficiency and robustness of operation. Any specifications provided by the user (Iteration limits etc.) are incorporated. A solver is chosen which is either the default solver for that problem type, the solver specified on the command line or the solver chosen by an option statement. For details see section [Choosing a Solver](#).
6. GAMS passes control to the solution subsystem and waits while the problem is being solved.
7. GAMS reports on the status of the solution process and loads solution values back into the GAMS database. This causes new values to be assigned to the `.l` and `.m` fields for all individual equations and variables in the model. In addition, the post solution model attributes are assigned. The procedure for loading back the data associated with level and marginal values may be customized using the `SolveOpt` model attribute and option. A row by row and column by column listing of the solution is provided by default. It may be suppressed by the `SolPrint` model attribute or option. Any apparent difficulty with the solution process will cause explanatory messages to be displayed. Errors caused by forbidden nonlinear operations are reported at this stage.

Note

When the solver does not provide a dual solution (`.m`), then GAMS does not print the marginal column in the solution listing and set the marginal field in variables and equations to `NA`.

The outputs from these steps, including any possible error messages, are discussed in detail in chapter [GAMS Output](#).

4.30.4 Programs with Several Solve Statements

Several solve statements can be processed in the same program. The next few subsections discuss various instances where several `solve` statements may be needed in the same file. If sequences of expensive or difficult models are to be solved, it might be useful to interrupt program execution and continue later. For details on this topic, see chapter [The Save and Restart Feature](#).

4.30.4.1 Several Models

If there are different models then the solves may be sequential, as below. Each of the models in [PROLOG] consists of a different set of equations, but the data are identical, so the three solves appear in sequence with no intervening assignments:

```
Solve nortonl using nlp maximizing z;
Solve nortonn using nlp maximizing z;
Solve nortone using nlp maximizing z;
```

When there is more than one `solve` statement in the program, GAMS uses as much information as possible from the previous solution to provide a starting point or `basis` in the search for the next solution.

4.30.4.2 Loop: One Model, Different Data

Multiple solves may also occur as a result of a `solve` statement within a `loop` statement. Loop statements are introduced and discussed in detail in chapter [Programming Flow Control Features](#); here we show that they may contain a `solve` statement and thus lead to multiple solves within one model. The example from [MEANVAR] computes the efficient frontier for return and variance for a portfolio selection problem at equidistance points.

```
loop(p(pp),
  v.fx = vmin + (vmax-vmin)/(card(pp)+1)*ord(pp) ;
  Solve var1 maximizing m using nlp ;
  xres(i,p)      = x.l(i);
  xres('mean',p) = m.l;
  xres('var',p)  = v.l;
);
```

The set `p` is a set of point between the minimum and maximum variance, it is the driving set of the loop. A variance variable `v` is fixed at a equidistance points. With each iteration through the loop another variance level is used, the NLP model `var1` is solved for each iteration and the outputs are stored in the parameter `xres(*,pp)`, to be used later for reporting. As often for reporting purposes, the [universal set](#) `*` is used.

This example demonstrates how to solve the same model (in terms of variables and equations) multiple times with slightly different data. For such situations the [Gather-Update-Solve-Scatter](#) (GUSS) facility improves on the loop implementation by saving generation time and minimizing the communication with the solver. GUSS is activated by the additional keyword `scenario` in the `solve` statement followed by a set name that provides mapping information between parameters in the model and the scenario containers. A GUSS implementation of the loop would look as follows:

```
parameter vfx(p), px(p,i), pm(p);
set dict / p .scenario.'
  v .fixed .vfx
  x .level .px
  m .level .pm /;
vfx(p(pp)) = vmin + (vmax-vmin)/(card(pp)+1)*ord(pp);
Solve var1 maximizing m using nlp scenario dict;
xres(i,p)      = px(p,i);
xres('mean',p) = pm(p);
xres('var',p)  = vfx(p);
```

4.30.4.3 Customizing Solution Management: SolveOpt

It is important to consider how GAMS manages solutions if multiple models are solved. By default, GAMS merges subsequent solutions with prior solutions. This is not an issue if all models operate over the same set of variables. However, recursive procedures, different equation inclusions or logical conditions may cause only part of the variables or different variables to appear in the models to be solved. In such a case it might be useful to modify the solution management procedure using the model attribute or option [SolveOpt](#).

4.30.4.4 Sensitivity or Scenario Analysis

Multiple solve statements can be used not only to solve different models, but also to conduct sensitivity tests, or to perform case (or scenario) analyses of models by changing data or bounds and then solving the same model again. While some commercial LP systems allow access to "sensitivity analysis" through GAMS it is possible to be far more general and not restrict the analysis to either solver or model type. This facility is even more useful for studying many scenarios since no commercial solver will provide this information.

An example of sensitivity testing is in the simple oil-refining model [[MARCO](#)]. Because of pollution control, one of the key parameters in oil refinery models is an upper bound on the sulfur content of the fuel oil produced by the refinery. In this example, the upper bound on the sulfur content of fuel oil is set to 3.5 percent in the original data for the problem. First, the model is solved with this value. Next, a slightly lower value of 3.4 percent is used and the model is solved again. Finally, the considerably higher value of 5 percent is used and the model is solved for the last time. Key solution values are saved for later reporting after each solve. This is necessary because a following solve replaces any existing values. The key solution values are the activity levels of the process level *z*, a variable that is defined over a set of processes *p* and a set of crude oils *cr*. The complete sequence is:

```
parameter report(*,*,*) "process level report";

qs('upper','fuel-oil','sulfur') = 3.5 ;
Solve oil using lp maximizing phi;
report(cr,p,'base') = z.l(cr,p) ;
report('sulfur','limit','base') = qs('upper','fuel-oil','sulfur');

qs ('upper','fuel-oil','sulfur') = 3.4 ;
Solve oil using lp maximizing phi ;
report(cr,p,'one') = z.l(cr,p) ;
report('sulfur','limit','one') = qs ('upper','fuel-oil','sulfur');

qs('upper','fuel-oil','sulfur') = 5.0 ;
Solve oil using lp maximizing phi ;
report(cr,p,'two') = z.l(cr,p) ;
report('sulfur','limit','two') = qs('upper','fuel-oil','sulfur');

Display report ;
```

Note that the parameter `report` is defined over the [universal set](#) or short *universe*. In general, the universe is useful when generating reports, otherwise it would be necessary to provide special sets containing the labels used in the report. Any mistakes made in spelling labels used only in the report should be immediately apparent, and their effects should be limited to the report. The parameter `qs` is used to set the upper bound on the sulfur content in the `fuel-oil`, and the value is retrieved for the report. Note that the `display` statement in the final line is introduced and discussed in detail in chapter [The Display Statement](#). This example shows not only how simply sensitivity analysis can be done, but also how the associated multi-case reporting can be handled.

The output from the `display` statement is shown below. Observe that there is no production at all if the permissible sulfur content is lowered. The *case attributes* have been listed in the row `SULFUR.LIMIT`. Section [Global Display Controls](#) contains more details on how to arrange reports in a variety of ways.

```

----      225 PARAMETER report   process level report

                base           one           two

mid-c .a-dist      89.718                35.139
mid-c .n-reform    20.000                6.772
mid-c .cc-dist     7.805                 3.057
w-tex .cc-gas-oil                5.902
w-tex .a-dist                64.861
w-tex .n-reform           12.713
w-tex .cc-dist            4.735
w-tex .hydro                28.733
sulfur.limit          3.500          3.400          5.000

```

Note

For other ways to do comparative analyses with GAMS, see the tutorial [Comparative Analyses with GAMS](#).

4.30.4.5 Iterative Implementation of Non-Standard Algorithms

Another use of multiple solve statements is to permit iterative solution of different blocks of equations, most often using solution values from the first solve as data for the next solve. These decomposition methods are useful for certain classes of problems because the subproblems being solved are smaller, and therefore more tractable. One of the most common examples of such a method is the [Dantzig-Wolfe decomposition](#).

An example of a problem that is solved in this way is a multi-commodity network flow problem in [DANWOLFE].

4.30.5 Choosing a Solver

After a model has been checked and prepared as described above, GAMS passes the model to a solver. When the GAMS system is installed default solvers for all model types are specified and these solvers are used if the user doesn't specify anything else. It is easy to switch to other appropriate solvers provided the user has the corresponding [license](#). There are multiple ways to switch solvers:

1. Using a [command line parameter](#) of the following form:

```
gams mymodel model_type=solver name
```

For example,

```
gams mymodel lp=cbc
```

2. With an [option command](#) of the following form that is placed before the `solve` statement:

```
Option model_type=solver_name;
```

Here `option` is a keyword, `model_type` is the same model type that is used in the `solve` statement and `solver_name` is the name of one of the available solvers. For example,

```
Option LP=cbc, NLP=conopt, MIP=cbc, MINLP=default;
```

The `MINLP=default` switches back to the default solver for the MINLP model type.

3. Instead of providing a particular solver for a model type, the option [Solver](#) can be used to use a given solver for all model types this solver can handle.

```
Option Solver=cbc;
```

4. (Re)running `gamsinst` at any time and altering the choice of default solver as described in the [installation notes](#).

Note

A list of all solvers and current default solvers may be generated in the `listing` file with `Option SubSystems;`.

4.30.6 Making New Solvers Available with GAMS

This short section is to encourage those of you who have a favorite solver not available through GAMS. Linking a solver program with GAMS requires some programming skills and the use of libraries provided by GAMS. There is a collection of open source solver links to GAMS at the [COIN-OR project GAMSLinks](#). The benefits of a link with GAMS to the developer of a solver are several. They include:

- Immediate access to a wide variety of test problems.
- An easy way of making performance comparisons between solvers.
- The guarantee that a user has not somehow provided an illegal input specification.
- Elaborate documentation, particularly of input formats, is not needed.
- Access to the existing community of GAMS users, for marketing or testing.

This completes the discussion of the model and solve statements.

4.31 Conditional Expressions, Assignments and Equations

4.31.1 Introduction

This chapter deals with the way in which conditional assignments, expressions and equations are made in GAMS. The [index operations](#) already described are very powerful, but it is necessary to allow for exceptions of one sort or another. For example, heavy trucks may not be able to use a particular route because of a weak bridge, or some sectors in an economy may not produce exportable products. Exceptions such as these may easily be modeled with a logical condition combined with the dollar operator '\$', a very powerful feature of GAMS introduced in this chapter.

This chapter is organized as follows: We will introduce the general form of the [dollar condition](#) first and then we will focus on the various types of [logical conditions](#). Next, we will discuss how dollar conditions are used to build [conditional assignments](#), [conditional indexed operations](#) and [conditional equations](#). We will conclude the chapter by showing that in certain cases conditions may be modeled using [filtering sets](#) instead of the dollar operator. Programming flow control features such as the [if](#) statement, the [loop](#), the [while](#) statement, and the [for](#) statement are not covered in this chapter. These can be found in the chapter [Programming Flow Control Features](#).

4.31.2 The Dollar Condition

The dollar operator is one of the most powerful features in GAMS. The general syntax for a conditional expression is:

```
term $ logical_condition
```

Here, `term` can be a number, a (indexed) symbol, and also a complex expression. The dollar operator may be read as *under the condition that* the following `logical_condition` evaluates to TRUE (or is unequal 0).

Consider the following simple condition, where `a` and `b` are scalars.

```
if (b > 1.5), then a = 2
```

This can be written in GAMS using the dollar operator as follows.

```
a $ (b > 1.5) = 2 ;
```

Note that the `term` is the scalar `a` and the `logical condition` is the expression $(b > 1.5)$. If the condition is not satisfied, no assignment is made. To make it clear, this conditional assignment may be read as: *'given that b is greater than 1.5, a equals 2'*.

Logical conditions may take various forms, they are introduced in the next section. Conditional expressions may be used in the context of assignments, indexed operations and equations. These topics are covered in later sections of this chapter.

Note

Logical conditions used with the dollar operator cannot contain variables. However, [variable attributes](#) are allowed.

4.31.3 Logical Conditions

Logical conditions are special expressions that evaluate to a value of either TRUE or FALSE. Logical conditions may be numerical expressions and numerical relations, they may refer to set membership and they may also contain acronyms. In the following subsections this is shown in the context of simple conditional assignments with the dollar operator on the left-hand side (compare section [Dollar on the Left](#)).

In this section we use many examples to illustrate the concepts that are being introduced. In all these examples `a` and `b` are scalars, `s`, `t`, `u` and `v` are parameters, and `i` and `j` are sets.

4.31.3.1 Logical Conditions: Numerical Expressions

Numerical expressions may serve as logical conditions: a result of zero is treated as the logical value `FALSE` and a non-zero result is treated as the logical value `TRUE`. The following example illustrates this point.

```
b $ (2*a - 4) = 7;
```

Here the numerical expression $(2 * a - 4)$ is the logical condition. The numerical expression is zero if `a` equals 2, and non-zero otherwise. Hence the logical value of the expression is `FALSE` for `a = 2` and `TRUE` for all other values of `a`. The assignment is only made if the numerical expression evaluates to `TRUE`, otherwise no assignment is made.

Attention

Values of the [extended range arithmetic](#) such as `inf` are also allowed in logical conditions. If the result of a numerical expression used as a logical condition takes any of these values, the logical value is `TRUE`, even for e.g. `eps`, which is numerically 0.

Observe that [functions](#) are also allowed in logical conditions. If they evaluate to zero, the logical condition is `FALSE`, otherwise it is `TRUE`. Consider the following example:

```
b $ cos(a) = 7;
```

Note that the assignment is only made if the cosine of `a` does not equal zero.

4.31.3.2 Logical Conditions: Numerical Relational Operators

Numerical relational operators compare two numerical expressions and return a logical value. For completeness, all numerical relational operators are listed in [Table 1](#).

Relation	Operator	Alternative Notation	Return Values
Strictly less than	<code>x < y</code>	<code>x lt y</code>	Returns <code>TRUE</code> if $x < y$, else returns <code>FALSE</code> .
Less than or equal to	<code>x <= y</code>	<code>x le y</code>	Returns <code>TRUE</code> if $x \leq y$, else returns <code>FALSE</code> .
Equal to	<code>x = y</code>	<code>x eq y</code>	Returns <code>TRUE</code> if $x = y$, else returns <code>FALSE</code> .
Not equal to	<code>x <> y</code>	<code>x ne y</code>	Returns <code>TRUE</code> if $x \neq y$, else returns <code>FALSE</code> .
Greater than or equal to	<code>x >= y</code>	<code>x ge y</code>	Returns <code>TRUE</code> if $x \geq y$, else returns <code>FALSE</code> .
Strictly greater than	<code>x > y</code>	<code>x gt y</code>	Returns <code>TRUE</code> if $x > y$, else returns <code>FALSE</code> .

Table 1: Numerical Relational Operators

Consider the following examples.

```
b $ (a < 0) = 10;
```

```

b $ (sqr(a) > a) = 12;
a $ ( sum(i, s(i)) > 0 ) = 7;
t(i) $ (a <> 0) = t(i) + 1;

```

In the first line the logical condition is the relational expression ($a < 0$). The assignment is only made if this expression is **TRUE**, that is, if the scalar **a** is negative. The logical condition in the second line is a bit more complex. It evaluates to **FALSE** if $0 \leq a \leq 1$. For all other values of **a**, it evaluates to **TRUE**. So the assignment is made for all values of **a**, except for those values of **a** that are in the closed interval $[0, 1]$. Note that if $a = -3$, then the logical condition in the first line will be **TRUE**, so **b** will become 10. In addition, the logical condition in the second line will be **TRUE**, so **b** will change to 12. The logical condition in the third line evaluates to **TRUE** if the sum of all values of the parameter **s** is strictly positive. Then **a** is assigned the value of 7. The assignment in the last line depends on whether **a** is non-zero. If **a** is zero no assignment is made, otherwise all entries of the parameter **t** are updated.

Note that [acronyms](#) may also be used with relational operators to build logical conditions. However, only the equality operator = and inequality operator <> are allowed in the context of acronyms, since they have no numerical values and the other operators would be meaningless. For an example, see section [Acronym Usage](#).

4.31.3.3 Logical Conditions: Logical Operators

GAMS offers standard logical operators that may combine two or more logical conditions to build complex logical expressions. For example, if several expressions are required to be **TRUE** simultaneously, they may be connected with the operator **and**. The logical operators available in GAMS are listed in [Table 2](#) and [Table 3](#). Another way to construct complex logical conditions is by nesting them. For details, see subsection [Nested Dollar Conditions](#) below.

Operation	Operator	Alternative Notation	Description
Negation	not x		The logical condition x has to be FALSE , in order for the expression to be TRUE .
Logical conjunction	x and y		Two logical conditions are TRUE simultaneously.
Logical disjunction	x or y		At least one of two logical conditions applies.
Exclusive disjunction	x xor y		Exactly one of two logical conditions applies.
Logical implication	x imp y	x -> y	If the logical condition x is TRUE but at the same time the logical condition y is FALSE , then the whole expression is FALSE , in all other cases the expression evaluates to TRUE .
Logical equivalence	x eqv y	x <=> y	Both logical conditions are either TRUE simultaneously or FALSE simultaneously for the whole expression to be TRUE .

Table 2: Logical Operators

The logical values of these operators are summarized in the following truth table.

x	y	not x	x and y	x or y	x xor y	x imp y	x eqv y
FALSE	FALSE	TRUE	FALSE	FALSE	FALSE	TRUE	TRUE

x	y	not x	x and y	x or y	x xor y	x imp y	x eqv y
FALSE	TRUE	TRUE	FALSE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	FALSE	FALSE	TRUE	TRUE	FALSE	FALSE
TRUE	TRUE	FALSE	TRUE	TRUE	FALSE	TRUE	TRUE

Table 3: Truth Table of Logical Operators

The following somewhat artificial examples serve as illustration.

```

Set      i      / i1*i5 /
Parameter s(i) / i1 3, i2 5, i4 8 /
          t(i) / i1*i4 13 /
          u(i) / i2 1 /
          v(i) / i1 7, i3 2 /;

u(i) $ (not s(i))           = v(i);
u(i) $ (s(i) and u(i) and t(i)) = s(i);
u(i) $ (s(i) or v(i) or t(i)) = 4;

```

Note that there are three conditional assignments for the parameter `u`. In the first assignment the logical condition is `(not s(i))`. This condition holds for all entries of `s` that are not specified and therefore zero by default: `s('i3')` and `s('i5')`. Hence `u('i3')` and `u('i5')` are assigned the values of `v('i3')` and `v('i5')` respectively. The value of `v('i3')` is 2 and the value of `v('i5')` is zero by default. After the first assignment we have `u('i2')=1` and `u('i3')=2`, all other values of `u` are zero. Note that the logical condition failed for `u('i2')` and therefore its value remained unchanged. The logical condition in the second assignment is `TRUE` for those labels of the set `i` that have non-zero entries in the parameters `s`, `u` and `t` simultaneously. This condition holds only for `i2`. Therefore `u('i2')=s('i2')=5` and all other values of `u` remain unchanged, resulting in non-zero values only for `u('i2')` and `u('i3')`. The logical condition in the last assignment evaluates to `TRUE` for all labels of the set `i` that have at least one non-zero entry in the parameters `s`, `v` and `t`. This holds for all labels except for `i5`. Therefore `u('i5')` stays zero and all other values of `u` are changed to 4. These examples demonstrate the power of the dollar operator combined with logical operators. Even more complex logical conditions are possible; see subsection [Mixed Logical Conditions](#) below for details.

4.31.3.4 Logical Conditions: Set Membership and Set Functions

Apart from numerical and relational expressions, set membership and functions referencing set elements may be used as a logical condition. Consider the following example as illustration for set membership as logical condition.

```

Set      i      / i1*i5 /
          j(i) / i1*i3 / ;
Parameter s(i) / i1 3, i2 5, i3 11, i4 8, i5 1 /
          t(i);
t(i) $ j(i) = s(i) + 3;

```

Note that the set `j` is a subset of the set `i` and that the parameter `t` is declared but not defined. The conditional expression `t(i)$j(i)` in the last line restricts the assignment to the members of the subset `j` since only they satisfy the condition `j(i)`. The values for `t('i4')` and `t('i5')` remain unchanged. In this case this means that they are zero (by default). Note that there is an alternative formulation for this type of conditional assignment; for details see subsection [Filtering Sets in Assignments](#) below.

Note

Only the membership of [subsets](#) and [dynamic sets](#) may be used as logical conditions.

The use of set membership as a logical condition is an extremely powerful feature of GAMS, see section [Conditional Equations](#) below for more examples.

Logical conditions may contain functions that return particular values depending on the position of elements in sets, the size of sets or the comparison of set elements to each other or text strings. These functions are presented in [Table 4](#).

Function		Description and Comments
<code>sameAs(element1,element2)</code> <code>sameAs("text",element2)</code> <code>sameAs(element1,"text")</code>	or or	Returns TRUE if <code>element1</code> is identical to <code>element2</code> or <code>element1</code> is identical to <code>text</code> , and FALSE otherwise.
<code>diag(element1,element2)</code> <code>diag("text",element2)</code> <code>diag(element1,"text")</code>	or or	Same as function <code>sameAs</code> , but returns numerical value 1 for TRUE and 0 for FALSE.
<code>card(set_name)</code>		Returns the number of elements in a set. Note that this can also be called with a quoted text and returns the number of characters of that text in that case. For more details, see section The Card Operator .
<code>ord(set_name)</code>		Returns the relative position of an element in a set. Note that <code>ord</code> may be used <i>only</i> with one-dimensional, static, ordered sets. For more details, see section The Ord Operator .

Table 4: Functions Referencing Sets

In the following example we have two sets of cities and we want to know how many of them feature in both sets.

```
Set      i      / Beijing, Calcutta, Mumbai, Sydney, Johannesburg, Cairo /;
Set      j      / Rome, Paris, Boston, Cairo, Munich, Calcutta, Barcelona /;
Scalar  b;
b = sum((i,j)$sameAs(i,j),1);
```

Note that in the assignment statement we `sum` over both sets and we use the function `sameAs` to restrict the domain of the indexed operation to those label combinations `(i,j)` where the function `sameAs` evaluates as TRUE. Thus only identical elements are counted.

Note that in this example the function `diag` could have been used with the same result.

The functions `ord` and `card` are frequently used to single out the first or last element of an [ordered set](#). For example, we may want to fix a variable for the first and last elements of a set:

```
x.fx(i) $ (ord(i) = 1)      = 3;
x.fx(i) $ (ord(i) = card(i)) = 7;
```

In the first assignment the variable `x` is fixed for the first element of the set `i` and in the second assignment `x` is fixed for the final element of `i`.

Note

As an alternative to the formulation above, one could also use the [set attributes](#) `first` and `last` to get the same result:

```
x.fx(i) $ (i.first) = 3;
x.fx(i) $ (i.last) = 7;
```

4.31.3.5 Numerical Values of Logical Conditions

We have seen that logical conditions may take the form of numerical expressions, expressions with relational operators, complex expressions using logical operators, set membership and set functions. However, GAMS does not have a Boolean data type.

Attention

GAMS follows the convention that the result of a relational operation is zero if the assertion is `FALSE`, and 1 if it is `TRUE`.

Consider the following example as illustration.

```
x = (1 < 2) + (2 < 3);
```

The expression to the right of the assignment evaluates to 2 since both logical conditions within parentheses are `TRUE` and therefore assume a value of 1. Note that this is different from the assignment below:

```
x = (1 < 2) or (2 < 3)
```

This assignment evaluates to 1, since both statements to the left and right of `or` are `TRUE` and therefore the whole expression is `TRUE`.

4.31.3.6 Mixed Logical Conditions

The building blocks introduced in the subsections above may be combined to generate more complex logical conditions. These may contain [standard arithmetic operations](#), [numerical relational operations](#) and [logical operations](#). All operations, their symbols and their order of precedence are given in [Table 5](#). Note that 1 denotes the highest order of precedence and 7 denotes the lowest order of precedence. As usual, the default order of precedence holds only in the absence of parentheses and operators (symbols) on the same level are evaluated from left to right.

Type of Operation	Operation	Operator	Order of precedence
Standard arithmetic operation	Exponentiation	**	1
Standard arithmetic operation	Multiplication, Division	*, /	2
Standard arithmetic operation	Unary operators: Plus, Minus	+, -	3
Standard arithmetic operation	Binary operators: Addition, Subtraction	+, -	3
Numerical Relational operation	All	<, <=, =, <>, >=, >	4
Logical operation	Negation	not	5
Logical operation	Logical Conjunction	and	6
Logical operation	All other logical operations	or, xor, imp, eqv	7

Table 5: Complete Hierarchy for Operator Precedence in GAMS

Note

We recommend to use parentheses rather than relying on the order of precedence of operators. Parentheses prevent errors and make the intention clear.

Consider the following example:

$x - 5*y$ and $z - 5$
 $(x - (5*y))$ and $(z-5)$

These two complex logical conditions are equivalent. However, the parentheses make the second expression easier to understand.

Some simple examples of complex logical conditions, their numerical values and their logical values are given in [Table 6](#).

Logical Condition	Numerical Value	Logical Value
$(1 < 2) + (3 < 4)$	2	TRUE
$(2 < 1) \text{ and } (3 < 4)$	0	FALSE
$(4*5 - 3) + (10/8)$	18.25	TRUE
$(4*5 - 3) \text{ or } (10 - 8)$	1	TRUE
$(4 \text{ and } 5) + (2*3 \leq 6)$	2	TRUE
$(4 \text{ and } 0) + (2*3 < 6)$	0	FALSE

Table 6: Examples of Complex Logical Conditions

4.31.3.7 Nested Dollar Conditions

An alternative way to model complex logical conditions is by nesting them. The syntax is:

```
term $ (logical_condition1$(logical_condition2$(...)))
```

Note that in nested dollar conditions all succeeding expressions after the dollar operator must be enclosed in parentheses. The nested expression is equivalent to the following conditional expression that uses the logical operator `and` instead of the nesting:

```
term $ (logical_condition1 and logical_condition2 and ...)
```

Consider the following example. Note that i , $j(i)$ and $k(i)$ are sets, and $u(i)$ and $v(i)$ are parameters.

```
u(i) $ (j(i)$k(i)) = v(i) ;
```

The assignment will be made only for those members of the set i that are members of both sets j and k . Note the position of the parentheses in the dollar condition. The assignment statement above can be rewritten in the following way.

```
u(i) $ (j(i) and k(i)) = v(i) ;
```

Note

We recommend to use the logical `and` operator instead of nesting dollar operators, because this formulation is easier to read.

4.31.4 Conditional Assignments

A conditional assignment is an assignment statement with a dollar condition on the left-hand side or on the right-hand side. Most examples until now were conditional assignments with the dollar operator on the left.

Attention

The effect of the dollar condition is significantly different depending on which side of the assignment it is located.

The next two subsections describe the use of the dollar condition on each side of the assignment. Note that in many cases it may be possible to use either of the two forms of the dollar condition to describe an assignment. We recommend to choose the clearer formulation.

Note that if the logical condition in an assignment statement refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section [Filtering Sets in Assignments](#) below.

4.31.4.1 Dollar on the Left

If the dollar condition is on the left-hand side of an assignment, an assignment is made only in case the logical condition is satisfied. If the logical condition is not satisfied then no assignment is made and the previous content of the parameter on the left will remain unchanged. In case the parameter on the left-hand side of the assignment has not previously been initialized or assigned any values, zeros will be used for any label for which the assignment was suppressed.

Consider the following example adapted from [CHENERY]. Note that the parameter `sig` has been previously defined in the model.

```
rho(i) $ (sig(i) <> 0) = (1./sig(i)) - 1. ;
```

In this assignment `rho(i)` is calculated and the dollar condition on the left protects against dividing by zero. If any of the values associated with the parameter `sig` turns out to be zero, no assignment is made and the previous values of `rho(i)` remain. As it happens, `rho(i)` was not previously initialized, and therefore all the labels for which `sig(i)` is zero will result in a value of zero.

Now recall the convention that non-zero implies `TRUE` and zero implies `FALSE`. The assignment above could therefore be written as:

```
rho(i) $ sig(i) = (1./sig(i)) - 1. ;
```

In the following examples `i` is a set and `s` and `t` are parameters.

```
s(i) $ t(i) = t(i);
s(i) $ ((t(i)-1) > 0) = t(i)**0.5;
```

Note that the first assignment is suppressed if the value of the parameter `t` equals zero. The second assignment is suppressed for values of the parameter `t` that are smaller or equal to 1.

Note

The first of the last two examples is special in the way that the logical condition used with the dollar on the left and the expression on the right hand side of the assignment are actually the same. This allows to use a shorter notation using the combined `$=` assignment. That assignment is equivalent to the following one (which called [sparse assignment](#)):

```
s(i) $= t(i);
```

4.31.4.2 Sparse Assignments

Sparse assignments will assign a value to the left-hand side of the = sign only if the right-hand side is nonzero. This behavior is triggered using the \$= notation as in the following example.

```

Set          i                /a,b,c/
Parameter d1(i) "Initial data" /a 1, b 1, c 1/
           d2(i) "Data to be used to overwrite d1" /a 0, b -2 /
           d3(i) "Empty data parameter";

* Initialize d3 to d1
d3(i) = d1(i);
* Use dollar on the left to overwrite d3 with non-zero values from d2
d3(i)$d2(i) = d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;

* Re-Initialize d3 to d1
d3(i) = d1(i);
* Use sparse assignment to overwrite d3 with non-zero values from d2
d3(i) $= d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;

```

Note that in the final assignments above, the values of the parameter `d3(i)` are replaced with values from parameter `d2(i)` only if the entry in `d2(i)` is non-zero, the other values are left untouched. Both assignments are equivalent.

4.31.4.3 Dollar on the Right

If the dollar condition is on the right-hand side of an assignment statement, an assignment will *always* be made. In case the logical condition is not satisfied the value of zero is assigned.

Above we had the following simple conditional assignment:

```
a $ (b > 1.5) = 2;
```

Now we move the dollar condition to the right-hand side:

```
a = 2 $ (b > 1.5) ;
```

This is equivalent to:

```
if (b > 1.5) then (a = 2), else (a = 0)
```

Note that an `if-then-else` type of construct is implied, but the `else` operation is predefined and never made explicit. The `else` could be made explicit with the following formulation:

```
a = 2 $ (b > 1.5) + 0 $ (b <= 1.5) ;
```

The use of this feature is more apparent in instances when an `else` condition needs to be made explicit. Consider the next example adapted from the fertilizer model [FERTD]. The set `i` is the set of plants, and we are calculating `mur(i)`, the cost of transporting imported raw materials. In some cases a barge trip must be followed by a road trip because the plant is not alongside the river and we must combine the separate costs. The assignment is:

```
mur(i) = (1.0 + .0030*ied(i,'barge')) $ ied(i,'barge')
        + (0.5 + .0144*ied(i,'road' )) $ ied(i,'road' );
```

This means that if the entry in the distance table `ied` is not zero, then the cost of shipping using that link is added to the total cost. If there is no distance entry, there is no contribution to the cost, presumably because that mode is not used.

Consider another example for a conditional assignment with the dollar operator on the right:

```
b = sum(i,t(i)) $ (a > 0) + 4;
```

Here `a` and `b` are scalars, `i` is a set and `t` is a parameter. If the scalar `a` is positive, the scalar `b` is assigned the sum of all values of the parameter `t` plus 4. If `a` is zero or negative, `b` becomes just 4. Note that the `sum` is only computed if the condition holds, this potentially makes the program faster.

4.31.5 Conditional Indexed Operations

We have seen how exceptions in assignments are modeled with dollar conditions. Dollar conditions are also used in [indexed operations](#), where they control the domain of operation. This is conceptually similar to the conditional assignment with the [dollar on the left](#).

Consider the following example adapted from [GTM], a gas trade model for interrelated gas markets. Here the set `i` contains supply regions and the parameter `supc` models supply capacities. The scalar `tsupc` is computed with the following statement:

```
tsupc = sum(i $ (supc(i) <> inf), supc(i)) ;
```

This assignment restricts the sum to the *finite* values of the parameter `supc`.

In indexed operations the logical condition is often a set. This set is called the *conditional set* and assignments are made only for labels that are elements of the conditional set. This concept plays an important role in [dynamic sets](#).

Multi-dimensional sets are introduced in section [Multi-Dimensional Sets](#). In the example used there a two-dimensional set is used to define the mapping between countries and ports. Another typical example for a multi-dimensional set is a set-to-set mapping that defines the relationship between states and regions. This is useful for aggregating data from the state to the regional level. Consider the following example:

```
Sets r          "regions" / north, south /
     s          "states" / florida, texas, vermont, maine /
     corr(r,s)  / north.(vermont,maine)
                south.(florida,texas) /;

Parameter y(r)  "income for each region"
               income(s) "income of each state"
                   / florida  4.5, vermont  4.2
                   texas    6.4, maine   4.1 / ;
```

The set `corr` links the states to their respective regions, the parameter `income` is the income of each state. The parameter `y` is computed with the following assignment statement:

```
y(r) = sum(s $ corr(r,s), income(s)) ;
```

The conditional set `corr(r,s)` restricts the domain of the summation: for each region `r` the summation over the set `s` is restricted to the label combinations `(r,s)` that are elements of the set `corr(r,s)`. Conceptually, this is analogous to the Boolean value `TRUE` or the arithmetic value `non-zero`. The effect is that only the contributions of `vermont` and `maine` are included in the total for `north`, and `south` is the sum of the incomes from only `texas` and `florida`.

Note that the summation above can also be written as:

```
y(r) = sum(s, income(s) $ corr(r,s));
```

In this formulation the parameter `income` is controlled by the conditional set `corr` instead of the index `s`. Note that both formulations yield the same result, but the second alternative is more difficult to read.

In the next example the logical condition on the right-hand side appears in the context of an indexed operation, but it does not refer to the index. Thus it is treated similarly to a [dollar on the right](#) logical condition. Note that `a` and `b` are scalars, `i` is a set and `s` is a parameter.

```
b = sum(i $ a, s(i));
```

Here the scalar `b` is assigned the sum of the values of the parameter `s` only if `a` does not equal zero. Otherwise `b` will be assigned the value zero. Observe that the following alternative formulation will generally be faster than the assignment above:

```
b = sum(i, s(i)) $ a;
```

Note that if the logical condition in the context of indexed operations refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section [Filtering Controlling Indices in Indexed Operations](#) below.

4.31.6 Conditional Equations

The dollar operator is also used for exception handling in equations. The next two subsections discuss the two main uses of dollar operators in the context of equations: in the body of an equation and over the domain of definition.

4.31.6.1 Dollar Operators within the Algebra of Equations

A dollar operator in the algebraic formulation of an equation is analogous to the dollar control on the right of assignments, as presented in section [Dollar on the Right](#). Assuming that "the right" means the right of the '.' then the analogy is even closer. As in the context of assignments, an `if-else` operation is implied. It is used to exclude parts of the definition from some of the generated constraints.

Consider the following example adapted from the production model `[CHENERY]`.

```
Set      i      "sectors"      / light-ind, food+agr, heavy-ind, services /
        t(i)    "tradables"    / light-ind, food+agr, heavy-ind /;

Variables x(i)    "quantity of output"
          y(i)    "final consumption"
          e(i)    "quantity of exports"
          m(i)    "quantity of imports";

Equations mb(i)    "material balance";

mb(i)..   x(i) =g= y(i) + (e(i) - m(i)) $ t(i) ;
```

Note that in the equation definition in the last line, the term $(e(i) - m(i))$ on the right-hand side of the equation is added only for those elements of the set `i` that also belong to the subset `t(i)`, so that the element `services` is excluded.

Further, conditional indexed operations may also feature in expressions in equation definitions. The supply balance equation from the gas trade model `[GTM]` is an example. Note that the set `i` contains the supply regions, the set `j` contains the demand regions, and the two-dimensional set `ij` is the set of feasible links; the variable `x` denotes the shipment of natural gas and the variable `s` denotes the regional supply.

```
sb(i)..  sum(j $ ij(i,j), x(i,j)) =l= s(i) ;
```

Similar to the assignment example seen before, the conditional set `ij(i,j)` restricts the domain of the summation: for each supply region `i` the summation over the demand regions `j` is restricted to the label combinations `(i,j)` that are elements of the set of feasible links `ij(i,j)`.

4.31.6.2 Dollar Control over the Domain of Definition

In case constraints should only be included in the model if particular conditions are met, a dollar condition in the domain of definition of an equation may be used to model this restriction. Such a dollar condition is analogous to the [dollar control on the left of assignments](#). Assuming that "the left" means the left of the symbols '.' then the analogy is even closer.

Note

The dollar control over the domain of definition of equations restricts the number of constraints generated to less than the number implied by the domain of the defining sets.

Consider the following example adapted from the Andean fertilizer model `[ANDEAN]` :

```
gple(w,wp,te) $ pple(w,wp).. yw(w,te) - yw(wp,te) =l= dpack;
```

Here w , w_p and t_e are sets, $p_l e$ is a two-dimensional parameter, y_w is a variable and d_{pack} is a scalar. Note that the dollar condition restricts the first two indices of the domain of the equation to those label combinations that have non-zero entries in the two-dimensional parameter $p_l e$.

Sometimes the desired restriction of an equation may be achieved either way: through a condition in the algebra or a condition in the domain of definition. Compare the following two lines, where $eq1$ and $eq2$ are equations, i and j are sets, b is a scalar, s is a parameter and x is a two-dimensional variable.

```
eq1(i) $ b.. sum(j, x(i,j)) =g= -s(i);
eq2(i).. sum(j, x(i,j)) $ b =g= -s(i) $ b;
```

In the first line the dollar condition is in the domain of definition, in the second line the dollar conditions are in the algebraic formulation of the equation. If b is non-zero, the generated equations $eq1$ and $eq2$ will be identical. However, if b is 0, no equation $eq1$ will be generated, but for each i we will see a trivial equation $eq2$ of the form $0 =g= 0$;

Note that if the logical condition in the domain of definition of an equation refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section [Filtering the Domain of Definition](#) below.

4.31.7 Filtering Sets

If the logical condition refers to set membership, the restriction modeled with a dollar condition may sometimes be achieved *without* the dollar operator. Consider the following statement, where i and $j(i)$ are sets, and u and s are parameters:

```
u(i) $ j(i) = s(i) ;
```

Note that the assignment is made only for those elements of the set i that are also elements of the subset j . This conditional assignment may be rewritten in a shorter way:

```
u(j) = s(j) ;
```

In this statement the assignment has been filtered through the condition without the dollar operator by using the subset j as the domain for the parameters u and s . This formulation is cleaner and easier to understand. It is particularly useful in the context of multi-dimensional sets (tuples), and it may be used in [assignments](#), [indexed operations](#) and the [domain of definition](#) of equations.

4.31.7.1 Filtering Sets in Assignments

Suppose we want to compute the transportation cost between local collection sites and regional transportation hubs for a fictional parcel delivery service. We define sets for the collection sites and transportation hubs and a two-dimensional set where the collection sites are matched with their respective hubs:

```
Set i      "local collection sites"      / miami, boston, chicago, houston, phoenix /
j      "regional transportation hubs" / newyork, detroit, losangeles, atlanta / ;
```

```
Set r(i,j) "regional transportation hub for each local collection site" /
  boston .newyork
  miami .atlanta
  houston .atlanta
  chicago .detroit
  phoenix .losangeles / ;
```

```
Table distance(i,j)      "distance in miles"
      newyork  detroit  losangeles  atlanta
miami      1327      1387      2737      665
boston      216      699      3052      1068
chicago    843      275      2095      695
houston    1636      1337      1553      814
phoenix    2459      1977      398      1810;
```

```
Parameter factor      "cost estimate per unit mile"
      shipcost(i,j) "cost of transporting parcels from a local collection site to a regional hub
```

```
factor = 0.009 ;
shipcost(i,j) $ r(i,j) = factor*distance(i,j) ;
```

The distance between collection sites and transportation hubs is given in the table. The last line is a conditional assignment for the parameter `shipcost`. This assignment is only made if the label combination (i, j) is an element of the set `r`. Note that in each instance the indices `i` and `j` appear together. Thus the assignment may be simply written as:

```
shipcost(r) = factor*distance(r) ;
```

Note that the assignment is explicitly restricted to the members of the set `r`; the dollar operator is not necessary. Observe that if the indices `i` or `j` appear separately in any assignment, the above simplification cannot be made. For example, consider the case where the shipping cost depends not only on the parameter `factor` and the distance between collection sites and regional hubs, but also on the congestion at the regional hub. We introduce a new parameter `congestfac` that models the congestion at each regional hub and is indexed only over the set `j`:

```
Parameter congestfac(j) "congestion factor" /
  newyork      1.5
  detroit      0.7
  losangeles   1.2
  atlanta      0.9/ ;
```

The new cost of shipment is computed as follows:

```
shipcost(i,j) $ r(i,j) = factor*congestfac(j)*distance(i,j) ;
```

Note that this conditional assignment *cannot* be reformulated as:

```
shipcost(r) = factor*congestfac(j)*distance(r) ;
```

In the representation above the index `j` appears on the right-hand side, but not on the left-hand side. GAMS will flag this assignment as an error. However, the following representation will work:

```
shipcost(r(i,j)) = factor*congestfac(j)*distance(r) ;
```

In this formulation the set `r` is explicitly denoted as a tuple of the sets `i` and `j`. The set `j` may then appear on the right-hand side.

4.31.7.2 Filtering Controlling Indices in Indexed Operations

Similarly, the controlling indices in indexed operations may be filtered through the [conditional set](#) without the use of the dollar operator. We continue with the shipping cost example from the last subsection. The total cost of shipment is obtained through the equation that follows. We also include the variable definitions for clarity.

```
Variable shipped(i,j), totcost ;
Equation costequ ;

costequ.. totcost =e= sum((i,j) $ r(i,j), shipcost(i,j)*shipped(i,j));
```

Here the variable `shipped` is the number of parcels shipped from the local collection site `i` to the regional transportation hub `j`, and the variable `totcost` is the total cost of all shipments. Note that the summation in the equation is restricted to the label combinations that are elements of the set `r`. Alternatively, the equation above may be written as:

```
costequ.. totcost =e= sum(r, shipcost(r)*shipped(r));
```

In this formulation the summation is performed explicitly only over the elements of the set `r`, no dollar condition is necessary. However, if the expression in the equation included a term dependent only on index `j`, then we would have to reformulate differently. Suppose the equation included also the congestion factor `congestfac` that is indexed only over `j`:

```
cost.. totcost =e= sum((i,j) $ r(i,j), factor*congestfac(j)*distance(i,j)*shipped(i,j));
```

In this case the equation needs to be simplified in the following way:

```
cost.. totcost =e= sum(r(i,j), factor*congestfac(j)*distance(r)*shipped(r));
```

Like before, the domain of the indexed operation `sum` is the set `r`. But this time the domain of `r` has to be named explicitly, so that the parameter `congestfac` which is indexed only over the set `j` is permitted in the scope of the indexed operation. Note that this reasoning is analogous to the reasoning for filtering sets in assignments in the subsection above.

4.31.7.3 Filtering the Domain of Definition

The rules for filtering sets that we have introduced in subsections [Filtering Sets in Assignments](#) and [Filtering Controlling Indices in Indexed Operations](#) also apply in the context of equation domains. We continue with the parcel transport example introduced above and add a binary variable `bin`, the parameter `bigM` and the equation `connect` to the model. Recall that `shipped(i,j)` is a variable and `r(i,j)` is a set.

```
Parameter          bigM(i,j) ;
Binary variable    bin(i,j) ;

Equation           connect(i,j) ;

connect(i,j) $ r(i,j).. shipped(i,j) =l= bigM(i,j)*bin(i,j) ;
```

The dollar condition restricts the domain of definition of the equation `connect` to those label combinations of the sets `i` and `j` that are elements of the set `r`. The equation relates the continuous variable `shipped(i,j)` to the binary variable `bin(i,j)`. Note that each domain in the equation is the index pair `(i,j)`. So the equation may be simplified as follows:

```
connect(r).. shipped(r) =l= bigM(r)*bin(r) ;
```

In this formulation the domain of the equation is explicitly restricted to the members of the set `r`, without the use of a dollar condition. Note that if the right-hand side of the equation contained any term that was indexed over `i` or `j` separately, then the domain of definition of the equation would have to be simplified as:

```
connect(r(i,j))
```

The reasoning is the same as in the case of assignments and indexed operations.

4.32 The Display Statement

4.32.1 Introduction

The `display` statement in GAMS is a quick way to write data into the listing file. It does not provide a publication quality reporting function, but is instead aimed at functionality that is easy to use and provides graceful defaults. These defaults may be modified by the user to control the layout and appearance of the output. Both defaults and customization options are presented in this chapter. For information on the listing file, see chapter [GAMS Output](#). In addition to the `display` statement, GAMS offers [the put writing facility](#), a more sophisticated way to generate reports, where the user has much more flexibility and control over the output of individual items.

4.32.2 The Syntax

In general, the syntax for the `display` statement in GAMS is as follows:

```
display ident | quoted text {, ident | quoted text};
```

The keyword `display` indicates that this is a `display` statement. It is followed by an [identifier](#). If the identifier is a set or a parameter, only the name of the set or parameter itself is specified. If the identifier is a variable, an equation or a model, it must be followed by a suffix, i.e. a [variable attribute](#), [equation attribute](#) or [model attribute](#) respectively. As usual, `quoted text` must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines. For [conditional displays](#) a dollar condition may follow the keyword `display`.

The output produced by a `display` statement consists of labels and data. For multi-dimensional sets the keyword `yes` (indicating membership) is used instead of values.

Note

Only the non-default values are displayed for all data types.

The default value is generally zero. Exceptions are some upper and lower bounds of variables and equations (the attributes `.lo` and `.up`). Their default values are listed in sections [Variable Attributes](#) and [Equation Attributes](#) respectively.

The syntax of the display statement is illustrated by the following example:

```
Sets      s      / s1*s4 /
          t      / t5*t7 /
          st(s,t) / s1.t5, s1.t7, s2.t6, s3.t7, s4.t5 / ;
Parameters p(s)  / s1 0.33, s3 0.67 /
          q(t)   / t5 0.33, t7 0.67 / ;
Variable  v(s,t) ;
v.l(s,t) = p(s)*q(t);
display 'first a simple set', s, 'then a two-dimensional set', st, 'then a parameter', p,
       'then the activity level of a variable', v.l;
```

The display statement will generate the following lines in the listing file:

```
----      8 first a simple set

----      8 SET s

s1,      s2,      s3,      s4

----      8 then a two-dimensional set

----      8 SET st

          t5          t6          t7

s1      YES          YES
s2          YES
s3          YES
s4      YES

----      8 then a parameter

----      8 PARAMETER p

s1 0.330,      s3 0.670

----      8 then the activity level of a variable

----      8 VARIABLE v.L

          t5          t7

s1      0.109      0.221
s3      0.221      0.449
```

In the case of multi-dimensional identifiers like the set `st` and the level values of the variable `v`, the data is by default reported in a tabular form that is easy to read. Note that only the non-default values are displayed. To display zero values, the special value `EPS` can be used. In the example above, all values of the parameter `p` can be displayed by adding the following lines.

```
display 'display all values';
p(s)$(not p(s)) = EPS;
display p;
```

The following lines will be displayed in the listing file.

```
----      11 display all values
----      13 PARAMETER p

s1 0.330,   s2  EPS,   s3 0.670,   s4  EPS
```

An alternative to displaying `EPS` is to use `acronym` but computations cannot be done with the resulting parameters.

4.32.3 Displaying Multi-Dimensional Identifiers: Label Order

We have seen that two-dimensional identifiers are displayed in table format. The default layout for displaying multi-dimensional identifiers is summarized in [Table 1](#). Note that the default format may be modified with the [local display control](#). The figures in the table refer to the index position in the domain list of the identifier. For example, if we display `x`, where `x` has been declared as `x(i,j,k,l)`, then the `i` labels (the first index) will by default be associated with the individual subtables, the `j` and `k` with the row labels and the `l` (the fourth and last index) with the column headings.

Number of Indices	Subtable	Index Position(s) on the Row	Column
1		list format	
2	-	1	2
3	-	1,2	3
4	1	2,3	4
5	1,2	3,4	5
6	1,2,3	4,5	6

Table 1: Default Layout for Displaying Multi-Dimensional Identifiers

For 7 to the maximum number of indices the natural progression is followed. For the current maximum number of indices, see [Dimensions](#). The labels vary slowest for the first index position and quickest for the highest. Within each index position the order of the label is the GAMS entry order of the labels. Some users may need to manipulate the order of the labels.

Note

The only way to change the order in which the labels for each index position appear in the display output is to change the order of appearance of the labels in the GAMS program.

This is most easily done by declaring a set whose only purpose is to list all the labels in the order that is needed. Make this set the very first declaration in the GAMS program.

Note that the order of the indices in an identifier is always as the order in the declaration statement. One can declare them in the order that is found appealing, or make an assignment to a new identifier with a different order, as illustrated in the [example](#) below.

4.32.3.1 Example for Multi-Dimensional Displays

Consider the following example. The parameter `x` has four dimensions or index positions. It is initialized using parameter format and then displayed as shown below.

```
Set i  first index      / first, second /
    j  second index     / one, two, three /
    k  third index      / a, b /
    l  fourth index     / i, ii / ;

Parameter
  x(i,j,k,l) a four dimensional structure /
      second.one.a.i      0.00013,  first .three.b.i      -6.3161
      first .one.b.i      5.63559,  second.two .b.i      20000.00
      second.one.b.ii     -17.29948,  first .two .b.ii     10.3457
      first .two.a.ii     0.02873,  second.one .a.ii     1.0037
      second.two.a.ii     +inf,      first .two .a.i      -2.9393
      first .one.a.ii     0.00000 /
  y(k,l,i,j) a four dimensional structure with changed index order;
y(k,l,i,j) = x(i,j,k,l);
display x, y;
```

For variable `x` the code fragment produces the following output:

```
----      16 PARAMETER x  a four dimensional structure

INDEX 1 = first

           i           ii

one .b      5.636
two .a     -2.939      0.029
two .b           10.346
three.b    -6.316

INDEX 1 = second

           i           ii

one.a 1.300000E-4      1.004
one.b           -17.299
two.a           +INF
two.b  20000.000
```

Notice that there are two subtables, one for each label in the first index position. Note further that the order of the labels is not the same as in the input data list of the parameter `x`, but is according to the label order in the driving sets. Observe that the numbers are rounded, three decimals are displayed by default. This default may be modified with [display controls](#), which is the topic of the next section. Note that the zero in the list for `x('first', 'one', 'a', 'ii')` has vanished, since default values are not shown. Similarly, rows and columns containing only zero values are suppressed in each subtable separately. Note further that the especially small value appears in E-format.

Notice furthermore how parameter `y` can be used to display the same data with a different index order.

4.32.4 Display Controls

GAMS allows the user to modify the number of row and column labels in the display listing as well as the accuracy of the data being displayed. There are global and local display controls. Global display controls allow the user to affect more than one display statement. The local display control may be used to override the global controls if specific data need to be listed in a particular format. Both controls are expressed with [option statements](#).

4.32.4.1 Global Display Controls

The first option for global display controls specifies the number of digits shown after the decimal point. It affects the numbers appearing in all display output following the option statement, unless it is changed for a specific identifier as shown below. The general form of this option statement is:

```
option decimals = value;
```

The keyword `option` indicates that this is an option statement, `decimals` is the specific option and `value` is an integer between 0 and 8. The value 0 suppresses decimals as well as the decimal point. Note that the default is 3. Note further that the width of the number field does not change, just the number of decimals. This may cause numbers which would normally be displayed in fixed format to appear in E-format, that is with the exponent represented explicitly.

Consider the following extension to the example discussed in the previous section.

```
option decimals = 1; display x;
```

GAMS will round or convert numbers to E-format where necessary and the output is as follows:

```
----      14 PARAMETER x  a four dimensional structure

INDEX 1 = first

           i           ii

one .b           5.6
two .a          -2.9 2.873000E-2
two .b                    10.3
three.b          -6.3

INDEX 1 = second

           i           ii

one.a 1.300000E-4           1.0
one.b                    -17.3
two.a                    +INF
two.b          20000.0
```

Note that GAMS overrode the decimal choice for `x('first','two','a','ii')` to ensure that small numbers are not displayed as zeroes.

Another option for global display control modifies the width of the display. This is particularly important for longer label names. Label names that are headers of columns are cut off after 9 characters when data is displayed in table format. The following option may be used to display longer names in full:

```
option dispwidth = value;
```

The name of the option is `dispwidth` and `value` is a positive integer smaller or equal to 31. An illustrative example follows.

```
Set i      'South African cities'      / Johannesburg, Cape_Town /
    j      'other African cities'      / Maputo, Dar_es_Salaam /
    f(i,j) 'direct flight connections' / Johannesburg.Maputo, Johannesburg.Dar_es_Salaam, Cape_Town
display f ;
```

The display statement generates the following output:

```
----      4 SET f  direct flight connections

                Maputo  Dar_es_Sa~
Johannesburg      YES      YES
Cape_Town         YES
```

Note that only the label 'Dar_es_Salaam' is cut off since it is heading a column. The label 'Johannesburg' is not cut off as it is the label for a row. Now we add the following line to change the width of the display statement:

```
option dispwidth = 15; display f;
```

As expected, the output changes and the label 'Dar_es_Salaam' is no longer cut off:

```
----      5 SET f  direct flight connections

                Maputo  Dar_es_Salaam
Johannesburg      YES      YES
Cape_Town         YES
```

4.32.4.2 Local Display Control

It is often useful to control the number of decimals for specific identifiers separately. The following option statement accomplishes this:

```
option ident:d-value;
```

`Ident` denotes the name of the identifier and `d-value` is an integer in the range 0 to 8. The number of decimal places shown on all displays of `ident` that follow will be `d-value`.

This option statement can be extended to control the layout of the data in addition to the decimal places. The general form is as follows:

```
option ident:d-value:r-value:c-value ;
```

Here **r-value** denotes the number of index positions that are combined to form the row label and **c-value** means the number of indices on the column headers.

The example discussed in the previous section is further extended in order to illustrate the local display control.

```
option x:5:3:1; display x;
```

These two statements generate the following output:

```
----      17 PARAMETER x  a four dimensional structure

                i          ii

first .one  .b      5.63559
first .two  .a     -2.93930      0.02873
first .two  .b                10.34570
first .three.b    -6.31610
second.one  .a      0.00013      1.00370
second.one  .b                -17.29948
second.two  .a                +INF
second.two  .b 20000.00000
```

Note that five decimal places are shown, three labels are used to mark the rows and one label acts as head of the column. Since this is a four-dimensional structure, all indices are accounted for.

The next example places two indices on each of the row and and column labels and retains five decimal places:

```
option x:5:2:2; display x;
```

The output is:

```
----      18 PARAMETER x  a four dimensional structure

                a.i          a.ii          b.i          b.ii

first .one                5.63559
first .two     -2.93930      0.02873                10.34570
first .three                -6.31610
second.one      0.00013      1.00370                -17.29948
second.two                +INF 20000.00000
```

If in the option statement less dimensions are specified than the number of indices in the domain, then subtables will be generated for the labels of the beginning indices. Observe how the display layout will change if we use the following statement:

```
option x:0:1:1; display x;
```

The output follows.

```

----      19 PARAMETER x  a four dimensional structure

INDEX 1 = first  INDEX 2 = one

          i

b          6

INDEX 1 = first  INDEX 2 = two

          i          ii

a          -3 2.873000E-2
b          10

INDEX 1 = first  INDEX 2 = three

          i

b          -6

INDEX 1 = second INDEX 2 = one

          i          ii

a 1.300000E-4          1
b          -17

INDEX 1 = second INDEX 2 = two

          i          ii

a          +INF
b          20000

```

The option statement is checked for consistency against the dimensionality of the identifier and error messages will be issued if the number of the dimensions specified in the option statement is larger than the number of indices in the domain of the identifier.

4.32.4.3 Display Statement to Generate Data in List Format

The option statement for local display controls may be used to generate data in list format by setting the `r-value` to zero:

```
option ident:d-value:0:c-value;
```

In this case the `c-value` specifies the maximum number of items displayed on a line. The actual number will depend on the page width and the number and length of the labels.

Using the same example as in the previous sections, we change the `r-value` to zero in the option statement:

```
option x:5:0:1; display x;
option x:5:0:2; display x;
```

Note that we specified one and two columns to illustrate the impact of different *c-value* settings. These statements will generate the following output:

```

----      20 PARAMETER x  a four dimensional structure

first .one .b.i      5.63559
first .two .a.i     -2.93930
first .two .a.ii    0.02873
first .two .b.ii   10.34570
first .three.b.i   -6.31610
second.one .a.i    0.00013
second.one .a.ii   1.00370
second.one .b.ii  -17.29948
second.two .a.ii   +INF
second.two .b.i  20000.00000

----      21 PARAMETER x  a four dimensional structure

first .one .b.i      5.63559,   first .two .a.i     -2.93930
first .two .a.ii    0.02873,   first .two .b.ii   10.34570
first .three.b.i   -6.31610,   second.one .a.i    0.00013
second.one .a.ii   1.00370,   second.one .b.ii  -17.29948
second.two .a.ii   +INF,      second.two .b.i  20000.00000

```

This output nicely illustrates the label order used. The first index varies the slowest, the last the fastest, and each one runs from beginning to end before the next one to the left advances. This ordering scheme is also used in equation and column lists and in the solution report which are all generated by the solve statement.

4.32.5 Conditional Displays

This section assumes familiarity with the [if statement](#) and the [dollar condition](#).

The display statement may be controlled by conditional expressions. Conditionals have the effect that the items are displayed only if a logical condition is satisfied. There are two ways to express conditional displays in GAMS: with dollar conditions and using if statements. The syntax using a dollar condition is as follows:

```
display$logical_condition ident | quoted text {, ident | quoted text};
```

Note that the dollar condition is inserted after the keyword `display`. For details on the various forms of conditional expressions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#). Consider the following simple example:

```

Scalars x, y;
x = 7;
y = 3;
display$(x-y < 0) "display if x minus y is less than 0", x, y;

```

The logical condition $(x-y < 0)$ controls the display statement. In this case it is not satisfied, hence there will be no display output. If the value of *y* is changed to, say 10, then the logical condition will be satisfied and the display statement will generate the following output:

```

----      4 display if x minus y is less than 0
          PARAMETER x                =          7.000
          PARAMETER y                =          10.000

```

The syntax for conditional displays using an `if` statement is as follows:

```
if( logical_condition, display statement );
```

The simple example above may be reformulated as follows:

```

Scalars x, y;
x = 7;
y = 3;
if( x-y < 0,
    display "display if x minus y is less than 0", x, y;
);

```

4.33 Programming Flow Control Features

4.33.1 Introduction

In this chapter we will describe the programming flow control features available in GAMS. The [if statement](#) facilitates expressing complex conditional statements (see also chapter [Conditional Expressions, Assignments and Equations](#)). In addition, GAMS offers four loop constructs to handle looping requirements: the [loop statement](#), the [while statement](#), the [for statement](#) and the [repeat statement](#). At the end of this chapter we will introduce the [break](#), and [continue statements](#), which give additional control over the execution of loop structures, and the [abort statement](#), a statement that may be used to terminate the execution of a program.

Note that this chapter deals with programming flow control features at execution time. In addition, GAMS provides a dollar control option that allows for *conditional processing of input files at compile time*. For more information, see the detailed description of the option [\\$if](#). For details on dollar control options in general, see chapter [Dollar Control Options](#).

4.33.2 The If Statement

The `if` statement is useful to branch conditionally around a group of statements. In some cases this can also be written as a set of [dollar conditions](#), but the `if` statement may make the GAMS code more readable. An optional `else` and/or `elseif` part allows the user to formulate traditional `if-then-else` constructs.

4.33.2.1 The If Statement: Syntax

The syntax for an `if` statement in GAMS is as follows:

```
if (logical_condition,
    statement; {statement;})
{ elseif logical_condition,
    statement; {statement;}} }
[ else
    statement; {statement;} ]
);
```

The keyword `if` indicates that this is an `if` statement. The logical condition is followed by one or more [statements](#) that are executed if the logical condition is satisfied. For details on the various forms of logical conditions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#). The `if` statement may end at this point, without any specifications for cases when the logical condition is `FALSE` and no action is taken in these cases. However, GAMS also allows further specifications: optional alternative `if` tests and optional statements for cases when all previous `if` tests have failed. The keyword `elseif` introduces an alternative `if` test with a logical condition and one or more [statements](#). Note that the `elseif` case is optional and may be repeated multiple times. Note further that the `elseif` case implies that the logical condition of the `if` case has not been satisfied. The keyword `else` introduces the final part of the construct. It is optional and allows specification for cases when the logical condition of the `if` case (and possibly the `elseif` case(s)) has not been satisfied.

Attention

Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside an `if` statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option [onEnd](#).

4.33.2.2 The If Statement: Examples

Consider the following set of conditional assignment statements that use dollar conditions:

```
p(i)$ (f <= 0) = -1 ;
p(i)$ ((f > 0) and (f < 1)) = p(i)**2 ;
p(i)$ (f >= 1) = p(i)**3 ;
q(j)$ (f <= 0) = -1 ;
q(j)$ ((f > 0) and (f < 1)) = q(j)**2 ;
q(j)$ (f >= 1) = q(j)**3 ;
```

They may be expressed using an `if-elseif-else` statement:

```
if (f <= 0,
    p(i) = -1 ;
    q(j) = -1 ;
elseif ((f > 0) and (f < 1)),
    p(i) = p(i)**2 ;
    q(j) = q(j)**2 ;
else
    p(i) = p(i)**3 ;
    q(j) = q(j)**3 ;
) ;
```

Note that the body of the `if` statement may contain `solve` statements. For instance, consider the bit of GAMS code that follows. Note that `m1` is a GAMS model, `z` is a free variable, `j` is a set and `x` is a variable.

```
solve m1 using lp minimizing z;
if (m1.modelstat = 4,
    display "model m1 was infeasible, relax bounds on x and solve again";
    x.up(j) = 2*x.up(j) ;
    solve m1 using lp minimizing z ;
else
    if (m1.modelstat <> 1,
        abort "error solving model m1" ;
    );
);
```

First the model `m1` is solved. For details on `solve` statements in GAMS, see section [The Solve Statement](#). Then a post solution analysis is done with the `if` statement. If the model is infeasible, the upper bound on the variable `x` is relaxed and the model is solved again. If the original model is not infeasible and it is not optimal either, then the compilation is aborted and the error message above is reported. For more information on GAMS output, see chapter [GAMS Output](#), particularly subsection [Model Status](#) for a list of all GAMS model statuses. The `display` statement is introduced in chapter [The Display Statement](#). For details on the `abort` command, see [abort](#).

The following GAMS code is illegal since it is not permitted to define equations inside an `if` statement.

```
if (s > 0,
    eq.. sum(i,x(i)) =g= 2 ;
);
```

The following GAMS code is also illegal since declarations inside an `if` statement are not allowed.

```
if (s > 0,
    scalar y ; y = 5 ;
);
```

4.33.3 The Loop Statement

The `loop` statement facilitates executing a group of statements for each member of a set. `Loop` statements are particularly useful for cases when parallel assignments are not sufficient. This is the case most often when there is no analytic relationship between the values to be assigned to a parameter. It is, of course, also useful to have a looping statement for general programming.

4.33.3.1 The Loop Statement: Syntax

The syntax for the `loop` statement in GAMS is as follows:

```
loop(index_list[$(logical_condition)],
    statement; {statement;}
) ;
```

The keyword `loop` indicates that this is a loop statement. The `index_list` is the controlling domain of the loop. Note that loops may be controlled by more than one set. In this case parentheses are required around the index list, which is also called the *loop set(s)*. Observe that dynamic sets are allowed as loop sets. The loop set(s) may be restricted by a logical condition. For details on the various forms of logical conditions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#). For an introduction to dollar conditions in general, see chapter [Conditional Expressions, Assignments and Equations](#). The index list is followed by one or more [statements](#). Except for the final statement, each statement must end with a semicolon `';`. The loop statements are executed for each member of the controlling domain in turn. The order of evaluation is the entry order of the labels. A loop is thus another, more general, type of [indexed operation](#).

Attention

- Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `loop` statement.
- It is illegal to modify any controlling set inside the body of the loop.

`Loop` statements in GAMS are often used for iterative calculations, generating reports with [put statements](#) and doing scenario based studies with [solve statements](#). Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option [onEnd](#).

4.33.3.2 The Loop Statement: Examples

Consider a hypothetical case when a growth rate is empirical:

```
Set      t          / 1985*1990 /
Parameter pop(t)    / 1985  3456 /
          growth(t) / 1985  25.3, 1986  27.3, 1987  26.2
                      1988  27.1, 1989  26.6, 1990  26.6 /;
```

The `loop` statement is then used to calculate the cumulative sums iteratively:

```
loop(t, pop(t+1) = pop(t) + growth(t) ) ;
```

In this example the driving set is `t` and we have just one statement in the scope of the loop.

The following small artificial examples illustrate the effects of a dollar condition in a `loop` statement.

```
Sets      i          / i1*i3 /
          j          / j1*j5 /
          k(i,j)     / i1.j1, i1.j3, i3.j3, i3.j5 /;
Parameter c(i)      / i1 3, i2 1 /
          q(i,j)     / i1.j1 1, i1.j2 3, i1.j4 2 / ;
Scalars  x, y, z;
x = 1; y = 3; z = 1;

loop ( (i,j) $ (q(i,j) > 0), x = x + q(i,j));
loop ( i $ (c(i) + c(i)**2), z = z + 1);
loop ( i $ sum(j, abs(q(i,j))), z = z + 1);
loop ( j $ (ord(j) > 1 and ord(j) < card(j)), z = z + 1);
loop ( (i,j) $ k(i,j), y = y + ord(i) + 2*ord(j));
```

In the first `loop` statement the controlling domain is the set pair (i, j) . It is restricted to those label combinations whose values associated with the parameter `q` are greater than zero. The logical condition in the second `loop` statement is $c(i) + c(i)^2$. This is shorthand for $c(i) + c(i)^2 \neq 0$. The domain in the third `loop` statement is restricted to those elements of the set `i` where the sum over `j` of the absolute values of the parameter `q` does not equal zero. Note that this condition is satisfied only for the label "i1". Observe that `i` and `j` are both [ordered sets](#). In the fourth `loop` statement the first and the last element of the set `j` are excluded. For more on the set operators `ord` and `card`, see sections [The Ord Operator](#) and [The Card Operator](#) respectively. The dollar control in the last `loop` statement excludes all label combinations that are not members of the set `k`. For further details on dollar conditions, see chapter [Conditional Expressions, Assignments and Equations](#).

Note

The dollar condition may be replaced by an [if statement](#); see the [example](#) below.

The next example shows how a model can be solved for each element of a set `i` with different data using a `loop` statement. Note that `problemdata` is a scalar, `g(i)` and `d(i)` are parameters, `mymodel` is a GAMS model and `profit` is a free variable.

```
loop (i,
  problemdata = g(i);
  solve mymodel using lp maximizing profit;
  d(i) = profit.l;
);
```

In the first statement some data in the model is updated in accordance with the i^{th} element of the parameter `g`. In the second statement the model is solved. For details on the `solve` statement, see section [The Solve Statement](#). The objective value for each iteration is saved in the parameter `d` in the third statement.

A loop is often used to perform iterative calculations. Consider the following example, which finds square roots by Newton's method. This example is purely for illustration - in practice, the function `sqrt` should be used. Newton's method is based on the assertion that if x is an approximation to the square root of v , then $(x + v/x)/2$ is a better approximation.

```
Set      i          "set to drive iterations"          / i-1*i-100 /;
Parameter value(i) "used to hold successive approximations";
Scalars  target     "number whose square root is needed" / 23.456 /
         sqrtval    "final approximation to sqrt(target)"
         curacc     "accuracy of current approximation"
         reltol     "required relative accuracy"        / 1.0e-06 /;

abort$(target <= 0) "argument to newton must be positive";
value("i-1") = target/2 ;
curacc      = 1 ;
loop(i$(curacc > reltol),
  value(i+1) = 0.5*(value(i) + target/value(i));
  sqrtval   = value(i+1);
  curacc    = abs (value(i+1)-value(i))/(1+abs(value(i+1)))
) ;
abort$(curacc > reltol) "square root not found"
option decimals=8;
display "square root found within tolerance", sqrtval, value;
```

Note that in this example the dollar condition in the loop does not restrict the driving set `i`, but it is used to terminate the loop procedure. The scalar `curacc` is updated in every iteration. As soon as it becomes equal to or smaller than the required relative accuracy `reltol` the loop stops. As the output below shows, this is the case after seven iterations. The body of the `loop` statement consists of three statements. The first statement calculates the current approximation and assigns it to the parameter `value`. The second statement updates the scalar `sqrtval`, and the third statements computes the accuracy of the current approximation in each iteration. Note that before and after the loop statement we added lines to account for special cases. For details on the `abort` statement, see section [The Abort Statement](#) at the end of this chapter. The output generated by the [display statement](#) is given below.

```

----      19 square root found within tolerance

----      19 PARAMETER SQRVAL                =  4.84313948 final approximation
                                                to sqrt(target)

----      19 PARAMETER VALUE                used to hold successive approximations

i-1 11.72800000,   i-2 6.86400000,   i-3 5.14062471,   i-4 4.85174713
i-5 4.84314711,   i-6 4.84313948,   i-7 4.84313948

```

Note that a statement within the body of a loop may be an [if statement](#) (or any other programming flow control statement). Moreover, the logical condition in a `loop` statement may be expressed with an `if` statement instead of a dollar condition. The following example serves as illustration. Observe that `k` is a set and `s`, `t`, `u` and `a` are parameters.

```

loop (k,
      if((s(k) < 0 and t(k)),
          u(k) = a(k);
      );
);

```

Note that if the logical condition is not satisfied the assignment is not made and the parameter `u` remains unchanged.

Recall that subsets are connected with their supersets by arcs thus building a [domain tree](#) where the root node is the [universal set](#). The following example demonstrates how the domain tree may be used in a `loop` statement.

```

Set i      / i1*i10 /
  ii(i)
  j(i)     / i1*i9  /
  jj(j)    / i1*i8  /
  jjj(jj)  / i1*i7  /;

loop(i(jjj), ii(i) = yes;);
display ii;

```

Observe that the looping set is `i(jjj)`. This means that we loop over those elements of `i` that are also elements of the set `jjj`. This construct is permitted since `i` is in the domain tree on the path from `jjj` to the universe or universal set. It is allowed to go up the domain tree on one path and go down on another path. Therefore all the elements of `jjj` are assigned to `ii`. The outcome of the `display` statement confirms this:

```

----      8 SET ii

i1,      i2,      i3,      i4,      i5,      i6,      i7

```

4.33.4 The While Statement

The `while` statement facilitates the repeated execution of one or more statements as long as a logical condition is satisfied.

4.33.4.1 The While Statement: Syntax

The syntax for the `while` statement in GAMS is as follows:

```
while(logical_condition,  
      statement; {statement;}  
);
```

The keyword `while` indicates that this is a `while` statement. Inside the `while` statement a logical condition is followed by one or more `statements`. For details on the various forms of logical conditions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#). The statements are executed as long as the logical condition is `TRUE`.

Attention

Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `while` statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option [onEnd](#).

4.33.4.2 The While Statement: Examples

Consider the following simple example:

```
Scalar x; x = 1;  
while ( round(x,2) < 10,  
      x = x + 0.01;  
);  
display x;
```

Note that the scalar `x` is increased in each iteration until it equals 10. Note further, that to ensure an exact result, in numerical comparisons we need a stable check like we have above (`round(x,2) < 10`), otherwise rounding errors may occur. As soon as `x` reaches 10, the logical condition is no longer satisfied and therefore there will be no further passes. Hence the final value of `x` equals 10.

Note that the number of passes in a `while` statement may be restricted using the command line parameter or option [forlim](#). For details on command line parameters and options, see section [Specifying Options Through the Command Line](#) and chapter [The Option Statement](#) respectively.

`While` statements may be used to control the `solve` statement. For instance, consider the following implementation of a random multi-start method for non-convex optimization.

```

scalar count / 1 /;
scalar globmin / inf /;
option bratio = 1 ;
while(count <= 1000,
    x.l(j) = uniform(x.lo(j),x.up(j)) ;
    solve ml using nlp minimizing obj ;
    if (obj.l < globmin,
        globmin = obj.l ;
        bestsol(j) = x.l(j) ;
    ) ;
    count = count+1 ;
) ;

```

Note that we start from a random starting point by setting the initial level values randomly between the upper and lower bounds. This assumes that the bounds have been previously specified and are not infinity. When the method improves, that is, if the logical condition (`obj.l < globmin`) is satisfied, the best known solution is stored in the scalar `globmin`. The level values associated with the best known solution so far are then saved in the parameter `bestsol`. This procedure is repeated 1000 times. The model **[PRIME]** is another example where the use of the `while` statement is illustrated. In this model the set of all prime numbers smaller than 200 is generated.

The following GAMS code is illegal since equation definitions inside a `while` statement are not permitted.

```

while(s > 0,
    eq.. sum(i,x(i)) =g= 2 ;
);

```

The following GAMS code is also illegal since declarations inside a `while` statement are not allowed.

```

while(s > 0,
    scalar y ; y = 5 ;
);

```

4.33.5 The For Statement

The `for` statement provides a compact way to iterate over a range of values and execute one or more statements each time.

4.33.5.1 The For Statement: Syntax

The syntax for the `for` statement in GAMS is as follows:

```

for (a = start_value to|downto end_value [by incr],
    statement; {statement;}
);

```

The keyword `for` indicates that this is a `for` statement. The scalar `a` begins with the real number `start_value` and is changed after each pass of the loop by the increment `incr` until it reaches the real number `end_value`. Note that the specification of an increment is optional, the default is 1. If the increment is given, it has to be a positive real number. Note further that `to` indicates that the scalar `a` is *increased* and `downto` indicates that it is *decreased*. In each iteration one or more [statements](#) are executed.

Attention

Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `for` statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option [onEnd](#).

4.33.5.2 The For Statement: Examples

Consider the following simple example:

```
Scalar s;
for (s = -3.8 to -0.1 by 1.4,
     display s ;
);
```

Note that *negative* real numbers are possible for the start and end values. The resulting listing file will contain the following lines:

```
----      3 PARAMETER s                =      -3.800
----      3 PARAMETER s                =      -2.400
----      3 PARAMETER s                =      -1.000
```

Observe that the value of `s` was increased by 1.4 with each pass of the loop as long as it did not exceed -0.1. In the next example the value of `s` is *decreased*:

```
Scalar s;
for (s = 3 downto -0.1 by 1.4,
     display s ;
);
```

Note that the number of passes in a `for` statement may be restricted using the command line parameter or option `forlim`. For details on command line parameters and options, see section [Specifying Options Through the Command Line](#) and chapter [The Option Statement](#) respectively.

Like `while` statements, `for` statements may be used to control the `solve` statement. The following example illustrates the use of the `for` statement by replicating the [random search for a global optimum of a non-convex model](#) that we discussed above.

```
scalar i ;
scalar globmin / inf / ;
option bratio = 1 ;
for (i = 1 to 1000,
     x.l(j) = uniform(x.lo(j),x.up(j)) ;
     solve ml using nlp minimizing obj ;
     if (obj.l < globmin,
         globmin = obj.l ;
         bestsol(j) = x.l(j) ;
     );
);
```

Note that the logical condition in the `while` loop (`count <= 1000`) is replaced by the specification of the range of values for the scalar `i`. The body of the `for` loop is identical to the body of the `while` loop, except for the statement to update the scalar `count` that we needed in the `while` loop. This demonstrates the similarities and differences between the two loops.

The following GAMS code is illegal since it is not allowed to define equations inside a `for` statement.

```
for (s = 1 to 5,
     eq.. sum(i,x(i)) =g= 2 ;
);
```

The following GAMS code is also illegal since declarations inside a `for` statement are not permitted.

```
for (s = 1 to 5,
     scalar y ; y = 5 ;
);
```

4.33.6 The Repeat Statement

The `repeat` statement facilitates the repeated execution of one or more statements. This is done unconditionally at least once and stopped when a logical condition is satisfied.

4.33.6.1 The Repeat Statement: Syntax

The syntax for the `repeat` statement in GAMS is as follows:

```
repeat (
    statement; {statement;}
until logical_condition );
```

The keyword `repeat` indicates that this is a `repeat` statement. One or more [statements](#) are executed in each iteration. The keyword `until` introduces the termination criterion: if the logical condition is satisfied, the `repeat` loop is terminated. For details on the various forms of logical conditions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#).

Note that the `repeat` statement is similar to the `while` statement, but a `repeat` loop is guaranteed to be executed at least one time since the logical condition is stated *after* the statements.

Attention

Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `repeat` statement.

Examples are given in the next subsection.

4.33.6.2 The Repeat Statement: Examples

Consider the following simple example:

```
Scalar a / 1 /;
repeat (
    a = a + 1;
    display a;
until a = 5 );
```

The scalar `a` is increased in each iteration by 1. If `a` equals 5, the termination criterion is satisfied and the loop stops. Note that this example works nicely since both, the scalar and the increment, are integer. In case the entity on the right-hand side of the termination condition is not an integer or the increment is not an integer, we recommend a formulation of the check that is more stable to avoid rounding errors. An example for a stable termination condition follows.

```
Scalar a / 1 /;
repeat (
    a = a + 0.1;
    display a;
until abs(a-5) < 1e-6 );
```

Observe that in the next example the termination condition is TRUE from the start. In this case the statement in the body of the `repeat` statement is executed once and then the loop is terminated. Hence the final value of `a` will be 5.

```
Scalar a / 4 /;
repeat (
  a = a + 1;
  display a;
until a >= 3 );
```

Note that the number of passes in a while statement may be restricted using the command line parameter or option `forlim`. For details on command line parameters and options, see section [Specifying Options Through the Command Line](#) and chapter [The Option Statement](#) respectively.

Here is a little more complex example. A `repeat` statement is used to narrow the interval where a quadratic function passes through zero. Note that, as is often the case, one of the statements in the `repeat` loop is another programming flow control statement, in this case an `if` statement.

```
Scalar max          "current upper boundary of interval"  /10/
      min           "current lower boundary of interval"  /-10/
      root          "value where function equals zero"
      function_value1 "function value at min"
      function_value2 "function value at max"
      tolerance      "tolerance for root"                /0.00000001/
      signswitch     "indicates that sign switch was found" /0/
      inc            "increment to try to find sign switch" ;

function_value1 = 6 - 5*min + sqr(min);
inc              = (max - min)/37;
root             = min;

repeat (
  root = root + inc;
  function_value2 = 6 - 5*root + sqr(root);

  if((  sign(function_value1) <> sign(function_value2)
      and abs(function_value1) > 0
      and abs(function_value2) > tolerance ),
    max = root;
    signswitch = 1;
  else
    if(abs(function_value2) > tolerance,
      function_value1 = function_value2;
      min = root;
    );
  );
);
until (signswitch > 0) or (root > max) );
display min, max, function_value1, function_value2;
```

The result of the `display` statement shows that the value of `min` is 1.892 and the value of `max` is 2.432, the interval was narrowed to 0.54, which is just a little less than the value of `inc`. As expected, `function_value1` and `function_value2` differ in sign, confirming that the root of the quadratic function is indeed in the interval.

4.33.7 The Break Statement

The `break` statement gives additional control over the execution of loop structures, namely the [loop statement](#), the [while statement](#), the [for statement](#) and the [repeat statement](#). It allows to break the execution of a loop structure prematurely.

4.33.7.1 The Break Statement: Syntax

The syntax for the `break` statement is as follows:

```
break [n];
```

The keyword `break` indicates that this is a break statement. It terminates the `n` inner most control structures. `n` is optional and if it is omitted, it is set to 1.

Most often `break` statements are used in the context of [if statements](#) or with [dollar conditions](#). For details on the various forms of logical conditions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#).

4.33.7.2 The Break Statement: Examples

This is a simple, artificial example using the `break` statement to exit a `loop` statement:

```
Set    i    / i1*i10 /;
Scalar cnt / 0 /;

loop(i,
      break$sameas('i6',i);
      cnt = cnt+1;
);

display cnt;
```

The `break` statement in combination with the dollar condition terminates the execution of the loop body in the 6th iteration. This can be seen looking at the value of `cnt` after the loop, which will be 5.

Here is a little more complex example which uses the optional argument `n` to terminate more than one loop structure at once:

```
Set    i    / i1*i10 /;
Scalar x, y,
       cnt / 0 /;

for(x = 1 to 10,
    y = 0;
    while(y < 10,
        y = y+1;
        loop(i,
            break$sameas('i6',i) 2;
            cnt = cnt+1;
        );
    );
);

display cnt;
```

In this example, `cnt` will be 50 at the end. As in the previous example, it is increased 5 times in the inner most loop, before the `break` statement is executed. This time `break` is called with the argument 2, which causes the two inner most control structures (namely the `loop` and the `while`) to be terminated. The outer most control structure (the `for`) is not influenced, so that its body gets executed 10 times, which results in a total of 50 increments for the scalar `cnt`.

Note, if `break` would be called with the argument 3 instead of 2, also the `for` loop would be terminated, so that `cnt` would be 5 at the end. If `break` would be called with 1 (or without additional argument) instead of 2, only the inner most `loop` would be terminated so that `cnt` would be 500 at the end.

4.33.8 The Continue Statement

The `continue` statement gives additional control over the execution of loop structures, namely the [loop statement](#), the [while statement](#), the [for statement](#) and the [repeat statement](#). It allows to jump to the end of the inner most loop structure without executing the remaining statements in the body.

4.33.8.1 The Continue Statement: Syntax

The syntax for the `continue` statement is as follows:

```
continue;
```

The keyword `continue` indicates that this is a continue statement. It jumps to the end of the inner most control structure.

Most often `continue` statements are used in the context of [if statements](#) or with [dollar conditions](#). For details on the various forms of logical conditions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#).

4.33.8.2 The Continue Statement: Examples

This is a simple, artificial example using the `continue` statement to skip parts of a `loop` body:

```
Set    i    / i1*i10 /;
Scalar cnt / 0 /;

loop(i,
      continue$(mod(ord(i),2)=0);
      cnt=cnt+1
);

display cnt;
```

In that example, every 2nd iteration of the `loop` statement is skipped. Therefore, `cnt` will be 5 at the end of the `loop`.

4.33.9 The Abort Statement

The `abort` statement is used to terminate the *execution* of a program. Most often the abort statement is used in the context of conditionals. Examples are given below. Also it may be used to display a text or an identifier in the listing file similar to the [display statement](#) but mostly to present the reason for the termination of the execution.

Note that the `abort` statement is to be distinguished from the dollar control option `$abort` which may be used to terminate the *compilation* of a program.

4.33.9.1 The Abort Statement: Syntax

The syntax for the `abort` statement is as follows:

```
abort [ ident | quoted text {, ident | quoted text} ];
```

The keyword `abort` indicates that this is an abort statement, all other elements of the statement are optional. `ident` denotes an [identifier](#). If the identifier is a set or a parameter, only the name of the set or parameter itself is specified, without any domains. If the identifier is a variable, an equation or a model, it must be followed by a suffix, since only *attributes* of variables, equations and models can be displayed. For more on variable and equation attributes including full lists, see sections [Variable Attributes](#) and [Equation Attributes](#) respectively. For details on model attributes, see section [Model Attributes](#). Recall that sets also have attributes, they may also be displayed using the suffix notation. For details on set attributes, see section [Set Attributes](#). As usual, `quoted text` must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines.

An abort statement causes the termination of the execution with an execution error and the information in the statement will be displayed.

There is also a variant with the extension `.noError` that terminates the execution and displays the information, but does not cause an execution error. The syntax is as follows:

```
abort.noError [ ident | quoted text {, ident | quoted text} ];
```

Most often `abort` statements are used in the context of [if statements](#) or with [dollar conditions](#). The syntax is as follows:

```
if (logical_condition, abort [ ident | quoted text {, ident | quoted text} ] ; );
```

or

```
abort$logical_condition [ ident | quoted text {, ident | quoted text} ];
```

For details on the various forms of logical conditions in GAMS, see sections [Logical Conditions](#) and [Filtering Sets](#).

4.33.9.2 The Abort Statement: Examples

Consider the following artificial example:

```
Set      i      / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,
  if (p(i) > 3, abort "Parameter larger than 3", p);
  p(i) = p(i) + 2;
);
```

Note that the abort statement is part of an [if statement](#) which is part of a [loop statement](#). The execution of this program will be terminated with the following display and error message:

```
----      4 Parameter larger than 3
----      4 PARAMETER p
i1 3.000,   i2 4.000,   i3 5.000,   i4 5.000,   i5 8.000
**** Exec Error at line 4: Execution halted: abort 'Parameter larger than 3'
```

Observe that the values of p('1'), p('2') and p('3') were updated, but the values of p('4') and p('5') are equal to the initialization values since the program was terminated before they could be updated.

If the extension `.noError` is used in the example above, the following lines will appear in the listing file:

```
----      4 Parameter larger than 3
----      4 PARAMETER p
i1 3.000,   i2 4.000,   i3 5.000,   i4 5.000,   i5 8.000
****
**** Execution halted from line 4: abort.noError 'Parameter larger than 3'
****
```

Note that the execution of the program is aborted as before, but there is no execution error in this case.

Instead of an if statement we may use a dollar condition in the loop:

```
Set      i      / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,
  abort$(p(i) > 3) "Parameter larger than 3", p;
  p(i) = p(i) + 2;
);
```

Observe that this alternative formulation has the same outcome as above.

4.34 The Option Statement

4.34.1 Introduction

The `option` statement is used to set various global system parameters to control among other things output detail, the solution process and the layout of displays. GAMS provides default values for global system parameters that are adequate for the most purposes. However, there are always cases when the user would like to maintain control of some aspects of the run. In addition, the option statement provides an efficient and compact syntax to perform powerful operations on identifiers. Observe that option statements are processed at execution time unlike [dollar control options](#) that are processed at compile time.

This chapter is organized as follows. We will first introduce the [general syntax of the option statement](#), then we will continue with a list of all available options that may be used with option statements and provide links to their detailed explanations in the [GAMS Call](#) chapter. Finally we turn to the [special options that involve identifiers](#).

4.34.1.1 The Syntax of the Option Statement

The general form of an option statement is as follows:

```
option(s) key1 [= value1] { ,|EOL key2 [= value2] } ;
```

The keyword `option` or `options` indicates that this is an option statement. It is followed by `key1`, which is one of the options that are listed in this chapter. Consider the following simple example:

```
option reslim=800;
```

Here the keyword `option` is followed by the key `reslim`. The option `reslim` specifies the maximum time in seconds that a solver may run before it terminates. Thus, in this example we give the solver 800 seconds to come up with a solution.

Note

Option names are not [reserved words](#) and therefore they do not conflict with other uses of their names.

Observe that it depends on the respective option whether a value is expected and if so, what type of value. There are six different cases. An overview is given in [Table 1](#).

Key	Value	Type of Value	Examples
yes	no	-	dmpOpt , eject , memoryStat
yes	yes	integer number	decimals , limcol , seed
yes	yes	real number	FDDelta , optCR , resLim
yes	yes	text string	LP , solprint , sysout
yes	yes	identifier	See identifier options .
no	no	-	See identifier operations .

Table 1: Types of Options

Note that the last type is special: it does not involve a named option or **key**, but the keyword **option** is followed by identifiers and identifier operators. These special option statements are discussed in detail in section [Special Options: Identifier Operations](#).

Observe that the value of an option may be reset as often as necessary, the new value will replace the previous value each time. Further, more than one option may be specified with one option statement and commas or end-of-line characters are both legal separators between options.

We will demonstrate with the following example how several options may be used. The code snippet may be added to the model **[DICE]**.

```
option measure, limcol = 100
      optcr = 0.00, mip = xpress ;
solve xdice using mip max wnx;
option clear = comp;
```

Note that in the first option statement four options are specified: option **measure** has no associated value, option **limcol** expects an integer value, option **optcr** expects a real value and option **MIP** expects a text string as value. The second option statement specifies just one identifier option: **clear**, which has the variable **comp** as value.

Attention

Option statements are executed in sequence with other instructions. Therefore, if an option statement is located between two solve statements, the new values will be assigned between the solves and thus they will apply only to the second solve statement.

4.34.2 List of Options

The options available through the option statement are grouped into the following functional categories:

- Options that affect [output details](#)
- [Solver specific parameters](#)
- Options that control [choice of solver](#)
- Options that affect [input program control](#)
- [Other options](#)
- [Special options that involve identifiers](#)

In the following subsections we will offer brief descriptions of the options in the first five categories. Note that each entry is linked to a detailed description of the respective option. Observe that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section [Detailed Descriptions of All Options](#). The options that belong to the last category are special, they are introduced and discussed in section [Special Options that Involve Identifiers](#) below.

Option	Description
--------	-------------

4.34.2.1 Options that Control Output Details

Option	Description
asyncSolLst	Print solution listing when asynchronous solve (Grid or Threads) is used
decimals	Decimal places for display statements
dispWidth	Number of characters to be printed in the column labels of all subsequent display statements
eject	Inject a page break into the LST file
epsToZero	Treat eps as zero when unloading to GDX
limCol	Maximum number of columns listed in one variable block
limRow	Maximum number of rows listed in one equation block
maxGenericFiles	Maximum number of generic file names tried at execution time file creation
MCPRHoldFx	Print list of rows that are perpendicular to variables removed due to the holdfixed setting
profile	Execution profiling
profileTol	Minimum time a statement must use to appear in profile generated output
solPrint	Solution report print option
solSlack	Causes the equation output in the listing file to contain slack variable values instead of level values
sysOut	Solver Status file reporting option

4.34.2.2 Options that Control Solver-Specific Parameters

Option	Description
bRatio	Basis detection threshold
domLim	Domain violation limit solver default
holdFixedAsync	Allow HoldFixed for models solved asynchronously as well
intVarUp	Set mode for default upper bounds on integer variables
iterLim	Iteration limit of solver
optCA	Absolute Optimality criterion solver default
optCR	Relative Optimality criterion solver default
reform	Reformulation level
resLim	Wall-clock time limit for solver
savePoint	Save solver point in GDX file
solveLink	Solver link option
sys12	Pass model with generation errors to solver
threads	Number of threads to be used by a solver

4.34.2.3 Options that Control the Choice of Solver

Option	Description
CNS	Constrained Nonlinear Systems - default solver
DNLP	Non-Linear Programming with Discontinuous Derivatives - default solver
EMP	Extended Mathematical Programs - default solver

Option	Description
LP	Linear Programming - default solver
MCP	Mixed Complementarity Problems - default solver
MINLP	Mixed-Integer Non-Linear Programming - default solver
MIP	Mixed-Integer Programming - default solver
MIQCP	Mixed Integer Quadratically Constrained Programs - default solver
MPEC	Mathematical Programs with Equilibrium Constraints - default solver
NLP	Non-Linear Programming - default solver
QCP	Quadratically Constrained Programs - default solver
RMINLP	Relaxed Mixed-Integer Non-Linear Programming - default solver
RMIP	Relaxed Mixed-Integer Programming - default solver
RMIQCP	Relaxed Mixed Integer Quadratically Constrained Programs - default solver
RMPEC	Relaxed Mathematical Programs with Equilibrium Constraints - default solver
solver	Default solver for all model types that the solver is capable to process

4.34.2.4 Options that Affect Input Program Control

Option	Description
fdDelta	Step size for finite differences
fdOpt	Options for finite differences
gdxUels	Unload labels or UELs to GDX either squeezed or full
seed	Random number seed
solveOpt	Multiple solve management
strictSingleton	Error if assignment to singleton set has multiple elements
sys18	Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers
zeroToEps	Treat zero as eps

4.34.2.5 Other Options

Option	Description
checkErrorLevel	Check errorLevel automatically after executing external program
dmpOpt	Debugging option: causes GAMS to echo the runtime option settings
dmpSym	Debugging option: causes GAMS to echo the symbol table to the listing file
dmpUserSym	Debugging option: causes GAMS to echo the symbol table to the listing file for user defined symbols only
dualCheck	Output on the reduced cost condition
forLim	GAMS looping limit
integer1..5	Integer communication cells
measure	Output of time and memory use since the last measure statement or the program beginning
memoryStat	Show memory statistics in the LST file
real1..5	Real communication cells
subSystems	Lists all solvers available as well as the current default and active solvers in the LST file
sys10	Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer

Option	Description
sys11	Dynamic resorting if indices in assignment/data statements are not in natural order
sys15	Automatic switching of data structures used in search records
sys16	Disable search record memory (aka execute this as pre-GAMS 24.5)
sys17	Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)
sys19	Disable permutation on Column Generation (aka execute this as pre-GAMS 36)
threadsAsync	Limit on number of threads to be used for asynchronous solves (solveLink=6)

4.34.2.6 Special Options that Involve Identifiers

Several options involve identifiers: they either take identifiers as values or have no key and value, but perform an [operation](#) on an identifier. In the following two subsections we will introduce and discuss these special options.

4.34.2.6.1 Special Options: Identifier Options The value of identifier options is not a string or a number, but an [identifier](#). In this subsection we will describe these options in detail.

clear

This option resets an [identifier](#) to its default value to free memory. The syntax is as follows:

```
option clear = identifier;
```

The following identifier types may be reset: sets, parameters, equations and variables. The option will free up memory to the GAMS heap manager, thus the memory may be used by GAMS but not by the operating system. To force the memory to be freed up to the operating system, the GAMS process needs to be terminated. One way to do this is to restart the execution system by solving a dummy model with the option [SolveLink](#) set to zero.

kill

This option is a synonym to option [clear](#). Observe that the dollar control option [\\$kill](#) is *not* a synonym to [\\$clear](#).

shuffle

This option rearranges the values of a parameter in a random order. The syntax is as follows:

```
option shuffle = itemname;
```

Here `itemname` is a one-dimensional parameter. One-dimensional parameters may be declared (and defined) in four different ways, depending on the domain and the data. The following table gives an overview of the effect of the option `shuffle` in the four cases.

	No Data	Has Data
Universal set as domain	Use the universal set to initialize the data (case 1 in the example below).	Use the universal set to add zero values before shuffling the data (case 3 in the example below).
Specific set as domain	Use the domain to initialize the data (case 2 in the example below).	Use the domain to add zero values before shuffling the data (case 4 in the example below).

If the parameter was declared without data (the second column in the table above), the domain or the [universal set](#) will be used to assign the numbers 1 to N, where N is the number of elements in the domain or the universal set. If the parameter was declared with data (the third column in the table above), the domain or the universal set will be used to add zeroes for possibly missing entries. These zero values will participate in the random shuffle, but they will not be stored in the parameter. The following example serves as illustration:

```
Set i / i1*i5 /
    j / j1*j5 /;
option decimals = 0;

*Case 1: universal set as domain and no data
Parameter A(*) "The universe is used to fill the parameter";
option shuffle = A;
display A;

*Case 2: set j as domain and no data
Parameter B(j) "The set j is used to fill the parameter";
option shuffle = B;
display B;

*Case 3: universal set as domain and has data
Parameter C(*) "The universe is used to add zeroes" / j2 2, j4 4 /;
option shuffle = C;
display C;

*Case 4: set i as domain and has data
Parameter D(i) "The set i is used to add zeroes" / i1 10, i3 30, i5 50 /;
option shuffle = D;
display D;
```

The code above will generate the output that follows. Observe that in this example, the universal set is the union of the sets i and j, which means that all elements of the sets i and j are members of the universal set. Note that we use random numbers, therefore the outcomes from a different run may vary.

```
----      9 PARAMETER A  The universe is used to fill the parameter

i1  4,    i2  1,    i3  7,    i4  9,    i5  6,    j1 10,    j2  3,    j3  5
j4  8,    j5  2

----     14 PARAMETER B  The set j is used to fill the parameter

j1 1,    j2 5,    j3 2,    j4 4,    j5 3

----     19 PARAMETER C  The universe is used to add zeroes

j1 2,    j2 4

----     24 PARAMETER D  The set i is used to add zeroes

i2 30,    i4 50,    i5 10
```

In the next example we will demonstrate how to generate a random mapping of a set:

```

Set i          / i1*i6 /,
    rmi(i,i) "random mapping";
Parameter A(i);
option shuffle = A;

rmi(i, i + (- Ord(i) + A(i))) = yes;
display rmi;

```

A display of the set `rmi` follows. Note that there is exactly one element in each row and each column:

```

----      7 SET rmi  random mapping

          i1          i2          i3          i4          i5          i6

i1                                     YES
i2                                YES
i3          YES
i4                                     YES
i5                                     YES
i6          YES

```

Observe that each use of the option `shuffle` will generate a new random data rearrangement.

4.34.2.6.2 Special Options: Identifier Operations In some cases the keyword `option` in an option statement is followed by an [identifier](#) and one or more operators to perform identifier operations like [display control](#), [index matching](#), [projection and aggregation of sets and parameters](#) and [permutation of sets and parameters](#).

4.34.2.6.2.1 Display Control The `display` statement is introduced and discussed in chapter [The Display Statement](#). While GAMS provides defaults for the displayed identifiers that suffice in most cases, the print format may be customized with the following option statement:

```

option ident:d;
option ident:d:r:c;

```

The keyword `option` is followed by the name of an identifier `ident`, a colon and an integer value `d`. Note that `d` may be between 0 and 8 and specifies the number of decimal places that will be displayed for the respective identifier. The specifications `r` and `c` are optional. They denote the number of index positions printed as row labels and the number of index positions printed as column labels respectively. Note that if `r` is zero, a list format will be used. For more information and examples, see sections [Local Display Control](#) and [Display Statement to Generate Data in List Format](#).

4.34.2.6.2.2 Index Matching Index matching is a very compact way to define [multi-dimensional sets](#). The general syntax is as follows:

```

option set_name(index1:index2[:index3:...]);

```

The keyword `option` is followed by the name of the set, `set_name`, and two (or more) indices in parentheses that are linked with the matching operator `:`. Note that the set must have been declared earlier in the program. If the set has also been defined earlier in the program, it will be cleared first and then the matching operation will be processed. Note furthermore that the list of identifiers may be expanded to more than two and that besides the matching operator `:` also `,` may be used and will be interpreted as [product operator](#). Consider the following example which also makes use of [display control](#):

```
Set i / i1,i2/
    j / j1,j2,j3 /
    k / k1*k5 /
    ij(i,j), ijk(i,j,k), kij(k,i,j);
* index matching
Option ij(i:j), ijk(i,j:k), kij(k:i,j);
* display control
Option ij:0:0:1, ijk:0:0:1, kij:0:0:1;
Display ij, ijk, kij;
```

In its simplest form the matching operator is used to create the two dimensional set `ij`.

```
----      9 SET ij

i1.j1
i2.j2
```

Note that each member of the index `i` has been matched with a member of the index `j` until one of the indices ran out of members.

The index matching operations to define the three-dimensional sets `ijk` and `kij` illustrate a more sophisticated usage of the index operator. The sets `ijk` and `kij` are built with the indices from left to right using the product operator when a `,` is encountered or the matching operator when a `:` is found.

For `ijk` the first operator is the `,` which is interpreted as product operator for the sets `i` and `j` and hence builds the Cartesian product of the two sets which has six 2-tuples as elements (`i1.j1`, `i1.j2`, `i1.j3`, `i2.j1`, `i2.j2`, `i2.j3`). The matching operator `:` is then applied to match those 2-tuples with the five set elements in `k`. The resulting sets are:

```
----      9 SET ijk

i1.j1.k1
i1.j2.k2
i1.j3.k3
i2.j1.k4
i2.j2.k5

----      9 SET kij

k1.i1.j1
k1.i1.j2
k1.i1.j3
k2.i2.j1
k2.i2.j2
k2.i2.j3
```

The previous example can be extended to define sets of even higher dimension in the following way:

```
set h / h1*h4 /
    hijk_1(h,i,j,k)
    hijk_2(h,i,j,k);
* index matching
Option hijk_1(h:ijk);
Option hijk_2(h:i,j:k);
* display control
Option hijk_1:0:0:1, hijk_2:0:0:1;
Display hijk_1, hijk_2;
```

Note that sets `hijk_1` and `hijk_2` will be different even though `hijk_1` uses set `ijk` and `hijk_2` uses the same matching and product operation used at definition of `ijk` but spelled out. As already mentioned above, the matching operator builds up the sets with the indices from left to right. Hence, as set `ijk` is build first and then used on the right of the matching operator the two sets are built up differently.

```
-----      19 SET hijk_1

h1.i1.j1.k1
h2.i1.j2.k2
h3.i1.j3.k3
h4.i2.j1.k4
```

```
-----      19 SET hijk_2

h1.i1.j1.k1
h1.i1.j2.k2
h1.i1.j3.k3
h2.i2.j1.k4
h2.i2.j2.k5
```

4.34.2.6.2.3 Projection and Aggregation of Sets and Parameters In GAMS, projection and aggregation operations on sets may be performed in two different ways: with an assignment and the `sum` operator, and with an option statement.

Using an assignment and the `sum` operator is the slower but more intuitive way. Assignments and the `sum` operator are introduced and discussed in detail in chapter [Data Manipulations with Parameters](#) and section [Indexed Operations](#) respectively. Here we only show how they may be used in the context of sets to perform projections and aggregations. The following example serves as illustration.

```
Sets i          / i1*i3 /
     j          / j1*j2 /
     k          / k1*k4 /
     ijk(i,j,k) / #i.#j.#k /
     ij1a(i,j)
     ij1b(i,j);
```

```
Scalars Count_1a, Count_1b, Count_2a, Count_2b;
```

```
* Method 1: Using an assignment and the sum operator for a projection
ij1a(i,j) = sum(k,ijk(i,j,k));
```

```
* Method 1: Using an assignment and the sum operator for aggregations
Count_2a = sum(ijk(i,j,k),1);
Count_1a = sum(ij1a(i,j),1);
```

Note that the set `ijk` is a three-dimensional set, its elements are 3-tuples and all permutations of the elements of the three sets `i`, `j` and `k` are in its domain. Thus the number of elements of the set `ijk` is $3 \times 2 \times 4 = 24$. The sets `ij1a` and `ij1b` are two-dimensional sets that are declared in the [set statement](#), but not defined. The first assignment statement defines the members of the set `ij1a`. This is a projection from the set `ijk` to the set `ij1a` where the three-tuples of the first set are mapped onto the pairs of the second set, such that the dimension `k` is eliminated. This means that the four elements "`i1.j1.k1`", "`i1.j1.k2`", "`i1.j1.k3`" and "`i1.j1.k4`" of the set `ijk` are all mapped to the element "`i1.j1`" of the set `ij1a`. Note that in this context, the result of the `sum` operation is *not* a number but a set. The second and third assignments are aggregations, where the number of elements of the two sets are computed. As already mentioned, the result of the first aggregation is 24 and the result of the second aggregation is $6 = 24 / 4$.

The second way to perform projections and aggregations is faster and more compact, it uses an option statement. The general syntax of this option statement is as follows.

```
option ident1 < ident2 ;
option ident1 <= ident2 ;
```

The keyword `option` is followed by the [identifiers](#) `ident1` and `ident2` which are linked by the symbol '`<`' or '`<=`'. Observe that in most cases the two symbols have the same effect. The exception is the special case when both identifiers are defined over domains that use at least one shared index set more than once, see the example [below](#). Note that in general the dimension of the item on the left has to be equal or less than the dimension of the item on the right. Further, the index space of the two identifiers must be matchable. If the dimensions of the two identifiers are equal, then the same indices must appear in both, albeit the order may differ. If the dimension of the left item is less than the dimension of the right item, then the indices on the left must also appear on the right.

Observe that if both identifiers are sets, the operation will be a *projection*. However, if the identifier on the left-hand side is a [scalar](#) or a [parameter](#) and the identifier on the right-hand side is a set it will be an *aggregation*. The example that follows shows how the projection and the two aggregations above are accomplished with the option statement.

```
* Method 2: Option statement performs a projection
Option ij1b < ijk;

* Method 2: Option statements performs aggregations (counting of elements)
Option Count_2b < ijk;
Option Count_1b < ij1b;

display ijk, ij1a, ij1b, Count_1a, Count_1b, Count_2a, Count_2b;
```

In the example above, the set on the left-hand side, `ij1b`, has fewer indices than the set on the right-hand side, `ijk`. Observe that if the two sets differ only in the *order* of the indices then a projection will have the effect of a *permutation* of the tuple.

Note

The option statement for projection and aggregation operations may also be applied to parameters.

Until now the indices in the domain of the sets were unique. A special case arises when sets are defined over a domain with the same indices, for example the set `s(i,i,i)`. In this case, a projection always has the effect of a permutation. Users may choose whether they wish to perform the permutation from left to right or from right to left. The option statement

```
Option item1 < item2 ;
```

means a right-to-left permutation, while the option statement

```
Option item1 <= item2 ;
```

entails a left-to-right permutation. The following example clarifies the difference:

```
Set i / i1*i3 /
  s(i,i,i) "Set members" / i1.i2.i3, i3.i3.i1/
  pR1(i,i) "projection right to left with assignment"
  pR2(i,i) "projection right to left with option statement"
  pL1(i,i) "projection left to right with assignment"
  pL2(i,i) "projection left to right with option statement" ;
Alias (i,ii,iii);

* Right-to-left permutation, two ways
pR1(i,ii) = sum(s(iii,ii,i),1);
option pR2 < s;

* Left-to-right permutation, two ways
pL1(i,ii) = sum(s(i,ii,iii),1);
option pL2 <= s;

option s:0:0:1, pR1:0:0:1, pR2:0:0:1, pL1:0:0:1, pL2:0:0:1;
display s, pR1, pR2, pL1, pL2 ;
```

Note that in the right-to-left permutation, the element "i1.i2.i3" is projected to "i3.i2" and the element "i3.i3.i1" is projected to "i1.i3". In the left-to-right permutation however, the the element "i1.i2.i3" is projected to "i1.i2" and the element "i3.i3.i1" is projected to "i3.i3". Hence, the left-to-right permutation (<=) might be more intuitive.

Our examples so far involved only sets. As mentioned above, projections and aggregations may also be performed with parameters. However, there are some subtle differences. The first difference refers to the terminology: we *aggregate* sets, but we *count* parameters. The second difference is the result of the operation if the domain of the left symbol is just a permuted version of the domain of the right symbol. Consider the following example:

```
Set i / i1*i3 /
  j / j1*j2 /;

Table p(i,j)
  j1 j2
i1  1  2
i2  3  4
i3  5  6;

parameter pperm(j,i);
option pperm < p;
option decimals = 0;
display p, pperm;
```

The output generated by the display statement follows:

```

----      13 PARAMETER p
          j1          j2
i1         1          2
i2         3          4
i3         5          6

```

```

----      13 PARAMETER pperm
          i1          i2          i3
j1         1          3          5
j2         2          4          6

```

4.34.2.6.2.4 Permutation of Sets and Parameters In GAMS, the > sign can be used to create complete permutations of one- and multi-dimensional sets and parameters. Consider the following example based on the test library model **[PERM1]**:

First, a set *i* for which all permutations should be computed is declared and defined. A permutation of a one-dimensional set *i* can be represented by a two-dimensional set like `perm(i,i)` where the *i* index is duplicated. In the example, set `perm(i,i)` represents permutation (1 2)(3) in cycle notation. For a set with three elements, there are $3*2*1=6$ permutations. The statement `option pall > i;` results in all permutations of *i* being computed and stored in three-dimensional set `pall(p,i,i)` where the first index *p* serves as a counter to enumerate all permutations.

```

set i          'set to permute'          / i1*i3 /
  perm(i,i)    'exemplary permutation' / i1.i2, i2.i1, i3.i3 /
$eval pmax fact(card(i))
  p           'permutation index' / p1*p%pmax% /
  pall(p,i,i) 'permutation set';
option pall > i;
option pall:0:0:1;
display pall;

```

Note that we use [display control](#) such that the display statement results in:

```

----      8 SET pall  permutation set

p1.i1.i1
p1.i2.i2
p1.i3.i3
p2.i1.i1
p2.i2.i3
p2.i3.i2
p3.i1.i2
p3.i2.i1
p3.i3.i3
p4.i1.i2
p4.i2.i3
p4.i3.i1
p5.i1.i3
p5.i2.i1
p5.i3.i2
p6.i1.i3
p6.i2.i2
p6.i3.i1

```

For multi-dimensional sets, the permutation operator follows the same logic. Consider the following example:

Sets j , k and a two-dimensional set $jk(j,k)$ are defined. In order to find all permutations of $jk(j,k)$, the indices are again duplicated and a permutation index is introduced:

```
set j / j1*j2 /, k / k1*k5 /
     jk(j,k) / j1.k3, j1.k5, j2.k1 /
$eval pmax fact(card(jk))
     p / p1*p%pmax% /
     pall(p,j,k,j,k);
option pall > jk;
option pall:0:0:1;
display pall;
```

The display statement results in:

```
-----      8 SET pall

p1.j1.k3.j1.k3
p1.j1.k5.j1.k5
p1.j2.k1.j2.k1
p2.j1.k3.j1.k3
p2.j1.k5.j2.k1
p2.j2.k1.j1.k5
p3.j1.k3.j1.k5
p3.j1.k5.j1.k3
p3.j2.k1.j2.k1
p4.j1.k3.j1.k5
p4.j1.k5.j2.k1
p4.j2.k1.j1.k3
p5.j1.k3.j2.k1
p5.j1.k5.j1.k3
p5.j2.k1.j1.k5
p6.j1.k3.j2.k1
p6.j1.k5.j1.k5
p6.j2.k1.j1.k3
```

In addition to set elements, it is also possible to permute numerical data in a GAMS parameter. Consider the following example where all permutations of the numerical values stored in the one-dimensional parameter $a(i)$ are computed:

```
set i / i1*i3 /
$eval pmax fact(card(i))
     p / p1*p%pmax% /;
Parameter a(i) /i1 1, i2 2, i3 3/
     pall_a(p,i);
option pall_a > a;
option pall_a:0:1:1;
display pall_a;
```

The display statement results in:

```

----      8 PARAMETER pall_a

          i1          i2          i3

p1         1          2          3
p2         1          3          2
p3         2          1          3
p4         2          3          1
p5         3          1          2
p6         3          2          1

```

The permutation can also be extended to multi-dimensional parameters. Consider the following example where all permutations of the numerical values stored in the two-dimensional parameter $b(j,k)$ are computed:

```

set j / j1*j2 /, k / k1*k5 /;
Parameter b(j,k) /j1.k3 1, j1.k5 2, j2.k1 3/;
$eval pmax fact(card(b))
set p / p1*p%pmax% /;
parameter pall_b(p,j,k);
option pall_b > b;
option pall_b:0:1:2;
display pall_b;

```

The display statement results in:

```

----      8 PARAMETER pall_b

          j1.k3          j1.k5          j2.k1

p1         1          2          3
p2         1          3          2
p3         2          1          3
p4         2          3          1
p5         3          1          2
p6         3          2          1

```

4.35 System Attributes

4.35.1 Introduction

System attributes give access to string constants in the GAMS system environment. We will refer to these string constants as system suffixes. Moreover, there are attributes that can be used as data elements for user symbols. This way one can get access e.g. to the solvers (as set elements) in the system. We will refer to these data elements as system data. Two special system data attributes, namely `powerSetLeft` and `powerSetRight`, for a three dimensional set `setName(n,s,b)` create data which can be interpreted as a numbering system with base b and s digits. Finally, a system attribute can provide access to a system function that was hidden by the compiler because of a name conflict with a user symbol.

4.35.2 System Suffixes

System suffixes contain information about the GAMS system environment during a run. There are two ways to reference them: `system.suffix` and `%system.suffix%`. Here `system` is a keyword and `.suffix` is the name of the system suffix. A full list is given in section [List of all System Suffixes](#) below. Note that `system.suffix` references the *execution-time* version of the system suffix and `%system.suffix%` references the *compile-time* version resulting in a textual replacement. The execution-time system suffix can only be used in the context of [put files](#). Consider the following example where both versions are used:

```
file fx;
put fx 'lp:' system.LP;
option lp=gurobi;
put / 'lp:' system.LP
put / 'lp:%system.LP%';
```

Observe that the compile-time string `%system.LP%` is evaluated at compile time and does not change. However, the execution-time system suffix `system.LP` is evaluated at execution time and it does change. It is first CPLEX, since CPLEX is the default LP solver. Then it changes to GUROBI as a result of the [execution-time command](#) `option LP=gurobi;`. The resulting put file `fx.put` follows:

```
lp:CPLEX
lp:GUROBI
lp:CPLEX
```

In the following two subsection we will discuss execution-time suffix in more detail.

4.35.2.1 Execution-Time System Suffixes

Execution-time system suffixes are only used in the context of the [put writing facility](#) with commands like `put`, `putclose` and `put_utility`. Consider the following simple example. We have the files `x.gms` and `dummy.gms`, where `x.gms` contains just the following line:

```
file fx; put fx system.version;
```

The file `dummy.gms` contains the following:

```
$exit;
```

We run these files with the following calls:

```
> c:\gams\win64\24.7\gams x.gms action=c s=putVersion
```

Note that the value `c` for the command-line parameter `action` causes the first input file to be compiled only. The result is saved in the [work file](#) `putVersion`. Then we restart and execute `dummy.gms`. Now, depending on the GAMS release version, the put file `fx` will have a different content:

```
c:\gams\win64\24.7\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 24.7"
c:\gams\win64\24.8\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 24.8"
```

In contrast, the value of the compile-time system suffix `%system.version%` is determined at compile time. Suppose we change the file `x.gms` to contain the following line:

```
file fx; put fx "%system.version%";
```

The file `dummy.gms` is not changed and we use the same calls as above. Note that the put file will have the same content for both versions of GAMS:

```
c:\gams\win64\24.7\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 24.7"
c:\gams\win64\24.8\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 24.7"
```

4.35.2.2 Compile-Time System Suffixes

Compile-time system suffixes may be placed anywhere a [compile-time variables](#) makes sense, including code for [conditional compilation](#). The quoting of these compile-time system suffixes depends on their use in the code. Consider the following example:

```
$set systemDATE %system.date%
display "system.date", "%system.date%";
$if %system.LP% == Xpress $log "LP solver is Xpress."
```

The resulting output generated by the display statement follows:

```
----      3 system.DATE
           11/07/16
```

4.35.2.3 List of all System Suffixes

In the following table all system suffixes are listed.

System Suffix	Description
BuildCode	System build code
computerName	Operating system computer name
date	Job date
date1	Job date (different format)
dirSep	File or directory separator in file names, either \ or /
elapsed	Elapsed time in seconds since start of job
FE	File extension of input file
fileSys	Name of the operating system (MSNT for Windows, UNIX for Linux and MacOS)
FN	File name stem of input file
FP	File path of input file
gamsReleaseMaint	GAMS Release number with maintenance number suffix
gdxFileNameIn	GDX file name for input, set by <code>put_utility</code> command gdxin
gdxFileNameOut	GDX file name for output, set by <code>put_utility</code> command gdxout
gString	GAMS system audit string (exact GAMS version being used)
hostPlatform	Host platform
iFile	Main input file
iLine	Current source line number being executed
incLine	Line number of include file being executed
incName	Name of include file
incParent	Parent file of include file

System Suffix	Description
incParentL	Line number of parent file of include file
isAlphaBeta	Indicates an Alpha or Beta distribution
lice1	License display line 1
lice2	License display line 2
licenseDateEvalN	Evaluation date (serial number)
licenseDateEvalS	Evaluation date (date format)
licenseDateMaintN	Maintenance date (serial number)
licenseDateMaintS	Maintenance date (date format)
licenseDateN	License date (serial number)
licenseDateS	License date (date format)
licenseDateSysN	GAMS module system date (serial number)
licenseDateSysS	GAMS module system date (date format)
licenseDaysEval	License evaluation days left
licenseDaysMaint	License maintenance days left
licenseDC	License number
licenseEval	License is eval license
licenseFileName	The file name of the license file currently used
licenseID	License ID string
licenseInstitution	License holding institution
licenseLevelText	GAMS license level text
licenseLicensee	License Holder
licenseMudText	License MUD type
licensePlatform	License Platform abbreviation
licensePlatformText	License Platform Text
licenseStatusText	License validation status text
licenseType	License type
licenseVendor	License Vendor
line	Line number in source code
listLine	Line number on listing file
MACAddress	MAC address of the first network adapter
maxInput	Max input line length that can be processed
memory	Memory (in Mb) in use
model_type (LP, MIP, ...)	Solver that is active for the respective GAMS model type (for example, LP or MIP)
nullFile	The null filename (e.g. on Unix <code>/dev/null</code>)
oFile	Output (Listing) file

System Suffix	Description
oPage	Current page number in output (listing) file
page	Current page number
pFile	Current put file
platform	Job platform (DEX for MacOS, LEX for Linux, WEX for Windows)
prLine	Line on listing file page
prPage	Listing file page number
putFileName	The filename of the currently active put file
rDate	Restart file date
reDirLog	Append redirection string into the logfile, e.g. >> mylog.log
rFile	Restart file name
rTime	Restart file time
sFile	Save file name
sString	Subsystem (Solver) audit string (last solver used)
tab	Tab character
tClose	Time to save GAMS
tComp	Time to compile
tExec	Time to execute
time	Job time
title	Current listing title
tStart	Time to restart GAMS
userConfigDir	User writable directory that is searched for gamsconfig.yaml
userDataDir	User writable directory that is searched for gamslice.txt and others
userName	Operating system user name
verID	GAMS version ID
version	GAMS compiler version

A model that prints all system suffixes with its current values to a put file can be found in model [SSUFFIX].

4.35.3 System Data

Some of the system relevant information does not fit into a single string. Such system data can be stored in GAMS symbols. The system data for this symbol can be accessed in the data statement of the symbol, e.g. `set allSolvers / system.solverNames /;`. Now you can work with the solver names as you can work with any set. The system data can be viewed as an internal set, so it can be you can to create more complex GAMS symbols with this information. For example:

```
set seq / 1*1000 /;
set solvermap(seq,*) / set.seq:system.solverNames /;
parameter solverpar(*) / system.solverNames 1 /;
```

Here is the list and dimensionality of the system data:

System Data	Dimension	Description
dollarOptions	1	Dollar control options
empty	1	Empty label
gamsParameters	1	Command line parameters
gamsParameterSynonyms	1	Synonyms for command line parameters
gamsParameterSynonymMap	2	Map between command line parameters and their synonyms
gamsFunctions	1	Intrinsic functions
modelTypes	1	Model types, e.g. LP, MIP, ...
platforms	1	Platform code
predefinedSymbols	1	Predefined symbols, e.g. SameAs, Diag, ...
setConstants	1	System data names (this list)
solverNames	1	Names of solvers and tools
solverPlatformMap	2	Map between solvers and platforms
solverTypePlatformMap	3	Map between solvers, model types and platforms
systemSuffixes	1	System suffixes

Here is a secondary list of system attributes provide access to system data. This information allows to print the license memorandum [**LICEMEMO**] and is only used for internal purposes:

System Data	Dimension
clipCodes	1
components	1
clipComponentMap	2
componentSolverMap	2
gamsLicenseTypes	1
gamsLicenses	1
vendors	1

4.35.3.1 Power Set

The very special system attribute `powerSetLeft` and `powerSetRight` do not provide access to static data relevant to the system but produce data based on existing sets `b` and `s`. This system data produced can be interpreted as a numbering system with base `b` and `s` digits. The total number of tuples created is `power(card(b), card(s))`. The first index of the resulting set has to have at least this size. The following small example demonstrates the functionality of `powerSetRight`:

```
$set digits 3
set s / s1*s%digits% /, b / 0,1 /;
$eval nMax power(card(b),card(s))
set n      / n1*n%nMax% /
      x(n,s,b) / system.powerSetRight /;
option x:0:0:%digits%; display x;
```

With 3 digits the display results in the following output:

```

----      6 SET x
n1.s1.0,   n1.s2.0,   n1.s3.0
n2.s1.0,   n2.s2.0,   n2.s3.1
n3.s1.0,   n3.s2.1,   n3.s3.0
n4.s1.0,   n4.s2.1,   n4.s3.1
n5.s1.1,   n5.s2.0,   n5.s3.0
n6.s1.1,   n6.s2.0,   n6.s3.1
n7.s1.1,   n7.s2.1,   n7.s3.0
n8.s1.1,   n8.s2.1,   n8.s3.1

```

Changing `powerSetRight` to `powerSetLeft` reassigns the order of the digits. So the lowest digit is on the left:

```

----      6 SET x
n1.s1.0,   n1.s2.0,   n1.s3.0
n2.s1.1,   n2.s2.0,   n2.s3.0
n3.s1.0,   n3.s2.1,   n3.s3.0
n4.s1.1,   n4.s2.1,   n4.s3.0
n5.s1.0,   n5.s2.0,   n5.s3.1
n6.s1.1,   n6.s2.0,   n6.s3.1
n7.s1.0,   n7.s2.1,   n7.s3.1
n8.s1.1,   n8.s2.1,   n8.s3.1

```

4.35.4 Access to Hidden Functions

Intrinsic functions are not keywords but they are stored in a list of predefined names. If a user program uses such a predefined name of a function for a user symbol, GAMS will hide the original function. For example,

```

set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = uniform(0,1);

```

will result in a compilation error in the second line because GAMS expects `uniform` to be a set. The function `uniform` is hidden for this GAMS program. Renaming the user symbol that hides a function is often the best solution for this, but there are a few cases (including GAMS code already compiled and stored in a [restart file](#)) where renaming is not an option. A hidden function can be accessed via the system attribute `system.functionName`. So the following will successfully compile and execute:

```

set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = system.uniform(0,1);

```

4.36 The Grid and Multi-Threading Solve Facility

4.36.1 Introduction

The GAMS Grid facility allows to take advantage of High Performance Computing Grids and systems with multiple CPUs. This language feature facilitates the management of asynchronous submission and collection of model solution tasks in a platform independent fashion. A simple architecture, relying on

existing operating system functionality allows for rapid introduction of new environments and provides for an open research architecture.

A typical application uses a coarse grain approach involving hundreds or thousands of model solutions tasks which can be carried out in parallel. Examples include but are not limited to scenario analysis, Monte Carlo simulations, Lagrangian relaxation, decomposition algorithms and advanced solution approaches.

The grid features work on all GAMS platforms and have been tailored to many different environments, like the **Condor** Resource Manager, a system for high throughput computing from the University of Wisconsin-Madison. Researchers using Condor reported a delivery of 5000 CPU hours in 20 hours wall clock time.

Similarly, the GAMS Multi-Threading Solve Facility allows the asynchronous submission and collection of model solution tasks on a single, multi-threaded machine while using efficient in-memory communication between GAMS and the solver.

Disclaimer: The use of the term grid computing may be offensive to some purists in the computer science world. We use it very loosely to refer to a collection of computing components that allow us to provide high throughput to certain applications. One may also think of it as a resurrection of the commercial service bureau concept of some 30 years ago.

Caution: Although these features have been tested on all platforms and are part of our standard release we may change the approach and introduce alternative mechanisms in the future.

Acknowledgments: Prof. Monique Guignard-Spielberg from the Wharton School at the University of Pennsylvania introduced us to parallel Lagrangian relaxation on the SUN Grid Environment. Prof. Michael Ferris from the University of Wisconsin-Madison adopted our original GAMS grid approach to the high throughput system Condor and helped to make this approach a practical proposition.

4.36.2 The Grid Facility: Basic Concepts

The Grid facility separates the solution process into several steps which then can be controlled separately. First we will review the steps taken during synchronous solution and then we will introduce the asynchronous or parallel solution steps.

When GAMS encounters a [solve statement](#) during execution it proceeds in three basic steps:

1. **Generation:** The symbolic equations of the model are used to instantiate the model using the current state of the GAMS data base. This instance contains all information and services needed by a solution method to attempt a solution. This representation is independent of the solver and computing platform.
2. **Solution:** The model instance is handed over to a solver and GAMS will wait until it terminates.
3. **Update:** The detailed solution and statistics are passed to GAMS from the solver to update the GAMS data base.

In most cases, the time taken to generate the model and update the data base with the solution will be much smaller than the actual time spent in a specific solver. The model generation will take a few seconds, whereas the time to obtain an optimal solution may take a few minutes to several hours or even longer. If sequential model solutions do not depend on each other, we can solve in parallel and update the data base in a random order. All we need is a facility to generate models, submit them for solution and continue. At a convenient point in our GAMS program we will then look for the completed solutions and update the data base accordingly. To summarize, solving in parallel entails two steps:

1. **Submission Loop:** In this phase we will generate and submit models for solutions that can be solved independently.
2. **Collection Loop:** The solutions of the previously submitted models are collected as soon as a solution is available. It may be necessary to wait for some solutions to complete by pausing the execution for some time.

Note that we have assumed that there will be no errors in any of these steps. Of course, this will not always be the case and elaborate mechanisms are in place to make the operation fail-safe.

Note

For scenario analysis the solver [GUSS](#) might be of particular interest. The model [\[GUSSGRID\]](#) demonstrates how GUSS is used together with the Grid facility.

4.36.3 The Grid Facility: A First Example

In this section we will illustrate the use of the basic grid facility with the model [\[QMEANVAR\]](#). This model traces an efficiency frontier for restructuring an investment portfolio. Each point on the frontier requires the solution of independent quadratic mixed integer models. The *original solution loop* is shown below:

```
loop(p(pp),
  ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp) ;
  solve minvar min var using miqcp ;
  xres(i,p) = x.l(i);
  report(p,i,'inc') = xi.l(i);
  report(p,i,'dec') = xd.l(i);
);
```

This [loop](#) will save the solutions of the model `minvar` for different returns `ret`. As the solutions do not depend on the order in which they are carried out, we can rewrite this loop to operate in parallel.

4.36.3.1 The Submission Loop

The first step for solving in parallel using the Grid facility is to write the submission loop:

```
Parameter h(pp) 'model handles';
minvar.solveLink = 3;
loop(p(pp),
  ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp) ;
  solve minvar min var using miqcp;
  h(pp) = minvar.handle;
);
```

The model attribute [solveLink](#) controls the behavior of the [solve statement](#). The value of 3 (which is equivalent to the [compile-time constant](#) `%solveLink.Async Grid%`) directs GAMS to generate the model and submit it for solution and then continue without waiting for the completion of the solution step. Thus with setting `minvar.solveLink` to 3 we activate grid computing.

A *handle* in the grid environment identifies the particular model and data instances available. The model attribute [handle](#) contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The specific numerical values of handles are assigned by GAMS and may be used to recover solutions and manage models that are solved on the grid. In our example, the handle parameter is `h` and the set of all model instances is `pp`. The handle values that are stored in `h` are later used to collect the solutions once the solution processes are completed.

4.36.3.2 The Collection Loop

We collect the solutions with the following collection loop:

```
loop(pp$handleCollect(h(pp)),
  xres(i,pp)      = x.l(i);
  report(pp,i,'inc') = xi.l(i);
  report(pp,i,'dec') = xd.l(i);
);
```

Note that the [dollar condition](#) restricts the looping set `pp` to those elements which return a nonzero value to the function `handleCollect(h(pp))`. The function `handleCollect` tests the solution status for each element of the set `pp`. And if the solution is available, it is read into the GAMS data base. In this case the function returns a value of 1. If the solution is not ready to be retrieved, the value zero will be returned.

Observe that the collection loop above has one big flaw. If a solution has not been ready (that is if `handleCollect` equaled zero), it will not be retrieved. We need to call this loop several times until all solutions have been retrieved or we get tired of it and quit. We will use a [repeat until construct](#) and the handle parameter `h` to control the loop to look only for the solutions that have not been loaded yet. The code follows:

```
repeat
  loop(pp$handleCollect(h(pp)),
    xres(i,pp)      = x.l(i);
    report(pp,i,'inc') = xi.l(i);
    report(pp,i,'dec') = xd.l(i);
    display$handleDelete(h(pp)) 'trouble deleting handles' ;
    h(pp) = 0;
  ) ;
  display$readyCollect(h, 100) 'Problem waiting for next instance to complete';
until card(h) = 0 or timeelapsed > 100;
xres(i,pp)$h(pp) = na;
```

Once we have extracted a solution we will set the handle parameter `h` to zero. In addition, we want to remove the instance from the system by calling the function `handleDelete` which returns zero if successful. No harm is done if it fails but we want to be notified via the [conditional display statement](#). Before running the collection loop again, we may want to wait a while to give the system time to complete more solution steps. This is done with the function `readyCollect` which waits until another model instance with a handle in `h` is ready to be collected (or the optionally defined number of seconds has passed). The final wrinkle is to terminate if all model instances have been deleted from the system since their solutions were retrieved or after 100 seconds have elapsed, even if we did not get all solutions. This is accomplished with the function `timeElapsed` and is important, because if one of the solution steps fails our program would never terminate. Recall that the handle parameter `h` equals zero for all elements of the set `pp` whose related models have been solved and their solutions have been extracted. The last statement in the code above sets the results of the *missed* solves to `na` to signal the failed solve. The parameter `h` will now contain the handles of the failed solves for later analysis.

Alternatively, we could use the function `handleStatus` and collect the solutions that are stored in a [GDX file](#). For example, we could write:

```
loop(pp$(handleStatus(h(pp)) = 2),
  minvar.handle = h(pp);
  execute_loadhandle minvar;
  xres(i,pp)      = x.l(i);
  report(pp,i,'inc') = xi.l(i);
  report(pp,i,'dec') = xd.l(i);
);
```

The function `handleStatus` tests the solution process and returns the value 2 if the solution process has been completed and the results can be retrieved. The solution is stored in a GDX file which can be loaded in a way similar to other GDX solution points. First, we need to specify which solution to retrieve by setting the the model attribute `minvar.handle` to the appropriate value. Then we can use the statement `execute_loadhandle minvar;` to load the solution for the model `minvar` back into the GAMS data base.

Note

Except for the requirement of a model with a previously specified handle, the command `execute_loadhandle` operates like the procedure `execute_loadpoint`.

Using the function `handleStatus` and the command `execute_loadhandle` instead of the simpler `handleCollect`, adds one more layer of control to the final collection loop. Now we need one additional `if statement` inside the collection loop above:

```
repeat
  loop(pp$h(pp),
    if(handleStatus(h(pp)) = 2,
      minvar.handle = h(pp);
      execute_loadhandle minvar;
      xres(i,pp)      = x.l(i);
      report(pp,i,'inc') = xi.l(i);
      report(pp,i,'dec') = xd.l(i);
      display$handleDelete(h(pp)) 'trouble deleting handles' ;
      h(pp) = 0;
    );
  );
  display$readyCollect(h, 100) 'Problem waiting for next instance to complete';
until card(h) = 0 or timeelapsed > 100;
xres(i,pp)$h(pp) = na;
```

Finally, we are ready to run the modified model.

4.36.3.3 The Execution Log

The execution log will contain some new information that may be useful for more advanced applications:

```
--- LOOPS pp = p1
--- 46 rows 37 columns 119 non-zeroes
--- 311 nl-code 7 nl-non-zeroes
--- 14 discrete-columns
--- Submitting model minvar with handle grid137000002
--- Executing after solve
...
--- GDXin=C:\answerv5\gams_srcdev\225j\grid137000003\gmsgrid.gdx
--- Removing handle grid137000003
```

Note that the log contains some additional information about the submission, retrieval and removal of the solution instance. In the following sections we will make use of this additional information.

For a complete example for grid computing, see the grid enabled transport model `[TRNSGRID]`.

Observe that we have made no assumptions about what kind of solvers and what kind of computing environment we will operate. The example above is completely platform and solver independent and it runs on a Windows laptop or on a massive grid network like the Condor system without any changes in the GAMS source code.

4.36.4 Advanced Use of Grid Features

In this section we will describe a few special application requirements and show how this can be handled with the current system. Some of those applications may involve thousands of model instances with solution times of many hours each. Some may fail and require resubmission. More complex examples require communication and the use of GAMS facilities like the [Branch-and-Cut-and-Heuristic Facility \(BCH\)](#), which submit other models from within a running solver.

Imagine a situation with thousands of model instances each taking between minutes and many hours to solve. We will break the master program into a *submitting* program, an *inquire* program and a final *collection* program. We will again use the model `[QMEANVAR]` to demonstrate the principle. We will split the code of the modified `[QMEANVAR]` GAMS code into three components: `qsubmit`, `qcheck` and `qreport`.

4.36.4.1 Very Long Job Durations: The Submitting Program

The file `qsubmit.gms` will include everything up to and including the new submission loop. To save the instances we will need a unique [grid directory](#) `gdir` and to restart the problem we will have to create a `save file`. For details on the save and restart facility in GAMS, see chapter [The Save and Restart Feature](#). When running the first job, we will use the command line parameter `save` or its synonym `s` to create the required `save file`:

```
> gams qsubmit s=submit gdir=c:\test\grid
```

4.36.4.2 Very Long Job Durations: The Inquire Program

The solution of all the model instances may take hours. From time to time we may run a quick inquiry job to learn about the status. The following program `qcheck.gms` will list the current status:

```
Parameter status(pp,*);
Scalar    handle;
Acronym   BadHandle, Waiting, Ready;
loop(pp,
  handle = handleStatus(h(pp));
  if(handle=0,
    handle = BadHandle;
  elseif handle=2,
    handle = Ready;
    minvar.handle = h(pp);
    execute_loadhandle minvar;
    status(pp,'solvestat') = minvar.solvestat;
    status(pp,'modelstat') = minvar.modelstat;
    status(pp,'seconds') = minvar.resusd;
  else
    handle = Waiting;
  );
  status(pp,'status') = handle;
);
display status;
```

For details on the [model attributes](#) referenced in the code above, see [handle](#), [solveStat](#), [modelStat](#) and [resUsd](#). To run the program above, we will restart from the previous `save file` by using the command line parameter `restart` or its synonym `r`.

```
> gams qcheck r=submit gdir=c:\test\grid
```

The output generated by the display statement may look like the following:

```
---- 173 PARAMETER status

      solvestat   modelstat   seconds   status
p1      1.000      1.000      0.328    Ready
p2      1.000      1.000      0.171    Ready
p3                      Waiting
p4                      Waiting
p5      1.000      1.000      0.046    Ready
```

We may want to do some more detailed analysis on one of the solved model instances. The respective program, called `qanalyze.gms`, may include the following lines of code:

```
$if not set instance $abort --instance is missing
if(not handleStatus(h('%instance%'))),
    abort$yes 'model instance %instance% not ready';
minvar.handle = h('%instance%');
execute_loadhandle minvar;
display x.l,xi.l,xd.l;
...
```

For information on dollar control options, see chapter [Dollar Control Options](#), especially the detailed descriptions of the options `$if` and `$abort`. Note that `instance` is a [compile-time variable](#). The program may be called using a [double dash parameter](#), which defines and sets a GAMS compile-time variable:

```
> gams qanalyze r=submit gdir=c:\test\grid --instance=p4
```

4.36.4.3 Very Long Job Durations: The Collection Program

Once all jobs are completed we are ready for the collection loop. For simplicity, we will not include the repeat loop, because we would not run the final collection program unless we were satisfied that we got most of the solutions that we wanted. The file `qreport.gms` could look like the following:

```
loop(pp$handleStatus(h(pp)),
    minvar.handle = h(pp);
    execute_loadhandle minvar;
    xres(i,pp) = x.l(i);
    report(pp,i,'inc') = xi.l(i);
    report(pp,i,'dec') = xd.l(i);
    display$handleDelete(h(pp)) 'trouble deleting handles' ;
    h(pp) = 0;
);
xres(i,pp)$h(pp) = na;
...
```

We will restart the program above from the `save file` that was created earlier:

```
> gams qreport r=submit gdir=c:\test\grid
```

Note that it is not necessary to run the job from the same directory that we have used for the initial submission; it is even possible to use a different operating system.

4.36.5 Summary of Grid Features

We introduced several GAMS features to facilitate the asynchronous or parallel execution of the [solve statement](#). These GAMS features are summarized in the following subsections.

In addition to the features described below, the option or command line parameter [ThreadsAsync](#) was introduced. [ThreadsAsync](#) controls the number of threads or CPU cores that are used in [multi-threading computing](#).

4.36.5.1 Grid Handle Functions

The grid handle functions are listed in [Table 1](#). For details on functions in GAMS in general and complete lists of all GAMS functions, see section [Functions](#). Note that the desired return values - the return values that indicate that no error has occurred - are marked with bold letters.

Function	Description	Return Values
<code>handleCollect(HANDLE)</code>	Tests if the solve of the model instance identified by <code>HANDLE</code> is done: if so, it loads the solution into the GAMS data base. If the option asyncSolLst is active the solution listing is printed to the listing file. Note that <code>handleCollect</code> ignores the setting of the option SolveOpt and always uses the default value <code>merge</code> .	0: The model instance was not ready or could not be loaded. >0: The model instance solution has been loaded. (When using the Grid facility, this is always 1; when using the multi-threading option, this returns the thread ID used.)
<code>handleStatus(HANDLE)</code>	Tests if the solve of the model instance identified by <code>HANDLE</code> is done. Note that there are compile-time constants that are related to this function.	0: The model instance is not known to the system. 1: The model instance exists but the solution process is incomplete. 2: The solution process has terminated and the solution is ready for retrieval. 3: The solution process signaled completion but the solution cannot be retrieved.
<code>handleDelete(HANDLE)</code>	Deletes the model instance identified by <code>HANDLE</code> and returns a numerical indicator of the status of the deletion. If the <code>HANDLE</code> given is not valid, an execution error is triggered.	0: The model instance has been removed. 1: The argument <code>HANDLE</code> is not a legal handle. 2: The model instance is not known to the system. 3: The deletion of the model instance encountered errors.

Function	Description	Return Values
<code>handleSubmit(HANDLE)</code>	Resubmits the model instance identified by <code>HANDLE</code> for solution. In case of a nonzero return an execution error is triggered.	0: The model instance has been resubmitted for solution. 1: The argument <code>HANDLE</code> is not a legal handle. 2: The model instance is not known to the system. 3: The completion signal could not be removed. 4: The resubmit procedure could not be found. 5: The resubmit process could not be started.
<code>readyCollect(HANDLES[,maxWait])</code>	Waits until a model solution is ready to be collected. <code>HANDLES</code> must be either a scalar or parameter containing one or more model handles or a model with its handle attribute. <code>MaxWait</code> specifies the maximum time to wait in seconds, the default value is <code>+inf</code> .	0: One or more of the requested jobs is/are ready. 1: There is no active job to wait for. 2: The handle symbol is empty. 3: The argument is not a legal handle. 4: User specified time-out (using a <code>solveLink = 6</code> handle). 5: User specified time-out (using a <code>solveLink = 3</code> handle). 8: Unknown error (should not happen).

Table 1: Grid Handle Functions

Note that GAMS might issue execution errors which could give additional information that may help to identify the source of problems. The function `execError` may be used to get and set the number of execution errors.

4.36.5.2 Grid Model Attributes

Model attributes are introduced in section [Model Attributes](#). The following three model attributes are particularly relevant for grid computing:

Function	Description
<code>solveLink</code>	Specifies the solver linking conventions. The following values direct the solve statement to use grid computing or multi-thread computing: 3, 4, 6 and 7. Note that the default for this model attribute can be set as command line parameter and option statement . For more information, see the detailed description .
<code>handle</code>	Specifies the current instance handle. This is used to identify a specific model instance and to provide additional information needed for the process signal management (compare subsections The Submission Loop and The Collection Loop above).
<code>number</code>	Specifies the current instance number. Any time a solve is attempted for a model, the instance number is incremented by one and the handle is update accordingly. The instance number can be reset by the user which then resynchronizes the handle.

Table 2: Grid Handle Attributes

4.36.5.3 Grid Solution Retrieval

As an alternative to the function `handleCollect` a solution may be retrieved with the following statement:

```
execute_loadhandle mymodel;
```

This statement will update the GAMS data base with the status and solution for the current instance of `mymodel`. Note that the underlying mechanism is a [GDX file](#). Except for the requirement of a model with a previously specified handle, this command operates like the procedure `execute_loadpoint`. If the option `asyncSolLst` is active the solution listing is printed to the listing file.

4.36.5.4 The Grid Directory

The instantiated (generated) models and their corresponding solutions are kept in unique directories that may be reached from the submitting system. Each GAMS job may have only one *grid directory*. By default, the grid directory is assumed to be the scratch directory. This may be overwritten by using the GAMS command line parameter `GridDir`, or short `GDir`. An example follows.

```
> gams myprogram ... GDir=gridpath
```

If `gridpath` is not a fully qualified name, the name will be completed using the current directory. If the grid path does not exist, an error will be issued and the GAMS job will be terminated. A related GAMS parameter is `ScrDir` or short `SD`.

Recall the following default mechanism: When a GAMS job is started a unique process directory is created in the current directory. These directories are named 225a to 225zz. When a GAMS job terminates, the system will remove the process directory at the completion of a GAMS job. Any file that has not been created by the GAMS core system will be flagged. If the call `gamskeep` instead of `gams` is used, another exit script will be activated that results in the process directory to be kept.

Note that if we do not specify a scratch directory, the scratch directory will be the same as the process directory. If we do not specify a grid directory, the grid directory will be the same as the scratch directory.

Observe that if we assume that some of the model instances may fail or we want to break the GAMS program into several pieces to run as separate jobs, we need to be careful not to remove the model instance we have not completely processed. In such cases we have to use the parameter `GridDir`, so that we may access previously created model instances.

4.36.6 The Grid Facility: Architecture and Customization

The current Grid facility relies on very basic operating system features and does not attempt to offer real and direct job or process control. The file system is used to signal the completion of a submitted task and GAMS has currently no other way to interact with the submitted process directly, like forcing termination or change the priority of a submitted task. This approach has its obvious advantages and disadvantages. There are a number of attempts to use grid computing to provide value added commercial remote computing services.

When GAMS executes a solve with the option [solveLink](#) set to 3 it will perform the following steps:

1. Create a subdirectory in the [GridDir](#) with the name `gridnnn`. Here `nnn` stands for the numeric value of the handle. The handle value is the internal symbol ID number x 1e6 + the model instance number. For example, in the `[QMEANVAR]` example the first grid subdirectory was `grid137000002`.
2. Remove the completion signal in case the file already exists. Currently the signal is a file called `finished`. For example, `grid137000002/finished`.
3. Create or replace a GDX file called `gmsgrid.gdx` which will contain a dummy solution with failed model and solver status. This file will be overwritten by the final step of the solution process and will be read when calling [execute_loadhandle](#).
4. Place all standard GAMS solver interface files into the above instance directory.
5. Execute the submission wrapper called `gmsgrid.cmd` under Windows or `gmsgrid.run` under Unix. These submission scripts are usually located in the GAMS system directory, they may be located via the current path if they are not found in the GAMS system directory.

The grid submission script `gmsgrid.cmd` or `gmsgrid.run` is called with four arguments that are needed to make a standard GAMS solver call: the solver executable file name, the solver control file name, the solver scratch directory, and the solver name. The submission script then does the final submission to the operating system. This final script will perform the following steps:

1. call the solver,
2. call a utility that will create the final GDX file `gmsgrid.gdx`,
3. set the completion signal `finished`.

If we want to use the function [handleSubmit](#) we will also have to create the script `gmsrerun.cmd` or `gmsrerun.run`. This script could later be used to resubmit the job.

For example, the default submission script for Windows is shown below:

```
@echo off

: gams grid submission script
:
: arg1 solver executable
:   2 control file
:   3 scratch directory
:   4 solver name
:
: gmscr_nx.exe processes the solution and produces 'gmsgrid.gdx'
:
: note: %3 will be the short name, this is needed because
:       the START command cannot handle spaces or "...'
```

```

:      before we use %~3 will strip surrounding "..."
:      makes the name short
:
: gmsrerun.cmd will resubmit runit.cmd

echo @echo off > %3runit.cmd
echo %1 %2 %4 >> %3runit.cmd
echo gmscr_nx.exe %2 >> %3runit.cmd
echo echo OK ^> %3finished ^& exit >> %3runit.cmd

echo @start /b /belownormal %3runit.cmd ^> nul > %3gmsrerun.cmd

start /b /belownormal %3runit.cmd > nul

exit

```

4.36.6.1 Grid Submission Testing

The grid submission process can be tested on any GAMS program without having to change the source text. The option `solveLink=4` instructs the solve statement to use the grid submission process and then wait until the results are available. Note that the option `solveLink` may be set via a GAMS command line parameter, a GAMS option statement or via assignment to the model attribute. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the `reslim` seconds allocated for this optimization job and report a failure if this limit has been exceeded. After successful or failed retrieval of the solution, GAMS will remove the grid directory, unless we have used the call `gamskeep` or have set the GAMS command line parameter `keep`.

4.36.7 Multi-Threading

As we have described in this chapter, each solve is handled in its own process space with the Grid facility. Recall that the Grid facility is activated by setting the option or model attribute `solveLink` to 3 or 4. If `solveLink` is set to 6 (or the `compile-time constant %solveLink.Async Threads%`) instead, a separate thread is used. This allows efficient in-memory communication between GAMS and the solver, like it is done if the option `solveLink` is set to 5 (or the `compile-time constant %solveLink.Load Library%`).

Apart from this, the multi-threading facility works in the same way as the Grid facility. The solve statement generates the model and passes it to the solver in a separate thread, then a handle of the model instance may be stored using the model attribute `handle` and the `grid handle functions` may be used to collect the solution and deal with the model instance, namely `handleCollect`, `handleDelete`, `handleStatus` and `readyCollect`.

Note that the option or command line parameter `ThreadsAsync` sets the maximum number of threads that should be used for the asynchronous solves.

The following matrix shows which solvers may be used with `solveLink = 6` on which platform:

Solver	x86 64bit MS Windows	x86 64bit Linux	x86 64bit Mac OS X
CONOPTD	×	×	×
CONOPT4	×	×	×
CONVERT	×	×	×
COPT	×	×	×
CPLEX	×	×	×
GUROBI	×	×	×

Solver	x86 64bit MS Windows	x86 64bit Linux	x86 64bit Mac OS X
IPOPT	×	×	×
MOSEK	×	×	×
ODHCPLEX	×	×	
OsiCplex	×	×	×
OsiGurobi	×	×	×
SCIP	×	×	×
SHOT	×	×	×
SNOPT		×	
Soplex	×	×	×
XPRESS	×	×	×

If a solver is selected for which `solveLink = 6` is not supported on the corresponding platform, `solveLink = 3` will be used instead and it will be noted in the log.

4.36.7.1 Multi-threading Submission Testing

The multi-threading submission process may be tested on any GAMS program without having to change the source text. The option `solveLink = 7` (or, equivalently, the `compile-time constant %solveLink.Threads Simulate%`) instructs the solve statement to use the multi-threading submission process, wait until the results are available and then load the solution into the GAMS data base. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the `reslim` seconds allocated for this optimization job and report a failure if this limit has been exceeded. After successful or failed retrieval of the solution GAMS will remove the thread handle.

4.37 Special Features for Mathematical Programs

4.37.1 Introduction

In this chapter we will introduce special GAMS features that are useful for specific model types. The features include [model scaling](#), [conic programming](#) and features that facilitate [mixed integer](#) as well as [indicator constraints](#), a feature that does not translate across solvers.

4.37.2 Special Mixed Integer Programming (MIP) Features

Some special features have been added to GAMS to help simplifying the modeling of [Mixed Integer Programming \(MIP\)](#) problems. In GAMS MIP is the model type for mixed integer *linear* programs, this section used MIP more generally, we consider model with discrete variables, including non-linear expressions and pure discrete problem. We will first present details on discrete variables in GAMS, then we will discuss how to customize priorities for the branching process. Next, we will cover the model attributes that are important for MIPs and we will conclude with some hints that will make mixed integer programming with GAMS easier.

4.37.2.1 Types of Discrete Variables

Variables and [variable types](#) are introduced in chapter [Variables](#). GAMS provides six discrete variable types: `binary`, `integer`, `sos1`, `sos2`, `semicont` and `semiint`. In the following subsections we will present details and examples for each of these discrete variable types. Note that if any discrete variables feature in a model, it has to be a mixed integer model or one of the related model types, like [MINLP](#) or [MIQCP](#). See section [Classification of Models](#) for a full listing of all GAMS model types.

4.37.2.1.1 Binary Variables Binary variables can take values of 0 (zero) and 1 (one) only. They are declared as follows:

```
Binary Variable var_name [(index_list)] [text];
```

The keyword `binary` indicates that this is a binary variable and then the usual conventions for [variable declarations](#) are followed. Alternatively, the variable may be declared first and specified as `binary` later. Consider the following code snippets from the orthogonal Latin Square model [**LATIN**]:

```
Sets k  "rows"      / row1*row4 /
     l  "columns"   / col1*col4 /
     v  "values"    / val1*val4 /;
alias (i,j,v);

Variables x(i,j,k,l) "pairs (i,j) allocated to cell(k,l)"
          z          "some objective";
Binary Variable x;

Equations c1(i,j)    "for each cell pick only one item pair";
c1(i,j).. sum((k,l), x(i,j,k,l)) =e= 1;
```

Note that the binary variable `x` is used in equation `c1` to model the restriction that in each cell only one item pair is allowed. Binary variables are often used to model logical conditions such as imposing mutual exclusivity or complementarity.

Note that the default lower bound is 0 (zero) and the default upper bound is 1 (one). If the relaxed versions of the discrete models is solved, binary variables are treated like positive variables with the upper bound of 1. In addition, an infinite priority may be used to override binary specifications, see section [Setting Priorities for Branching](#) below for more information.

Even though the only possible values are 0 and 1, a solver might return a value for binary variable that is only *close* to 0 or 1. Every solver works with tolerances and also uses a tolerance to determine if a value is *close enough* to an integer values. So it is unwise to use code as `a(i)$(b.l(i)=1) = yes;` because one will potentially miss some elements. A safe way to write such code is: `a(i)$(b.l(i)>0.5) = yes;`. Rounding the level of a binary variable after the solve is also possible, but it is not done by the solver or the solver link because even small rounding can lead to infeasibilities.

A binary variable can also have a truly fractional value after a solver if the model status does not indicate a feasible integer solution (model status 1 or 8).

4.37.2.1.2 Integer Variables Integer variables are discrete variables that can take only values between their bounds. The user may change both bounds from the default value. The default lower bound is 0 (zero) and the default upper bound inside GAMS is `+inf`, and the same upper bound is passed on to the solver.

Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section [Setting Priorities for Branching](#) below for more information. Integer variables are declared as follows:

```
Integer Variable var_name [(index_list)] [text];
```

The keyword `integer` indicates that this is an integer variable and then the usual conventions for [variable declarations](#) are followed. Alternatively, the variable may be declared first and specified as `integer` later. Consider the following code snippets from the power scheduling model [**MAGIC**]:

```

Sets t  "demand blocks" / 12pm-6am, 6am-9am, 9am-3pm, 3pm-6pm, 6pm-12pm /
      g  "generators"    / type-1, type-2, type-3 /;

Variables x(g,t) "generator output (1000mw)"
          n(g,t) "number of generators in use"
          cost   "total operating cost (l)";
Integer Variable n;

```

The integer variable `n` models the number of generators of various types that are in use at any of the time blocks.

4.37.2.1.3 Special Order Sets of Type 1 (SOS1) SOS1 variables are a set of variables, such that at most one variable within the group may have a nonzero value. This variable may take any positive value. Special ordered sets of type 1 are defined as follows:

```
SOS1 Variable var_name (index_list) [text];
```

The keyword `SOS1` indicates that this is a `SOS1` variable and then the usual conventions for [variable declarations](#) are followed. Alternatively, the variable may be declared first and specified as `SOS1` later. Consider the following example:

```
SOS1 Variable s1(i), t1(k,j), w1(i,j,k) ;
```

Note that the members of the innermost (the right-most) index belong to the same SOS set. For example in the sets defined above, `s1` represents one special ordered set of type 1 with `i` elements, `t1` defines `k` sets with `j` elements each and `w1` defines `(i,j)` sets with `k` elements each.

The default bounds for `SOS1` variables are zero and `+inf`. As with any other variable, the user may change these bounds. Further, the user may explicitly provide whatever convexity row that the problem may need through an equation that requires the members of the `SOS1` set to be less than a certain value. Any such convexity row will implicitly define bounds on each of the variables.

Consider the following example:

```
SOS1 Variable s1(i); Equation defsoss1;
defsoss1.. sum(i,s1(i)) =l= 3.5 ;
```

The equation `defsoss1` implicitly defines the nonzero value that one of the elements of the `SOS1` variable `s1` may take as equal to or smaller than 3.5. Note that it is also possible that all variables `s1` equal zero.

A special case arises when one of the elements of the set has to be nonzero and equal to a number, say 3.5. In this case equation `defsoss1` will be:

```
defsoss1.. sum(i,s1(i)) =e= 3.5 ;
```

Frequently the nonzero value equals 1. As a result, the `SOS1` variable is effectively a binary variable. It is only treated differently by the solver at the level of the branch and bound algorithm. For example, consider the following example where we want to model that one out of `n` options has to be selected. This is expressed as:

```
SOS1 Variable x(i); Equation defx;
defx.. sum(i, x(i)) =e= 1 ;
```

The variable `x` can be made binary without any change in meaning and the solution provided by the solver will be indistinguishable from the `SOS1` case.

The use of special ordered sets may not always improve the performance of the branch and bound algorithm. If there is no natural *order* the use of binary variables may be a better choice. A good example of this is the classical assignment problem (see [H.P. Williams (2013) [Model Building in Mathematical Programming](#)], Wiley, Section 9.3).

Note that any model with `SOS1` variables requires a MIP solver, because the solution process needs to impose the restrictions of at most one nonzero level values may be present.

For an example where `SOS1` variables are used, see the production scheduling model [[PRODSCHX](#)].

4.37.2.1.4 Special Order Sets of Type 2 (SOS2) `SOS2` variables are a set of variables, such that at most two variables within the set may have nonzero values and these variables have to be adjacent. This requirement implies that the set is *ordered*, see chapter [Sets as Sequences: Ordered Sets](#) for details on ordered sets in GAMS. Note that the nonzero variables may take any positive value. Special ordered sets of type 2 are defined as follows:

```
SOS2 Variable var_name [(index_list)] [text];
```

The keyword `SOS2` indicates that this is a `SOS2` variable and then the usual conventions for [variable declarations](#) are followed. Alternatively, the variable may be declared first and specified as `SOS2` later. Consider the following example:

```
Set i / i1*i5 /;
SOS2 Variable s2(i), t2(k,j), w2(i,j,k);
```

The members of the innermost (the right-most) index belong to the same set. For example, in the sets defined above, `s2` represents one special ordered set of type 2 with elements for each member of the set `i`. At most two variables `s2` may be nonzero and they must reference adjacent elements of the set `i`. Note that the variables `s2('i1')` and `s2('i2')` are adjacent, but the variables `s2('i1')` and `s2('i3')` are not. Further, `t2` defines `k` sets of `SOS2` variables with `j` elements each and the adjacency requirement refers to the set `j` which must be ordered. Similarly, `w2` defines `(i,j)` sets with `k` elements each and the adjacency requirement refers to the set `k` which must be ordered.

The default bounds for `SOS2` variables are zero and `+inf`. As with any other variable, the user may change these bounds. `SOS2` variables are most often used to model piece-wise linear approximations to nonlinear functions. The production scheduling model [[PRODSCHX](#)] shows `SOS` type formulations with binary, `SOS1` and `SOS2` sets.

Note that any model with `SOS2` variables requires a MIP solver, because the solution process needs to impose the restrictions of adjacency and that no more than two nonzero level values may be present.

4.37.2.1.5 Semi-Continuous Variables Semi-continuous variables are either zero or above a given minimum level. This can be expressed algebraically as: either $x = 0$ or $L \leq x \leq U$. By default, the lower bound L is 1 and the upper bound U is `+inf`. As usual, these bounds may be changed with the [variable attributes](#) `.lo` and `.up`. Semi-continuous variables are defined as follows:

```
SemiCont Variable var_name [(index_list)] [text];
```

The keyword `semicont` indicates that this is a semi-continuous variable and then the usual conventions for [variable declarations](#) are followed. Alternatively, the variable may be declared first and specified as `semicont` later. Consider the following example:

```
SemiCont Variable x;
x.lo = 1.5; x.up = 23.1;
```

The slice of code above declares the variable `x` to be a semi-continuous variable that may either be zero or behave as a continuous variable between 1.5 and 23.1.

Note that any model with semi-continuous variables requires a MIP solver, because the solution process needs to impose the discontinuous jump between zero and the threshold value.

Note

- Not all MIP solvers allow semi-continuous variables. We recommend users to verify how the solver they are interested in handles semi-continuous variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-continuous variables.
- Semi-continuous variables are especially helpful if the upper bound is `+inf` and no implicit bound can be easily derived. If a finite upper bound is available it can be computationally more efficient to replace the semi-continuous variable `sc` with lower bound `scLow` by a continuous variable `x` and binary variable `b` and the following equations:

```
Equation xForceLowerBnd "Force x to be greater than scLow if b is 1"
        xForceZero      "Force x to be zero if b is zero";
xForceLowerBnd.. x =g= scLow*b;
xForceZero..     x =l= x.up*b;
```

4.37.2.1.6 Semi-Integer Variables Semi-integer variables are either zero or integer and above a given minimum value. This can be expressed algebraically as: either $x = 0$ or $x \in \{L, \dots, U\}$. By default, the lower bound L is 1 and the upper bound U inside GAMS is `+inf` and the same values are passed on to the solver. As usual, these default bounds may be changed with the [variable attributes](#) `.lo` and `.up`. Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section [Setting Priorities for Branching](#) below for more information.

Semi-integer variables are defined as follows:

```
SemiInt Variable var_name [(index_list)] [text];
```

The keyword `semiint` indicates that this is a semi-integer variable and then the usual conventions for [variable declarations](#) are followed. Alternatively, the variable may be declared first and specified as `semiint` later. Consider the following example:

```
SemiInt Variable x;
x.lo = 2; x.up = 25;
```

The slice of code above declares the variable `x` to be a semi-integer variable that may either be zero or take any integer value between 2 and 25. Note that the bounds for `semiint` variables have to take integer values, otherwise GAMS will flag an error during model generation. Note further, that any model with semi-integer variables requires a MIP solver.

Note

- Not all MIP solvers allow semi-integer variables. We recommend users to verify how the solver they are interested in handles semi-integer variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-integer variables.
- Semi-integer variables are especially helpful if the upper bound is `+inf` and no implicit bound can be easily derived (together with the appropriate [IntVarUp](#) setting). If a finite upper bound is available, it can be computationally more efficient to replace the semi-integer variable `si`, with lower bound `siLow`, by an integer variable `i` and a binary variable `b` and the following equations:

```
Equation iForceLowerBnd  "Force i to be greater than siLow if b is 1"
          iForceZero     "Force i to be zero if b is zero";
iForceLowerBnd.. i =g= siLow*b;
iForceZero..     i =l= i.up*b;
```

4.37.2.2 Setting Priorities for Branching

By setting priorities users may specify an order for choosing variables to branch on during a branch and bound search for MIP models. Without priorities the MIP algorithm will internally determine which variable is the most suitable to branch on. Priorities for individual variables may be used only if the [model attribute](#) `.prioropt` is set to 1; the respective GAMS statement is:

```
mymodel.prioropt = 1;
```

Here `mymodel` is the name of the model specified in the model statement. The default value is NA.

If the model attribute `.prioropt` is set to 1, the [variable attribute](#) `.prior` may be used to set the priorities of individual discrete variables. Note that there is one `.prior` value for each individual component of a multidimensional variable. Priorities may be set to any real value; the default value is 1. As a general rule, the most important variables should be given the highest priority. The highest priority is denoted by the lowest nonzero value in the `.prior` attribute. Functionally, the attribute `.prior` establishes in what order variables are to be branched on in the branch-and-bound algorithm while searching for a solution. Variables with a specific `.prior` value will be branched on earlier until all fractional variables with higher `.prior` values have been branched on.

Note

The variable attribute `.prior` of a *discrete* variable may be used to relax the discrete restriction on that variable: setting the `.prior` value to `+inf` will relax a variable permanently (or until `.prior` gets a finite value assigned). This relaxation is done independently of the model attribute `.prioropt`.

Consider the following example:

```
z.prior(i,'small')   = 3;
z.prior(i,'medium') = 2;
z.prior(i,'large')  = 1;
```

In this example the variables `z(i,'large')` are branched on before the variables `z(i,'medium')`, which in turn are branched on before the variables `z(i,'small')`.

Note that knowledge about the problem may help to determine which variables should be considered first. For example, consider a problem with a binary variable `u` representing a yes/no decision whether to build a factory and other binary variables representing equipment selections within that factory. We would naturally want to explore whether or not the factory should be built before considering what specific equipment to be purchased within the factory. Therefore we would set the priority values lower for `u`. By assigning a higher priority - a lower value of the attribute `.prior` - to the build/nobuild decision variable `u`, we can force this logic into the tree search and thus speed up computation time since uninteresting portions of the tree are left unexplored.

Note

- The lower the value given to the `.prior` suffix, the higher the priority for branching.
- All members of any `SOS1` or `SOS2` set should be given the same priority value since it is the set itself which is branched upon rather than the individual members of the set.
- While any value is accepted for `.prior` many solvers scale all giving priorities in the integer range of 0, ..., 1000.
- Branching priorities were a very important feature in the early days of mixed integer programming. Nowadays, it is not easy to find branching priorities that improve on the solvers default selection.
- Global non-linear optimization solvers branch on continuous variables too (see, for example [BARON](#)). In GAMS one cannot set the branching priority of a continuous variable. Such branching priorities need to be communicated via a solver option file.

4.37.2.3 Miscellaneous Hints

We will conclude the discussion of mixed integer models in GAMS with this section where we offer a variety of hints that are meant to make special facilities of mixed integer programming solvers more accessible.

4.37.2.3.1 Model Attributes for Mixed Integer Programming in GAMS GAMS offers several [model attributes](#) that may be used to influence MIP solver performance or report on results of MIPs. These model attributes include [Cheat](#), [CutOff](#), [NodLim](#), [ObjEst](#), [OptCA](#), [OptCR](#), [PriorOpt](#) and [TryInt](#).

4.37.2.3.2 The Branch and Cut and Heuristic Facility Hard MIP problems can be solved faster with the help of user supplied routines that generate cutting planes and good integer feasible solutions. The GAMS Branch-and-Cut-and-Heuristic (BCH) automates all major steps necessary to define, execute and control the use of user defined routines within the framework of general purpose branch-and-cut codes. It is documented in [Branch-and-Cut-and-Heuristic Facility \(BCH\)](#).

4.37.2.3.3 Branch and Bound Output While the log output for each solver differs, some key figures are usually displayed for branch-and-bound based solvers. For example, solving a linear mixed integer model with CPLEX will yield output like the following:

```

      Nodes
      Node Left      Objective  IInf  Best Integer      Cuts/
                                         Best Bound      ItCnt      Gap
*      0+      0
Found incumbent of value 0.000000 after 0.01 sec. (0.73 ticks)
      0      0  2.23031e+07      12      0.0000  2.23031e+07      17      ---
      0      0  2.23031e+07      7      0.0000      Cuts: 8      23      ---
*      0+      0
                                         2.23031e+07  2.23031e+07      0.00%
Found incumbent of value 2.2303094e+07 after 0.02 sec. (1.08 ticks)
...

Fixing integer variables, and solving final LP...
...

Solution satisfies tolerances.

MIP Solution:      22303093.628684      (23 iterations, 0 nodes)
Final Solve:      22303093.628684      (0 iterations)

Best possible:      22303113.950091
Absolute gap:      20.321407
Relative gap:      0.000001

```

A brief explanation of the columns follows:

- **Node** is the number of branch and bound nodes so far.
- **Nodes Left** is the number of problems created during the branching process that are yet to be examined.
- **Objective** gives the current objective function value of the relaxes node problem.
- **IInf** gives the number of discrete variables with fractional solution levels.
- **Best Integer** gives the incumbent solution. Note the last solution in that column is not necessarily the global best solution.
- **Cuts/Best Bound** gives the current lower bound on the solution.
- **ItCnt** gives the accumulated LP iteration count
- **Gap** gives the maximum percentage difference from the theoretical optimum.

Note that it is common that solves of mixed integer models end with a gap between the solution found and the best possible solution. This may be controlled by limits (e.g. time), solver options and model attributes like [.OptCR](#) and [.OptCA](#).

4.37.2.3.4 Nonlinear MIPs Modelers may wish to impose integer restrictions on nonlinear formulations combining two hard model types: MIP and NLP. Such MINLP models can be solved with a selection of solvers. Many solvers, e.g. DICOPT and SBB, provide a local optimum where others, e.g. ANTIGONE and BARON provide a global optimum. In most cases both types of MINLP solver make use of MIP and NLP solvers to calculate a solution. Such *subsolvers* need to be licensed for the solver to succeed.

4.37.2.3.5 Model Termination Conditions and Recommended Actions Recall that the termination condition of the model after the solution process has been completed is stored in the model attribute `.modelStat`. A list of all possible model statuses is given in section [Model Status](#). We can easily check for the existence of a feasible solution (status 1 and 8). Linear models and MINLP problems solved with global solvers can achieve the "OPTIMAL" status, given sufficient resources (time) and a setting of `OptCR` and `OptCA` to 0. All other cases do not yield a feasible integer solution. If a problem is reported as infeasible (status 4,5,10, and 19), it might be a good idea to see if the relaxed version of the model is already infeasible. Debugging models that are relaxed feasible but integer infeasible is very difficult.

4.37.2.3.6 Frequent Problems There are some problems users frequently encounter either due to GAMS settings or problem characteristics:

Default bounds

One needs to be aware that while the GAMS upper bound for integer and semi-integer variables is `+inf`, the bound that is passed to the solver can be different, namely 100 (see the discussion about [integer variables](#)). This can lead to unexpected results (e.g. infeasibilities or suboptimal solutions declared as optimal).

Ending with a gap – large default for `optCR` (10%)

MIP solves often end with a gap between the solution found and the best possible solution. This is controlled by `OptCR` or `OptCA` or by non-convergence. Note that the default value of 0.1 for `optCR` is relatively large. Users may want to reduce this to a smaller value. We will discuss the other cause of a gap next.

The nonending quest

Integer programming is a quite desirable formulation technique. However, integer problems are theoretically hard and the solution process (in the worst case) of exponential complexity. There are many ways that focus on improving the solution time of the solver. As with all models scaling is important (especially when using bigM formulations). For particular problems many different formulations exist and the literature about a particular problem together with the ability of GAMS to rapidly prototype and experiment is the best constellation to get the best results for the problem at hand. For fine tuning, some MIP solvers provide automated tuning tools (see e.g. [Cplex tuning](#)) that tweak the solver options to get the best performance.

4.37.3 Model Scaling - The Scale Option

The rules for good scaling are exclusively based on algorithmic needs. GAMS has been developed to increase the efficiency of modelers, and one of the best ways seems to be to encourage modelers to write their models using a notation that is as *natural* as possible. The units of measurement are one part of this natural notation. However, there is a potential conflict between what the modeler thinks is a good unit and what constitutes a well-scaled model.

4.37.3.1 The Scale Option

To facilitate the translation between a natural model and a well scaled model, GAMS has introduced the concept of a *scale factor*, both for variables and equations. The notations and definitions are quite simple. Scaling is turned off by default. Setting the [model attribute](#) `.scaleopt` to 1 turns on the scaling feature. For example,

```
model mymodel /all/ ;
mymodel.scaleopt = 1 ;
solve mymodel using nlp maximizing dollars ;
```

The statement should be inserted somewhere after the `model` statement and before the `solve` statement. To turn scaling off again, `mymodel.scaleopt` has to be set to zero before the next solve.

In most respects GAMS scaling is hidden from the user. The solution values reported back from a solution algorithm are always reported in the notation of the user. The algorithm's internal representation of the equations and variables are only reflected in the derivatives in the equation and column listings in the GAMS output if the values of the options `limrow` and `limcol` are positive. In addition, the internal representations will appear in the debugging output from the solution algorithm if the option `sysout` is set to `on`.

4.37.3.2 Scaling Variables

The scale factor of a variable is defined using the `variable attribute` `.scale` in the following way:

```
myvar.scale(i,j) = c;
```

The scale factor `c` is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Note that there is one scale value for each individual component of a multidimensional variable.

Assume that c is the scale factor of a variable V_u . Assume further, that the variable seen by the algorithm is V_a . Then we have: $\mathbf{V}_a = \mathbf{V}_u/c$. This means that each variable as seen by the user is *divided by* the scale factor.

For example, consider the following code snippet:

```
Positive Variables x1, x2;
Equation eq;
eq.. 200*x1 + 0.5*x2 =l= 5;
x1.up = 0.01;
x2.up = 10;
x1.scale = 0.01;
x2.scale = 10;
```

By setting `x1.scale` to 0.01 and `x2.scale` to 10, the model seen by the solver is:

```
Positive Variables xPrime1, xPrime2;
Equation eq;
eq.. 2*xPrime1 + 5*xPrime2 =l= 5;
xPrime1.up = 1;
xPrime2.up = 1;
```

Note that the solver does not see the variables `x1` or `x2`, but rather the scaled (and better-behaved) variables `xPrime1` and `xPrime2`. Note further, that upper and lower bounds on variables are automatically scaled in the same way as the variable itself.

Attention

- **Discrete variables** cannot be scaled.
- **Expert Note.** Internally, GAMS stores with each variable and equation one additional attribute or field (besides fields for level, marginal and lower and upper bound). Depending on the type of variable and sometimes even model type or solver, this field has different names in the GAMS language. For continuous variables, the field is called *scale*, while for discrete variable it is called *prior*. For stochastic 2-stage linear program models solved with DECIS, this field is called *stage*. The field `.stage` can lead to confusing results. Consider the following example:

```
Variable x;
x.scale = 0.1;
display x.stage;
```

The output is:

```
----          3 VARIABLE x.scale = 0.100
```

The field `.scale` has to be in a certain range ($>1e-20$ and no special value), but this is only checked at model generation time. The field `.prior` can be any number and even `+inf` (but no other special values). For further information on `.prior`, see section [Setting Priorities for Branching](#). For an introduction to variable and equation fields, see sections [Variable Attributes](#) and [Equation Attributes](#) respectively.

4.37.3.3 Scaling Equations

The scale factor of an equation is defined using the [equation attribute](#) `.scale` in the following way:

```
mzeqn.scale(i,j) = d;
```

The scale factor d is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Assume that d is the scale factor of an equation G_u . Assume further, that the equation seen by the algorithm is G_a . Then we have: $\mathbf{G}_a = \mathbf{G}_u/d$. This means that each equation as seen by the user is *divided by* the scale factor.

For example, consider the following equations:

```
Positive Variables y1, y2;
Equations eq1, eq2;
eq1..    200*y1 + 100*y2 =l= 500;
eq2..    3*y1 - 4*y2 =g= 6;
```

By setting `eq1.scale` to 100, the model seen by the solver is:

```
Positive Variables y1, y2;
Equations eqPrime1, eq2;
eqprime1.. 2*y1 + 1*y2 =l= 5;
eq2..    3*y1 - 4*y2 =g= 6;
```

Note

The user may have to perform a combination of equation and variable scaling to obtain a well-scaled model.

Consider the following example:

```
Positive variables x1, x2;
Equations eq1, eq2;
eq1.. 100*x1 + 5*x2 =g= 20;
eq2.. 50*x1 - 10*x2 =l= 5;
x1.up = 0.2;
x2.up = 1.5;
```

Setting the following scale values:

```
x1.scale = 0.1;
eq1.scale = 5;
eq2.scale = 5;
```

will result in the solver seeing the following well-scaled model:

```
Positive Variables xPrime1, x2;
Equations eqPrime1, eqPrime2;
eqPrime1.. 2*xPrime1 + x2 =g= 4;
eqPrime2.. xPrime1 - 2*x2 =l= 1;
xPrime1.up = 2;
x2.up = 1.5;
```

4.37.3.4 Scaling Derivatives

In nonlinear models the derivatives also need to be well-scaled. Assume that the derivatives in the model of the user are denoted by $d(G_u)/d(V_u)$. Assume further, that the derivatives in the scaled model seen by the algorithm are denoted by $d(G_a)/d(V_a)$. Then we have: $\mathbf{d}(\mathbf{G}_a)/\mathbf{d}(\mathbf{V}_a) = \mathbf{d}(\mathbf{G}_u)/\mathbf{d}(\mathbf{V}_u) \cdot \mathbf{c}/\mathbf{d}$, where c is the scale factor for the variable and d is the scale factor for the equation.

The user may affect the scaling of derivatives by scaling both the equation and variable involved.

4.37.3.5 Scaling Data

Scaling input data is independent of the model attribute `.scaleopt` and may contribute considerably towards achieving a well-scaled model. We recommend users to try to define the units of the input data such that the largest values expected for decision variables and their marginals is under a million, if possible.

For example, in US agriculture about 325 million acres are cropped and the corn crop is 9-10 billion bushels per year. When defining production data, we could enter land in 1000's of acres and all other resources in 1000's of units. We could also define the corn crop in millions of bushels. The data will be simultaneously scaled, hence if resource endowments are quoted in 1000's, corn yields are divided by 1000. This scaling results in a corn production variable in the units of millions. Consumption statistics would need to be scaled accordingly. Money units could also be in millions or billions of dollars. Such data scaling generally greatly reduces the disparity of coefficients in the model.

4.37.4 Conic Programming in GAMS

Conic programming models minimize a linear function over the intersection of an affine set and the product of nonlinear cones. The problem class involving second order (quadratic) cones is known as Second Order Cone Programs (SOCP). These are nonlinear convex problems that include linear and (convex) quadratic programs as special cases.

Conic programs allow the formulation of a wide variety of application models, including problems in engineering and financial management. Examples are portfolio optimization, Truss topology design in structural engineering, Finite Impulse Response (FIR) filter design and signal processing, antenna array weight design, grasping force optimization, quadratic programming, robust linear programming and norm minimization problems.

For more information, see [References and Links](#) at the end of this section.

4.37.4.1 Introduction to Conic Programming

Conic programs can be thought of as generalized linear programs with the additional nonlinear constraint $x \in C$, where C is required to be a convex cone. The resulting class of problems is known as *conic optimization* and has the following form:

$$\begin{aligned} & \text{minimize} && c^T x \\ & \text{subject to} && Ax \leq r^c, \\ & && x \in [l^x, u^x] \\ & && x \in C \end{aligned}$$

where $A \in \mathbb{R}^{m \times n}$ is the constraint matrix, $x \in \mathbb{R}^n$ the decision variable and $c \in \mathbb{R}^n$ the objective function cost coefficients. The vector $r^c \in \mathbb{R}^m$ represents the right-hand side and the vectors $l^x, u^x \in \mathbb{R}^n$ are lower and upper bounds on the decision variable x .

Now partition the set of decision variables x into sets $S^t, t = 1, \dots, k$, such that each decision variables x is a member of at most one set S^t . For example, we could have

$$S^1 = (x_1, x_4, x_7) \quad \text{and} \quad S^2 = (x_6, x_5, x_3, x_2).$$

Let x_{S^t} denote the variables x belonging to set S^t . Then define

$$C := \{x \in \mathbb{R}^n : x_{S^t} \in C_t, t = 1, \dots, k\},$$

where C_t must have one of the following forms:

- **Quadratic cone** (also referred to as Lorentz or ice cream cone):

$$C_t = \left\{ x \in \mathbb{R}^{n^t} : x_1 \geq \sqrt{\sum_{j=2}^{n^t} x_j^2} \right\}.$$

- **Rotated quadratic cone** (also referred to as hyperbolic constraints):

$$C_t = \left\{ x \in \mathbb{R}^{n^t} : 2x_1x_2 \geq \sum_{j=3}^{n^t} x_j^2, x_1, x_2 \geq 0 \right\}.$$

These two types of cones allow the formulation of quadratic, quadratically constrained and many other classes of nonlinear convex optimization problems.

4.37.4.2 Implementation of Conic Constraints in GAMS

The recommended way to write conic constraints is by using a quadratic formulation. Many solvers have the capability to identify the conic constraints in a QCP model even if it is not in perfect form but can be easily reformulated to fit in the described form. However, some solvers (namely MOSEK) expect the conic constraints to be precisely in the form given above. In earlier versions this form was enforced by a special type of equation, the =c= equation type. Moreover, such solvers have other requirements (e.g. disjunctive cones) that can be easily fulfilled by simple reformulation steps. Much progress is expected on the solver side in the coming years, so we don't go into much detail here.

Observe that we could formulate conic problems as regular NLPs using the following constraints:

- **Quadratic cone:**

```
x('1') =g= sqrt[ sum(i$[not sameas(i,'1')], sqr[x(i)]) ];
```

- **Rotated quadratic cone:**

```
2*x('1')*x('2') =g= sum(i$[not sameas(i,'1') and not sameas(i,'2')], sqr[x(i)]);
```

Here x('1') and x('2') are positive variables.

The following example illustrates the different formulations for conic programming problems. Note that a conic optimizer usually outperforms a general NLP method for the reformulated (NLP) cone problems.

4.37.4.3 Example

Consider the following example, which illustrates the use of rotated conic constraints. We will give reformulations of the original problem in regular NLP form and in conic form (with conic constraints).

The original problem is:

$$\text{minimize } \sum_{i=1}^n \frac{d_i}{x_i} \quad (4.2)$$

$$\text{subject to } ax \leq b \quad (4.3)$$

$$x_i \in [l_i, u_i], \quad i = 1, \dots, n \quad (4.4)$$

where $x \in \mathbb{R}^n$ is the decision variable, $d, a, l, u \in \mathbb{R}^n$ are parameters with $l_i > 0$ and $d_i \geq 0$ and $b \in \mathbb{R}$ is a scalar parameter. The original model may be written in GAMS using the equations:

```
defobj.. sum(n, d(n)/x(n)) =e= obj;
e1.. sum(n, a(n)*x(n)) =l= b;
Model orig /defobj, e1/;
x.lo(n) = l(n);
x.up(n) = u(n);
```

We can write an equivalent QCP formulation by using the substitution $t_i = 1/x_i$ in the objective function and adding a constraint. As we are dealing with a minimization problem, $d_i \geq 0$ and $x_i \geq l_i > 0$, we can relax the equality $t_i x_i = 1$ into an inequality $t_i x_i \geq 1$, which results in an equivalent problem with a convex feasible set:

$$\text{minimize } \sum_{i=1}^n d_i t_i \quad (4.5)$$

$$\text{subject to } a x \leq b \quad (4.6)$$

$$t_i x_i \geq 1, \quad i = 1, \dots, n \quad (4.7)$$

$$x \in [l, u], \quad (4.8)$$

$$t \geq 0, \quad (4.9)$$

$$(4.10)$$

where $t \in \mathbb{R}^n$ is a new decision variable. The GAMS formulation of this QCP is:

```
defobjc..      sum(n, d(n)*t(n)) =e= obj;
e1..          sum(n, a(n)*x(n)) =l= b;
coneqcp(n)..  t(n)*x(n)          =g= 1;
```

```
Model cqcp /defobjc, e1, coneqcp/;
t.lo(n) = 0;
x.lo(n) = l(n);
x.up(n) = u(n);
```

Note that the constraints $t_i x_i \geq 1$ are almost in rotated conic form. If we introduce a variable $z \in \mathbb{R}^n$ with $z_i = \sqrt{2}$, then we can reformulate the problem using conic constraints as:

$$\text{minimize } \sum_{i=1}^n d_i t_i \quad (4.11)$$

$$\text{subject to } a x \leq b \quad (4.12)$$

$$z_i = \sqrt{2}, \quad i = 1, \dots, n \quad (4.13)$$

$$2t_i x_i \geq z_i^2, \quad i = 1, \dots, n \quad (4.14)$$

$$x \in [l, u], \quad (4.15)$$

$$t \geq 0, \quad (4.16)$$

$$(4.17)$$

The GAMS formulation using conic equations is:

```
defobjc..      sum(n, d(n)*t(n)) =e= obj;
e1..          sum(n, a(n)*x(n)) =l= b;
e2(n)..       z(n) =e= sqrt(2);
coneperfect(n).. 2*x(n)*t(n) =g= sqr(z(n));
```

```
Model cperfect /defobjc, e1, e2, coneperfect/;
t.lo(n) = 0;
x.lo(n) = l(n);
x.up(n) = u(n);
```

The complete model is listed below:

```
Set          n / n1*n10 /;
Parameter d(n), a(n), l(n), u(n);
Scalar      b;

d(n) = uniform(1,2);
```

```

a(n) = uniform (10,50);
l(n) = uniform(0.1,10);
u(n) = l(n) + uniform(0,12-l(n));

Variables x(n);
x.l(n) = uniform(l(n), u(n));
b      = sum(n, x.l(n)*a(n));

Variables t(n), z(n), obj;
Equations defobjc, defobj, e1, e2(n), coneqcp(n), coneperfect(n), conenlp(n);

defobjc..      sum(n, d(n)*t(n)) =e= obj;
defobj..      sum(n, d(n)/x(n)) =e= obj;
e1..          sum(n, a(n)*x(n)) =l= b;
coneqcp(n)..  t(n)*x(n) =g= 1;
e2(n)..       z(n) =e= sqrt(2);
coneperfect(n).. 2*x(n)*t(n) =g= sqrt(z(n));

Model cqcp      /defobjc, e1, coneqcp/;
Model cperfect /defobjc, e1, e2, coneperfect/;
Model orig      /defobj, e1/;

t.lo(n) = 0;
x.lo(n) = l(n);
x.up(n) = u(n);

Option qcp=cplex;
Solve cqcp min obj using qcp;
Option qcp=mosek;
Solve cperfect min obj using qcp;
Solve orig min obj using nlp;

```

4.37.4.4 Sample Conic Models in GAMS

Conic models in the GAMS model library include:

- [EMFL]: a multiple facility location problem,
- [QP7]: a portfolio investment model using rotated quadratic cones (quadratic program using a Markowitz model),

4.37.5 Indicator Constraints

An indicator constraint is a way of expressing relationships between variables by specifying a binary variable to control whether or not a constraint takes effect. For example, indicator constraints are useful in problems where there are fixed charges to express only if a given variable comes into play.

So-called Big M formulations require to estimate an upper bound of an expression in a model. In most cases the model data can be used to determine relatively small number for such coefficients. In some cases it is not possible to find small Big M values and a resulting solution may exhibit trickle flow and have other unwanted side-effects. The main purpose of indicator constraints is to overcome these limitations of Big M formulations. Generally, the use of indicator constraints is not warranted when the unwanted side-effects of Big M formulations are not present.

Consider the following example:

```
constr01.. x1 + x2 + x3 =l= 1e+9*y; // may cause problems
```

Here we use a Big M formulation, that relies on the x values to sum to less than one billion. Note that this formulation may cause numeric instability or undesirable solutions in some situations. Alternatively, we could use an indicator constraint:

```
constr01$(y=0).. x1 + x2 + x3 =l= 0; // alternative
```

Note that y is a binary variable; the [logical condition](#) makes sure that the constraint is only active if $y = 0$. Unfortunately, the $\$()$ expressions do not allow endogenous variables and we need a different way to specify such implications. Indicators are supported by CPLEX, GUROBI, SCIP, and XPRESS.

We should mention a formulation of indicators without the explicit indicator constraints. We can use a SOS1 constraint to express that a constraint holds or not based on a binary variable by having a SOS1 set of a slack variable and the binary variable $\text{SOS1}(\text{slack}, 1-y)$:

```
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack; // alternative
```

Recall that only one of the variables in a SOS1 constraint can be non-zero, so if $1-y$ is non-zero (i.e. $y=0$) then slack must be zero, i.e. the constraint holds. If $1-y=0$ is non-zero, i.e. $y=1$ then slack can be used to make the constraint feasible for any setting of x_1 , x_2 , and x_3 . Here two unrelated variable, slack and y are part of an SOS1 constraint and some tricks are required to formulate this properly in GAMS:

```
Set oo / slack, yExpr /;
SOS1 variable indic(oo);
Equation iOn, iOff;
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack;
iOn..      indic('slack') =e= slack;
iOff..     indic('yExpr') =e= 1-y;
```

4.37.5.1 Indicator Constraints with GAMS

In the remainder of this section we will describe how to specify indicator constraints when using GAMS. Please consult the corresponding solver manual for information on whether indicator constraints are supported and possible differences in their specification.

The example from above will be implemented with a constraint in combination with additional information in a solver option file, e.g. CPLEX: `cplex.opt`:

```
constr01.. x1 + x2 + x3 =l= 0;
```

and the following entry in the option file:

```
indic constr01$y 0
```

This has the following effect: equation `constr01` will become an indicator constraint and becomes active in a solution where the binary variable takes the value 0. If the value of y in a solution is 1, the constraint is not active.

Note that this way of entering an indicator constraint is dangerous since the option files changes the model (usually an option file has some effect on the performance of the algorithm). Therefore, the solver will abort if there is a problem processing the indicator options in the solver option file.

Attention

If the model is given to a solver without the option file containing the indicator mapping (or to a solver that does not understand the `indic` keyword, a very different model will be solved. The current implementation of indicator constraints requires a significant amount of caution from the user.

There are two ways of entering the equation/binary variable mapping in a solver option file: with an indexed format and using labels.

The *indexed format* is a convenient shorthand notation which borrows its syntax from the GAMS syntax. It requires that the indices for the binary variable are already present in the index set of the equation.

Consider the following example of an invalid GAMS syntax with an endogenous variable in the dollar condition:

```
equ1(i,j,k)$ (ord(i) < ord(j) and bin1(i,k)=1) .. lhs =l= rhs;
```

This may be specified with the following equation in the GAMS file:

```
equ1(i,j,k)$ (ord(i) < ord(j)) .. lhs =l= rhs;
```

plus a solver option file with the following entry:

```
indic equ1(i,j,k)$bin1(i,k) 1
```

The *label format* is used in cases where the binary variable indices are not present in the equation indices or the binary variable is adjusted with [lags or leads](#). In these cases the mapping of all individual equations and variables of the indicator constraints need to be specified. An example follows.

```
Set          i /i1*i3/, j /j1*j2/;
Binary variable bin1(j);
Equation     equ1(i,j);

equ1(i,j)$(bin1(j++1)=0).. lhs =e= 0;
```

Note that the example above is not valid GAMS code. Instead, we will combine a valid GAMS equation and a solver option file using the label format as follows:

```
equ1(i,j).. lhs =e= 0;
```

and the solver option file

```
indic equ1('i1','j1')$bin1('j2') 0
indic equ1('i1','j2')$bin1('j1') 0
indic equ1('i2','j1')$bin1('j2') 0
indic equ1('i2','j2')$bin1('j1') 0
indic equ1('i3','j1')$bin1('j2') 0
indic equ1('i3','j2')$bin1('j1') 0
```

Note that the lines in such option files need not be entered manually. They may be easily generated using the GAMS [The Put Writing Facility](#). For example, the lines above may be generated as follows:

```
file fcpx / cplex.opt /;
fcpx.pc=8;
loop((i,j), put fcpx 'indic' equ1(i,j) '$' bin1(j++1) '0'/);
putclose fcpx;
```

There are situations where the indicator binary variable exist in the indicator constraint only and hence will *not* be *generated* by GAMS to be passed on to the solver. In such cases the solver will issue the following error message:

```
Error: Column is not of type Variable
```

There is an easy way to fix this problem: adding the binary indicator variable artificially to the model. For example, it may be added with the coefficient `eps` to the objective:

```
defobj.. z =e= ... + eps*sum(j, bin1(j));
```

4.37.5.2 An Example for Indicator Constraints with GAMS

In this subsection we will comment on parts of the model [TRNSINDIC]. This model uses big M formulations and indicator constraints to solve the same problem. In addition, a formulation that makes it easy to switch between these two is presented. It is a fixed-charge network example based on the well-known model [TRANSPORT].

Recall that i is the set of canning plants and j is the set of markets where cases of some product are to be shipped. First, the basic model is reformulated to a MIP by introducing the binary variable $use(i,j)$ and two new equations:

```
Binary Variable use(i,j)      is 1 if arc is used in solution;

Equations      minship(i,j) ensure minimum shipping
               maxship(i,j) ensure zero shipping if use variable is 0;

minship(i,j).. x(i,j) =g= minshipping*use(i,j);
maxship(i,j).. x(i,j) =l= bigM*use(i,j);
```

Note that $minshipping$ is a scalar denoting the minimum amount of cases that may be shipped and $bigM$ is a sufficiently large number, as usual.

Next, the same problem is solved with indicator constraints: the two new equations are reformulated and a CPLEX option file with information on indicator constraints is added:

```
Equations  iminship(i,j) ensure minimum shipping using indicator constraints
           imaxship(i,j) ensure zero shipping if use variable is 0 using indicator constraints;

iminship(i,j).. x(i,j) =g= minshipping;
imaxship(i,j).. x(i,j) =e= 0;

Model indicatorModel /cost, supply, demand, iminship, imaxship/ ;

file fcpX Cplex Option file / cplex.opt /;
putclose fcpX 'indic iminship(i,j)$use(i,j) 1' / 'indic imaxship(i,j)$use(i,j) 0';
indicatorModel.optfile = 1;

Solve indicatorModel using mip minimizing z ;
```

Note that the option file contains an entry for each of the two equations. Note further, that the binary variable use moved from the equations to the option file. However, it also features in the objective equation of the model, therefore this is not problematic. Observe that the indexed format for the equation/binary variable mapping was used in the option file. Alternatively, the label format may be used:

```
loop((i,j),
      put fcpX 'indic ' iminship.tn(i,j) '$' use.tn(i,j) yes
              / 'indic ' imaxship.tn(i,j) '$' use.tn(i,j) no / );
putclose fcpX;
```

In a final step the model is reformulated again such that the same problem may be solved with and without indicator constraints. This can be especially useful for debugging a model with indicator constraints. For details, see [TRNSINDIC].

Another example of a model with indicator constraints is the model [BILINEAR] where various formulations to represent bilinear product terms are demonstrated.

4.38 GAMS Output

4.38.1 Introduction

The output from GAMS contains many components in support for checking and comprehending a model. This chapter discusses the components of the GAMS output file generated from a GAMS run as well as ways to control the amount of diagnostic output produced. A GAMS run also generates a log which serves as a useful first step in analysing a GAMS run. The details regarding the log can be found in the [GAMS log](#) chapter.

The output file generated from a GAMS run is called *listing file*. The listing file has the file extension `.lst` and can be read using any text editor. By default the listing file has the same file name as the input file, but this can be changed using the command line parameter `Output`. See chapter [The GAMS Call and Command Line Parameters](#) for more information. The main components in the listing file are:

1. **Compilation.** The [compilation output](#) contains an [echo print](#) of the input file, possibly error messages, along with lists of GAMS objects and cross reference maps.
2. **Execution.** The [execution output](#) contains the results of display statements and possibly execution error messages.
3. **Model Generation.** The output generated during model generation contains [listings of equations](#) and [variable listings](#) as well as [model statistics](#) and possibly generation execution error messages.
4. **Solution.** The output generated when an external solver program processes the model is the [solution report](#) including the [solve summary](#), the [solver report](#), the [solution listing](#) and the [report summary](#).
5. **Post-Solution.** The final components added to the listing file are the [final execution summary](#) and the [file summary](#).

A small nonlinear program `[ALAN]` will be used to illustrate every component of the listing file. The possibilities for extension to large models with voluminous output (which is when the diagnostics are really useful) should be apparent. After covering all the components of the listing file we will discuss [error reporting](#) and conclude the chapter with a compiled list of how to [customize the output file](#).

This chapter does not cover the output that can be generated by the user through display statements and put statements. This output is covered in the chapters [The Display Statement](#) and [The Put Writing Facility](#) respectively.

4.38.2 An Illustrative Model

`[ALAN]` is a portfolio selection model whose objective is to choose a portfolio of investments whose expected return meets a target while minimizing the variance. We will discuss a simplified version of this model. The input file is listed for reference.

```

4.38.3 Compilation Output

The compilation output is the output produced during the initial check of the program, often referred to as compilation. It contains the following parts: the [echo print of the input file](#), the [symbol reference map](#), the [symbol listing map](#), the [unique element listing map](#), and the [include file summary](#).

By default only the echo print and the include file summary is shown, the other parts are suppressed and may be turned on with [dollar control options](#). See also section [Customizing the Output File](#) on how to control the appearance and amount of detail in the output file produced by the GAMS compiler.

4.38.3.1 The Echo Print of the Input File

The *echo print* of the program is always the first part of the output file. It is a listing of the input with added line numbers. It is possible to control the listing output using `$offlisting` to suppress the echo print and `$onlisting` to turn the echo print on again. The first few lines of the echo print of the [Illustrative Model](#) follow:

```
A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)

 2
 4
   This is a mini mean-variance portfolio selection problem described in
   'GAMS/MINOS:Three examples' by Alan S. Manne, Department of Operations
   Research, Stanford University, May 1986.
10
11 * This model has been modified for use in the documentation
```

The default header of the GAMS listing file is `General Algebraic Modeling System`. This may be replaced using the `$title` at the start of a line. The text on that line will be the new header, as demonstrated above. After the header the compilation output is announced with the title `Compilation`.

The first three line numbers refer to empty lines in the input and line 11 is a comment line. If the lines on the input file are counted, it can be seen that this comment line appears after ten lines of dollar directives, comments and empty lines.

The dollar control options that follow in the model are used to display more information in the output file than the default and will be discussed in the subsections below.

Note

By default, dollar control option lines are not listed in the echo print. The `$onDollar` and `$offDollar` controls the echoing of [Dollar Control Options](#) lines in the listing file. Dollar control option lines are also listed if they contain errors.

The [block comment](#) enclosed by `$ontext` and `$offtext` is listed without line numbers, while [single line comments](#) starting with asterisks (*) are listed with the respective line numbers. Observe that line numbers always refer to the physical line number in the input file. The remainder of the echo print follows:

```
12
13 Set i securities /hardware, software, show-biz, t-bills/;
14 alias (i,j);
15
16 Scalar target target mean annual return on portfolio % /10/,
17         lowyield yield of lowest yielding security,

```

Lines in the echo print can be set to double space using `$double` and then reset to single space with `$single`. If errors were detected, the explanatory messages would be found at the end of the echo print. All discussions of error messages have been grouped together in the section [Error Reporting](#) below.

4.38.3.2 The Symbol Reference Map

The other parts of the compilation outputs are maps. They are extremely useful for users looking at a model written by someone else or trying to make changes in their own model after spending some time away from it. By default all maps are suppressed and can be turned on with dollar control options that are specified below.

The first map is the *symbol cross reference*. It can be turned on with the dollar control option `$onSymXRef` at the beginning of the program. The symbol cross reference map lists all identifiers (symbols) from the model in alphabetical order, identifies them as to data type, shows the line numbers where the symbols appear and classifies each appearance. The map that was generated as part of the output of our [Illustrative Model](#) is shown below:

Symbol Listing

SYMBOL	TYPE	REFERENCES
dmean	EQU	declared 42 defined 46 impl-asn 50 ref 49
dvar	EQU	declared 43 defined 47 impl-asn 50 ref 49
fsum	EQU	declared 41 defined 45 impl-asn 50 ref 49
highrisk	PARAM	declared 18 assigned 34 ref 35
i	SET	declared 13 defined 13 ref 14 20 26
37 45	2*46	2*47 control 33 34 45 46 47
j	SET	declared 14 ref 26 2*47 control 47

lowyield	PARAM	declared	17	assigned	33	ref	35			
mean	PARAM	declared	20	defined	21	ref	33	46		
portfolio	MODEL	declared	49	defined	49	impl-asn	50	ref	50	
target	PARAM	declared	16	defined	16	ref	46			
v	PARAM	declared	26	defined	26	ref	34	47		
variance	VAR	declared	38	impl-asn	50	ref	47	50	51	
x	VAR	declared	37	impl-asn	50	ref	39	45	46	2*47

In the first two columns the name and type of each identifier are given. For example, the last symbol listed is `x` which is defined to be of type `VAR`, a shorthand symbol for variable. The complete list of data types and their shorthand symbols is given below:

Shorthand Symbol	GAMS Data Type
ACRNM	acronym
EQU	equation
FILE	put file
MODEL	model
PARAM	parameter
SET	set
VAR	variable

For further details on data types in GAMS, see section [Data Types and Definitions](#).

The symbol `highrisk` was declared as a `scalar`, but is listed as a `parameter` in the map above. Recall that `parameters`, `scalars`, and `tables` are three *input formats* for the data type `parameter`. For more information, see the overview [Parameters, Scalars and Tables](#).

After the name and type of the identifier, a list of references to the symbol is given. References are grouped by reference type and identified by the line number in the output file. The actual reference can be found by referring to the echo print of the program, which has line numbers on it. In the case of the symbol `x` in the example above, the list of references as shown in the symbol reference map are as follows:

declared	37				
impl-asn	50				
ref	39	45	46	2*47	51

This means that `x` is declared on line 37, implicitly assigned through a `solve` statement on line 50 and referenced on lines 39, 45, 46, 47, and 51. The entry `2*47` means that there are two references to `x` on line 47 of the input file.

The complete list of reference types and their shorthand symbols in GAMS Output is given below:

Shorthand Symbol	Reference Type	Description
declared	Declaration	The identifier is declared as to type . This must be the first appearance of the identifier.
defined	Definition	An initialization (for a table or a data list between slashes) or symbolic definition (for an equation) starts for the identifier.
assigned	Assignment	Values are replaced because the identifier appears on the left-hand side of an assignment statement.
impl-asn	Implicit Assignment	An equation or variable will be updated as a result of being referred to implicitly in a solve statement.

Shorthand Symbol	Reference Type	Description
control	Control	A set is used as (part of) the driving index in an assignment, equation, loop or indexed operation .
ref	Reference	The symbol has been referenced on the right-hand side of an assignment or in a display, equation, model, solve statement or put statement.
index	Index	Like <code>control</code> , but used only for set <i>labels</i> . Appears only in the cross reference map of unique elements. See section The Unique Element Listing Map for details.

Note that the symbol reference map may be useful in model development, documentation preparation, and to make sure that all declared items are actually used in the model (by checking that they all have reference symbols in addition to `declared` and `defined`).

4.38.3.3 The Symbol Listing Map

The second optional map is the *symbol listing*. In the symbol listing map all identifiers are grouped alphabetically by [data type](#) and listed with their explanatory texts. This is another very useful aid for trying to understand a large model prepared by someone else. Note that expressive explanatory text is particularly helpful here. The symbol listing map can be turned on by entering a line containing the dollar control option `$onSymList` at the beginning of the program. The symbol listing map generated from our [Illustrative Model](#) follows:

SETS

```
i      securities
j      Aliased with i
```

PARAMETERS

```
highrisk  variance of highest security risk
lowyield  yield of lowest yielding security
mean      mean annual returns on individual securities (%)
target    target mean annual return on portfolio %
v         variance-covariance array (%-squared annual return)
```

VARIABLES

```
variance  variance of portfolio
x         fraction of portfolio invested in asset i
```

EQUATIONS

```
dmean    definition of mean return on portfolio
dvar     definition of variance
fsum     fractions must add to 1.0
```

MODELS

```
portfolio
```

4.38.3.4 The Unique Element Listing Map

The last optional map is the *Unique Element Listing* (UEL). The unique element listing map can be turned on by entering a line containing the dollar control option `$onUELList` at the beginning of the program. All unique elements are first grouped in entry order and then in sorted order with their explanatory texts:

Unique Element Listing

Unique Elements in Entry Order

```
1 hardware    software    show-biz    t-bills
```

Unique Elements in Sorted Order

```
1 hardware    show-biz    software    t-bills
```

In addition, a map with [references](#) for every label is given if the dollar control option `$onUELXRef` appears at the beginning of the program.

ELEMENT	REFERENCES					
hardware	declared	13	ref	21	27	28
show-biz	declared	13	ref	23	27	30
software	declared	13	ref	22	27	29
t-bills	declared	13	ref	24	27	31

The unique element list is important in the context of ordered sets. For details see section [Ordered and Unordered Sets](#).

4.38.3.5 The Include File Summary

Often the GAMS program includes a text file specified by the dollar control option `$include`. Consider the following example:

```
$include 'file1.inc'
Set i / i1*i10 /;
Scalar a; a = 7;
$include 'file2.inc'
```

The file `file1.inc` contains the following two lines:

```
Set j / j1*j5 /;
Parameter k(j);
```

The file `file2.inc` contains the following line:

```
a = a+3;
```

The echo print follows:

```
INCLUDE    C:\models\file1.inc
  2 Set j / j1*j5 /;
  3 Parameter k(j);
  4 Set i / i1*i10 /;
  5 Scalar a; a = 7;
INCLUDE    C:\models\file2.inc
  7 a = a+3;
```

Note that the contents of the two include files are expanded in the echo print and the include file names and their path is echoed in the lines with the dollar control option `$include`. If we insert the dollar control option `$offinclude` in the first line of the code, the echo print will not include the lines with the names of the include files any more, but the contents will still be echoed:

```
3 Set j / j1*j5 /;
4 Parameter k(j);
5 Set i / i1*i10 /;
6 Scalar a; a = 7;
8 a = a+3;
```

If the program contains include files, there will be an **Include File Summary** at the end of the compilation output. The include file summary of the simple example above (without the line `$offinclude`) follows. If `$offinclude` is active, it will be suppressed.

Include File Summary

SEQ	GLOBAL TYPE	PARENT	LOCAL	FILENAME
1	1 INPUT	0	0	C:\models\test.gms
2	1 INCLUDE	1	1	.C:\models\file1.inc
3	6 INCLUDE	1	4	.C:\models\file2.inc

In the first column the sequence number of the input files is given. Note that the parent file called by the GAMS call is always listed first. The second column gives the global (expanded) line number which contains the respective option `include` or one of its variants. The third column indicates the type of the respective file. An overview of the file types is given below:

File Type	Description
INPUT	The GAMS input file that was called with the GAMS call.
INCLUDE	A file that was inserted with the dollar command option <code>\$include</code> .
BATINCLUDE	A file that was inserted with the dollar command option <code>\$batinclude</code> .
LIBINCLUDE	A file that was inserted with the dollar command option <code>\$libinclude</code> .
SYINCLUDE	A file that was inserted with the dollar command option <code>\$sysinclude</code> .

The next column, named **PARENT**, provides the sequence number of the respective parent file. The column with the header **LOCAL** gives the local line number in the parent file where the file was included. The last column shows the path and the name of the respective file.

Note that compilation error messages in include files have additional information about the name of the include file and the local line number. For information on compilation errors, see section [Compilation Errors](#) below.

4.38.4 Execution Output

The execution output follows the compilation output in the GAMS listing file. It is introduced with the title `Execution`. The execution output is the output generated while GAMS is performing data manipulations and results from [display statements](#). The output from the display statement on line 33 of our [Illustrative Model](#) is shown below.

`E x e c u t i o n`

```
----      33 PARAMETER lowyield      =      7.000  yield of lowest yielding security
           PARAMETER highrisk       =      10.000  variance of highest security risk
```

If errors are detected because of illegal data operations, a brief message indicating the cause and the line number of the offending statement will appear. For further information on execution errors, see section [Execution Errors](#) below.

Note

In case there is no display statement before [The Solve Statement](#) in the model and there are no execution errors, there will be no execution output in the GAMS listing file.

4.38.5 Model Generation Output

The [model generation output](#), the [solution report](#), and the [post-solution Output](#) are produced when a [solve statement](#) is executed. The actions that are initiated by a solve statement are presented in section [Actions Triggered by the Solve Statement](#). All output generated as a result of a solve is labeled with a subtitle identifying the model, its type and the line number of the solve statement.

The output generated during model generation includes [equations listing](#), [variable listing](#), and [model statistics](#).

4.38.5.1 The Equation Listing

The *equation listing* is the first part of the output generated by a solve statement. It is marked with the subtitle `Equation Listing`. By default, the first three equations in every block are listed. This can be modified with the option [limrow](#). If there are three or fewer single equations in any equation block, then all the single equations are listed.

Note that by studying the equation listing the user may determine whether the model generated by GAMS is the the model that the user has intended - an extremely important question. This component of the output shows the specific equations generated within the model when the current values of the sets and parameters are plugged into the general algebraic form of the model.

The equation listing from our [Illustrative Model](#) is given below. In our case we have three equation blocks, each producing one single equation.

A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)
 Equation Listing SOLVE portfolio Using NLP From line 50

---- fsum =E= fractions must add to 1.0

fsum.. x(hardware) + x(software) + x(show-biz) + x(t-bills) =E= 1 ; (LHS = 0, INFES = 1 ****)

---- dmean =E= definition of mean return on portfolio

dmean.. 8*x(hardware) + 9*x(software) + 12*x(show-biz) + 7*x(t-bills) =E= 10 ; (LHS = 0, INFES = 10)

---- dvar =E= definition of variance

dvar.. (0)*x(hardware) + (0)*x(software) + (0)*x(show-biz) - variance =E= 0 ; (LHS = 0)

Note

The equation listing is an extremely useful debugging aid. It shows the variables that appear in each constraint. In addition, it shows what the individual coefficients and right-hand side values evaluate to after the data manipulations have been done.

Each equation block is marked with four dashes which are useful for mechanical searching. The name, [type of equation](#) and explanatory text is shown, followed by the individual equations.

Note

All the terms that depend on variables are collected on the left-hand side and all the constant terms are combined into one number on the right-hand side, any necessary sign changes being made.

Four places of decimals are shown if necessary, but trailing zeroes following the decimal point are suppressed. E-format is used to prevent small numbers to be displayed as zeros.

Note

Nonlinear equations are treated differently. If the coefficient of a variable in the equation listing is enclosed in parentheses, then the corresponding constraint is nonlinear, and the value of the coefficient depends on the activity levels of one or more of the variables. The listing is not algebraic, but shows the partial derivative of each variable evaluated at their current level values.

Note that in the equation listing from our example the equation dvar is nonlinear. A simpler example will help to clarify the point. Consider the following equation and associated level values.

eq1.. 2*sqr(x)*power(y,3) + 5*x - 1.5/y =e= 2; x.l = 2; y.l = 3 ;

This equation will appear in the equation listing as:

eq1.. (221)*x + (216.1667)*y =E= 2 ; (LHS = 225.5 ***)

The coefficient of x is determined by first differentiating the equation above with respect to x . This results in $2 \times (2 \times x.l) \times (y.l)^3 + 5$, which evaluates to 221, given that $x.l$ equals 2 and $y.l$ equals 3. Similarly, the coefficient of y is obtained by differentiating the equation above with respect to y , which results in $2 \times (x.l)^2 \times 3 \times (y.l)^2 + \frac{1.5}{(y.l)^2}$, giving 216.1667. Observe that the coefficient of y could not have been determined if its level had been left at zero. The attempted division by zero would have produced an error and premature termination. For further information on modeling NLP problems with GAMS, see the tutorial [Good NLP Formulations](#).

The result of evaluating the left-hand side of the equation at the initial point is shown at the end of each individual equation listing. In the example above it is 225.5, and the three asterisks(***) are a warning that the constraint is infeasible at the starting point.

Note

The order in which the equations are listed depends on how the model was defined. If it was defined with a list of equation names, then the listing will be in the order of that list. If it was defined as /all/, then the list will be in the order of declaration of the equations. The order of the entries for the individual constraints is determined by the label entry order.

4.38.5.2 The Column Listing

The *column listing* or *variable listing* is the next part of the output. It is marked with the title **Column Listing** and contains a list of the individual coefficients sorted by column rather than by row (like in the [equation listing](#)). By default the first three entries for each variable are shown, along with their lower bound .lo, upper bound .up and current level values .l. Note that the default number of entries shown may be modified with the option [limcol](#).

The format for the coefficients is exactly as in the equation listing, with the nonlinear coefficients enclosed in parentheses and the trailing zeroes dropped. The column listing from our [Illustrative Model](#) follows.

A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)

Column Listing SOLVE portfolio Using NLP From line 50

```
---- x  fraction of portfolio invested in asset i

x(hardware)
          (.LO, .L, .UP, .M = 0, 0, +INF, 0)
          1      fsum
          8      dmean
          (0)    dvar

x(software)
          (.LO, .L, .UP, .M = 0, 0, +INF, 0)
          1      fsum
          9      dmean
          (0)    dvar

x(show-biz)
          (.LO, .L, .UP, .M = 0, 0, +INF, 0)
          1      fsum
          12     dmean
          (0)    dvar
```

REMAINING ENTRY SKIPPED

```

---- variance  variance of portfolio

variance
          (.LO, .L, .UP, .M = -INF, 0, +INF, 0)
      -1   dvar

```

Note

The order in which the variables appear is the order in which they were declared.

4.38.5.3 The Model Statistics

The final information generated while a model is being prepared for solution is the statistics block. It is marked with the title `Model Statistics`. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of our [Illustrative Model](#) follow:

```

A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Model Statistics      SOLVE portfolio Using NLP From line 50

```

MODEL STATISTICS

BLOCKS OF EQUATIONS	3	SINGLE EQUATIONS	3
BLOCKS OF VARIABLES	2	SINGLE VARIABLES	5
NON ZERO ELEMENTS	12	NON LINEAR N-Z	3
CODE LENGTH	25	CONSTANT POOL	17

```

GENERATION TIME      =      0.004 SECONDS      4 MB

```

```

EXECUTION TIME      =      0.005 SECONDS      4 MB

```

The `BLOCK` counts indicate the number of GAMS symbols (`equations` and `variables`, respectively) appearing in the problem generated. The `SINGLE` counts indicate the number of individual rows and columns in the problem generated. The `NON ZERO ELEMENTS` entry refers to the number of nonzero coefficients in the problem matrix. To understand the remaining elements, some background will be useful.

For linear models, the model can be completely specified by the problem matrix and vectors for the RHS, etc. More is needed for nonlinear models. GAMS passes the nonlinear expressions defining the model algebra to the solvers in the form of *NL code* - opcode/address pairs in a simple stack-based language. For example, the expression `exp(x*y-1.675)` results in code similar to this:

```

PUSHV  column-index-of-x
MULV   column-index-of-y
SUBC   index-of-1.675
FUNC1  index-of-exp-function
STOR   index-of-row

```

In addition to containing indices referring to the rows and columns of the model, the NL code contains indices of constants used to define the model algebra. These constants are not contained in the NL code directly but rather in a separate pool or list of constants used for the model.

There are three entries that provide additional information about nonlinear models. The `NON LINEAR N-Z` entry refers to the number of nonlinear matrix entries in the model. Nonlinear models may differ in the complexity or size of the nonlinear expressions defining them. For example, `x*y` is a simpler form of nonlinearity than `exp(x*y)` and will require a shorter list of instructions to define, even though both of these terms result in two nonlinear entries in the matrix (one for `x` and one for `y`). The `CODE LENGTH` entry indicates the length of the NL code (i.e. number of instructions) required to define the model algebra, while the `CONSTANT POOL` indicates the length of the constant pool that is used by the NL code. In general, the more nonlinear a problem is, the more difficult it tends to be to solve.

The times that follow statistics are also useful. The `GENERATION TIME` is the time used since compilation (syntax check) is finished. This includes the time spent in generating the model. The measurement units are given and represent ordinary clock time on personal computers or central processor usage (CPU) time on other machines. Memory use is given in megabytes.

4.38.6 The Solution Report

The *solution report* is the next part of the output. It is marked with the title `Solution Report` and includes the [solve summary](#), the [solver report](#), the [solution listing](#), and the [report summary](#).

4.38.6.1 The Solve Summary

The *solve summary* contains details about the solution process and is marked with the title `SOLVE SUMMARY`. The first part of the solve summary is common to all solvers and is discussed in this subsection. The second part of the solve summary is solver specific, it is covered in the subsection [Solver Report](#) below. The first part of the solve summary for our [Illustrative Model](#) follows.

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Solution Report      SOLVE portfolio Using NLP From line 50
```

```

                S O L V E      S U M M A R Y

MODEL  portfolio                OBJECTIVE  variance
TYPE   NLP                      DIRECTION  MINIMIZE
SOLVER MINOS                    FROM LINE  50

**** SOLVER STATUS      1 Normal Completion
**** MODEL STATUS      2 Locally Optimal
**** OBJECTIVE VALUE                2.8990

RESOURCE USAGE, LIMIT      0.188      1000.000
ITERATION COUNT, LIMIT     5      2000000000
EVALUATION ERRORS          0          0
```

The entry `MODEL` contains the name of the model being solved, `TYPE` provides the [model type](#) of the model, `SOLVER` shows the name of the solver used to solve the model, `OBJECTIVE` gives the name of the objective variable being optimized, `DIRECTION` shows the direction of optimization being performed and the entry `FROM LINE` provides the line number of the solve statement the solve summary refers to.

Note that the four asterisks make it easy to find the solve summary if it is searched for mechanically.

The entries `SOLVER STATUS` and `MODEL STATUS` contain the solver and model status for the problem respectively. Their possible values are given in [Model Status](#) table and [Solver Status](#) tables below. The entry `OBJECTIVE VALUE` provides the value of the objective function at the termination of the solve. This value is the optimum value for the problem provided the solver and model have the right status.

The entry `RESOURCE USAGE, LIMIT` reports the amount of wall clock time (in seconds) taken by the solver and the upper limit allowed for the solver. Note that the solver will stop as soon as the limit on time usage has been reached. The default limit may be changed with the option `reslim`. Observe that the option statement `option reslim = x;` - where `x` is the desired limit in wall clock seconds - must be entered in the model *before* the solve statement.

The entry `ITERATION COUNT, LIMIT` provides the number of iterations used by the solver and the upper limit allowed for the solver. The solver will stop as soon as this limit is reached. The default limit on iterations used is practically infinity. This limit may be changed with the option `iterlim`. Observe that the option statement `option iterlim = n;` - where `n` is the desired limit of the iterations used - must be entered in the model *before* the solve statement.

Finally, the entry `EVALUATION ERRORS` reports the number of numerical errors encountered by the solver and the upper limit allowed for the solver. These errors result from numerical problems like division by zero. Note that this is suppressed for LP, RMIP and MIP models since evaluation errors are not applicable for these model types. The default limit on evaluation errors used is zero. This limit may be changed with the option `domlim`. Observe that the option statement `option domlim = n;` - where `n` is the desired limit of the evaluation errors allowed - must be entered in the model *before* the solve statement.

Value	Message	Description
1	OPTIMAL	The solution is optimal, that is, it is feasible (within tolerances) and it has been proven that no other feasible solution with better objective value exists. Note that the latter criterion is not influenced by the <code>optcr</code> and <code>optca</code> options.
2	LOCALLY OPTIMAL	A local optimum for an NLP has been found. That is, a solution that is feasible (within tolerances) and it has been proven that there exists a neighborhood of this solution in which no other feasible solution with better objective value exists.
3	UNBOUNDED	The solution is unbounded. This message is reliable if the problem is linear, but occasionally it appears for difficult nonlinear problems that are not truly unbounded, but that lack some strategically placed bounds to limit the variables to sensible values.
4	INFEASIBLE	The problem has been proven to be infeasible. If this was not intended, something is probably misspecified in the logic or the data.
5	LOCALLY INFEASIBLE	No feasible point could be found for the NLP problem from the given starting point. It does not necessarily mean that no feasible point exists.
6	INTERMEDIATE INFEASIBLE	The current solution is not feasible, but the solver stopped, either because of a limit (for example, iteration or resource) or because of some sort of difficulty. The solver status will give more information.
7	FEASIBLE SOLUTION	A feasible solution to a problem without discrete variables has been found.
8	INTEGER SOLUTION	A feasible solution to a problem with discrete variables has been found. There is more detail following about whether this solution satisfies the termination criteria (set by options <code>optcr</code> and <code>optca</code>).

Value	Message	Description
9	INTERMEDIATE NON-INTEGER	An incomplete solution to a problem with discrete variables. A feasible solution has not yet been found. See section Model Termination Conditions for MIPs for more information.
10	INTEGER INFEASIBLE	It has been proven that there is no feasible solution to a problem with discrete variables. See section Model Termination Conditions for MIPs for more information.
11	LIC PROBLEM - NO SOLUTION	The solver cannot find the appropriate license key needed to use a specific subsolver.
12	ERROR UNKNOWN	After a solver error the model status is unknown.
13	ERROR NO SOLUTION	An error occurred and no solution has been returned. No solution will be returned to GAMS because of errors in the solution process.
14	NO SOLUTION RETURNED	A solution is not expected for this solve. For example, the CONVERT solver only reformats the model but does not give a solution.
15	SOLVED UNIQUE	Indicates the solution returned is unique, i.e. no other solution exists. Used for CNS models. Examples where this status could be returned include non-singular linear models, triangular models with constant non-zero elements on the diagonal, and triangular models where the functions are monotone in the variable on the diagonal.
16	SOLVED	Indicates the model has been solved: used for CNS models. The solution might or might not be unique. If the solver uses status 17 - SOLVED SINGULAR wherever possible then this status implies that the Jacobian is non-singular, i.e. that the solution is at least locally unique.
17	SOLVED SINGULAR	Indicates the CNS model has been solved, but the Jacobian is singular at the solution. This can indicate that other solutions exist, either along a line (for linear models) or a curve (for nonlinear models) including the solution returned.
18	UNBOUNDED - NO SOLUTION	The model is unbounded and no solution can be provided.
19	INFEASIBLE - NO SOLUTION	The model is infeasible and no solution can be provided.

4.38.6.1.1 Model Status Note that the model status is stored in the model attribute [modelStat](#). For details on model attributes, see section [Model Attributes](#). Observe that there are [compile-time constants](#) that are related to this model attribute.

Value	Message	Description
1	NORMAL COMPLETION	The solver terminated in a normal way: it was not interrupted by a limit (resource, iterations, nodes or other) or by internal difficulties. The model status describes the characteristics of the accompanying solution.
2	ITERATION INTERRUPT	The solver was interrupted because it used too many iterations. The option iterlim may be used to increase the iteration limit if everything seems normal.
3	RESOURCE INTERRUPT	The solver was interrupted because it used too much time. The option reslim may be used to increase the time limit if everything seems normal.

Value	Message	Description
4	TERMINATED BY SOLVER	The solver encountered some difficulty and was unable to continue. More details will appear following the message.
5	EVALUATION INTERRUPT	Too many evaluations of nonlinear terms at undefined values. We recommend to use variable bounds to prevent forbidden operations, such as division by zero. The rows in which the errors occur are listed just before the solution.
6	CAPABILITY PROBLEMS	The solver does not have the capability required by the model. For example, some solvers do not support certain types of discrete variables or support a more limited set of functions than other solvers.
7	LICENSING PROBLEMS	The solver cannot find the appropriate license key needed to use a specific subsolver.
8	USER INTERRUPT	The user has sent a message to interrupt the solver via the interrupt button in the IDE or sending a Control+C from a command line.
9	ERROR SETUP FAILURE	The solver encountered a fatal failure during problem set-up time.
10	ERROR SOLVER FAILURE	The solver encountered a fatal error.
11	ERROR INTERNAL SOLVER FAILURE	The solver encountered an internal fatal error.
12	SOLVE PROCESSING SKIPPED	The entire solve step has been skipped. This happens if execution errors were encountered and the GAMS parameter ExecErr has been set to a nonzero value or the property MaxExecError has a nonzero value.
13	ERROR SYSTEM FAILURE	This indicates a completely unknown or unexpected error condition.

4.38.6.1.2 Solver Status Note that the solver status is stored in the model attribute [solveStat](#). For details on model attributes, see section [Model Attributes](#). Observe that there are [compile-time constants](#) that are related to this model attribute.

4.38.6.2 Solver Report

The next section in the listing file is the part of the solve summary that is particular to the solver program that has been used. This section normally begins with a message identifying the solver and its authors: [MINOS and QUADMINOS](#) was used in the example here. There will also be diagnostic messages in plain language if anything unusual was detected and specific performance details, some of them probably technical. The solver manual of the respective solver will help explain these. In case of serious trouble, the GAMS listing file will contain additional messages printed by the solver. This may help identify the cause of the difficulty. If the solver messages do not help, a perusal of the solver documentation or help from a more experienced user is recommended. The solver report from our [Illustrative Model](#) follows.

```
GAMS/MINOS
M I N O S  5.6      (Nov 2014)
```

```
GAMS/MINOS 5.6, Large Scale Nonlinear Solver
B. A. Murtagh, University of New South Wales
P. E. Gill, University of California at San Diego,
W. Murray, M. A. Saunders, and M. H. Wright,
Systems Optimization Laboratory, Stanford University
```

```

Work space allocated      --      0.77 Mb

EXIT - Optimal Solution found, objective:      2.899038

```

Note that the line `Work space allocated -- 0.77 MB` provides the amount of memory used by the solver for the problem. The solver estimates the amount of memory it will need to solve the problem. If this amount is not available on the machine used, GAMS will return a message saying that not enough memory was allocated. In addition, GAMS will return the maximum amount of memory available on the machine. The user may direct the solver to use less memory with the [model attribute](#) `.workspace`:

```
mymodel.workspace = x;
```

Here `mymodel` is the name of the model being solved as specified by the model statement and `x` is the amount of memory in Megabytes. Note that the solver will attempt to solve the problem with `x` MB of memory. However, it is not guaranteed to succeed since the problem may require more memory.

Note that more information for a successful run may be obtained using the option [sysout](#). As usual, the respective option statement should be placed *before* the solve statement.

4.38.6.3 The Solution Listing

The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed with four pieces of information. The solution listing may be suppressed with the option [solprint](#):

```
option solprint = off ;
```

This option statement should be placed *before* the solve statement. The solution listing generated from our [Illustrative Model](#) is shown below.

	LOWER	LEVEL	UPPER	MARGINAL
---- EQU fsum	1.0000	1.0000	1.0000	-13.5288
---- EQU dmean	10.0000	10.0000	10.0000	1.9327
---- EQU dvar	.	.	.	-1.0000

```

fsum  fractions must add to 1.0
dmean  definition of mean return on portfolio
dvar  definition of variance

```

```
---- VAR x  fraction of portfolio invested in asset i
```

	LOWER	LEVEL	UPPER	MARGINAL
hardware	.	0.3029	+INF	.
software	.	0.0865	+INF	6.217249E-15
show-biz	.	0.5048	+INF	.
t-bills	.	0.1058	+INF	EPS

	LOWER	LEVEL	UPPER	MARGINAL
---- VAR variance	-INF	2.8990	+INF	.

```
variance  variance of portfolio
```

The order of the equations and variables is the same as in the [symbol listing map](#).

The four columns associated with each entry correspond to the equation and variable attributes and have the following meaning:

LOWER lower bound (.lo)
 LEVEL level value (.l)
 UPPER upper bound (.up)
 MARGINAL marginal (.m)

For variables, the values in the LOWER and UPPER columns refer to the lower and upper bounds. For equations, they are obtained from the (constant) right-hand side value and from the relational type of the equation. For details see section [Variable Attributes](#) and [Equation Attributes](#). Note that instead of level values, slack values may be shown in equations. For more information, see section [Customizing the Output File](#) below.

Note

The LEVEL and MARGINAL values have been determined by the solver and the values shown are used to update the GAMS values. In the list they are shown with fixed precision, but the values are returned to GAMS with full machine accuracy. The single dots '.' on the list represent zeros.

EPS is the GAMS extended value used for a stored zero. It is common to see a marginal value given as EPS, since GAMS uses the convention that marginals are necessarily zero for basic variables and typically non-zero for other variables.

Note

EPS is used to indicate non-basic variables whose marginal values are at or close to zero, and for nonlinear problems to indicate superbasic variables whose marginals are at or close to zero. A superbasic variable is one between its bounds at the final point but not in the basis.

Note that in the [Glossary](#) there are brief explanations of technical terms that were used in this section.

For models that are not solved to optimality or for models types without an objective, some constraints may additionally be marked with certain flags. The list of these flags and their description is given in the following table.

Shorthand Symbol	Description
INFES	The row or column is infeasible . This mark is made for any entry where the level value is not between the upper and lower bounds.
NOPT	The row or column is non-optimal . This mark is made for any non-basic entries for which the marginal sign is incorrect, or superbasic ones for which the marginal value is too large.
UNBND	The row or column can increase without limit (e.g. in an unbounded ray) or has an excessively large magnitude.
REDEF	The equation type has been ignored or redefined for this solution point, e.g. because this is an MCP
REDIR	The equation has been flipped (i.e. negated or reoriented) in the model statement: useful for MCP and EMP
DEPND	The row or column is dependent on other rows or columns in the system: see CNS

4.38.6.4 Report Summary

The final section of the solution report is the report summary, marked with four asterisks (as are all important components of the output) followed by the title `REPORT SUMMARY`. It shows the count of rows or columns that have been marked `INFES`, `NOPT` or `UNBND` in the [solution listing](#). For model types like `MCP` where `REDEFs` and `REDIRs` are possible, the counts for these markers may also be shown. The sum of infeasibilities will be shown if the reported solution is infeasible. The domain error count is only shown if the problem is nonlinear. If there are variables or equations where the levels were projected to one of the bounds, the count of those is also shown here.

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Solution Report      SOLVE portfolio Using NLP From line 50
```

```
**** REPORT SUMMARY :           0      NONOPT
                                0 INFEASIBLE
                                0 UNBOUNDED
                                0      ERRORS
                                42 PROJECTED
```

4.38.7 Post-Solution Output

The final part of the listing file is the post-solution output. It contains [Final Execution Summary](#) and the [File Summary](#).

4.38.7.1 Final Execution Summary

The final execution summary is marked with the title `Execution` and contains the output from display statements that were placed *after* the solve statement in the model, allowing simple reporting. In addition, it shows the final execution time and memory use. The respective output from our [Illustrive Model](#) follows.

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
E x e c u t i o n
```

```
----      51 VARIABLE x.L  fraction of portfolio invested in asset i
hardware 0.303,      software 0.087,      show-biz 0.505,      t-bills 0.106
```

```
----      51 VARIABLE variance.L          =          2.899  variance of portfolio
```

```
EXECUTION TIME          =          0.001 SECONDS          3 MB
```

For further information on this output and ways to customize it, see chapter [The Display Statement](#).

4.38.7.2 File Summary

The file summary is the very last part of the output file. If output has been written to [put files](#), there will be a `REPORT FILE SUMMARY` that is marked with four asterisks. The report will list the put files with their internal names and the full paths of their external names.

All listing files have a `FILE SUMMARY` that is marked with four asterisks and that reports the names of the input and output (listing) files.

```
**** FILE SUMMARY
```

```
Input      C:\PROGRAM FILES\gamsIDE\ALAN.GMS
Output     C:\PROGRAM FILES\gamsIDE\ALAN.LST
```

If [work files](#) (save or restart) have been used, they will be listed in the file summary as well.

4.38.8 Error Reporting

All comments and descriptions about errors have been collected in this section for easy reference when disaster strikes.

Effective error detection and recovery are important parts of any modeling system. GAMS is designed around the assumption that the *error state* is the normal state of modeling. Experience shows that most compilations during the early stages of development will produce errors. Not to worry! The computer is much better at checking details than the human mind and should be able to provide positive feedback and suggestions about how to correct errors or avoid ambiguities. Developing a model is like writing a paper or an essay; many drafts and rewrites are required until the arguments are presented in the most effective way and meet all the requirements of proper English. GAMS acts like a personal assistant with knowledge of mathematical modeling and of the syntactic and semantic details of the language.

Errors are detected at various stages in the modeling process. Most of them are caught at the compilation stage, which behaves like the proofreading stage of the modeling process. Once a problem has passed through the rigorous test of this stage, the error rate drops to almost zero. Most of the execution runs, which are much more expensive than compilation, proceed without difficulties because GAMS *knows* about modeling and has anticipated problems. Many of the typical errors made with conventional programming languages are associated with concepts that do not exist in GAMS. Those error sources – like address calculations, storage assignment, subroutine linkages, input-output and flow control – create problems at execution time, are difficult to locate, often lead to long and frustrating searches, and leave the computer user intimidated. GAMS takes a radically different approach. Errors are spotted as early as possible, they are reported in a way that is comprehensible to the user, including clear suggestions for how to correct the problem and a presentation of the source of the error in terms of the problem of the user.

Note

All errors are marked with four asterisks '****' at the beginning of a line in the output listing.

As soon as an error is detected, processing will be stopped at the next convenient opportunity. A model will never be solved after an error has been detected. The only remedy is to fix the error and repeat the run.

Errors are grouped into the three phases of GAMS modeling: compilation, execution and model generation (which includes the solution that follows). In the following subsections we will discuss the errors that may occur in each of these phases.

4.38.8.1 Compilation Errors

Compilation errors are discussed in some detail in the tutorial [A GAMS Tutorial by Richard E. Rosenthal](#) and the tutorial [Fixing Compilation Errors](#). Note that there is some overlap between the material in the tutorials and this section. Several hundred different types of errors can be detected during compilation and can often be traced back to just one specific symbol in the GAMS input. Most of the errors are caused by simple mistakes: forgetting to declare an identifier, putting indices in the wrong order, leaving out a necessary semicolon or misspelling a label. For errors that are not caused by such simple mistakes, the explanatory error message text will help diagnose the problem and correct it.

Note

When a compilation error is discovered, a dollar symbol and error number are printed below the offending symbol (usually to the right) on a separate line that begins with four asterisks.

If more than one error is encountered on a line (possibly because the first error caused a series of other spurious errors) the dollar signs may be suppressed and error number squeezed. GAMS will not list more than 10 errors on any one line.

Note

A list of all error numbers encountered and a description of the probable cause of each error is printed at the end of the echo print of the program. The error messages are self-explanatory. For further information on compilation errors and advice on how to resolve them, see the tutorial [Fixing Compilation Errors](#).

It is worth noting that it is easy to produce a model that does not do what you want it to do, but does not contain errors in the sense that the term is being used in this section. The best precaution is to check your work carefully and build in as many automatic consistency checks as possible.

Note that if a GAMS reserved word is accidentally used for the name of a label or an identifier it is impossible to provide helpful error messages for technical reasons. This may cause confusion. We recommend users to familiarize themselves with the [reserved words](#).

Attention

In some cases an error may not be detected until the statement following its occurrence, where it may produce a number of error conditions whose explanations seem quite silly. We recommend to always check carefully for the cause of the first error in such a group. If nothing obvious is wrong, look at the previous statement and particularly watch out for missing semicolons.

The following example illustrates the general reporting format for compilation errors.

```

1 Set c crops / wheat, corn, wheat, longaname /
****
           $172
2 Parameter price(c) / wheat 200, cotton 700 /
****
           $170
3
Error Messages

170 Domain violation for element
172 Element is redefined

**** 2 ERROR(S)    0 WARNING(S)
..
**** USER ERROR(S) ENCOUNTERED
```

4.38.8.2 Compilation Time Errors

The reporting format for errors found while analyzing solve statements is more complicated than for normal compilation errors, mainly because many things must be checked. All identifiers referenced must be defined or assigned, the mathematics in the equations must match the model class, and so on. More elaborate reporting is required to accurately describe any problems found. The solve statement is only checked if the model has been found to be error free up to this point. This is not only because the check is comparatively expensive, but also because many erroneous and confusing messages can be produced while checking a solve in a program containing other errors.

Attention

Compiler error messages related to a solve statement are reported in two places and in two formats:

1. They are shown immediately after the solve statement with a short text including the name of any offending identifier and the type of model involved. This will be sufficient in most cases.
2. A longer message with some hints appears with the other error messages at the end of the compilation.

The example below illustrates the general reporting format for compiler errors associated with a solve statement.

```

1 Variables x, y, z ;
2 Equations eq1 , eq2 ;
3
4 eq1.. x**2 - y =e= z ;
5 eq2.. min(x,y) =l= 20 ;
6
7 Model silly / all / ;
8 solve silly using lp maximizing z ;
****                               $54,51,256
**** THE FOLLOWING LP ERRORS WERE DETECTED IN MODEL SILLY:
**** 54 IN EQUATION EQ1           .. ENDOG OPERANDS FOR **
**** 51 IN EQUATION EQ2           .. ENDOG ARGUMENT(S) IN FUNCTION
9

```

Error Messages

```

51 Endogenous function argument(s) not allowed in linear models
54 Endogenous operands for ** not allowed in linear models
256 Error(s) in analyzing solve statement. More detail appears
    Below the solve statement above

**** 3 ERROR(S)    0 WARNING(S)
**** USER ERROR(S) ENCOUNTERED

```

4.38.8.3 Execution Errors

Execution time errors are usually caused by illegal arithmetic operations such as division by zero or taking the log of a negative number. GAMS prints a message on the output file with the line number of the offending statement and continues execution. A GAMS program should never abort with an unintelligible message from the computer's operating system if an invalid operation is attempted. GAMS has rigorously defined an extended algebra that contains all operations including illegal ones. Note that the model [**CRAZY**] contains all non-standard operations and should be executed

to study for its exceptions. For advice on detecting and resolving execution errors, see the tutorial [Finding and Fixing Execution Errors and Performance Problems](#).

Recall that the GAMS arithmetic is defined over the closed interval $[-\text{INF}, +\text{INF}]$ and contains the [extended range arithmetic](#) values EPS (small but not zero), NA (not available) and UNDF (the result of an illegal operation). The results of illegal operations are propagated through the entire system and can be displayed with standard display statements. However, observe that, if errors have been previously detected, a model cannot be solved and a [work file](#) cannot be saved.

4.38.8.4 Solve Errors

The execution of a `solve` statement can trigger additional errors called *matrix errors*. They report on problems encountered during transformation of the model into a format required by the solver. Problems are most often caused by illegal or inconsistent bounds, or by an [extended range value](#) that is used as a matrix coefficient. The example below shows the general format of these errors:

```

1 Variable x;
2 Equation eq1;
3
4 eq1.. x =l= 10 ;
5 x.lo = 10 ;
6 x.up = 5 ;
7 Model wrong /eq1/;
8 solve wrong using lp maximizing x ;
9

**** Matrix error - lower bound > upper bound
x  (.LO, .L, .UP = 10, 0, 5)
...
**** SOLVE from line 8 ABORTED, EXECERROR = 1
...
**** USER ERROR(S) ENCOUNTERED

```

Some `solve` statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the [solution report](#). Note that by default the subsystems will interrupt the solution process if arithmetic exceptions are encountered. This may be changed with the option [domlim](#). They are then reported on the listing as shown in the following example:

```

1 Variable x, y;
2 Equation one;
3
4 one.. y =e= sqrt(10/x);
5 x.l = 10;
6 x.lo = 0;
7
8 Model divide / all / ;
9 solve divide maximizing y using nlp;

                S O L V E          S U M M A R Y

MODEL  divide          OBJECTIVE  y
TYPE   NLP             DIRECTION MAXIMIZE
SOLVER MINOS          FROM LINE  9

```

```

**** SOLVER STATUS      5 Evaluation Interrupt
**** MODEL STATUS      7 Feasible Solution
**** OBJECTIVE VALUE   3.1622776602E+0149

RESOURCE USAGE, LIMIT      0.182      1000.000
ITERATION COUNT, LIMIT    0      2000000000
EVALUATION ERRORS        2          0

EXIT - Function evaluation error limit exceeded.

**** ERRORS/WARNINGS IN EQUATION one
      2 error(s): div: FUNC SINGULAR: x/y, |y| <= 1e-150 (RETURNED 1E299)

**** REPORT SUMMARY :
          1      NONOPT ( NOPT)
          0 INFEASIBLE
          0 UNBOUNDED
          1      ERRORS ( ****)

```

Note that the solver status returned with a value of 5, meaning that the solver has been interrupted because more than `domlim` evaluation errors have been encountered. The type of evaluation error and the equation causing the error are also reported.

In case the solver returns an intermediate feasible solution because of evaluation errors, the following solve will still be attempted. The only fatal GAMS error that can be caused by a solver program, is the failure to return any solution at all. If this happens all possible information is listed on the GAMS output file and any solves that follow will not be attempted.

4.38.9 Customizing the Output File

This section reviews the most commonly used [dollar control options](#), [options](#), and [command line parameters](#) to customize output in the listing file. [Table 1](#) lists [dollar control options](#), [options](#), and [command line parameters](#) that are used in the input file to control the amount of detail in the output file produced by the GAMS compiler. [Table 2](#) lists [dollar control options](#) and [command line parameters](#) that can change the layout and appearance of the output. The first column of the two tables shows the purpose of customizing the output that differs from the GAMS default behavior.

The output generated by display statements can also be customized. This topic is covered in section [Display Controls](#) from chapter [The Display Statement](#). See also the complete list of dollar control options that affect the output format in section [Dollar Control Options Affecting the Output Format](#).

Table 1: *Customization of output to be included in the listing file*

Customization	Method	Further Details
suppress the echo print	\$offlisting	\$onlisting restores the default behavior. Any lines between \$offlisting and \$onlisting will not appear in the echo print.
suppress include files in the echo print	\$offinclude	\$oninclude restores the default behavior.
activate the symbol reference map	\$onSymXRef	Maps are most often turned on or off at the beginning of the program and left as initially set. \$onSymXRef activates the symbol reference map and \$offSymXRef restores the default behavior.

Customization	Method	Further Details
activate the symbol listing map	\$onSymList	Maps are most often turned on or off at the beginning of the program and left as initially set. \$onSymList activates the symbol listing map and \$offSymList restores the default behavior.
activate the unique element listing	\$onUELList	Maps are most often turned on or off at the beginning of the program and left as initially set. \$onUELList activates the unique element listing map and \$offUELList restores the default behavior.
activate the unique element reference map	\$onUELXRef	Maps are most often turned on or off at the beginning of the program and left as initially set. \$onUELXRef activates the unique reference map \$offUELXRef restores the default behavior.
suppress or expand the equation listing	option limrow	The statement <code>option limrow = 0;</code> will suppress the equation listing; the statement <code>option limrow = n;</code> will expand it to <code>n</code> equations. The statement must be placed <i>before</i> The Solve Statement .
suppress or expand the column listing	option limcol	The statement <code>option limcol = 0;</code> will suppress the column listing; the statement <code>option limcol = n;</code> will expand it to <code>n</code> columns. The statement must be placed <i>before</i> The Solve Statement .
suppress the solution listing	option solprint	The statement <code>option solprint = off;</code> will suppress the solution listing. The statement must be placed <i>before</i> The Solve Statement .
restrict output to just a few displays	save restart feature	With this strategy the listing file will contain only the output generated by the desired display statements. This facilitates concentrating on a narrow set of output while remaining capable of generating a lot more output. For details see section Generating Concise Listing Files in chapter The Save and Restart Feature .
show slack variables in the solution listing	option solslack	The statement <code>option solslack = 1;</code> causes the equation output in the solution listing to show slack (<code>.slack</code>) variable values instead of level (<code>.l</code>) values. The statement must be placed <i>before</i> The Solve Statement .

Table 2: Customization that changes the output layout

Customization	Method	Further Details
change the default header	<code>\$title</code>	The directive <code>\$title</code> causes every page on the output to have the header specified in <code>text</code> . The header may be reset later by using another line starting with <code>\$title</code> . Currently, the <code>text</code> may have up to 80 characters.
add a subheader	<code>\$stitle</code>	The statement <code>\$stitle text</code> causes every page on the output to have the subheader specified in <code>text</code> . The header may be reset later by using another line starting with <code>\$stitle</code> . Currently, the <code>text</code> may have up to 80 characters.
start a new page in the <code>echo print</code>	<code>\$seject</code>	
start a new page in LST file if less than <code>n</code> lines are left	<code>\$lines</code>	The directive is <code>\$lines</code> , where <code>n</code> is the number of lines left on the current page.
change width and length of a page	command line parameters <code>PageWidth</code> and <code>PageSize</code>	The general syntax is: <code>gams mymodel pw=n ps=m</code> . Here <code>n</code> is desired page width and the desired page length is <code>m</code> . Note that <code>pw</code> and <code>ps</code> are synonyms of <code>PageWidth</code> and <code>PageSize</code> respectively.
change the <code>echo print</code> to upper case only	<code>\$onUpper</code>	The directive <code>\$offUpper</code> restores the default.
change lines in the <code>echo print</code> to be double spaced	<code>\$double</code>	The directive <code>\$single</code> restores the default behavior.
change the marker <code>****</code>	<code>\$stars</code>	

4.39 GAMS Log

4.39.1 Introduction

The GAMS log provides the log of a GAMS run including the GAMS job description, defined command line parameters, license information, solver log, and GAMS compilation and execution output. Looking at the log gives a brief idea about the success of a GAMS run and is usually a useful first step in debugging a GAMS model. The detailed output from GAMS is displayed in the `output file`. Log output can be obtained in the form of a text file (typically with `.log` extension) that is generated with each GAMS run based on the command line parameters `logOption` and `logFile`. The GAMS log consists of three major sections: header, compilation log, and execution log.

4.39.2 Header

The header of the GAMS log consists of information that is independent of the content of the executed GAMS file. It contains the job description, parameter log, and license log.

4.39.2.1 Job Description

In this line, the name of the GAMS file being run along with a timestamp, the GAMS version and operating system information is provided.

```
--- Job trnsport.gms Start 08/30/21 17:29:15 36.1.0 r2c0a44a WEX-WEI x86 64bit/MS Windows
```

4.39.2.2 Parameter Log

The default parameters for the operating system and configuration are obtained via parameter file (gmsprmNT.txt on Windows, gmsprmun.txt on Linux, gmsprmun.txt on MacOS) and [gamsconfig.yaml](#) files. The parameter log explicitly lists all additional parameters in the following lines. For example, input displays the full path of the GAMS input file. In the example log provided below, the output file option [PageSize](#) is set to 0. ScrDir is the full path to the scratch directory; SysDir is the full path to the systems directory, [logOption](#) is defined that controls the location of the output log.

```
--- Applying:
    C:\GAMS\36\gmsprmNT.txt
    C:\Users\jsmith\Documents\GAMS\gamsconfig.yaml
--- GAMS Parameters defined
    Input C:\test\trnsport.gms
    PageSize 0
    ScrDir C:\test\225a\
    SysDir C:\GAMS\36\
    LogOption 3
    ErrMsg 1
    ErrorLog 99
    IDE 1
    LstTitleLeftAligned 1
```

4.39.2.3 License Log

This section provides information about the license such as licensee, the organization, and the license number is provided on the second line. The full path to the license file that is being read is provided on the third line. The last line in the image shows the GAMS license type being used.

```
Licensee: John Smith                                G201001/0001CS-GEN
           The ACME Corporation, USA                  DC0000
           C:\Users\jsmith\Documents\GAMS\gamslice.txt
           Other time limited license
```

4.39.2.4 Processor Information and GAMS version

This section provides information about the processor and GAMS version being used.

```
Processor information: 1 socket(s), 8 core(s), and 16 thread(s) available
GAMS 36.1.0 Copyright (C) 1987-2021 GAMS Development. All rights reserved
```

4.39.3 Compilation Log

A GAMS run consists of two phases: [compilation and execution](#). The following lines provide details about the compilation, memory usage, the time elapsed in compilation. The number in parentheses refers to the line number in the [echo print](#) of the input file. In addition to the above-mentioned output, this part of the log also contains information about the output such as [GDX files](#), the files included using [\\$include](#), and outputs of commands such as [\\$call](#) as shown in the following lines.

```

--- Starting compilation
--- clad.gms(27) 2 Mb
--- $echo File C:\test\includefilename.gms
--- clad.gms(30) 2 Mb
--- . includefilename.gms(1) 2 Mb
--- clad.gms(32) 2 Mb
--- call echo "hello!"
"hello!"
--- clad.gms(45) 3 Mb
--- GDXin=C:\test\claddat.gdx
--- GDX File ($gdxIn) C:\test\claddat.gdx
--- clad.gms(164) 3 Mb

```

4.39.4 Execution Output

The beginning of the execution phase of the GAMS run is clearly indicated in the GAMS log:

```

--- Starting execution: elapsed 0:00:00.010

```

In general, the execution log output indicates the progress of the GAMS job, including line numbers, memory usage, elapsed time for the run, and time required for long-running statements. Several statements also result in specific log output.

Output of GDX files generated using [execute_unload](#) is shown in the log as follows.

```

--- GDX File (execute_unload) path\to\outputfile.gdx

```

The output for [reference files](#) generated is shown in the log as follows.

```

--- RefFile path\to\trnsport.ref

```

Similarly, the information about a file written using the [Put writing facility](#) is mentioned in the log as follows.

```

--- Putfile results path\to\results.txt

```

The output of the program flow control features such as [abort](#) is shown as follows.

```

*** Error at line 61: Execution halted: abort$1 'model not solved as expected'

```

If there are loops in the program, the log shows information about the current iteration as follows.

```
--- LOOPS scen = s1
```

Similar to the output of call command shown during compilation phase, the output for execute command is shown in the execution phase. The following line of GAMS code

```
execute "echo output of execute command";
```

will result in the following output in the log.

```
--- trnsport.gms(67) 4 Mb  
output of execute command
```

For each [solve statement](#), there will also be a [solver log](#) embedded in the execution output (see [below](#) for details regarding the solver log). After a solver log, the execution output continues. It ends with the status of the GAMS Job (here ***** Status: Normal completion**), a timestamp and the total run time of the GAMS job.

```
--- Executing after solve: elapsed 0:00:02.892  
--- trnsport.gms(66) 4 Mb  
*** Status: Normal completion  
--- Job trnsport.gms Stop 08/30/21 17:29:18 elapsed 0:00:02.892
```

4.39.4.1 Solver Log

One of the most important GAMS statements is the [solve statement](#): a solve results in a substantial amount of log output.

The first line in the execution output is about model generation. Model generation can take a long time in which case the log also shows progress and equations that take long to generate.

```
--- Generating LP model transport  
--- trnsport.gms(64) 4 Mb  
--- 6 rows 7 columns 19 non-zeroes
```

After model generation, the solver name and [solveLink](#) are displayed.

```
--- Executing CPLEX (SolveLink=2): elapsed 0:00:02.066
```

The log output following this line is specific to the solver and will usually display the objective function value.

```
Optimal solution found  
Objective:          153.675000
```

4.40 The GAMS Call and Command Line Parameters

There are multiple ways to trigger the run of a GAMS model: Running a model via F9 from [GAMS Studio](#), executing `GAMSJob.Run` method in the object oriented APIs or calling the `gams` executable from a command line. In all cases the same GAMS engine runs the user's model. Several options are available to customize the GAMS run. Depending on the particular way GAMS is triggered these options are supplied in different ways. For example, in Studio via the parameter editor in the [toolbar](#), in the object oriented API through the `GAMSOptions` class, and from the command line via command line arguments. In order to avoid confusion with the often used word *option* we refer to these entities as *command line parameters* and demonstrate its with the `gams` executable from the command line. Although details will vary with the type of computer and operating system used, the general operating principles are the same on all machines.

In this chapter we will introduce how GAMS is called from the command line and how parameters may be specified on the command line or in other ways. In addition, we will discuss [user-defined command line parameters](#), [compile-time variables](#) and [compile-time constants](#), which are GAMS specialties, and [environment variables in GAMS](#). Moreover, most of the chapter is dedicated to the [detailed description of all GAMS options](#) (i.e. options available via command line parameters, [option statement](#), and [model attribute](#)).

In almost all cases such a run continues from start to end without any user interaction. A GAMS run usually consists of two phases: the [compilation and execution phase](#).

4.40.1 The Generic GAMS Call

The simplest way to start GAMS from a command shell is to enter the following command from the system prompt:

```
> gams myfile
```

GAMS will compile and execute the GAMS statements in the file `myfile`. If a file with this name cannot be found, GAMS will look for a file with the extended name `myfile.gms`. During the run GAMS will print a log to the console and create a [listing file](#) that is written by default to the file `myfile.lst`. For example, the following statements retrieves and runs the model `[TRANSPORT]` from the GAMS model library with the responds from the GAMS system:

```
> gamslib transport
Copy ASCII : transport.gms
> gams transport
--- Job transport Start 06/21/17 06:23:45 24.8.4 r60966 WEX-WEI x86 64bit/MS Windows

--- trnsport.gms(68) 3 Mb
*** Status: Normal completion
--- Job trnsport.gms Stop 06/21/17 06:23:46 elapsed 0:00:01.249

```

Note

GAMS can also run source files that have been compressed with [Posix utility gzip](#) or have been encrypted with tool [ENDECRYPT](#), for example

```

> gamslib trnsport
> gzip trnsport.gms
> gams trnsport.gms.gz

```

results in

- retrieval of the **[TRANSPORT]** model from the **GAMS Model Library**
- compression the source file `trnsport.gms`
- GAMS running the compressed file `trnsport.gms.gz`.

Observe that some GAMS options may be [specified on the command line](#) as part of the GAMS call. In addition, command line parameters may be set by [specifying a secondary customization parameter file](#) and by [modifying the GAMS system parameter file](#). As command line parameters may be specified in several different ways, there are [rules of precedence](#) in case of conflicting instructions. We will discuss these topics in the next four subsections.

4.40.1.1 Specifying Options Through the Command Line

GAMS permits certain options to be passed through the command line. The syntax of the simple GAMS call is extended as follows:

```
> gams myfile key1=value1 key2=value2 ...
```

Here `key1` is the name of the option that is being set on the command line and `value1` is the value to which the option is set. Depending on the option, `value1` could be a character string, an integer number or a real number. Note that the options that may be set on the command line are called *GAMS command line parameters*.

For example, consider the following commands to run the transportation model **[TRANSPORT]**:

```

> gams trnsport o myrun.lst logOption 2
> gams trnsport -o myrun.lst -logOption 2
> gams trnsport /o myrun.lst /logOption 2
> gams trnsport o=myrun.lst logOption=2
> gams trnsport -o=myrun.lst -logOption=2
> gams trnsport /o=myrun.lst /logOption=2

```

All six commands above are equivalent: each directs the output listing to the file `myrun.lst`. Note that `o` is the synonym of the command line parameter `output` and it is set to the value `myrun.lst`. In addition, the parameter `LogOption` is set to 2, which has the effect that the log output is redirected to the file `trnsport.log`. Please also note that the option name can be specified without consideration of the casing of the option. Hence `logoption` works as well as `LogOption` or any other casing. The way options are specified can vary with each option. So a mixed alternative, e.g. `gams trnsport -o=myrun.lst /logoption 3` is valid too.

In addition to predefined command line parameters, GAMS also allows user-defined command line parameters which work in tandem with compile-time variables. User-defined parameters, also called *double dash parameters*, and compile-time variables are introduced in section [Double Dash Parameters, Compile-Time Variables and Environment Variables](#) below.

4.40.1.1.1 Option Values with Spaces One may want to set string valued options including double dash parameters to an empty string or a string containing spaces, even trailing or leading spaces. All this requires the use of quotes. Quotes may be handled differently, depending on the operating system. Users should be attentive when using such string values. This is also important if GAMS is called from within a GAMS program with `$call [=]gams ...` and `execute [=]gams ...` because platform independence might be violated.

A platform independent way to set a string value with spaces is to use the variant that separates the option name and option value by a space, e.g. `opt ""`. The variant without space, e.g. `opt=""` might cause issues on some Unix shells. Consider the following example where `spacy.gms` contains only the following line to write the content of the double dash parameter `dd` to the log:

```
$log value of dd: >%dd%<
```

Here is a sequence of GAMS runs with a variety of string values

```

> gams spacy --dd normal
> gams spacy --dd "normal"
> gams spacy --dd ""
> gams spacy --dd " leading"
> gams spacy --dd "trailing "
> gams spacy --dd " leading and trailing "
> gams spacy --dd "  "

```

that result on all platforms in the following log output (only relevant part):

```

value of dd: >normal<
value of dd: >normal<
value of dd: ><
value of dd: > leading<
value of dd: >trailing <
value of dd: > leading and trailing <
value of dd: >  <

```

An even better way to pass arguments to a GAMS run without the system shell interfering with interpretation of some characters is described in the next section.

Attention

GAMS options specifying file names may also contain leading and trailing blanks. Please be aware that while leading blanks in a file name are significant on all platforms, trailing blanks are only significant on some platforms (e.g. Linux). Hence output "my`model.lst` " and output "my`model.lst`" refer to the same file on Windows and to different files on Linux.

4.40.1.2 Specifying Options Through a Secondary Parameter File

Command line parameters may also be set by specifying a secondary customization parameter file. For example, we will create a file with the following two lines, call it `moreOptions.txt` and save it in the current working directory.

```
limCol=0  
limRow=0
```

Note that setting `limcol` and `limrow` to zero will suppress the [column listing](#) and [equation listing](#) respectively. Moreover, note that we can specify the option in different way in this secondary parameter file, even have multiple options on one line. In the next step we will use the following command to run the transportation model `[TRANSPORT]`:

```
> gams trnsport parmFile=moreOptions.txt
```

Note that this call has the same effect as the following specification:

```
> gams trnsport limCol=0 limRow=0
```

Observe that [command line parameter include files](#) are particularly useful if modelers wish to use the same set of command line parameters repeatedly.

If options are listed multiple times on the command line, the last specification sets the option. This is important in particular in combination with a secondary parameter file. In the following example, GAMS will operate with `limRow=0`:

```
> gams trnsport limRow=10 parmFile=moreOptions.txt
```

while with the order reversed, GAMS operates with `limrow=10`:

```
> gams trnsport parmFile=moreOptions.txt limRow=10
```

4.40.1.3 Specifying Options Through the GAMS System Parameter File

A third way to specify command line parameters is by modifying the GAMS system parameter file, which is part of the GAMS system. It has different names depending on the operating system: `gmsprmnt.txt` for Windows and `gmsprmun.txt` for UNIX/Linux and Mac OS X. The parameter file may be modified in the following way:

```
*****
* GAMS 2.50 default Unix parameter file *
* Gams Development Corp. *
* Date : 4 May, 1998 *
*****
* entries required by CMEX, put in by the gams script
* SYSDIR
* SCRDIR
* SCRIPTNEXT
* INPUT
PageWidth 95
ParmFile "c:\some\central\location\moreOptions.txt"
```

Note that the last two lines were added to the standard GAMS system parameter file. As a consequence, each GAMS run will have a print width of 95 columns on the pages of the listing file. In addition, the command line parameters specified in the file `moreOptions.txt` will now apply to each GAMS run.

4.40.1.4 The GAMS Configuration in YAML Format

The GAMS configuration file `gamsconfig.yaml` written in the [YAML](#) format is easy to process by humans and computers. The [GAMS Configuration Editor](#) can be used to view and edit the GAMS configuration file but any other text editor can be used as well. This file has three configuration sections: command line parameters (`commandLineParameters`), operating system environment variables (`environmentVariables`), and external solver configuration (`solverConfig`). The latter is only relevant if you need to make a solver available to GAMS that is not shipped with the GAMS distribution. The [COIN-OR GAMSlinks project](#) has solver (links), e.g. Couenne, that could be added this way.

The first two sections are most easily described by an example:

```
commandLineParameters:
  - intVarUp:
      value: 1
  - eolCom:
      value: '// '
      maxVersion: 31
  - eolCom:
      value: '#'
      minVersion: 32
environmentVariables:
  - GDXCOMPRESS:
      value: 1
      maxVersion: 31
  - GDXCOMPRESS:
      value: 0
      minVersion: 32
  - PATH:
      value: /my/path/to/R/bin:/my/path/to/R/site-bin
      minVersion: 31.1.0
      maxVersion: 31.1.0
      pathVariable: True
```

In this example, the `gamsconfig.yaml` initializes some command line parameters and some environment variables. It initializes `intVarUp` unconditionally to 1. It also sets `eolCom` to the character sequence `//` for GAMS version 31 and earlier, while it uses the character `#` for GAMS version 32 and later. The keywords `minVersion` and `maxVersion` allow to have different entries for the same command line parameter for different versions. Also the file `gamsconfig.yaml` allows the repetition of entries. Hence, when GAMS runs it will filter all entries with appropriate `minVersion` and `maxVersion` and applies the setting of entries in sequence, so the last entry wins. Similarly, GAMS sets the environment variables `GDXCOMPRESS` to 0 or 1 depending on the actual version of GAMS. The last entry to set the `PATH` environment variable will be only applied for the GAMS version 31.1.0. Moreover, the indicator `pathVariable` set to `True` will result in prefixing the environment variable `PATH` with `/my/path/to/R/bin:/my/path/to/R/site-bin`.

The YAML syntax for the `gamsconfig.yaml` file is straightforward. Each section starts with a fixed name (`commandLineParameters` or `environmentVariables`) and is followed by a list of entries. Each entry starts with `-` and the name of the command line parameter or the name of the environment variable followed by a colon `:`. The next lines start with a keyword (`value`, `minVersion`, `maxVersion` and for environment variables also `pathVariable`) followed by a colon `:` and a value. The syntax of YAML files is very simple but it is crucial to use a consistent alignment. So all entries of a section must be perfectly aligned. Please be careful when mixing spaces and the tab character. If GAMS complains during the processing of a `gamsconfig.yaml` file with e.g. `System problems in yaml_parser_parse: mapping values are not allowed in this context` most likely your alignment is off as in the following erroneous example:

```
commandLineParameters:
  - eolCom:
    value: '// '
    maxVersion: 31
```

The lines with `value` and `maxVersion` need to start in the same column. There are plenty of online syntax checkers for YAML files. Use your favorite search engine and search for `yaml validator` (check the popular [YAML validator](#)) and copy and paste your problematic `gamsconfig.yaml` to get more insight into the YAML syntax problem. Moreover, the `gamsconfig.yaml` file has some required fields and some requirements for the value of some keys. In fact there is a schema file that validates that a syntactically correct `gamsconfig.yaml` fulfills the GAMS schema for configuration files. The schema file is part of the distribution and can be found in the system directory (`gamsconfig_schema.json`). One can validate a `gamsconfig.yaml` against this schema via a Python program (you might need to install additional Python packages `jsonschema` and `ruamel.yaml`):

```
import jsonschema
from ruamel.yaml import YAML
import json

with open('gamsconfig_schema.json') as f:
    schema = json.load(f)

yaml = YAML(typ="safe")
with open('gamsconfig.yaml') as f:
    config = yaml.load(f)

print(jsonschema.validate(instance=config, schema=schema))
```

Besides the required fields like `value` the schema also imposes restrictions on some value types (e.g. `True` and `False` for `pathVariable` and a proper release number for `minVersion` and `maxVersion`). The form of the release number can be just the major release (e.g. 31), the major and minor release number (e.g. 31.1) or the full detailed release number, e.g. 31.1.0. So if `maxVersion` is set to e.g. 31 then all releases of 31 fulfill this version requirement.

Some parts of the GAMS system react on environment variables, e.g. the environment variable `GMSPYTHONLIB` decides about the Python library and installation used for embedded Python code. At the start of a GAMS run environment variables are set to the values given in the `gamsconfig.yaml` file. This is a convenient way to manage GAMS-related environment variables without utilizing OS-specific ways to set environment variables.

GAMS will process a sequence of `gamsconfig.yaml` files. It starts with the file in the GAMS system directory and then searches through some system-wide and user-specific [standard locations](#).

Note

With GAMS 32 new defaults for a couple of options have been introduced. The system directory contains a file `gams31config.yaml` with default values used by GAMS 31 (and previous versions). Copy this file as `gamsconfig.yaml` to a location searched by GAMS to continue to work with the older defaults.

4.40.1.4.1 Adding Solvers via `gamsconfig.yaml` The third section in the GAMS configuration file `gamsconfig.yaml` allows to make a solver not shipped with GAMS available to the GAMS system. For that, an interface between an instantiation of a GAMS model and a solver needs to be implemented by use of libraries `GMO` and `GEV`. The [COIN-OR GAMSlinks project](#) provides examples of such solver interfaces. For the remainder of this section assume that we want to introduce a new version of the MINLP/MIQCP solver `SHOT`. GAMS knows about available solvers from the sub-system configuration file `gmscmpNT.txt` (`gmscmpun.txt` for non-Windows platforms). Here is a section from this file for the MINLP/MIQCP solver `SHOT` on Windows:

```
SHOT 1001 5 000102030405 1 0 2 MINLP MIQCP
gmsgennt.cmd
gmsgennx.exe
shtclib64.dll sht 1 1
```

The `gamsconfig.yaml` file provides the same information in a more descriptive way:

```
solverConfig:
- SHOT2:
  minVersion: 33
  fileType: 1001
  dictType: 5
  licCodes: 000102030405
  defName: optshot.def
  scriptName: gmsgennt.cmd
  executableName: gmsgennx.exe
  library:
    libName: D:\Users\janeDoe\Downloads\gamslink\GamsShot-20.dll
    auditCode: sht
    solverInterfaceType: 1
    threadSafeIndic: True
  modelTypes:
    - MINLP
    - MIQCP
```

The new solver will be called `SHOT2` and has almost the identical information as the solver `SHOT` that comes with GAMS. We could also use the name `SHOT` again. This would hide the original solver `SHOT` and use the one described by `gamsconfig.yaml`. In addition to the solver information, this section allows the keywords `min/maxVersion` that instructs whether to include the solver depending on the GAMS version.

The `fileType` (line 1 second item in the section of `gmscmpNT.txt`) determines the type of the scratch files that contain the model instance. The one-digit determines binary (1) or text (0) format of the scratch files. The ten-digit determines whether GAMS puts the initial marginal information into the scratch

files (1 for writing, 0 for not writing). The scratch file with the constraint matrix is stored column wise, the hundred-digit instructs GAMS to write (if at 1) the row count per column, so the solver can layout memory in advance for storing the constraint matrix. With GAMS' current libraries `gmo` and `gev` this information is not used and hence the hundred-digit should be at 0. The thousand-digit is about scaling. A non-zero value instructs GAMS to write the information stored in the `.scale/.prior/.stage` variable and equation attributes into the scratch files. With a value of 1 this is only done if `scaleOpt/priorOpt` are on. With a value of 2 this information is written independently of `scaleOpt/priorOpt`. With a value of 3 for models with variable and matching information (e.g. MCP) the reported marginals will be scaled by GAMS. The ten thousand-digit is always 0 and the hundred thousand-digit (if set to 1) instructs GAMS to write the variable/equation matching information to the scratch files for models that need this information (e.g. MCP). The leading zeros of the value for key `fileType` should be omitted.

The `dictType` (line 1 third item in the section of `gmscmpNT.txt`) decides about the type of the dictionary scratch file that contains the mapping information between the GAMS names and the variable and equation indexes seen by the solver. For example, this helps the solver to form good variable and equation names for error messages. Four values are allowed:

- 0: no dictionary information
- 5: dictionary with all labels that are used in the model instance
- 15: dictionary with all labels that are used in GAMS program
- 25: dictionary with all labels that are used in GAMS model plus an extra GDX file with the entire GAMS database (similar to `execute_unload "everything";` prior to the solve statement)

The `licCode` (line 1 fourth item in the section of `gmscmpNT.txt`) gives a guess about what license codes are required to run the solver. This is not the actual license information but allows other programs like e.g. "GAMS Studio" to list the solvers available with a particular license. In most cases solvers that are added this way should list the GAMS BASE license codes "000102030405".

The `defName` (line 2 second item in the section of `gmscmpNT.txt`) points to a file that contains all the solver options for the solver. This key does not need to be provided (same in `gmscmpNT.txt`) if the `defName` is `opt + solvername + .def` and the file resides in the GAMS system directory. Since we use the name SHOT2 GAMS would expect the solver options to be in `optshot2.def`. If there were an `optshot.def` in the GAMS system directory for the original SHOT, we could reuse that file and list `optshot.def` for the `defName` key. The `defName` provided here is used by other programs like "GAMS Studio" that can assist with building solver options files.

The next three items on line 1 in the section of `gmscmpNT.txt` are for internal purposes and not discussed here in detail. They can be set via `gamsconfig.yaml` via the keys `defaultOkFlag` and `hiddenFlag` with values `True` or `False`.

GAMS has different ways of calling a solver controlled by the `solveLink` option. The `scriptName` (line 2 in the section of `gmscmpNT.txt`) contains the name of the script that calls the solver (in case of `solveLink=0` (`chainScript`) or 1 (`callScript`)). For solvers that are capable of `solveLink=5` (`loadLibrary`) a generic script `gmsgennt.cmd` (or `gmsgenus.run`) can be used. The `executableName` (line 3 in the section of `gmscmpNT.txt`) provides the name of the solver executable. Again for solvers capable of `solveLink=5` (`loadLibrary`) a generic executable `gmsgennx.exe` (or `gmsgenux.out`) can be used.

The section `library` is necessary only for solvers capable of `solveLink=5` (`loadLibrary`). The `libName` contains the name of the solver library file (line 3 first item in the section of `gmscmpNT.txt`). The `auditCode` (line 3 second item in the section of `gmscmpNT.txt`) is the prefix of the functions in the solver library (e.g. `shtCallSolver`). The `solverInterfaceType` (line 3 third item in the section of `gmscmpNT.txt`) defines the API implemented by the solver library and loaded by GAMS. Currently, there are only two types: 1 (`xyzReadyApi` and `xyzCallSolver`) and 2 (`xyzCallSolver` only). The `threadSafeIndic` (line 3 third item in the section of `gmscmpNT.txt`) indicates whether the solver library is thread-safe and can be used in combination with `solveLink=6` (`aSyncThreads`).

The final section `modelTypes` is about the model types the solver can handle. This information can be found in line 1 after item 7 in `gmscmpNT.txt`.

4.40.1.5 Order of Precedence for Options

The order of precedence for command line parameters including customization specifications in the GAMS IDE is as follows:

1. Command line parameters that are specified on the command line or in the Studio/IDE command line field.
2. Command line specifications in the IDE options window **Execute** (this is reached through File|Options|Execute).
3. Command line specifications in the specific IDE dialogs, e.g. **Output** (this is reached through File|Options|...).
4. Entries in the GAMS configuration files `gamsconfig.yaml`.
5. Entries in the GAMS system parameter file.

Many command line parameters initialize the `default` for a GAMS Option also accessible inside the GAMS program. For example, the system default for option `MIQCP` is `SBB`. If the command line parameter `MIQCP` has been set, e.g. to `DICOPT`, `DICOPT` will be new default `MIQCP` solver. Inside the GAMS program, one can reset the `MIQCP` via option `MIQCP=BonMin`; but setting it back to the default will result in `DICOPT` (not `SBB`) being the default solver: `option MIQCP=default;`

4.40.2 Double Dash Parameters, Compile-Time Variables and Environment Variables

In this section we will cover double-dash parameters that enable users to set values for specific variables on the command line. These variables are substituted with their respective specified values at *compile* time. We will also discuss how operating system specific environment variables may be accessed and modified from a GAMS program.

4.40.2.1 Double Dash Parameters and Compile-Time Variables: A Simple Example

We will introduce double dash parameters and compile-time variables using as an example the well-known transportation model [`TRANSPORT`]. Assume we wish to explore how the solution changes if the demand assumes various values. To model this, we will introduce the compile-time variable `DMULT`, a multiplier for the demand `b`:

```
$set DMULT 1
...
demand(j) .. sum(i, x(i,j)) =g= %DMULT% * b(j) ;
```

Note that `DMULT` is defined with the dollar control option `$set` and its value is set to 1, which corresponds to the base line. Observe that the compile-time variable is referenced in the equation with the `%. . .%` notation. `%DMULT%` will be replaced at compile time by its value, in this case 1. We are now in the position to run the program multiple times by just changing the value of `DMULT` in the first line, which will automatically change the multiplier in the equation to the respective value.

GAMS offers a more convenient way for setting a compile-time variable like `DMULT` to a variety of values:

```

$if not set DMULT $set DMULT 1
...
demand(j) .. sum(i, x(i,j)) =g= %DMULT% * b(j) ;

```

Note that we set a default value for `DMULT` using [conditional compilation](#). We may change this default on the command line when calling GAMS by specifying `DMULT` as a [double dash parameter](#) as follows:

```
> gams trnsport.gms --DMULT=0.9
```

Observe that with the specification `--DMULT=0.9` the compile-time variable `DMULT` is set and therefore the default does not apply. Thus the double dash parameter facilitates changing the value of a compile-time variable directly on the command line as part of the GAMS call while the respective GAMS file remains unchanged.

Assume that the model contains a second compile-time variable called `METHOD` that acts as a switch for various methods of solving the model and it may take the values 1, 2 and 3. In this case both compile-time variables may be set on the command line as follows:

```
> gams trnsport.gms --DMULT=1.12 --METHOD=3
```

In the next two subsections we will discuss double dash parameters and compile-time variables in more detail.

4.40.2.2 Double Dash Parameters

Double dash parameters are user-defined command line parameters that are used to define [scoped compile-time variables](#) or to assign values to scoped compile-time variables. The general syntax is:

```
> gams myfile --NAME=value
```

Here `NAME` is the name of the double dash parameter and `value` is its assigned value that may be any string. If the string contains spaces or other token terminating characters, the string value should be quoted. Consider the following simple example:

```
> gams myfile --keycity=Boston --myvalue=7.6 --dothis="display x;"
```

Suppose that `myfile.gms` contains the following lines with the scoped compile-time variables `keycity`, `myvalue` and `dothis`:

```

x("%keycity%")=%myvalue%;
%dothis%

```

Note that the compile-time variables are referenced using the notation `%. . .%`. The GAMS call above has the effect that at compile time the compile-time variables are substituted with the values specified through the double dash parameters resulting in the following:

```

x("Boston")=7.6;
display x;

```

GAMS offers three alternative syntax variants for defining double dash parameters:

```
> gams myfile //NAME=value
> gams myfile /-NAME=value
> gams myfile -/NAME=value
```

Note that the four syntax variants may be used interchangeably and have the same effect.

Double dash parameters are particularly useful for specifying granularity when modeling a discretization of time and or space. For example, in the model [CHAIN] the problem is to find the chain with minimal potential energy, assuming the chain has uniform density, is suspended between two points and has a given length L. Consider the following code snippet:

```
$if not set nh $set nh 50
Set nh / i0*i%nh% /;
```

The first two lines use “conditional compilation” to set a default value for the compile-time variable `nh`. Note that the value of `nh` determines the cardinality of the set `nh`, which is used for the discretization. The value of `nh` may be easily set on the command line to any desired value using `nh` as a double dash parameter:

```
> gams chain --nh=100
```

Note that the double dash functionality supersedes the command line parameters `user1`, ..., `user5` which are accessible in the source file via `%gams.user1%`, ..., `%gams.user5%`. The example above would work with `user1` in the following way:

```
$set nh 50
$if not "%gams.user1"==" " $set nh %gams.user1%
Set nh / i0*i%nh% /;
```

The modified code could be called with:

```
> gams chain user1=100
```

Note that the double dash parameters facilitate using meaningful names instead of the generic names `user1`, ..., `user5`. This is especially useful if there are multiple parameters to pass on to the GAMS program.

Observe that the dollar control option `$setDDLlist` may be used to ensure that a model can only be run with the listed double dash parameters:

```
$setDDLlist nh
$if not errorFree $log *** Only allowed double dash options is: --nh=value
```

4.40.2.3 Compile-Time Variables

Compile-time variables are special variables that are substituted with their values at compile-time. They are not declared and defined with regular declaration statements like standard symbols (sets, parameters, ...), but they are defined with the dollar control option `$set` and its variants. There are three kinds of compile-time variables that differ in their scope level: local, scoped and global. An overview is given in [Table 1](#).

Scope	Availability	Defined with	Removed from the system with
Local	Available only in the input file where they are defined	<code>\$setLocal.</code>	<code>\$dropLocal</code>
Scoped	Available in the input file where they are defined and in all include files of the input file.	<code>\$set</code>	<code>\$drop</code>
Global	Available in the input file where they are defined, in all parent files and in all include files.	<code>\$setGlobal</code>	<code>\$dropGlobal</code>

Table 1: Scope Levels for Compile-Time Variables in GAMS

Note that *scoped* compile-time variables may also be defined on the command line with [double dash parameters](#). For example, in the example [above](#) the compile-time variable `DMULT` may be referenced in the equation `demand` without being defined with the dollar control option `$set` as long as it is defined and set on the command line. Note further, that *global* compile-time variables are saved in [work files](#).

While the scope of a compile-time variable cannot be directly changed, but dropping and adding variables in different scopes accomplishes the same. Consider the following example:

```
$set MYVAR xxx

* From scoped to global
$ifThen set MYVAR
$ setGlobal MYVAR %MYVAR%
$ show
$ drop MYVAR
$ show
$endif

* From global to local
$ifThen setGlobal MYVAR
$ setLocal MYVAR %MYVAR%
$ show
$ dropGlobal MYVAR
$ show
$endif
```

Note that the compile-time variable `MYVAR` is first defined as a *scoped* variable with the value `xxx`. The dollar control option `ifThen` tests whether `MYVAR` was defined with `$set` and since this is `TRUE` the next four dollar control statements are processed: a new *global* compile-time variable called `MYVAR` is defined and is set to the value of the *scoped* compile-time variable `MYVAR`, the resulting compile-time variables are shown, the *scoped* compile-time variable is removed from the system with the option `$drop` and the resulting compile-time variables are shown again. A similar procedure is followed to change the *global* compile-time variable `MYVAR` to a *local* compile-time variable with the same name and value.

The output generated by the four dollar control options `$show` follows:

Level	SetVal	Type	Text
0	MYVAR	SCOPED	xxx
0	MYVAR	GLOBAL	xxx

Level	SetVal	Type	Text
0	MYVAR	GLOBAL	xxx
Level	SetVal	Type	Text
0	MYVAR	LOCAL	xxx
0	MYVAR	GLOBAL	xxx
Level	SetVal	Type	Text
0	MYVAR	LOCAL	xxx

Observe that this report is called *Environment Report*. This name is unfortunate, since the variables reported are in fact compile-time variables. Environment variables in GAMS are discussed in section [Environment Variables in GAMS](#) below.

Note that if a compile-time variable is referenced with `%MYVAR%`, it could reference a global, scoped or local compile-time variable called `MYVAR`. GAMS will always access the compile-time variable `MYVAR` with the most local scope. Thus if all three scopes are defined, the local compile-time variable is accessed first, then the scoped and then the global, as demonstrated in the following example:

```
$set XXX scoped
$setLocal XXX local
$setGlobal XXX global
$log %XXX%
$dropLocal XXX
$log %XXX%
$drop XXX
$log %XXX%
$dropGlobal XXX
$log %XXX%
```

The resulting log output will be:

```
local
scoped
global
%XXX%
```

Note that how `%XXX%` will be handled if no compile-time variable `XXX` is defined, is determined by the command line parameter [stringChk](#).

For a full list of dollar control options that affect compile-time variables, see section [Dollar Control Options for Compile-Time](#)

4.40.2.4 Environment Variables in GAMS

GAMS programs have access to operating system s via `%sysEnv.NAME%`. Operating system environment variables may be modified or new environment variables may be defined with the dollar control option [\\$setEnv](#). Consider the following artificial example:

```

$log %sysEnv.GEORGE%
$setEnv GEORGE Dantzig
$log %sysEnv.GEORGE%
$dropEnv GEORGE
$log %sysEnv.GEORGE%

```

Note that the dollar control option `$dropEnv` removes an environment variable. The log output follows:

```

%sysEnv.GEORGE%
Dantzig
%sysEnv.GEORGE%

```

There are two environment variables in GAMS that are specific to the [GDX facility](#): `GD_CONVERT` and `GD_COMPRESS`. Since GDX is used by utilities and other programs some general customization can be achieved via these environment variables. Their values determine the type of GDX files that are written. These environment variables may be overwritten through the command line parameters `gd_convert` and `gd_compress` or inside the GAMS file with the dollar control option `$setEnv`. Consider the following example that uses the latter functionality:

```

Scalar x /1/;
$log %sysEnv.GD_CONVERT%
$log %sysEnv.GD_COMPRESS%
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

$setEnv GD_CONVERT v6
$setEnv GD_COMPRESS 1
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

$setEnv GD_CONVERT v7
$setEnv GD_COMPRESS 0
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

```

Note that `gdxdump` is a [GDX utility](#) that writes the contents of a GDX file as a GAMS formatted text file. The switch `-v` lets `gdxdump` print the file version information. With the `grep` utility we filter the lines that contain either `File format` or `Compression`. This code is run with the following call that initializes `GD_COMPRESS` and `GD_CONVERT`:

```
> gams gdxenv.gms gd_compress=0 gd_convert=v6 lo=3
```

The output follows:

```

--- Starting compilation
v6
0
--- gdxenv.gms(7) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
* File format      :    6
* Compression      :    0
--- gdxenv.gms(14) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
* File format      :    6
* Compression      :    1
--- gdxenv.gms(21) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
* File format      :    7
* Compression      :    0
--- gdxenv.gms(22) 2 Mb
--- Starting execution - empty program

```

4.40.3 Compile-Time Constants

Compile-time constants are constants that are related to some [functions](#), [model attributes](#) or [options](#). They have a fixed value and are referenced as `%prefix.constant%`. Here `prefix` is the name of the respective function, model attribute or option and `constant` is the name of the constant.

For example, the function [handleStatus](#) is used in the context of [grid computing](#). Typically, a [collection loop](#) may take the following form:

```
loop(pp$(handleStatus(h(pp)) = 2), ... );
```

Alternatively, the following formulation may be used:

```
loop(pp$(handleStatus(h(pp))=%handleStatus.ready%), ... );
```

Observe that the compile-time constant `%handleStatus.ready%` equals the value of 2. See the table below for other compile-time constants that are related to the function `handleStatus`.

Note

Compile-time constants are replaced at compile time and cannot be manipulated or reassigned.

Though compile-time constants are most often used in the context of the function, model attribute or option indicated with the prefix, they are in fact context free and may be used anywhere where an integer is expected. Consider the following example:

```
Scalar x / %solPrint.on% /; display x;
```

A complete list of the compile-time constants is given in [Table 2](#).

Table 2: Compile-Time Constants

Compile-Time Constant	Value
%handleStatus.Unknown%	0
%handleStatus.running%	1
%handleStatus.ready%	2
%handleStatus.failure%	3
%modelStat.optimal%	1
%modelStat.locally Optimal%	2
%modelStat.unbounded%	3
%modelStat.infeasible%	4
%modelStat.locallyInfeasible%	5
%modelStat.intermediateInfeasible%	6
%modelStat.feasibleSolution%	7
%modelStat.integerSolution%	8
%modelStat.intermediateNon-Integer%	9
%modelStat.integerInfeasible%	10
%modelStat.licensingProblem%	11
%modelStat.errorUnknown%	12
%modelStat.errorNoSolution%	13
%modelStat.noSolutionReturned%	14
%modelStat.solvedUnique%	15
%modelStat.solved%	16
%modelStat.solvedSingular%	17
%modelStat.unbounded-NoSolution%	18
%modelStat.infeasible-NoSolution%	19
%platformCode.Unknown%	0
%platformCode.DEG%	1
%platformCode.LEG%	2
%platformCode.WEX%	3
%solPrint.off%	0
%solPrint.on%	1
%solPrint.silent%	2
%solPrint.summary% (deprecated)	0
%solPrint.report% (deprecated)	1
%solPrint.quiet% (deprecated)	2
%solveLink.chainScript%	0
%solveLink.callScript%	1
%solveLink.callModule%	2
%solveLink.aSyncGrid%	3
%solveLink.aSyncSimulate%	4
%solveLink.loadLibrary%	5
%solveLink.aSyncThreads%	6
%solveLink.threadsSimulate%	7
%solveOpt.replace%	0
%solveOpt.merge%	1
%solveOpt.clear%	2
%solveStat.normalCompletion%	1

Compile-Time Constant	Value
%solveStat.iterationInterrupt%	2
%solveStat.resourceInterrupt%	3
%solveStat.terminatedBySolver%	4
%solveStat.evaluationInterrupt%	5
%solveStat.capabilityProblems%	6
%solveStat.licensingProblems%	7
%solveStat.userInterrupt%	8
%solveStat.setupFailure%	9
%solveStat.solverFailure%	10
%solveStat.internalSolverFailure%	11
%solveStat.solveProcessingSkipped%	12
%solveStat.systemFailure%	13

4.40.4 GAMS Compile Time and Execution Time Phase

The GAMS log indicates different phases of a job run in the log file:

```
...
--- Starting compilation
...
--- Starting execution: elapsed 0:00:00.056
...
```

During compilation GAMS converts the GAMS user program into lower-level instructions that are executed during execution time. Before the user program is converted into lower-level instructions the compiler processes the input: the [compile time variables](#) and [macros](#) are substituted and comments are removed. Moreover, during compilation any [dollar control option](#) present in the user code is *executed*. Many of these dollar control options impact the behavior of the compilation phase (e.g. [\\$include](#) instructs the compiler to process a file before continuing processing the remaining part of the current file). The code the compiler actually converts into lower-level instructions is echoed (by default) to the [listing file](#). The compiler also assembles the [list of user symbols](#) (sets, parameters, variables, ...) and the [list of labels](#). These lists become immutable after the compiler finishes. So during execution time, for example, no new labels can be added. The only exception from this is during a continued compilation/execution using the [save and restart facility](#). The separation between compile time and execution time is confusing especially for novice users and mistakes as the following are frequent:

```
file fInput / data.txt /;
scalar iCnt; for (iCnt=1 to 100, put fInput iCnt:0:0 /); putClose fInput;
set i /
$include data.txt
    /;
```

The intention of the code, that does *not* work, is clear: The [put facility](#) is used to create the input file `data.txt` that is included via the [\\$include](#) instruction. The problem with this code is that the [\\$include](#) instruction is *executed* at compile time while the code using the `put` statement is executed at execution time, i.e. after the compilation phase is over. Hence, the compiler tries to include this file *before* the `put` instructions are executed. If the file `data.txt` is not present, the compiler will terminate with a compilation error, but if a file with name `data.txt` is present this one will be processed by the [\\$include](#) and a mistake like this might remain undiscovered for a long time.

Most of the time GAMS performs compilation and execution in one GAMS job which makes it even harder to grasp the concept of compile and execution time. The command line parameter [action](#) can be used to separate the compilation and execution phase into multiple jobs.

4.40.5 List of Command Line Parameters

In the following two subsections we will present an overview of the command line parameters with brief descriptions. Detailed descriptions of all command line parameters follow in section [Detailed Descriptions of All Options](#) below.

4.40.5.1 General Options

Option	Description
action	GAMS processing request
appendExpand	Expand file append option
appendLog	Log file append option
appendOut	Output file append option
asyncSolLst	Print solution listing when asynchronous solve (Grid or Threads) is used
captureModelInstance	Switch to capture all model instances within a run
case	Output case option for LST file
cErr	Compile time error limit
charSet	Character set flag
checkErrorLevel	Check errorLevel automatically after executing external program
curDir	Current directory
decryptKey	Key to decrypt a text file that was encrypted via \$encrypt
dFormat	Date format
digit	Switch default for "\$on/offDigit"
docFile	Filename stem for documentation files
dumpOpt	Writes preprocessed input to the file input.dmp
dumpOptGDX	Defines a GDX file name stem created when using DumpOpt
dumpParms	GAMS parameter logging
dumpParmsLogPrefix	Prefix of lines triggered by DumpParms>1
empty	Switch default for "\$on/offEmpty"
encryptKey	Key to encrypt a text file using \$encrypt
eolCom	Switch default for "\$on/offEolCom" and "\$eolCom"
eolOnly	Single key-value pairs (immediate switch)
epsToZero	Treat eps as zero when unloading to GDX
errMsg	Placing of compilation error messages
errNam	Name of error message file
error	Force a compilation error with message
errorLog	Max error message lines written to the log for each error
etLim	Elapsed time limit in seconds
execMode	Limits on external programs that are allowed to be executed
expand	Expanded (include) input file name
fdDelta	Step size for finite differences
fdOpt	Options for finite differences
fErr	Alternative error message file
fileCase	Casing of file names and paths (put,.gdx, ref, \$include, etc.)
fileStem	Sets the file stem for output files which use the input file name as stem by default
fileStemApFromEnv	Append a string read from an environment variable to the "FileStem"
filtered	Switch default for "\$on/offFiltered"

Option	Description
forceWork	Force GAMS to process a save file created with a newer GAMS version or with execution errors
forLim	GAMS looping limit
freeEmbeddedPython	Free external resources at the end of each embedded Python code blocks
G205	Use GAMS version 2.05 syntax
GDX	GAMS data exchange file name
gdxCompress	Compression of generated GDX file
gdxConvert	Version of GDX files generated (for backward compatibility)
gdxUels	Unload labels or UELs to GDX either squeezed or full
gridDir	Grid file directory
gridScript	Grid submission script
heapLimit	Maximum Heap size allowed in MB
IDCGDXInput	GDX file name with data for implicit input
IDCGDXOutput	GDX file name for data for implicit output
IDCGenerateGDX	Specify GDX file name of input and output side of data contract
IDCGenerateGDXInput	Specify GDX file name of input side of data contract
IDCGenerateGDXOutput	Specify GDX file name of output side of data contract
IDCGenerateJSON	Specify JSON file name of data contract
IDCJSON	Specify JSON file name to verify data contract
IDCProtect	Flag to control assignment protection of external input symbols
IDE	Integrated Development Environment flag
inlineCom	Switch default for "\$on/offInline" and "\$inlineCom"
input	Input file
inputDir, inputDir1..40	Input file directories
interactiveSolver	Allow solver to interact via command line input
jobTrace	Job trace string to be written to the trace file at the end of a GAMS job
keep	Controls keeping or deletion of process directory and scratch files
libIncDir	LibInclude directory
license	Use alternative license file
listing	Switch default for "\$on/offListing"
logFile	Log file name
logLine	Amount of line tracing to the log file
logOption	Log option
lstTitleLeftAligned	Write title of LST file all left aligned
maxExecError	Execution time error limit
maxGenericFiles	Maximum number of generic file names tried at execution time file creation
maxProcDir	Maximum number of 225* process directories
MCPRHoldFx	Print list of rows that are perpendicular to variables removed due to the holdfixed setting
multiPass	Multipass facility
noNewVarEqu	Triggers a compilation error when new equations or variable symbols are introduced
on115	Generate errors for unknown unique element in an equation
output	Listing file name
pageContr	Output file page control option
pageSize	Output file page size (=0 no paging)
pageWidth	Output file page width
parmFile	Command Line Parameter include file

Option	Description
pLicense	Privacy license file name
prefixLoadPath	Prepend GAMS system directory to library load path
previousWork	Indicator for writing workfile with previous workfile version
procDir	Process Directory
procDirPath	Directory to create process directory in
procTreeMemMonitor	Monitor the memory used by the GAMS process tree
procTreeMemTicks	Set wait interval between memory monitor checks: ticks = milliseconds
profile	Execution profiling
profileFile	Write profile information to this file
profileTol	Minimum time a statement must use to appear in profile generated output
putDir	Put file directory
putND	Number of decimals for put files
putNR	Numeric round format for put files
putPS	Page size for put files
putPW	Page width for put files
pyMultInst	GAMS/Python Multiple Instance Interpreter
reference	Symbol reference file
referenceLineNo	Controls the line numbers written to a reference file
scrDir	Scratch directory
scrExt	Scratch file extension to be used with temporary files
scrNam	Work file names stem
seed	Random number seed
showOSMemory	Show the memory usage reported by the Operating System instead of the internal counting
stepSum	Summary of computing resources used by job steps
strictSingleton	Error if assignment to singleton set has multiple elements
stringChk	String substitution options
suffixDLVars	Switch default for "\$on/offSuffixDLVars"
suppress	Compiler listing option
symbol	Symbol table file
sys10	Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer
sys11	Dynamic resorting if indices in assignment/data statements are not in natural order
sys12	Pass model with generation errors to solver
sys15	Automatic switching of data structures used in search records
sys16	Disable search record memory (aka execute this as pre-GAMS 24.5)
sys17	Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)
sys18	Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers
sys19	Disable permutation on Column Generation (aka execute this as pre-GAMS 36)
sysDir	GAMS system directory where GAMS executables reside
sysIncDir	SysInclude directory
tabIn	Tab spacing
tFormat	Time format

Option	Description
threadsAsync	Limit on number of threads to be used for asynchronous solves (solveLink=6)
timer	Instruction timer threshold in milli seconds
trace	Trace file name
traceLevel	Modelstat/Solvestat threshold used in conjunction with action=GT
traceOpt	Trace file format option
user1..5	User strings
warnings	Number of warnings permitted before a run terminates
workDir	Working directory
zeroRes	The results of certain operations will be set to zero if abs(result) LE ZeroRes
zeroResRep	Report underflow as a warning when abs(results) LE ZeroRes and result set to zero

4.40.5.2 Solver-Related Options

Option	Description
bRatio	Basis detection threshold
CNS	Constrained Nonlinear Systems - default solver
DNLP	Non-Linear Programming with Discontinuous Derivatives - default solver
domLim	Domain violation limit solver default
EMP	Extended Mathematical Programs - default solver
forceOptFile	Overwrites other option file section mechanism
holdFixed	Treat fixed variables as constants
holdFixedAsync	Allow HoldFixed for models solved asynchronously as well
integer1..5	Integer communication cells
intVarUp	Set mode for default upper bounds on integer variables
iterLim	Iteration limit of solver
limCol	Maximum number of columns listed in one variable block
limRow	Maximum number of rows listed in one equation block
LP	Linear Programming - default solver
MCP	Mixed Complementarity Problems - default solver
MINLP	Mixed-Integer Non-Linear Programming - default solver
MIP	Mixed-Integer Programming - default solver
MIQCP	Mixed Integer Quadratically Constrained Programs - default solver
MPEC	Mathematical Programs with Equilibrium Constraints - default solver
NLP	Non-Linear Programming - default solver
nodLim	Node limit in branch and bound tree
optCA	Absolute Optimality criterion solver default
optCR	Relative Optimality criterion solver default
optDir	Option file directory
optFile	Default option file
QCP	Quadratically Constrained Programs - default solver
resLim	Wall-clock time limit for solver
RMINLP	Relaxed Mixed-Integer Non-Linear Programming - default solver
RMIP	Relaxed Mixed-Integer Programming - default solver
RMIQCP	Relaxed Mixed Integer Quadratically Constrained Programs - default solver
RMPEC	Relaxed Mathematical Programs with Equilibrium Constraints - default solver

Option	Description
savePoint	Save solver point in GDX file
scriptExit	Program or script to be executed at the end of a GAMS run
scriptFrst	First line to be written to GAMSNEXT file.
solPrint	Solution report print option
solveLink	Solver link option
solver	Default solver for all model types that the solver is capable to process
solverCntr	Solver control file name
solverDict	Solver dictionary file name
solverInst	Solver instruction file name
solverMatr	Solver matrix file name
solverSolu	Solver solution file name
solverStat	Solver status file name
subSys	Name of subsystem configuration file
sysOut	Solver Status file reporting option
threads	Number of threads to be used by a solver
workFactor	Memory Estimate multiplier for some solvers
workSpace	Work space for some solvers in MB

4.40.5.3 Save and Restart Options

Option	Description
fSave	Creates a forced work file , i.e., the file is saved even if execution errors or other errors occurred
restart	Name of a restart file, see The Save and Restart Feature
restartNamed	Name of another matching restart file, see Obfuscated Work Files
save	Creates a work file, see The Save and Restart Feature
saveObfuscate	Creates an obfuscated work file, see Obfuscated Work Files
symPrefix	Prefix all symbols encountered during compilation by the specified string in work file
xSave	Creates a compressed work file
xSaveObfuscate	Creates a compressed obfuscated work file

4.40.6 Detailed Descriptions of All Options

In this section we will give detailed descriptions of all options that may be used as command line parameters, in [option statements](#) or as [model attributes](#). Note that we indicate for each entry the context in which the option is available. Observe that the options are listed in alphabetical order for easy reference.

action (*string*): GAMS processing request

Synonym: A

Available: Command line

This option controls the way GAMS processes the input file. In particular GAMS currently processes the input file in [multiple phases](#) and this allows one to restrict the phases used. The two phases in order are:

- *Compilation* During this pass, the file is compiled, and syntax errors are checked for. Data initialization statements like scalar, parameter, and table statements are also processed during this stage.

- *Execution* During this stage, all execution time statements including assignments, loops, and solves are executed.

The special action **GT** is related to the creation of [trace reports](#). See also option [traceLevel](#) for details.

Default: **CE**

Value	Meaning
R	Restart After Solve
C	CompileOnly
E	ExecuteOnly
CE	Compile and Execute
GT	Trace Report

appendExpand (*boolean*): Expand file append option

Synonym: **AE**

Available: Command line

This option controls the manner of file opening of the option [expand](#).

Default: 1

Value	Meaning
0	Reset expand file
1	Append to expand file

appendLog (*boolean*): Log file append option

Synonym: **AL**

Available: Command line

This option is used in conjunction with the setting of [logOption](#) to 2 and 4, where the log from the GAMS run is redirected to a file. Setting this option to 1 will ensure that the log file is appended to and not overwritten (replaced).

Default: 0

Value	Meaning
0	Reset log file
1	Append to logfile

appendOut (*boolean*): Output file append option

Synonym: **AO**

Available: Command line

Setting this option to 1 will ensure that the listing file is appended to and not overwritten (replaced).

Default: 0

Value	Meaning
0	Reset listing file
1	Append to listing file

asyncSolLst (*boolean*): Print solution listing when asynchronous solve (Grid or Threads) is used

Available: Command line, Option statement

This option determines whether the solution listing is printed in the listing file when an asynchronous (grid or threads) solve is used and the function [handleCollect](#) or command [execute_loadHandle](#) successfully collect the results.

Default: 0

Value	Meaning
0	Do not print solution listing into lst file for asynchronous solves
1	Print solution listing into lst file for asynchronous solves

bRatio (*real*): Basis detection threshold

Available: Command line, Option statement, Attribute statement (use before solve)

The **bRatio** value is used to detect whether the initial point (levels and marginals) passed to the solver represents a basis suitable for use by the solver.

Certain (pivotal) solution procedures can restart from an advanced basis that is constructed automatically using existing basis information, i.e. they do a *warm start*. This option is used to influence whether a warm start is done or not. GAMS provides a hint to the solver to suggest whether a basis can or might be extracted from the initial point. The hint is based on the number of rows with nonzero marginals and is computed internally as:

```
hint := (0 == bRatio) or (rowsWithNonzeroMarg > nRows * bratio)
```

Note that setting **bRatio** to 1 causes the hint to be false, while setting **bRatio** to 0 causes the hint to be true. Note also that this is only a hint to the solver: some solvers (e.g. barrier methods) do not use this hint value.

Default: 0.25

captureModelInstance (*boolean*): Switch to capture all model instances within a run

Available: Command line

This option is a debugging option that helps to capture, if set to 1, the model instances that are generated and solved during the execution of the `solve` commands in a GAMS run. This is particularly important if one needs to make a model instance available to GAMS technical support to investigate a solver failure or analyze poor solver performance. The model instances are stored in separate files with names `gamsNNN.gms` where *NNN* is an increasing number. So sorting the files by time or name will correspond to the order in which these instances have been generated and solved. The format of the model instance is the [GAMS scalar format](#) and the instance is captured *before* the instance is solved by the selected solver, hence it contains the starting point but not the solution point.

Another way of capturing model instances becomes useful (and is triggered independent of this option) in case the user model does modularization by calling other GAMS programs that

execute a solve statement via the GAMS executable. Since options are not automatically passed on to the GAMS subprocesses one might miss capturing some model instances. Moreover, due to constant folding and rounding in the scalar model format, the run of a scalar model instance might not reproduce a particular problematic issue of the original solve. Hence GAMS can capture the binary scratch files produced by the solve statement when executed under `solveLink=0` in a ZIP file. This is activated by setting a system environment variable named `ZIPSCRDIR_PGAMS` (e.g. `set ZIPSCRDIR_PGAMS=mymodel`). The content of this environment variable is used as a prefix for the ZIP file names, e.g. `mymodelNNN.zip` where `NNN` is an increasing number. Such ZIP files can help GAMS support staff to execute the model and have an increased chance to reproduce a problematic issue.

Note

`CaptureModelInstance` cannot be used with `solveLink=6/7`. If this was set, GAMS will reset `solveLink` to 3/4 automatically.

Default: 0

Value	Meaning
0	Do not capture model instances
1	Capture model instances

case (*boolean*): Output case option for LST file

Available: Command line

This option controls the case of the text in the listing file.

Default: 0

Value	Meaning
0	Write listing file in mixed case
1	Write listing file in upper case only

cErr (*integer*): Compile time error limit

Available: Command line

The compilation will be aborted after `n` errors have occurred. By default, there is no error limit and GAMS compiles the entire input file and collects all the compilation errors that occur. If the file is too long and the compilation process is time consuming, `cErr` could be used to set to a low value while debugging the input file.

Default: 0

Value	Meaning
0	No error limit (default)
<code>n</code>	Stop after <code>n</code> errors

charSet (*boolean*): Character set flag

Available: Command line

This option specifies whether foreign language characters are permitted in comments and text items. For a list of standard GAMS characters, see table [Legal Characters](#).

Default: 1

Value	Meaning
0	Use limited GAMS characters set
1	Accept any character in comments and text items (foreign language characters)

cheat (*real*): Cheat value, i.e. minimum solution improvement threshold

Available: Attribute statement (use before solve)

For a branch-and-bound based solver, each new feasible solution must be at least the value of **cheat** better than the current best feasible solution. Note that this may speed up the search, but may cause some solutions, including optimal ones, to be missed. If a model has been solved with a nonzero cheat value, then the optimal solution will be within the cheat value or less of the found solution. Observe that the option **cheat** is specified in absolute terms (like the option [optCA](#)), therefore non-negative values are appropriate for both minimization and maximization models. Note that using this option will invalidate any reporting of the dual bound or optimality gaps. Further, certain solver options can override the cheat setting, e.g., the Cplex option [objDif](#), and some solvers may ignore the **cheat** option.

Default: 0

checkErrorLevel (*boolean*): Check errorLevel automatically after executing external program

Available: Command line, Option statement

If this option is set to 1, the [errorLevel](#) is checked implicitly after executing an external program via [execute](#), [put_utility exec](#) and [put_utility shell](#). An execution error is triggered and the execution is aborted, if it is not 0. So, with **checkErrorLevel** = 1 the before mentioned statements behave like [execute.checkErrorLevel](#), [put_utility exec.checkErrorLevel](#) and [put_utility shell.checkErrorLevel](#) respectively.

Also, if this option is set as a command line parameter it initializes the state of the dollar control option [\\$on/offCheckErrorLevel](#). So, with **checkErrorLevel** = 1, the [errorLevel](#) is checked implicitly after [\\$call](#) and [\\$hiddenCall](#). A compilation error is triggered and the compilation is aborted if that is not 0. So, [\\$call](#) behaves like [\\$call.checkErrorLevel](#) and [\\$hiddenCall](#) behaves like [\\$hiddenCall.checkErrorLevel](#) in this case.

Default: 0

Value	Meaning
0	Do not check errorLevel automatically after execution of external program
1	Check errorLevel automatically after execution of external program

CNS (*string*): Constrained Nonlinear Systems - default solver

Available: Command line, Option statement

The default solver for models of the type [Constrained Nonlinear Systems](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

curDir (*string*): Current directory

Synonym: CDir

Available: Command line

This option sets the current working directory. It is useful when GAMS is called from an external system like Visual Basic. If it is not specified, it will be set to the directory the GAMS module is called from.

cutOff (*real*): Cutoff value for branch and bound

Available: Attribute statement (use before solve, reset by solve statement)

Within a branch-and-bound based solver, the parts of the tree with an objective value worse than the cutoff value are ignored. Note that this may speed up the initial phase of the branch and bound algorithm (before the first integer solution is found). However, the true optimum may be beyond the cutoff value. In this case the true optimum will be missed and moreover, no solution will be found.

Observe that this option is specified in absolute terms (like the option `optCA`).

Default: 0

decimals (*integer*): Decimal places for display statements

Available: Option statement

This option specifies the number of decimals that will be printed for numeric values that do not have a specific print format attached. The range is $[0,8]$.

Default: 3

decryptKey (*string*): Key to decrypt a text file that was encrypted via `$encrypt`

Available: Command line

This option provides a key to decrypt a GAMS input file that has been encrypted with a key provided by `encryptKey` and `$encrypt`. For more information, see [Encrypting Files](#).

defPoint (*integer*): Indicator for passing on default point

Available: Attribute statement (use before solve, reset by solve statement)

This option determines the point that is passed to the solver as a basis. By default, the levels and marginals from the current basis are passed to the solver. In some circumstances (mostly during debugging), it can be useful to pass a standard default input point, i.e. with all levels set to 0 or lower bound.

Value	Meaning
0	Pass user defined levels and marginals to solver
1	Pass default levels and marginals to solver
2	Pass default marginals to solver

dFormat (*integer*): Date format

Synonym: DF

Available: Command line

This option controls the date format in the listing file. The three date formats correspond to various conventions used around the world. For example, the date December 2, 1996 will be written as 12/02/96 with the default `df` value of 0, as 02.12.96 with `df=1`, and as 96-12-02 with `df=2`.

Default: 0

Value	Meaning
0	Date as mm/dd/yy
1	Date as dd.mm.yy
2	Date as yy-mm-dy

dictFile (*real*): Force writing of a dictionary file if `dictfile > 0`

Available: Attribute statement (use before solve, reset by solve statement)

If this option is set to a value that is larger than zero, it will instruct GAMS to make the GAMS names of variables and equations that have been generated by the solve statement available to the solver. In many solver links these names are registered with the solver and hence messages from the solver that involve variables and equations (e.g. an infeasible row or duplicate columns) can be easily interpreted by the user. Consider the following example:

```
Row 'demand(new-york)' infeasible, all entries at implied bounds.
```

```
Duplicate columns x(san-diego.new-york) and x(san-diego.chicago) make problem unbounded.
```

If we have `modelname.dictfile=0` the same messages will read as follows:

```
Row 'c4' infeasible, all entries at implied bounds.
```

```
Duplicate columns x4 and x5 make problem unbounded.
```

Sometimes a dictionary is required for a successful run. Some solver option use the original GAMS names and need to be matched with the variables `1..n` and equations `1..m` in the solver. The dictionary file with its API allows to calculate such a mapping. Note that this is done automatically inside the solver links, so users do not need to be concerned with it.

For example, in the [indicator constraints](#) implementation a binary indicator variable is matched to a constraint. In the model `[INDIC01]` from the GAMS test library, this matching is done in the following GAMS/Cplex option file `cplex.opt`:

```
indic eq3(dice,f,fp)$comp(dice,f,fp) 1
```

Observe that if no dictionary is available, we will get an error:

```
**** Unable to read dictionary file required for indicator constraints
```

However, the dictionary comes at a price. Generating the names and calculating and storing the map takes time and space. In addition, GAMS names take up space in the solver. Thus, if the user needs very fast generation and does not need names, setting `dictFile` to zero is a good option.

Further, note that some solvers allow to suppress the loading of names (using the solver option `names=no`). Suppressing the loading of names facilitates to use the name mapping features required for models like INDIC01 above, but does not load the names into the solver name space for better reporting (and hence saves some space).

digit (*string*): Switch default for "\$on/offDigit"

Available: Command line

For more info see [\\$on/offDigit](#).

Default: on

Value	Meaning
off	Activate \$offDigit
on	Activate \$onDigit

dispWidth (*integer*): Number of characters to be printed in the column labels of all subsequent display statements

Available: Option statement

This option controls the number of characters that are shown for a label in a column in the context of the display statement. Consider the following example:

```
Set i / thislabelhas24characters /;
Parameter p(i,i) / thislabelhas24characters.thislabelhas24characters 2/;
display p;

option dispWidth=24;
display p;
```

The two display statements in this code will generate the following output:

```
----          3 PARAMETER p

                                thislabel~
thislabelhas24characters          2.000

----          6 PARAMETER p

                                thislabelhas24characters
thislabelhas24characters          2.000
```

Observe that in the first display, the label in the column is cut off after 10 characters, while in the second display it is shown in full.

Note that the default value is 10 and the range is [10,31].

Default: 10

dmpOpt (*no value*): Debugging option: causes GAMS to echo the runtime option settings

Available: Option statement

This debugging option has the effect that all available option statements and their current values are listed in the listing file.

dmpSym (*no value*): Debugging option: causes GAMS to echo the symbol table to the listing file

Available: Option statement

This debugging option is especially useful for diagnosing memory problems. It has the effect that GAMS will report the number of elements that are stored for each identifier at the point in the program where this option is inserted together with a memory estimate. The report that is generated in this way is called a *memory dump*. This is similar to the option [dmpUserSym](#), but prints GAMS internal symbols and information as well. For details, see section [Finding the Causes for Excessive Memory Use](#).

dmpUserSym (*no value*): Debugging option: causes GAMS to echo the symbol table to the listing file for user defined symbols only

Available: Option statement

This debugging option is especially useful for diagnosing memory problems. It has the effect that GAMS will report the number of elements that are stored for each identifier at the point in the program where this option is inserted together with a memory estimate. The report that is generated in this way is called a *memory dump*. This is similar to the option [dmpSym](#), but prints user defined symbols only and also leaves out some very technical information which are mostly for internal use. For details, see section [Finding the Causes for Excessive Memory Use](#).

DNLP (*string*): Non-Linear Programming with Discontinuous Derivatives - default solver

Available: Command line, Option statement

The default solver for models of the type [Nonlinear Programs with Discontinuous Derivatives](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

docFile (*string*): Filename stem for documentation files

Available: Command line

domLim (*integer*): Domain violation limit solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the maximum number of domain errors (undefined operations like division by zero) a nonlinear solver will perform, while calculating function and derivative values, before it terminates the run and returns solver status 5 `EVALUATION ERROR LIMIT`. Nonlinear solvers have difficulties recovering after attempting an undefined operation. Note that some solvers operate in a mode where trial function evaluations are performed. These solvers will not move to points at which evaluation errors occur, thus the evaluation errors at trial points are not counted against the limit.

Default: ∞

domUsd (*integer*): Number of domain violations

Available: Attribute statement (use after solve)

This model attribute returns the number of domain violations after a solve.

dualCheck (*integer*): Output on the reduced cost condition

Available: Option statement

If this option is set to 1, the reduced cost condition for each variable in the column listing will be evaluated using the equation marginals. The default value is zero, which means that the calculation will be omitted.

Default: 0

dumpOpt (*integer*): Writes preprocessed input to the file input.dmp

Available: Command line

This option with value larger than 9 creates a GAMS input file of that will reproduce results encapsulating all `include` files into one GAMS file. If activated, a file will be written containing GAMS source code for the entire problem. The file name is the input file name with the extension `dmp`. For values smaller than 10, this option tries to encapsulate all the items from a restart file that are needed to execute a solve.

For the values smaller than 10, consider the following example. We will split the transportation model [TRANSPORT] into two files and run them with the [save and restart feature](#). Then we will illustrate the option `dumpOpt`. The first file called `trans1.gms` contains the first part of the model up to and including the model statement:

Sets

```
i  canning plants  / seattle, san-diego /
j  markets         / new-york, chicago, topeka / ;
```

Parameters

```
a(i)  capacity of plant i in cases
      /  seattle      350
        san-diego    600 /
```

```
b(j)  demand at market j in cases
      /  new-york     325
        chicago      300
        topeka       275 / ;
```

Table d(i,j) distance in thousands of miles

	new-york	chicago	topeka
seattle	2.5	1.7	1.8
san-diego	2.5	1.8	1.4 ;

Scalar f freight in dollars per case per thousand miles /90/ ;

Parameter c(i,j) transport cost in thousands of dollars per case ;
 $c(i,j) = f * d(i,j) / 1000 ;$

Variables

```
x(i,j)  shipment quantities in cases
z        total transportation costs in thousands of dollars ;
```

Positive Variable x ;

```

Equations
  cost      define objective function
  supply(i) observe supply limit at plant i
  demand(j) satisfy demand at market j ;

cost ..      z =e= sum((i,j), c(i,j)*x(i,j)) ;
supply(i) .. sum(j, x(i,j)) =l= a(i) ;
demand(j) .. sum(i, x(i,j)) =g= b(j) ;

model transport /all/ ;

```

Note that we removed all comments for brevity. The second file called `trans2.gms` contains the solve statement and the display statement:

```

solve transport using lp minimizing z ;
display x.l, x.m ;

```

We run the first file with the command line parameter `save` and thus generate a work file. For details on work files, see chapter [The Save and Restart Feature](#). Then we run `trans2.gms` restarting from the saved work file. The result will be equivalent to running the original model [TRANSPORT].

Note

The option `dumpOpt` can only be used effectively, if the first line in the second file, `trans2.gms`, is the solve statement.

Now, we will illustrate the use of the option `dumpopt`, by running the second file with the following command:

```
> gams trans2 r=trans dumpopt=1
```

Here `trans` is the name of the saved files generated from the file `trans1.gms`. As a result of this call, a new file will be created. It is called `trans2.dmp` and has the following content:

```

* This file was written with DUMPOPT=1 at 11/25/21 15:15:17
*
*      INPUT = C:\tmp\trans2.gms
*      DUMP  = C:\tmp\trans2.dmp
*      RESTART = C:\tmp\0.g0?
*
*      with time stamp of 11/16/21 17:18:53
*
* You may have to edit this file and the input file.

* There are 5 labels

Set WorkFileLabelOrder dummy set to establish the proper order /
  seattle,san-diego,new-york,chicago,topeka /;

Model transport;

Variable z 'total transportation costs in thousands of dollars';

Set i(*) 'canning plants' /
  seattle,san-diego /;

Set j(*) 'markets' /

```

```

new-york,chicago,topeka /;

Parameter c(i,j) 'transport cost in thousands of dollars per case' /
  seattle.new-york 0.225,seattle.chicago 0.153,seattle.topeka 0.162,san-diego.new-york 0.225,sa

Positive Variable x(i,j) 'shipment quantities in cases';

Parameter a(i) 'capacity of plant i in cases' /
  seattle 350,san-diego 600 /;

Parameter b(j) 'demand at market j in cases' /
  new-york 325,chicago 300,topeka 275 /;

Equation demand(j) 'satisfy demand at market j';

Equation supply(i) 'observe supply limit at plant i';

Equation cost 'define objective function';

*      *** EDITS FOR INPUT FILE ***

*** END OF DUMP ***

```

Note that all the data that enters the model in the solve statement has been regenerated. Observe that the parameter `d` has not been regenerated since it does not appear in the model. Changing the value of the parameter `dumpopt` will have the effect that other names are used for the identifiers in the regenerated file, see table below.

Note

If `$onVerbatim` is active, `DumpOpt = 11` behaves like `DumpOpt = 21` (comments are kept)

See also [dumpOptGDX](#).

Default: 0

Value	Meaning
0	No dumpfile
1	Extract referenced data from the restart file using original set element names
2	Extract referenced data from the restart file using new set element names
3	Extract referenced data from the restart file using new set element names and drop symbol text
4	Extract referenced symbol declarations from the restart file
11	Write processed input file without comments
21	Write processed input file with all comments

dumpOptGDX (*string*): Defines a GDX file name stem created when using `DumpOpt`

Available: Command line

This parameter works together with the [dumpOpt](#) parameter. If that is set to 1, 11 or 21 while `dumpOptGDX` is set, GAMS will create a GDX file with the data used in the dump file instead of data statements, and the dump file will load the data from that GDX file. So, with the parameter `dumpOptGDX=trns2` the example [above](#) would generate the following dump file:

```

* This file was written with DUMPOPT=1 at 11/25/21 15:14:11
*
*     INPUT = C:\tmp\trans2.gms
*     DUMP  = C:\tmp\trans2.dmp
*     RESTART = C:\tmp\0.g0?
* DUMPOPTGDX = trans2
*
*         with time stamp of 11/16/21 17:18:53

$gdxIn trans2.gdx

*
* You may have to edit this file and the input file.

* There are 5 labels

Set WorkFileLabelOrder dummy set to establish the proper order;
$loadDCR WorkFileLabelOrder=*

Model transport;

Variable z 'total transportation costs in thousands of dollars';

Set i(*) 'canning plants';
$loadDCR i

Set j(*) 'markets';
$loadDCR j

Parameter c(i,j) 'transport cost in thousands of dollars per case';
$loadDCR c

Positive Variable x(i,j) 'shipment quantities in cases';

Parameter a(i) 'capacity of plant i in cases';
$loadDCR a

Parameter b(j) 'demand at market j in cases';
$loadDCR b

Equation demand(j) 'satisfy demand at market j';

Equation supply(i) 'observe supply limit at plant i';

Equation cost 'define objective function';

$gdxIn

*     *** EDITS FOR INPUT FILE ***

*** END OF DUMP ***

Note that more than one GDX file could be created with a common file stem defined by this
parameter. This will be necessary if the source model has multiple data definitions for the
same symbol like in this simple example:

Set      i      / i1*i3/;
Parameter a(i) / i1 1, i2 2/;
$onMulti

```

```

Parameter a(i) / i1 0, i3 3/;
Scalar    b    / 7 /;
Scalar    b    / 77 /;

```

Running this as

```
> gams dummy dumpOpt=11 dumpOptGDX=dummyIn
```

will generate this dump file:

```

* This file was written with DUMPOPT=11 at 11/25/21 15:26:02
*
*      DUMP = C:\tmp\dummy.dmp
*      INPUT = C:\tmp\dummy.gms
*      RESTART =
* DUMPOPTGDX = dummyIn
*
$gdxIn dummyIn.gdx

Set      i
$loadDCR i
;
Parameter a(i)
$loadDCR a
;
$onMulti
Parameter a(i)
$gdxIn dummyIn_m1.gdx
$loadDCR a
;
Scalar    b
$loadDCR b
;
Scalar    b
$gdxIn dummyIn_m2.gdx
$loadDCR b
;
* *** EXIT      C:\Data\gspTest\dummy.gms

$gdxIn
*** END OF DUMP ***

```

And this is the data found in the GDX files:

dummyIn.gdx:

```

Set i(*) /
'i1',
'i2',
'i3' /;

Parameter a(*) /
'i1' 1,
'i2' 2 /;

```

dummyIn_m1.gdx:

```

Parameter a(*) /
'i2' 2,
'i3' 3 /;

Scalar b / 7 /;

dummyIn_m2.gdx:

Scalar b / 77 /;

```

dumpParms (*integer*): GAMS parameter logging

Synonym: DP

Available: Command line

This option lists the settings of all command line parameters that were changed or set by the user, GAMS or an IDE during the current run. Note that with `dp=2` all file operations are listed, including the full path of each file on which any operation is performed.

Default: 0

Value	Meaning
0	No logging
1	Lists accepted/set parameters
2	Log of file operations plus list of accepted/set parameters

dumpParmsLogPrefix (*string*): Prefix of lines triggered by DumpParms>1

Synonym: DPLP

Available: Command line

This option prefixes in the log file the list of all command line parameters that were changed or set by the user, GAMS or an IDE during the current run. Note that the option `dumpParms` must be greater than 1 for `dumpParmsLogPrefix` to have an effect.

Default: ***

eject (*no value*): Inject a page break into the LST file

Available: Option statement

This option has the effect that a page break is inserted in the listing file.

EMP (*string*): Extended Mathematical Programs - default solver

Available: Command line, Option statement

The default solver for models of the type [Extended Mathematical Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

empty (*string*): Switch default for "\$on/offEmpty"

Available: Command line

For more info see [\\$on/offEmpty](#).

Default: on

Value	Meaning
off	Activate \$offEmpty
on	Activate \$onEmpty

encryptKey (*string*): Key to encrypt a text file using \$encrypt

Available: Command line

This option provides a key to encrypt a text file via [\\$encrypt](#). For more information, see [Encrypting Files](#).

eolCom (*string*): Switch default for "\$on/offEolCom" and "\$eolCom"

Available: Command line

If this is set to on on or off it sets the state of [\\$on/offEOLCom](#). Other strings (with not more than two characters) will set [\\$EOLCom](#).

Default: off

Value	Meaning
off	Activate \$offEolCom
on	Activate \$onEolCom using default EOL comment character
other	Activate \$onEolCom setting specific EOL comment character(s)

eolOnly (*integer*): Single key-value pairs (immediate switch)

Synonym: EY

Available: Command line

This option controls formatting of parameters on the command line and is useful in conjunction with the option [parmFile](#).

This option acts as an immediate switch that forces only one option-value pair to be read on a line. Note that by default, any number of option-value pairs may be present on the same line and termination characters and quoting is necessary to determine the end of key/value pair. With this option active the remainder after the key is used as the value independent of quoting or termination characters.

Default: 0

Value	Meaning
0	Any number of keys or values
1	Only one key-value pair on a line

epsToZero (*string*): Treat eps as zero when unloading to GDX

Available: Command line, Option statement

When this is set to on, EPS values are written as zero when unloading parameters or variable and equation levels to [GDX](#) at execution time. The command line parameter `EpsToZero`

initializes both, the option `EpsToZero` and the dollar control option `$onEpsToZero` for the compile-time equivalent behavior.

Default: `off`

Value	Meaning
<code>off</code>	Treat Eps as Eps
<code>on</code>	Treat Eps as Zero

errMsg (*integer*): Placing of compilation error messages

Available: Command line

This option controls the position of the compilation error messages in the listing file. To illustrate the option, consider the following slice of GAMS code:

```
Set      i      / 1*10 / ;
Set      j(i)   / 10*11 / ;
Parameter a(jj) / 12 25.0 / ;
```

After running this code, the listing file will contain the following lines:

```

1 Set      i      / 1*10 / ;
2 Set      j(i)   / 10*11 / ;
****                      $170
3 Parameter a(jj) / 12 25.0 / ;
****                      $120
4

120 Unknown identifier entered as set
170 Domain violation for element

**** 2 ERROR(S)    0 WARNING(S)
```

Note that numbers \$170 and \$120 flag the two errors as they occur, but the errors are explained only at the end of the [compilation output](#). However, if the code is run using the option `errmsg=1`, the resulting listing file will contain the following:

```

1 Set      i      / 1*10 / ;
2 Set      j(i)   / 10*11 / ;
****                      $170
**** 170 Domain violation for element
3 Parameter a(jj) / 12 25.0 / ;
****                      $120
**** 120 Unknown identifier entered as set
4

**** 2 ERROR(S)    0 WARNING(S)
```

Observe that the explanation for each error is provided immediately following the error marker.

Default: 1

Value	Meaning
0	Place error messages at the end of compiler listing
1	Place error messages immediately following the line with the error
2	Suppress error messages

errNam (*string*): Name of error message file

Available: Command line

This option specifies the name of a file defining the internally used compiler error messages. It is used to change the name from the default name `gamserrs.txt`.

error (*string*): Force a compilation error with message

Available: Command line

This option forces a parameter error with a specified message. It is useful in the context of incorporating a GAMS file within another batch file where the user needs to have control over the conditions when GAMS is called. See also section [Conditional Compilation](#).

To illustrate, the default GAMS log file from running a model with the option `error=Hallo` will look as follows:

```
gams: **** Error: Parameter error(s)
      :           Reading parameter(s) from "command line"
      :           *** Error Hallo
      :           Finished reading from "command line"
```

errorLog (*integer*): Max error message lines written to the log for each error

Synonym: ER

Available: Command line

This option controls the number of error message lines that are written to the log file.

Under GAMS Studio, the default is reset to 99.

Default: 2147483647

Value	Meaning
0	No error messages to LOG file
n	Number of lines for each error that will be written to LOG file

etAlg (*real*): Solver dependent timing information

Available: Attribute statement (use after solve)

Unlike `etSolve` and `etSolver`, this attribute is set by the individual solver links. If not set, it defaults to NA. This attribute was intended to allow solvers to return the elapsed time used by the solve algorithm without including any model generation, communication, or setup time. However, solvers are free to adapt this convention and return time-related information (but not necessarily elapsed time) for executing the solve algorithm. Please inspect your solver manual for the actual meaning of the value returned in this attribute.

etLim (*real*): Elapsed time limit in seconds

Synonym: ETL

Available: Command line

This option controls the time limit for a GAMS job. The system will terminate with a compilation or execution error if the limit is reached. A GAMS job will terminate if the elapsed time in seconds exceeds the value of `etLim`. If a solve statement gets executed, and the `resLim` for the model to be solved is greater than `etLim - timeElapsed`, `resLim` will be reduced automatically.

Default: ∞

etSolve (*real*): Elapsed time it took to execute a solve statement in total

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time it took to execute a solve statement in total. This time includes the model generation time, the time to read and write files, the time to create the solution report and the time taken by the actual solve. The time is expressed in seconds of wall-clock time.

etSolver (*real*): Elapsed time taken by the solver only

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time taken by the solver only. This does not include the GAMS model generation time and the time taken to report and load the solution back into the GAMS database. The time is expressed in seconds of wall-clock time.

execMode (*integer*): Limits on external programs that are allowed to be executed

Available: Command line

A higher value denotes a more restrictive alternative. If the restriction level `n` is chosen, then the restriction levels less than `n` will also be active. For example, if restriction level 3 is chosen, then restrictions 2 and 1 will apply too.

Default: 0

Value	Meaning
0	Everything allowed
1	Interactive shells in \$call and execute commands are prohibited
2	Embedded Code and all \$call and execute commands are prohibited
3	\$echo or put commands can only write to directories in or below the working or scratchdir
4	\$echo and put commands are not allowed

expand (*string*): Expanded (include) input file name

Synonym: EF

Available: Command line

This option generates a file that contains information about all the input files processed during a particular compilation. By default, the names of the input files are composed by completing the name with the current directory.

Consider the following example:

```

$call rm expfile.txt
$onecho > file1.inc
a = a*2; display a;
$include file2.inc
$offecho
$onecho > file2.inc
a = a+1; display a;
$include file3.inc
$offecho
$onecho > file3.inc
a = a**2; display a ;
$offecho
parameter a / 1 /;
$include file3.inc
$include file2.inc
$include file1.inc

```

If the model is run with the command line parameter `ef=expfile.txt`, a file called `expfile.txt` will be generated. This file will contain the following lines:

1	INPUT	0	0	0	1	29	C:\GAMS\Examples\expand.gms
2	CALL	0	1	1	1	1	rm expfile.txt
3	INCLUDE	1	1	14	14	15	C:\GAMS\Examples\file3.inc
4	INCLUDE	1	1	15	16	19	C:\GAMS\Examples\file2.inc
5	INCLUDE	2	4	2	18	19	C:\GAMS\Examples\file3.inc
6	INCLUDE	1	1	16	20	25	C:\GAMS\Examples\file1.inc
7	INCLUDE	2	6	2	22	25	C:\GAMS\Examples\file2.inc
8	INCLUDE	3	7	2	24	25	C:\GAMS\Examples\file3.inc
9	EXIT	0	1	20	29	29	C:\GAMS\Examples\expand.gms

Note that the first row always refers to the parent file, in this case the file `expand.gms`. The first column gives the sequence number of the input files that were encountered. The second column refers to the type of file that is referenced. The following file types are possible:

```

0  INPUT
1  INCLUDE
2  BATINCLUDE
3  LIBINCLUDE
4  SYSINCLUDE

```

Observe that `$call` is also listed. The third column describes the depth for nested include files. The fourth column provides the sequence number of the parent file for the file being referenced. The fifth column gives the local line number in the parent file where the dollar control option `$include` appeared. The sixth column gives the global (expanded) line number which contained `$include`. The seventh column provides the total number of lines in the file after it is processed. The last column provides the name of the file.

Note that the listing in the expand file is similar to the [include file summary](#) in the listing file of the model. And like the include file summary, this file will not be written, if `$offInclude` is set in the model.

fdDelta (*real*): Step size for finite differences

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control the step size while the numerical Hessian and numerical derivatives are computed in the context of the [function suffixes](#) `.hessn` and `.gradn`. For functions with one argument, GAMS evaluates the function at $f(x-d)$ and $f(x+d)$ for the

numerical gradient. If function values are used for the numerical Hessian, GAMS will evaluate at $f(x-2d)$, $f(x)$ and $f(x+2d)$. For functions with multiple arguments, the same calculations are performed for the components of the input argument vector.

Default: 1.0E-05

fdOpt (*integer*): Options for finite differences

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control how numerical derivatives are computed. The values provide choice regarding the scaling of steps, Hessian calculation method and the use of numerical first derivatives.

Default: 0

Value	Meaning
0	All derivatives analytically, for numerical Hessian use gradient values, scale delta
1	All derivatives analytically, for numerical Hessian use function values, scale delta
2	Gradient analytically, force Hessian numerically using gradient values, scale delta
3	Gradient analytically, force Hessian numerically using function values, scale delta
4	Force gradient and Hessian numerically, scale delta
10	Same as 0, but no scale of delta
11	Same as 1, but no scale of delta
12	Same as 2, but no scale of delta
13	Same as 3, but no scale of delta
14	Same as 4, but no scale of delta

fErr (*string*): Alternative error message file

Available: Command line

This option redirects the compilation error messages to a file and names the file. By default, the file name is composed by completing the name with the scratch directory and the scratch extension. Note that under default settings such a file with compilation error messages is not generated. This option can be used when GAMS is being integrated into other environments like Visual Basic. The error messages that are reported in the listing file may be extracted with this option and their display may be controlled from the environment that is calling GAMS.

To illustrate, consider the slice of GAMS code that we used to explain the option [errMsg](#). If we call this code with the command line parameter `ferr=myfile.err`, a file called `myfile.err` will be created in the scratch directory. This file will contain the following lines:

```

0      0      0      0 D:\GAMS\NEW.LST
1      1     170     31 D:\GAMS\NEW.GMS
2      2     120     14 D:\GAMS\NEW.GMS
```

Note that the first column refers to the global row number of the error in the listing file. The second column refers to the row number of the error in the individual file where the problem occurred. This will be different from the first column only if the error occurred in an include file. In this case, the second column will contain the line number in the include file where the error occurred, while the first number will contain the global line number (as reported in the listing file) where the error occurred. The number in the third column refers to the error number of the compilation error. The fourth number refers to the column number of the error in the source file. The last column contains the individual file in which the error occurred.

fileCase (*integer*): Casing of file names and paths (put,.gdx, ref, \$include, etc.)

Available: Command line

This option facilitates modifying the case of file names and paths. It applies to files created by a GAMS Job such as for example [put files](#), [GDX files](#) and [reference files](#). Under Windows, the casing of a created file will only be affected if the file does not yet exist, i.e. `fileCase=2` won't create `transport.ref` if there is already a file `TRANSPORT.ref`. It should be noted that `fileCase` also applies to existing files that are used but not created by a GAMS job such as for example [\\$include files](#) or [\\$batInclude files](#).

Note that many other file names and paths are affected by this option (e.g. the scratch directory ([scrDir](#)) or the GAMS system directory ([sysDir](#))) and that it is recommended to use this option with caution.

Default: 0

Value	Meaning
0	Causes GAMS to use default casing
1	Causes GAMS to upper case file names including path of the file
2	Causes GAMS to lower case file names including path of the file
3	Causes GAMS to upper case file names only (leave the path alone)
4	Causes GAMS to lower case file names only (leave the path alone)

fileStem (*string*): Sets the file stem for output files which use the input file name as stem by default

Available: Command line

By default, some output files use the input file name as base. If the names of these output files were not set explicitly, then this option may be used to set another name than the input file name as base for these output files. In particular, the names for the following files may be set with `fileStem`: dump files (see option [dumpOpt](#)), GDX files (if the option [GDX](#) was set to `default`), log files (see option [logFile](#)), lst files (see option [output](#)), reference files (if the option [reference](#) was set to `default`) and [trace summary files](#) (see also option [trace](#)).

fileStemApFromEnv (*string*): Append a string read from an environment variable to the "FileStem"

Available: Command line

This option for users that submit GAMS job via `mpirun/mpiexec`. Such commands will spawn multiple instances of GAMS (the precise number is an argument to `mpirun/mpiexec`). Each invocation of GAMS will run the identical job and only the contents of an environment variable (`PMI_RANK`) will differentiate the run. Since GAMS will normally write to `modelName.log/lst` if we run the GAMS file `modelName.gms` we will have many jobs writing to the same file. Therefore we use this option to append the content of a particular environment variable (name given by this option) to the default file names (see [fileStem](#)). Hence GAMS will create `modelName0.log/lst`, `modelName1.log/lst`, and so forth when started with `mpirun/mpiexec` and `fileStemApFromEnv` is set to the environment variable that provides the MPI rank of the invocation. We allow to specify the name of the environment variable because different MPI implementations use different variable names (e.g. `PMI_RANK` or `OMPI_COMM_WORLD_RANK`).

filtered (*string*): Switch default for "\$on/offFiltered"

Available: Command line

For more info see [\\$on/offFiltered](#).

Default: on

Value	Meaning
off	Activate \$offFiltered
on	Activate \$onFiltered

forceOptFile (*integer*): Overwrites other option file section mechanism

Available: Command line

Default: 0

forceWork (*boolean*): Force GAMS to process a save file created with a newer GAMS version or with execution errors

Synonym: FW

Available: Command line

Work files generated by GAMS using the command line parameter `save` are saved in binary format. The information inside these files will change from one GAMS version to another GAMS version. GAMS makes every attempt to be backward compatible and ensure that all new GAMS systems are able to read save files generated by older GAMS systems. However, this cannot be guaranteed the other way around. Thus, GAMS does not allow to process a save file, that was generated by a newer version of GAMS in general. This can be changed by setting `forceWork` to 1. Also, GAMS does not continue after processing a save while with an execution error by default. This behavior can be changed as well by setting `forceWork=1`.

Attention

Forcing GAMS to continue after reading a save file from a newer GAMS version or a save file with execution errors may lead to unexpected behavior. If it is about the GAMS version and you can recreate the save file you may write it using GAMS command line parameter `previousWork=1`.

Default: 0

Value	Meaning
0	No translation
1	Try translation

forLim (*integer*): GAMS looping limit

Available: Command line, Option statement

This option specifies the maximum number of permitted executions of control structures with a `for statement`, a `while statement` or a `repeat statement` before GAMS signals an execution error and terminates the control structure.

Default: ∞

freeEmbeddedPython (*boolean*): Free external resources at the end of each embedded Python code blocks

Available: Command line

This parameter changes the behavior of `$offEmbeddedCode` and `endEmbeddedCode`. When set to 1, internal resources get freed and with the next start of an embedded Python code section, the Python environment has to be reinitialized. This is not the case when this parameter is set to 0. In that case also the interpreter stays "alive", which allows to access Python symbols defined in one embedded code block in a following block.

Default: 0

Value	Meaning
0	Keep resources to reuse them potentially
1	Free resources

fSave (*boolean*): Creates a forced [work file](#), i.e., the file is saved even if execution errors or other errors occurred

Available: Command line

This option allows to save a file even in the face of execution or other errors. How it works depends on the command line parameter [save](#).

Note that the option value of 1 is mainly used by solvers that can be interrupted from the terminal.

Default: 0

Value	Meaning
0	Workfile only written to file specified by SAVE if no errors occur
1	Workfile always written to file specified by SAVE or if SAVE is not present to a name made up by GAMS

G205 (*integer*): Use GAMS version 2.05 syntax

Available: Command line

This option sets the level of the GAMS syntax and is mainly used to ensure backward compatibility. New keywords have been introduced in the GAMS language since Release 2.05. Models developed earlier that use identifiers that have since become keywords will cause errors when they are run with the latest version of GAMS. This option enables users to run such old models.

For example, the word "if" is a keyword in GAMS that was introduced with the first version of Release 2.25. Setting the option `g205=1` allows the word "if" to be used as an identifier since it was not a keyword in Release 2.05. As another example, the word "for" is a keyword in GAMS that was introduced with the later versions of Release 2.25. Setting the option `g205=2` allows "for" to be used as an identifier since it was not a keyword in the first version of Release 2.25.

Note

If the values 1 or 2 are specified for option `g205`, then it will not be permitted to use enhancements of the GAMS language that were introduced in later versions.

Default: 0

Value	Meaning
0	Use only latest syntax
1	Allow version 2.05 syntax only
2	Allow version 2.25 syntax only

GDX (*string*): GAMS data exchange file name

Available: Command line

This option specifies the name of the GAMS data exchange file and causes a [GDX file](#) to be written that contains all data in the model at the end of the job. Setting `gdx` to the string 'default' causes GAMS to create a GDX file with the gms file root name and a `gdx` extension. Thus gams the call

```
> gams trnsport gdx=default
```

will cause GAMS to write the GDX file `trnsport.gdx`.

gdxCompress (*boolean*): Compression of generated GDX file

Available: Command line

This option specifies whether the GDX files are compressed or not.

Default: 0

Value	Meaning
0	Do not compress GDX files
1	Compress GDX files

gdxConvert (*string*): Version of GDX files generated (for backward compatibility)

Available: Command line

This option specifies in which format the GDX files will be written.

Default: `v7`

Value	Meaning
<code>v5</code>	Version 5 GDX file, does not support compression
<code>v6</code>	Version 6 GDX file
<code>v7</code>	Version 7 GDX file

gdxUels (*string*): Unload labels or UELs to GDX either squeezed or full

Available: Command line, Option statement

This option specifies the UEL export mode. The UEL table may be written to a [GDX file](#) in two different modes. In `squeezed` mode, only the UELs that are required by the exported symbols are exported. In `full` mode, all UELs are exported. The following code snippet illustrates the difference:

```
Set      i      / i1*i15 /;
Parameter p(i) / i3 3 /;

option gdxuels = squeezed;
execute_unload 'squeezed' p;
execute 'gdxdump squeezed UelTable=i';
```

```
option gdxuels = full;
execute_unload 'full' p;
execute 'gdxdump full UelTable=i';
```

The file `squeezed.gdx` will contain the following lines:

```
Set i /
    'i3' /;

Parameter p(*) /
    'i3' 3 /;
```

The file `full.gdx` on the other hand, will contain the following lines:

```
Set i /
    'i1' ,
    'i2' ,
    'i3' ,
    'i4' ,
    'i5' /;

Parameter p(*) /
    'i3' 3 /;
```

Default: `squeezed`

Value	Meaning
Squeezed	Write only the UELs to Universe, that are used by the exported symbols
Full	Write all UELs to Universe

gridDir (*string*): Grid file directory

Synonym: GDir

Available: Command line

This option sets the grid file directory. Note that each GAMS job has only one grid file directory.

gridScript (*string*): Grid submission script

Synonym: GScript

Available: Command line

This option provides the name of a script file that is used to submit grid computing jobs. If only the file name is given the file is assumed to be located in the system directory. A fully qualified name can be given as well. The script needs to be similar to the file `gmsgrid.cmd` on Windows machines with arguments that give name and location of the solver executable, the solver control file name and the name of the scratch directory. For an example of such a script, see section [The Grid Facility: Architecture and Customization](#). However, note that advanced knowledge of how GAMS sets up and calls solvers is needed for successful use.

Default: `gmsgrid`

handle (*real*): Unique handle number of SOLVE statement

Available: Attribute statement (use after solve)

The model attribute `handle` contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The handle number may be used by the functions [handleCollect](#), [handleStatus](#), [handleDelete](#), [handleSubmit](#) and [readyCollect](#). For details see chapter [The Grid and Multi-Threading Solve Facility](#).

heapLimit (*real*): Maximum Heap size allowed in MB

Synonym: HL

Available: Command line

This option allows to limit the amount of memory a GAMS job may use during compilation and execution. If the needed data storage exceeds this limit, the job will be terminated.

Default: ∞

holdFixed (*boolean*): Treat fixed variables as constants

Available: Command line, Attribute statement (use before solve)

This option facilitates treating fixed variables as constants. Thus the problems size may be reduced.

Default: 0

Value	Meaning
0	Fixed variables are not treated as constants
1	Fixed variables are treated as constants

holdFixedAsync (*boolean*): Allow HoldFixed for models solved asynchronously as well

Available: Command line, Option statement

By default, [holdFixed](#) is automatically deactivated if a model is solved asynchronously, since this could lead to inconsistent solutions otherwise. To allow this anyway, this parameter can be set to 1.

Default: 0

Value	Meaning
0	Ignore HoldFixed setting for async solves
1	Allow HoldFixed for async solves

IDCGDXInput (*string*): GDX file name with data for implicit input

Available: Command line

Specify the name of a GDX file that is used for implicit loading of input data. Details about this are described with [\\$onExternalInput](#).

IDCGDXOutput (*string*): GDX file name for data for implicit output

Available: Command line

Specify the name of a GDX file that is used for implicit writing of output data. Details about this are described with [\\$onExternalOutput](#).

IDCGenerateGDX (*string*): Specify GDX file name of input and output side of data contract

Available: Command line

Specify the name of a GDX file that is used to store all symbols that are declared as [external input](#) or [external output](#) at the end of a GAMS run.

IDCGenerateGDXInput (*string*): Specify GDX file name of input side of data contract

Available: Command line

Specify the name of a GDX file that is used to store all symbols that are declared as [external input](#) at the end of a GAMS run.

IDCGenerateGDXOutput (*string*): Specify GDX file name of output side of data contract

Available: Command line

Specify the name of a GDX file that is used to store all symbols that are declared as [external output](#) at the end of a GAMS run.

IDCGenerateJSON (*string*): Specify JSON file name of data contract

Available: Command line

Specify the name of a JSON file that is used to store the information (but not the data) about all symbols that are declared as [external input](#) or [external output](#) at the end of a GAMS run.

IDCJSON (*string*): Specify JSON file name to verify data contract

Available: Command line

Specify the name of a JSON file that is read and used to verify that the implicit data contract given by the GAMS model by declaring symbols as [external input](#) or [external output](#) matches the expected symbol information given by this specified file. This is the expected schema of that file:

```
{
  "$schema": "http://json-schema.org/draft-07/schema#",
  "title": "Input/Output configuration file schema",
  "description": "Configuration file is automatically generated by GAMS and describes the data contract.",
  "type": "object",

      }
    }
  },
  "required":["modelTitle", "inputSymbols", "outputSymbols"]
}

```

IDCProtect (*boolean*): Flag to control assignment protection of external input symbols

Available: Command line

By default, it is not allowed to change symbols which are declared as [external input](#) at execution time. This parameter allows to ignore this restriction. It sets the initial state for the dollar control options [\\$on/offIDCProtect](#).

Default: 1

Value	Meaning
0	Allow to change external input symbols at execution time
1	Protect external input symbols from being changed at execution time

IDE (*boolean*): Integrated Development Environment flag

Available: Command line

This option instructs GAMS to write special instructions to the log file that are in turn read by an IDE.

Default: 0

Value	Meaning
0	Unknown environment
1	Runs under GAMS IDE

inlineCom (*string*): Switch default for "\$on/offInline" and "\$inlineCom"

Available: Command line

If this is set to on **on** or **off** it sets the state of [\\$on/offInline](#). Other strings (a pair with not more than two characters each) will set [\\$inlineCom](#).

Default: **off**

Value	Meaning
off	Activate \$offInline
on	Activate \$onInline using default inline comment characters
other	Activate \$onInline setting specific inline comment characters

input (*string*): Input file

Synonym: I

Available: Command line

Completing the input file name with the current directory composes the final name. If such a file does not exist and the extension was not specified, the standard input extension will be attached and a second attempt will be made to open an input file.

inputDir, inputDir1..40 (*string*): Input file directories (searched at compile time)

Synonym: IDIR

Available: Command line

In general, GAMS searches for input and include files in the current working directory only. This option allows the user to specify additional directories for GAMS to search for include and batinclude files as well as GDY file via `$gdxIn`. A maximum of 40 separate directories may be included. The directories are separated by Operating System specific symbols. For example, on a PC the separator is a semicolon (;) character and under Unix it is the colon (:) character. Note that `libinclude` and `sysinclude` files are handled differently. Their paths are specified with the command line parameters `libIncDir` and `sysIncDir` respectively.

Consider the following illustration:

```
> gams myfile idir \mydir;\mydir2
```

Note that the search order for the file `myfile.gms` and all included files in PC systems will be as follows: (1) the current directory, (2) the directories specified by `inputdir` in their respective order (here the directories: `\mydir` and `\mydir2`). Under Unix, the corresponding GAMS call will be:

```
> gams myfile idir \mydir:\mydir2
```

Note that the information in the option `inputDir` may be also transferred to GAMS by entering the individual directories separately. A maximum of 40 directories may be passed on in this manner. The number appended to `InputDir` is important since the earlier `InputDir` directories will be searched first.

The example above may alternatively be formulated in the following way:

```
> gams myfile idir1 mydir1 idir2 mydir2
```

Note that in this case the search order will be as follows:

1. current directory
2. `mydir1`
3. `mydir2`

Observe that we could modify the command in the following way:

```
> gams myfile idir3 \mydir1 idir2 \mydir2
```

Note that in this case the search order will be as follows:

1. current directory
2. mydir2
3. mydir3

Thus it is not the order in which the directories are specified that matters, but the number of the option `inputDir` that they have been assigned to.

integer1..5 (*integer*): Integer communication cell N

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an integer communication cell that may contain any integer number.

interactiveSolver (*boolean*): Allow solver to interact via command line input

Available: Command line

Default: 0

Value	Meaning
0	Interaction with solvelink 0 is not supported
1	Interaction with solvelink 0 is supported

intVarUp (*integer*): Set mode for default upper bounds on integer variables

Available: Command line, Option statement

Default: 0

Value	Meaning
0	Set default upper bound for integer variables to +INF
1	Pass a value of 100 instead of +INF to the solver as upper bound for integer variables
2	Same as 0 but writes a message to the log if the level of an integer variable is greater than 100
3	Same as 2 but issues an execution error if the level of an integer variable is greater than 100

iterLim (*integer*): Iteration limit of solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the maximum number of permitted solver iterations, before the solver terminates the run. If this limit is reached, the solver will terminate and will return solver status 2 `ITERATION INTERRUPT`. Note that the definition of what constitutes an iteration depends on the solver. For LP solvers, `iterlim` often refers to the number of simplex iterations (i.e., pivots). For MIP solvers, `iterlim` often refers to the cumulative number of simplex iterations over all solves of LP relaxations. Observe that `iterlim` does not apply to all iterations. For example, it might not apply to barrier iterations and major iterations in nonlinear solvers.

For these iterations solver-specific options need to be set. Moreover, some solver links might *reinterpret* the value of this option. For example, if left at default, the solver link might use the default iteration limit of the solver.

Default: 2147483647

iterUsd (*integer*): Number of iterations used

Available: Attribute statement (use after solve)

This model attribute returns the number of iterations used after a solve.

jobTrace (*string*): Job trace string to be written to the trace file at the end of a GAMS job

Synonym: JT

Available: Command line

This option specifies a string that is written to the [trace file](#) at the end of a GAMS job.

keep (*boolean*): Controls keeping or deletion of process directory and scratch files

Available: Command line

This option controls whether to keep the process directory. In the process directory the temporary/scratch files are located, unless the options [scrDir](#) or [procDir](#) were used.

Default: 0

Value	Meaning
0	Delete process directory
1	Keep process directory

libIncDir (*string*): LibInclude directory

Synonym: LDIR

Available: Command line

This option specifies the name of the directory to be used by GAMS for [\\$libInclude](#) files that do not have a full path specification. An absolute or relative path may be specified. If the option [libIncDir](#) is not set, it will be set to the subdirectory [inclib](#) in the [GAMS standard locations](#). A relative path is relative to the GAMS system directory.

Note that if the option [libIncDir](#) parameter is set, the default library include directories will only be searched, if the libInclude file cannot be found in the specified folder.

Attention

Only *one* directory may be set with the option [libIncDir](#). Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

```
> gams myfile libIncDir mydir
```

Note that GAMS will search for any referenced [libInclude](#) file in the directory <GAMS System Directory>/mydir first.

license (*string*): Use alternative license file

Available: Command line

This option specifies the name the file that contains the GAMS license. It may be used to point to an explicit license file rather letting GAMS search for the default `gamslice.txt` in various locations including the GAMS system directory. The locations ("Data directories") can be printed by running `gamsinst -listdirs`, see [installation notes](#) for details. The `license` option should only be used by advanced users attempting to override internal license information.

limCol (*integer*): Maximum number of columns listed in one variable block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of columns that are listed for each variable in the [column listing](#) in the listing file. Note that the value of zero will suppress the column listing.

Default: 3

limRow (*integer*): Maximum number of rows listed in one equation block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of rows that are listed for each equation in the [equation listing](#) in the listing file. Note that the value of zero will suppress the equation listing.

Default: 3

line (*integer*): Line number of last solve of the corresponding model

Available: Attribute statement (use after solve)

This model attribute returns the line number of the last solve of the respective model.

linkUsed (*integer*): Integer number that indicates the value of SolveLink used for the last solve

Available: Attribute statement (use after solve)

listing (*string*): Switch default for "\$on/offListing"

Available: Command line

For more info see [\\$on/offListing](#).

Default: on

Value	Meaning
off	Activate \$offListing
on	Activate \$onListing

logFile (*string*): Log file name

Synonym: LF

Available: Command line

logLine (*integer*): Amount of line tracing to the log file

Synonym: LL

Available: Command line

This option may be used to limit the number of line tracing sent out to the log file during the compilation phase of a GAMS run. Note that setting this option to zero will cause the line tracing to be suppressed for all phases of the GAMS processing.

The log file that results from running the model **[TRANSPORT]** with the option `ll=0` is shown below.

```

--- Starting compilation
--- Starting execution: elapsed 0:00:00.018
--- Generating LP model transport
---   6 rows   7 columns  19 non-zeroes
--- Executing CPLEX: elapsed 0:00:00.060

IBM ILOG CPLEX   24.8.2 r59988 Released Jan  3, 2017 DEG x86 64bit/Mac OS X
Cplex 12.7.0.0

Reading data...
Starting Cplex...
Space for names approximately 0.00 Mb
Use option 'names no' to turn use of names off
Tried aggregator 1 time.
LP Presolve eliminated 1 rows and 1 columns.
Reduced LP has 5 rows, 6 columns, and 12 nonzeros.
Presolve time = 0.01 sec. (0.00 ticks)

Iteration      Dual Objective          In Variable          Out Variable
   1              73.125000    x(Seattle.New-York) demand(New-York) slack
   2             119.025000    x(Seattle.Chicago) demand(Chicago) slack
   3             153.675000    x(San-Diego.Topeka)  demand(Topeka) slack
   4             153.675000    x(San-Diego.New-York) supply(Seattle) slack
LP status(1): optimal
Cplex Time: 0.03sec (det. 0.01 ticks)

Optimal solution found.
Objective :           153.675000

--- Restarting execution
--- Reading solution for model transport
instructions that will go to the log file
more instructions that will go to the log file
*** Status: Normal completion
--- Job trnsport.gms Stop 02/09/17 15:43:43 elapsed 0:00:00.275

```

If we compare this output to the output shown in the example of option [logFile](#), we will observe that the line numbers are missing from this log file.

Default: 2

Value	Meaning
0	No line tracing
1	Minimum line tracing
2	Automatic and visually pleasing

logOption (*integer*): Log option

Synonym: LO

Available: Command line

This option controls the location of the output log of a GAMS run. By default, GAMS directs the log of the run to the screen/console. If `logOption` is set to 2, the log will be redirected to a file. With `logOption=3` all the output goes to the standard output. Note that if no file name is provided for the log through the option `logFile`, the file name will be the input file name with the extension `.log`. Observe that the settings zero and 2 may be used to permit jobs to run in the background.

To illustrate, consider the following call:

```
> gams trnsport lo=2
```

Note that the resulting log file, `trnsport.log`, will be identical to the file `myfile.log` that is shown as part of the description of the option `logFile`.

Default: 3

Value	Meaning
0	No log output
1	Log output to screen (console)
2	Log output to logfile
3	Log output to standard output
4	Log output to logfile and standard output

LP (*string*): Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type [Linear Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

lstTitleLeftAligned (*boolean*): Write title of LST file all left aligned

Available: Command line

Default: 1

Value	Meaning
0	Split LST title into left and right aligned part
1	Write LST title completely left aligned

marginals (*integer*): Indicator for marginals present

Available: Attribute statement (use after solve)

maxExecError (*integer*): Execution time error limit

Synonym: ExecErr

Available: Command line

This option puts an upper limit on the number of errors that may be found during execution or preprocessing associated with a solve statement. If more than **maxExecError** errors have been found GAMS will abort. This value can be overwritten with the function [maxExecError](#).

Default: 0

Value	Meaning
0	No errors allowed limit
n	Max number allowed

maxGenericFiles (*integer*): Maximum number of generic file names tried at execution time file creation

Available: Command line, Option statement

In case of a failed writing of [put files](#) and GDX files via [execute_unload](#) (e.g. because the given path is invalid or the file is open by another program), GAMS tries to write to a generic file name instead. The number of file names tried can be specified with this option. To avoid this completely and throw an error right away, if the given name is invalid, set this to 0.

Default: 20

maxInfes (*real*): Maximum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the maximum number of infeasibilities after a solve.

maxProcDir (*integer*): Maximum number of 225* process directories

Available: Command line

This option controls the maximum number of work file directories that may be generated by GAMS. By default they are called 225a, 225b, ..., 225aa, 225ab ... Note that the label 225 may be changed with the option [procDir](#).

Default: 700

MCP (*string*): Mixed Complementarity Problems - default solver

Available: Command line, Option statement

The default solver for models of the type [Mixed Complementarity Problems](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

MCPRHoldFx (*boolean*): Print list of rows that are perpendicular to variables removed due to the holdfixed setting

Available: Command line, Option statement, Attribute statement (use before solve)

If option [holdfixed](#) is true, fixed columns in row.column matches are removed from MCP models but the matching rows remain. These rows are ignored by the solver. This option causes a list of such rows to be included in the listing file prior to the solve summary.

Default: 0

meanInfes (*real*): Mean of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the mean of the infeasibilities after a solve.

measure (*no value*): Output of time and memory use since the last measure statement or the program beginning

Available: Option statement

This option has the effect that three measurements will be displayed: the memory and time usage since the last option statement **measure** and the total time used. See also the related option [profile](#).

memoryStat (*no value*): Show memory statistics in the LST file

Available: Option statement

This option has the effect that memory statistics will be shown in the listing file.

MINLP (*string*): Mixed-Integer Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type [Mixed Integer Nonlinear Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

MIP (*string*): Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type [Mixed Integer Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

MIQCP (*string*): Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type [Mixed Integer Quadratically Constrained Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

modelStat (*integer*): Integer number that indicates the model status

Available: Attribute statement (use after solve)

This model attribute returns the model status after a solve. Observe that there are [compile-time constants](#) that are related to **modelStat**. Note that additional information to the values given in the table below is provided in section [Model Status](#).

Value	Meaning
1	Optimal
2	Locally Optimal
3	Unbounded
4	Infeasible
5	Locally Infeasible
6	Intermediate Infeasible
7	Intermediate Nonoptimal
8	Integer Solution
9	Intermediate Non-Integer
10	Integer Infeasible
11	Licensing Problem
12	Error Unknown
13	Error No Solution
14	No Solution Returned
15	Solved Unique
16	Solved
17	Solved Singular
18	Unbounded - No Solution
19	Infeasible - No Solution

MPEC (*string*): Mathematical Programs with Equilibrium Constraints - default solver

Available: Command line, Option statement

The default solver for models of the type [Mathematical Program with Equilibrium Constraints](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

multiPass (*boolean*): Multipass facility

Synonym: MP

Available: Command line

This option may be used to instruct GAMS to use a quick syntax checking compilation facility which does not require all items to be declared. This alternative is useful when a large model is assembled from smaller pieces. It allows slices of GAMS code to be independently checked for syntax errors.

Consider the following example:

```
a(i) = b(i)*5 ;
b(i) = c(j) ;
```

By default, running a file containing just these two statements will generate the following listing file:

```

1  a(i) = b(i)*5 ;
**** $140,120,140
2  b(i) = c(j) ;
**** $140,120,149

120 Unknown identifier entered as set
140 Unknown symbol
149 Uncontrolled set entered as constant

**** 6 ERROR(S)    0 WARNING(S)

```

Note that both sets *i* and *j* have not been defined or initialized. In addition, the identifiers *a*, *b* and *c* have not been defined either. Further, an assignment cannot be made without the right-hand side of the assignment being known. However, in both assignments there is no data available for the right-hand side. If we run the same two lines with the option `mp=1`, we will get the following listing file:

```

1  a(i) = b(i)*5 ;
2  b(i) = c(j) ;
**** $149

149 Uncontrolled set entered as constant

**** 1 ERROR(S)    0 WARNING(S)

```

Observe that the statements have now been processed independently of their context. They are now checked only for consistency. GAMS now assumes that the sets *i* and *j*, as well as the identifiers *a*, *b*, and *c* have been defined and, if necessary, initialized elsewhere. The only error that is reported is the inconsistency of indices in the second statement.

Default: 0

Value	Meaning
0	Standard compilation
1	Check-out compilation
2	As 1, and skip \$call and ignore missing file errors with \$include and \$gdxin as well as unknown dimension errors with empty data statements

NLP (*string*): Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type [Nonlinear Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

nodLim (*integer*): Node limit in branch and bound tree

Available: Command line, Attribute statement (use before solve)

This option specifies the maximum number of nodes that are to be processed in the branch and bound tree search for a MIP problem. Note that setting `nodLim` can stop solutions that are exhibiting "excessive" iterations: if the limit is reached the algorithm will terminate, without obtaining optimality. In this case the solver status will be 4 `TERMINATED BY SOLVER`. Observe that a value of zero is interpreted as 'not set'.

Default: 0

nodUsd (*integer*): Number of nodes used by the MIP solver

Available: Attribute statement (use after solve)

This model attribute returns the number of nodes used by the MIP solver after a solve.

noNewVarEqu (*integer*): Triggers a compilation error when new equations or variable symbols are introduced

Available: Command line

Default: 0

Value	Meaning
0	AllowNewVarEqu
1	DoNotAllowNewVarEqu

number (*real*): Model instance serial number

Available: Attribute statement (use after solve)

This model attribute returns the model instance serial number. Note that the first model solved is assigned number 1, the second number 2 etc. The user may also set a value **n** and the next model solved will be assigned the number **n+1**.

numDepnd (*integer*): Number of dependencies in a CNS model

Available: Attribute statement (use after solve)

This model attribute returns the number of dependencies identified in a CNS model after a solve.

numDVar (*integer*): Number of discrete variables

Available: Attribute statement (use after solve)

This model attribute returns the number of discrete variables after a solve.

numEqu (*integer*): Number of equations

Available: Attribute statement (use after solve)

This model attribute returns the number of equations after a solve.

numInfes (*integer*): Number of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the number of infeasibilities after a solve.

numNLIns (*integer*): Number of nonlinear instructions

Available: Attribute statement (use after solve)

This model attribute returns the number of nonlinear instructions after a solve.

numNLNZ (*integer*): Number of nonlinear nonzeros

Available: Attribute statement (use after solve)

This model attribute returns the number of nonlinear nonzeros after a solve.

numNOpt (*integer*): Number of nonoptimalities

Available: Attribute statement (use after solve)

This model attribute returns the number of nonoptimalities after a solve.

numNZ (*integer*): Number of nonzero entries in the model coefficient matrix

Available: Attribute statement (use after solve)

This model attribute returns the number of nonzero entries in the model coefficient matrix after a solve.

numRedef (*integer*): Number of MCP redefinitions

Available: Attribute statement (use after solve)

This model attribute returns the number of MCP equation-type redefinitions after a solve.

numVar (*integer*): Number of variables

Available: Attribute statement (use after solve)

This model attribute returns the number of variables after a solve.

numVarProj (*integer*): Number of bound projections during model generation

Available: Attribute statement (use after solve)

This model attribute returns the number of bound projections during model generation.

objEst (*real*): Estimate of the best possible solution for a mixed-integer model

Available: Attribute statement (use after solve)

This model attribute returns the estimate of the best possible solution for a MIP or other models with discrete variables. The model attribute is mainly used after solve.

Some GAMS solvers implement algorithms (e.g. branch-and-bound) that generate a bound on the objective function value for the best possible solution. Users may access this bound by using the model attribute **objEst**. Note that this is mainly used for models with discrete variables (e.g. MIP and MINLP), but some global solvers implement spatial branch-and-bound algorithms that also provide such a bound for purely continuous problems. In case the solver does not set the attribute, its value is **na**.

objVal (*real*): Objective function value

Available: Attribute statement (use after solve)

This model attribute returns the objective function value after a solve.

on115 (*boolean*): Generate errors for unknown unique element in an equation

Available: Command line

This option generates errors for unknown unique elements in an equation.

Default: 0

Value	Meaning
0	No error messages
1	Issue error messages

optCA (*real*): Absolute Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an *absolute termination tolerance* for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The absolute gap is defined to be $|\text{PB}-\text{DB}|$. Here the primal bound PB is the objective function value of the best feasible solution found thus far and the dual bound DB is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization).

If the absolute gap is not greater than **optCA**, the solver will terminate and return solver status 1 NORMAL COMPLETION and model status 8 INTEGER SOLUTION (for a problem with discrete variables) or 2 LOCAL OPTIMAL or 7 FEASIBLE SOLUTION (for a problem without discrete variables). Note that this is a termination test only; setting this option should not change the global search.

Note

As this is an *absolute* criterion, setting the value to 100 means that the objective value will be within the 100 units of the true objective value.

Observe that a nonzero value for **optCA** will reduce solution time. However, it may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by **optCA** of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: 0

optCR (*real*): Relative Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies a *relative termination tolerance* for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The precise definition of **optCR** depends on the solver. GAMS and some solvers use the following formula to compute the *optimality gap*:

$$|\text{PB}-\text{DB}| / \max(|\text{PB}|, |\text{DB}|)$$

Here the primal bound PB is the objective function value of the best feasible solution found thus far and the dual bound DB is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization). However, two other formulas are also widely used, namely

$$|\text{PB}-\text{DB}| / |\text{PB}|$$

and

$$|\text{PB}-\text{DB}| / |\text{DB}|$$

Different adjustments when the denominator approaches zero or bounds are of different signs will be applied. The solver will stop as soon as it has found a feasible solution proven to be within **optCR** of optimal, that is, the optimality gap falls below **optCR**.

Note

As `optCR` is specified in *proportional* terms relative to the objective value, a value of 0.1 means that the objective value will be within 10% of the true objective value.

Observe that the solver will stop after finding a solution proven to be optimal within the tolerance specified with `optCR` and thus the solution time may be reduced. However, setting this option may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by `optCR` of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: 1.0E-04

optDir (*string*): Option file directory

Available: Command line

This option may be used to specify the name of the directory for solver option files. By default, the directory will be set to the current working directory.

optFile (*integer*): Default option file

Available: Command line, Attribute statement (use before solve)

This option instructs the solver to read an option file. The value of `optFile` determines which option file is used (see table below). Solver options allow users to manipulate the way solvers work. This may affect various solver functions including the choice of the branch and bound tree handling strategies. Please consult the solver manuals for options for each solver.

Note that this option is available as model attribute and command line parameter. Consider the following GAMS call:

```
> gams myfile optfile=1
```

Observe that the value of 1 for `optFile` means that the option file with the name `solverName.opt` will be used. Here `solverName` is the name of the respective solver. For example, if the solver CONOPT is used, the name of the respective option file is `conopt.opt`.

Note

If `optFile` is set with the model attribute in the GAMS input file, the value of the model attribute will override any `optFile` specifications on the command line.

Different values for `optFile` allow access to different option files for the same solver. Note that the following rule is used: if we specify `optfile = n`, then `solvename.opt` will be used for `n=1`, otherwise `solvename.opX`, `solvename.oXX` or `solvename.XXX` will be used, where X's are the characters representing the value of `n`, for `n > 1`. Observe that no option file will be used if the value of `optFile` is zero.

Default: 0

Value	Meaning
0	No option file will be used
1	The option file <code>solvename.opt</code> will be used
2	The option file <code>solvename.op2</code> will be used
3	The option file <code>solvename.op3</code> will be used
15	The option file <code>solvename.o15</code> will be used
222	The option file <code>solvename.222</code> will be used
1234	The option file <code>solvename.1234</code> will be used

output (*string*): Listing file name

Synonym: OO

Available: Command line

By default, the name of the output file (or listing file) is automatically created by combining the name of the input file with the current directory and applying the standard output file extension `.lst`. This option may be used to specify an alternative name for the output file. If the value is a file name without an absolute path, the current directory will compose the final name. If the absolute path is included in the file name, then the name is used as specified.

Consider the following examples:

```
gams trnsport
gams trnsport o=trnsport.out
gams trnsport o=c:\test\trnsport.out
```

Note that the first call will create an output file called `trnsport.lst` (for PC and Unix platforms) in the current directory. The second call will create a file called `trnsport.out` in the current directory. The last call will create the file as listed. If the directory `c:\test` does not exist, GAMS will exit with a parameter error.

Creation of the `lst` file can be suppressed by setting `output` to `NUL` under Windows or to `/dev/null` on most Unix machines.

pageContr (*integer*): Output file page control option

Synonym: PC

Available: Command line

This option affects the page control in the listing file.

Default: 2

Value	Meaning
0	No page control, with padding
1	FORTTRAN style line printer format
2	No page control, no padding
3	Formfeed character for new page

pageSize (*integer*): Output file page size (=0 no paging)

Synonym: PS

Available: Command line

This option specifies the number of lines that are used on a page for printing the listing file. The lower bound is zero, which is interpreted as `+inf`. That means that everything is printed to one page.

Default: 0

pageWidth (*integer*): Output file page width

Synonym: PW

Available: Command line

This option sets the print width on a page in the listing file with a possible range from 72 to 32767. If the value is outside the allowed range, the default value will be used.

Note that `.pw` is also a [put file attribute](#). In the context of the [put writing facility](#), it may be used to set the page width of a put file. See [page width](#) for further details.

Default: 32767

parmFile (*string*): Command Line Parameter include file

Synonym: PF

Available: Command line

This option specifies the name of a secondary customization parameter file to use. It is used to augment the command line adding more command line parameters from a file. It is read from the current directory unless a path is specified. For an example, see section [Specifying Options Through a Secondary Parameter File](#).

pLicense (*string*): Privacy license file name

Available: Command line

This option gives the name of a privacy license file that contains file encryption codes. A full path should be used. For more information, see [Encrypting Files](#).

prefixLoadPath (*boolean*): Prepend GAMS system directory to library load path

Available: Command line

The OS environment variable to locate shared libraries used to be prefixed with the GAMS system directory. The option controls if this done or not. For the platforms Windows and AIX setting of this option has no impact.

Default: 0

Value	Meaning
0	Do not set GAMS system directory at beginning of library load path
1	Set GAMS system directory at beginning of library load path

previousWork (*boolean*): Indicator for writing workfile with previous workfile version

Available: Command line

When GAMS creates a workfile (e.g. using command line parameter [restart](#)) by default it uses the most recent version of the workfile format. GAMS is backward compatible with respect to workfile formats, i.e. newer GAMS versions can process workfiles generated by older GAMS version. As long as the workfile format has not changed older GAMS versions can even process workfiles generated by newer GAMS versions (using the [forceWork=1](#) command line parameter). This particular command line parameter allows to create a workfile using the *previous* workfile format with the current GAMS version, so the previous GAMS version

(and probably a few more versions back) will properly restart from this workfile even without issuing a warning.

This option is mostly used in combination with submissions to the NEOS server. Setting this option to 1 allows to submit NEOS jobs with a restart file even if the NEOS version is somewhat older than the local GAMS version.

Default: 0

Value	Meaning
0	Write workfile using the current version
1	Write workfile using the previous workfile version

priorOpt (*real*): Priority option for variable attribute .prior

Available: Attribute statement (use before solve)

Instructs the solver to use the [priority branching information](#) passed by GAMS through variable suffix values variable.prior. If and how priorities are used is solver-dependent.

Default: 0

procDir (*string*): Process Directory

Available: Command line

This option specifies the name of the process directory. If specified, the directory must already exist and it will not be deleted when GAMS cleans up. By default, the process directory name is chosen automatically from the list 225a, 225b, ..., 225aa, 225ab ..., by skipping over existing entries, and the directory will be deleted during cleanup if the option [keep](#) is not used. Very little is written to the process directory, but the scratch directory is used more, and the option [scrDir](#) takes its default from the process directory.

procDirPath (*string*): Directory to create process directory in

Available: Command line

This option specifies the directory where the process directory should be created. If specified, the directory must already exist. While the process directory does not get cleaned automatically if the option [procDir](#) is set, this is not the case if the option [procDirPath](#) is used instead. Thus it allows to conveniently change the location of the process directory without changing the GAMS cleanup behavior. Note that if the location of the process directory is changed, the location of the default scratch directory will be changed accordingly (see option [scrDir](#)).

procTreeMemMonitor (*boolean*): Monitor the memory used by the GAMS process tree

Available: Command line

Setting this option to 1 will cause GAMS to record the high-memory mark for the GAMS process tree (i.e. the `gams` or `gams.exe` process and all its children) and note this information in the log just prior to finishing. This is done via a separate thread that runs periodically (use option [procTreeMemTicks](#) to control how often) to construct the GAMS process tree and compute the memory usage for each process in it. There is some overhead with this so it is suggested to use this option only when needed and with a [procTreeMemTicks](#) value not smaller than the default.

In addition to the memory high-water marks (measured using both the size of the resident set and the virtual set used by each process in the tree) the report indicates the number of times this measurement was taken and any failures during this computation.

Default: 0

Value	Meaning
0	Do not monitor memory usage for the GAMS process tree
1	Start a thread to monitor memory usage for the GAMS process tree

procTreeMemTicks (*integer*): Set wait interval between memory monitor checks: ticks = milliseconds

Available: Command line

Sets the wait interval in milliseconds between checks of the GAMS process tree memory usage: see [procTreeMemMonitor](#) for details.

Default: 2000

procUsed (*integer*): Integer number that indicates the used model type

Available: Attribute statement (use after solve)

Value	Meaning
1	LP
2	MIP
3	RMIP
4	NLP
5	MCP
6	MPEC
7	RMPEC
8	CNS
9	DNLP
10	RMINLP
11	MINLP
12	QCP
13	MIQCP
14	RMIQCP
15	EMP

profile (*integer*): Execution profiling

Available: Command line, Option statement

The *execution profile* of a GAMS run contains the individual and cumulative time required to execute the sections of the GAMS model, as well as information on memory use. The option **profile** controls whether an execution profile will be generated in the listing file. Observe that **profile** is available as command line parameter and option statement.

Note

The value for **profile** that is specified with an option statement in the GAMS input file overrides the value of **profile** that is passed through the command line.

Observe that an execution profile will be generated if the option **profile** is assigned a value larger than zero (zero is the default). Setting **profile** to 1 has the effect that execution times for each statement and the number of set elements over which the particular statement is executed will be reported. However, statements in programming flow control structures like loops will be omitted. Information on the execution of these statements will be included in

the profile if the value is n , with $n > 1$. Note that an overview of the values for `profile` is given in the table at the end of this description.

Consider the following GAMS call:

```
> gams trnsport profile=1
```

This call causes the following additional lines to appear in the listing file:

```
-----      1 InitE                0.000      0.000 SECS      3 MB
-----      1 ExecInit            0.000      0.000 SECS      3 MB
-----     44 Assignment c         0.011      0.011 SECS      4 MB      6
-----     63 Assignment transport 0.000      0.011 SECS      4 MB      3
-----     65 Solve Init transport 0.000      0.012 SECS      4 MB
-----     57 Equation cost        0.001      0.013 SECS      4 MB      1
-----     58 Equation supply      0.000      0.013 SECS      4 MB      2
-----     59 Equation demand      0.000      0.013 SECS      4 MB      3
-----     65 Solve Fini transport 0.009      0.022 SECS      4 MB     19
-----     65 GAMS Fini           0.001      0.001 SECS      4 MB
-----      1 InitE                0.000      0.000 SECS      2 MB
-----      1 ExecInit            0.000      0.000 SECS      2 MB
-----     65 Solve Alg transport 0.000      0.000 SECS      2 MB
-----     65 Solve Read transport 0.002      0.002 SECS      2 MB
----      67 Display              0.000      0.002 SECS      3 MB
-----     69 Display              0.000      0.002 SECS      3 MB
-----     69 GAMS Fini           0.001      0.001 SECS      3 MB
```

Observe that the first column provides the line number in the input file of the statement that is executed.

The second column reports the type of the respective statement. For an overview of all GAMS statements, see section [Classification of GAMS Statements](#). In addition, `ExecInit` denotes the beginning of the execution phase of the GAMS input file and `GAMS Fini` denotes the end of this phase. Note that as soon as a solve statement is processed, GAMS will pass control to the solver system. Once the solver has completed its task, GAMS will restart. Thus we have two `ExecInit/ GAMS Fini` pairs in our example. Note that only equations are listed, and not variables. This reflects the fact that GAMS uses an equation based scheme to generate a model.

The third and fourth columns show the individual time needed to execute the statement and the cumulative time taken by the GAMS system so far.

The last column gives the number of assignments that were generated in the specified line.

In addition to the lines above, a *profile summary* is created at the end of the listing file. This summary contains (up to) ten of the slowest execution steps. The profile summary from `trnsport.lst` follows:

```
----- Profile Summary (17 records processed)
0.011  0.004GB      44 Assignment c (6)
0.009  0.004GB      65 Solve Fini transport (19)
0.002  0.002GB      65 Solve Read transport
0.001  0.004GB      65 GAMS Fini
0.001  0.004GB      57 Equation cost (1)
0.001  0.003GB      69 GAMS Fini
```

Note that execution profiles and profile summaries are particularly useful for detecting the sources of performance problems. For further details, see section [Finding the Causes for Slow Program Execution](#).

Default: 0

Value	Meaning
0	No profiling
1	Minimum profiling
n	Profiling depth for nested control structures

profileFile (*string*): Write profile information to this file

Synonym: PFILE

Available: Command line

This option causes profiling information to be written to a file. Note that profiling information is only created with the setting `profile=1` or `profile=2`. For example such a file may have the following content:

```

      1      -1      0.000      0.003 ExecInit
     45       6      0.000      0.004 Assignment c
     66      -1      0.000      0.004 Solve Init transport
     58       1      0.000      0.004 Equation cost
     60       2      0.000      0.004 Equation supply
     62       3      0.000      0.004 Equation demand
     66      19      0.015      0.004 Solve Fini transport
     66      -1      0.000      0.004 GAMS Fini
      1      -1      0.000      0.002 ExecInit
     66      -1      0.000      0.002 Solve Read transport
     68      -1      0.000      0.003 Display
     68      -1      0.000      0.003 GAMS Fini

```

profileTol (*real*): Minimum time a statement must use to appear in profile generated output

Synonym: PTOL

Available: Command line, Option statement

This option sets the profile tolerance in seconds. All statements that take less time to execute than this tolerance are not reported in the listing file. Note that this option is only effective if the value of the option `profile` is larger than zero.

Default: 0

putDir (*string*): Put file directory

Synonym: PDir

Available: Command line

By default, `put files` are generated and saved in the current working directory. This option may be used to specify an alternative directory. Note that this option does not work if an absolute file name is provided through the `file statement`.

putND (*integer*): Number of decimals for put files

Available: Command line

This sets the default for the put file attribute `.nd`.

Default: 2

putNR (*integer*): Numeric round format for put files

Available: Command line

This sets the default for the put file attribute `.nr`.

Default: 1

Value	Meaning
0	Item is displayed in F or E format
1	Item is rounded to fit fields
2	Item is displayed in scientific notation

putPS (*integer*): Page size for put files

Available: Command line

This sets the default for the put file attribute `.ps`.

Default: 58

putPW (*integer*): Page width for put files

Available: Command line

This sets the default for the put file attribute `.pw`.

Default: 32767

pyMultInst (*integer*): GAMS/Python Multiple Instance Interpreter

Available: Command line

This options controls the setup of the Python interpreter for use in embedded Python code sections. If this option is set to 1 the embedded Python code can work with multiple [independent Python sessions](#). If `pyMultInst` is set to 0 there is a single interpreter even with multiple parallel embedded Python sessions that all share the same data space. With `pyMultInst` set to 0 or 1, the environment variable `GMSPYTHONMULTINST` is set by GAMS to this value. If the option is not set the value will be taken from the user environment variable `GMSPYTHONMULTINST`. Note that setting this to 1 might cause problems when using third party modules and packages (e.g. `numpy` or modules that make use of it) and might also impact the performance.

Default: 0

Value	Meaning
0	Use a single-session Python interpreter
1	Use a multi-session Python interpreter

QCP (*string*): Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type [Quadratically Constrained Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

real1..5 (*real*): Real communication cell N

Available: Option statement, Attribute statement (use before solve)

This option specifies a real communication cell that may contain any real number.

reference (*string*): Symbol reference file

Synonym: RF

Available: Command line

If this option is specified, all symbol references will be written to the specified file. Setting **rf** or **Reference** to the string 'default' will cause GAMS to create a reference file with the file root name of the GAMS input file and the extension **ref**. Thus the call

```
> gams trnsport rf=default
```

will generate the reference file **trnsport.ref**.

referenceLineNo (*string*): Controls the line numbers written to a reference file

Synonym: RFLN

Available: Command line

Default: **actual**

Value	Meaning
actual	Actual line number of symbol reference
start	Line number where the statement with the reference starts

reform (*integer*): Reformulation level

Available: Option statement, Attribute statement (use before solve)

This option triggers an objective function reformulation. The interpretation depends on the solver. The solvers **MINOS** and **SNOPT** support this option. Note that the default value is zero and the range is [-2147483647,2147483647].

resCalc (*real*): Time spent in function and derivative calculations (deprecated)

Available: Attribute statement (use after solve)

resDeriv (*real*): Time spent in derivative calculations (deprecated)

Available: Attribute statement (use after solve)

resGen (*real*): Time GAMS took to generate the model in CPU seconds(deprecated)

Available: Attribute statement (use after solve)

This model attribute returns the time GAMS took to generate the model in CPU seconds.

resIn (*real*): Time to import model (deprecated)

Available: Attribute statement (use after solve)

resLim (*real*): Wall-clock time limit for solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the time in seconds that the solver can run before it can terminate and return the solver status 3 **RESOURCE INTERRUPT**. The solver should start the clock soon after it starts, so the time required to read in the problem and do any reformulations, preprocessing or presolving is included in the time limit. Where possible, the time limit applies to the wall-clock time: this behavior translates well to multi-threaded solves. Moreover, some solver links might *reinterpret* the value of this option. For example, if left at default (1e+10), the solver link might use the default time limit of the solver.

Note

This value could be automatically reduced, if required because of [etLim](#).

Default: 10000000000

resOut (*real*): Time to export solution (deprecated)

Available: Attribute statement (use after solve)

restart (*string*): Name of a restart file, see [The Save and Restart Feature](#)

Synonym: R

Available: Command line

This option specifies the name of a work file that was written with the option [save](#) that will be used to restart the GAMS program. The work file is also called *restart file*. For more information including examples, see chapter [The Save and Restart Feature](#).

restartNamed (*string*): Name of another matching restart file, see [Obfuscated Work Files](#)

Synonym: RN

Available: Command line

resUsd (*real*): Time the solver used to solve the model in seconds

Available: Attribute statement (use after solve)

This model attribute returns the time in seconds used by the solver. Wherever possible, the units used (wall-clock time vs. CPU time) will be the same as used by the [reslim](#) option.

RMINLP (*string*): Relaxed Mixed-Integer Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type [Relaxed Mixed Integer Nonlinear Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

RMIP (*string*): Relaxed Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type [Relaxed Mixed Integer Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

RMIQCP (*string*): Relaxed Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type [Relaxed Mixed Integer Quadratically Constrained Programs](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

RMPEC (*string*): Relaxed Mathematical Programs with Equilibrium Constraints - default solver

Available: Command line, Option statement

The default solver for models of the type [Relaxed Mathematical Program with Equilibrium Constraints](#) is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to **default**.

rObj (*real*): Objective function value from the relaxed solve of a mixed-integer model when the integer solver did not finish

Available: Attribute statement (use after solve)

This model attribute returns the objective function value from the relaxed solve of a MIP when the integer solver did not finish.

save (*string*): Creates a work file, see [The Save and Restart Feature](#)

Synonym: S

Available: Command line

This option specifies the name of a work file to be written. The work file is intended to be used later to restart the GAMS program and it is also frequently referred to as *save file* or *restart file*. If no explicit file extension is provided, the default file extension `.g00` is used. If no specific file path is provided the work file is created in the current directory.

Note

- The character "?" is not allowed in save file names - that use was intended for old (pre-GAMS 21.7) save files only.
- Save files are platform-independent.

For further information including examples, see chapter [The Save and Restart Feature](#).

saveObfuscate (*string*): Creates an obfuscated work file, see [Obfuscated Work Files](#)

Synonym: SO

Available: Command line

savePoint (*integer*): Save solver point in GDX file

Synonym: SP

Available: Command line, Option statement, Attribute statement (use before solve)

This option instructs GAMS to save a point format [GDX file](#) that contains the information on the current solution point.

Default: 0

Value	Meaning
0	No point GDX file is to be saved
1	A point GDX file from the last solve is to be saved
2	A point GDX file from every solve is to be saved
3	A point GDX file from the last solve is to be saved in the scratch directory
4	A point GDX file from every solve is to be saved in the scratch directory

scaleOpt (*boolean*): Employ user specified variable and equation scaling factors

Available: Attribute statement (use before solve)

This option determines whether GAMS will employ user-specified variable and equation scaling factors. It must be set to a nonzero value if scaling factors are to be used. For more details on scaling, see section [Model Scaling - The Scale Option](#).

Default: 0

scrDir (*string*): Scratch directory

Synonym: SD

Available: Command line

This option specifies the name of the scratch directory. The scratch directory is used by GAMS for intermediate files that are generated during execution. The scratch directory and all its contents are usually deleted at the end of the GAMS run. By default, the scratch directory takes its value from the process directory that is specified with the option [procDir](#). If neither the scratch directory nor the process directory are specified, the scratch directory will be set to a subdirectory of the current working directory with an internally generated name. If the scratch directory is specified, the respective directory must already exist and neither the content nor the directory itself will be deleted by GAMS at the end of the run.

Note that the option [solveLink](#) may be used to reduce or eliminate the need for intermediate files.

scrExt (*string*): Scratch file extension to be used with temporary files

Synonym: SE

Available: Command line

This option specifies the name of the extension for the temporary files that GAMS is generating during execution.

Default: dat

scriptExit (*string*): Program or script to be executed at the end of a GAMS run

Available: Command line

By default, GAMS does not call an exit script anymore. If this is required, the option **scriptExit** has to be set explicitly to the script that should be called after GAMS terminates. Note that an empty template of an exit script is in the GAMS system directory: it is called **gmsxitnt.cmd** for Windows and **gmsxitus.run** for Unix.

scriptFrst (*string*): First line to be written to GAMSNEXT file.

Synonym: SF

Available: Command line

This option specifies the first line written to `gamsnext`. The default is an empty string and the *first* line is not written.

scrNam (*string*): Work file names stem

Synonym: SN

Available: Command line

This option specifies the name stem that is used to complete the names of intermediate work files. Note that the name stem must have at least one '!'. The name will be completed with the scratch directory and the standard scratch name extension.

seed (*integer*): Random number seed

Available: Command line, Option statement

This option specifies the seed that is used for the pseudo random number generator.

Default: 3141

showOSMemory (*integer*): Show the memory usage reported by the Operating System instead of the internal counting

Available: Command line

Default: 0

Value	Meaning
0	Show memory by internal accounting
1	Show resident set size reported by operating system
2	Show virtual set size reported by operating system

solPrint (*int or string*): Solution report print option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the printing of the [solution listing](#) to the listing file.

N.B: the command line accepts the string and numeric value, the option statement only the string value, and the attribute statement accepts the numeric value and compile-time constant. The table below offers an overview of the different types of values and a description of the associated meaning.

String Value	Numeric Value	Compile-Time Constant	Meaning
<code>off</code>	0	<code>solprint.Off</code>	Remove solution listings following solves
<code>on</code>	1	<code>solprint.On</code>	Include solution listings following solves
<code>silent</code>	2	<code>solprint.Silent</code>	Suppress all solution information

Default: On

solSlack (*boolean*): Causes the equation output in the listing file to contain slack variable values instead of level values

Available: Option statement

If the value of this option is set to 1, the equation output in the listing file will contain slack variable values instead of level values.

Default: 0

Value	Meaning
0	includes equation levels in the solution part of the LST file following solves
1	includes equation slacks in the solution part of the LST file following solves

solveLink (*integer*): Solver link option

Synonym: SL

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies what solver linking conventions are used when GAMS executes a **solve** statement. Note that values 3 and 6 are relevant for [grid computing](#). Observe that there are [compile-time constants](#) that are associated with this option. When the model instance is saved to the scratch directory (values 0, 1, 2, and 3), the solution produced by the solve is also written to the scratch directory and read in by GAMS when the execution resumes.

Default: 2

Value	Meaning
0	Model instance and entire GAMS state saved to scratch directory, GAMS exits (and vacates memory), and the solver script is called. After the solver terminates, GAMS restarts from the saved state and continues to executing
1	Model instance saved to scratch directory, the solver is called from a shell while GAMS remains open
2	Model instance saved to scratch directory, the solver is called with a spawn (if possible) or a shell (if spawn is not possible) while GAMS remains open
3	Model instance saved to scratch directory, the solver starts the solution and GAMS continues in a grid computing environment
4	Model instance saved to scratch directory, the solver starts the solution and GAMS waits for the solver to come back but uses same submission process as 3 (test mode)
5	The model instance is passed to the solver in-memory
6	The model instance is passed to the solver in-memory, the solver starts the solution and GAMS continues in a grid computing environment
7	The model instance is passed to the solver in-memory, the solver starts the solution and GAMS waits for the solver to come back but uses same submission process as 6 (test mode)

solveOpt (*int or string*): Multiple solve management

Available: Option statement, Attribute statement (use before solve)

This option will instruct GAMS how to manage the model solution if only part of the variables and equations in the particular problem are solved.

Observe that this option is available as model attribute and option statement. The values for model attributes are numeric, while the values for option statements are text strings. In addition, there are [compile-time constants](#) that are associated with this option. The first of the two tables below offers an overview of how the different types of values are related and the second table gives the values in numerical terms and a description of the associated meaning.

Numeric Value	String Value	Compile-Time Constant
0	replace	solveOpt.Replace
1	merge	solveOpt.Merge
2	clear	solveOpt.Clear

Default: 1

Value	Meaning
0	The solution information for all equations appearing in the model is completely replaced by the new model results; variables are only replaced if they appear in the final model
1	The solution information for all equations and variables is merged into the existing solution information
2	The solution information for all equations appearing in the model is completely replaced; in addition, variables appearing in the symbolic equations but removed by conditionals will be removed

solver (*string*): Default solver for all model types that the solver is capable to process

Available: Command line, Option statement

The command line parameter `solver=abc` initializes the default solver for the model types the solver "abc" is capable of to `abc`. This initialization is done before the default solvers of individual model types are set via command line parameters. Consider the following example:

```
> gams trnsport lp=conopt solver=soplex
```

Note that this GAMS call will first set the solver SOPLEX as the solver for the model types LP and RMIP, since these are the model types that SOPLEX can handle. Then Conopt will be reset as the default solver for LPs. Observe that the order of these parameters on the command line is irrelevant. If multiple occurrences of the option `solver` appear, the last entry will set the value of the option.

In addition, the solver for multiple model types may be set in the GAMS model source code via the following statement:

```
option solver = abc;
```

This statement sets the solver for the model types the solver `abc` can handle to `abc`. Note that in such an option statement the order of other solver setting options is significant. Consider the following example:

```
option lp=conopt, solver=soplex;
```

This statement will first set the solver for LPs to Conopt and in the next step to SOPLEX because SOPLEX is capable of handling the model type LP. In some cases it makes sense to set a solver twice. Consider the following example:

```
option solver=conopt, solver=cbc;
```

This option statement has the effect that models of the types CNS, DNLP, NLP, QCP, RMIQCP or RMINLP will be solved with Conopt and models of the types LP, RMIP or MIP will be solved with CBC.

Note that as usual, a specification of a solver through an option statement in the GAMS source takes precedence over a specification on the command line.

solverCntr (*string*): Solver control file name

Synonym: SCNTR

Available: Command line

This option specifies the solver control file name. Note that the name is completed with the scratch directory and the scratch extension.

solverDict (*string*): Solver dictionary file name

Synonym: SDICT

Available: Command line

This option specifies the solver dictionary file name. Note that the name is completed with the scratch directory and the scratch extension.

solverInst (*string*): Solver instruction file name

Synonym: SINST

Available: Command line

This option specifies the solver instruction file name. Note that the name is completed with the scratch directory and the scratch extension.

solverMatr (*string*): Solver matrix file name

Synonym: SMATR

Available: Command line

This option specifies the solver matrix file name. Note that the name is completed with the scratch directory and the scratch extension.

solverSolu (*string*): Solver solution file name

Synonym: SSOLU

Available: Command line

This option specifies the solver solution file name. Note that the name is completed with the scratch directory and the scratch extension.

solverStat (*string*): Solver status file name

Synonym: SSTAT

Available: Command line

This option specifies the solver status file name. Note that the name is completed with the scratch directory and the scratch extension.

solveStat (*integer*): Indicates the solver termination condition

Available: Attribute statement (use after solve)

This model attribute indicates the solver termination condition. Observe that there are [compile-time constants](#) that are related to `solveStat`. Note that additional information to the values given in the table below is provided in section [Solver Status](#).

Value	Meaning
1	Normal Completion
2	Iteration Interrupt
3	Resource Interrupt
4	Terminated By Solver
5	Evaluation Interrupt
6	Capability Problems
7	Licensing Problems
8	User Interrupt
9	Setup Failure
10	Solver Failure
11	Internal Solver Failure
12	Solve Processing Skipped
13	System Failure

stepSum (*boolean*): Summary of computing resources used by job steps

Available: Command line

This option controls the generation of a step summary of the processing times taken by GAMS during a given run.

For example, the call

```
> gams transport stepsum=1
```

will generate the following *step summaries* in the listing file:

```
STEP SUMMARY:    0.016      0.016 STARTUP
                  0.005      0.005 COMPILATION
                  0.065      0.065 EXECUTION
                  0.001      0.001 CLOSEDOWN
                  0.087      0.087 TOTAL SECONDS
                  0.089      0.089 ELAPSED SECONDS
                  3.942      3.942 MAX HEAP SIZE (MB)
```

Note that this step summary will be printed before the model is sent to the solver, thus it may be found before the solve summary. The second step summary will be printed after solution, it will appear at the very end of the listing file:

```
STEP SUMMARY:    0.004      0.020 STARTUP
                  0.000      0.005 COMPILATION
                  0.003      0.068 EXECUTION
                  0.000      0.001 CLOSEDOWN
                  0.007      0.094 TOTAL SECONDS
                  0.239      0.328 ELAPSED SECONDS
                  2.899      3.942 MAX HEAP SIZE (MB)
```

Observe that the first column reports the time for the individual section of the run, while the second column reports accumulated times including previous sections.

Default: 0

Value	Meaning
0	No step summary
1	Step summary printed

strictSingleton (*boolean*): Error if assignment to singleton set has multiple elements

Available: Command line, Option statement

This option affects the behavior of a membership assignment to a [singleton set](#). If the value is set to zero, GAMS will not complain about a singleton set with more than one element, but will take only the first element. However, if the value is set to 1, a singleton set definition with more than one element will cause an error. Also, if this option is set as a command line parameter it initializes the state of the dollar control option [\\$on/offStrictSingleton](#). So, it influences the singleton set checking at both compile- and execution time.

Default: 1

Value	Meaning
0	Take first record if assignment to singleton set has multiple elements
1	Error if assignment to singleton set has multiple elements

stringChk (*integer*): String substitution options

Available: Command line

This option affects the result of the check for `%xxx%` symbols. Note that `%xxx%` symbols may be [environment variables](#) (also at [execution time](#)) or [compile-time variables](#).

Default: 0

Value	Meaning
0	No substitution if symbol undefined and no error
1	Error if symbol undefined
2	Remove entire symbol reference if undefined and no error

subSys (*string*): Name of subsystem configuration file

Available: Command line

This option specifies the name of the configuration file that contains solver defaults and other information. This option should be used only by advanced users who attempt to override internal subsystem information. In case you want to add a solver to your GAMS system, please inspect the section [Adding Solvers via gamsconfig.yaml](#).

subSystems (*no value*): Lists all solvers available as well as the current default and active solvers in the LST file

Available: Option statement

This option has the effect that all available subsystems will be displayed in the listing file. Note that a solver is considered a subsystem.

suffixDLVars (*string*): Switch default for `"$on/offSuffixDLVars"`

Available: Command line

For more info see [\\$on/offSuffixDLVars](#).

Default: `off`

Value	Meaning
off	Activate \$offSuffixDLVars
on	Activate \$onSuffixDLVars

sumInfes (*real*): Sum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the sum of infeasibilities after a solve.

suppress (*boolean*): Compiler listing option

Available: Command line

If set to 1, this option will suppress the echoing of the contents of the input file(s) to the listing file. Note that this option is similar in functionality to the dollar control option [\\$offlisting](#).

Note

The dollar control options [\\$on/offlisting](#) will affect the [echo print](#) in the listing file only if **suppress** is set to zero. If **suppress** is set to 1, the input file(s) will not be echoed to the listing file and the dollar control options will not have any effect on the listing file.

Default: 0

Value	Meaning
0	Standard compiler listing
1	Suppress compiler listing

symbol (*string*): Symbol table file

Available: Command line

This option specifies the name of a partial symbol table that may be written in conjunction with [reference files](#).

symPrefix (*string*): Prefix all symbols encountered during compilation by the specified string in work file

Available: Command line

sys10 (*boolean*): Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer

Available: Command line, Option statement

Default: 0

Value	Meaning
0	Disable conversion
1	Enable conversion

sys11 (*integer*): Dynamic resorting if indices in assignment/data statements are not in natural order

Available: Command line, Option statement

Speed-up for expressions containing constant indices or indices that are not in the natural order at the cost of increased memory use.

Default: 0

Value	Meaning
0	Automatic optimization/restructuring of data
1	No optimization
2	Always optimize/restructure

sys12 (*integer*): Pass model with generation errors to solver

Synonym: noSolveSkip

Available: Command line, Option statement

Default: 0

sys15 (*integer*): Automatic switching of data structures used in search records

Available: Command line, Option statement

Default: 0

Value	Meaning
0	Automatic switching to dense data structures
1	No switching
2	Always switch
1x	Print additional information in lst file

sys16 (*integer*): Disable search record memory (aka execute this as pre-GAMS 24.5)

Available: Command line, Option statement

Default: 0

sys17 (*integer*): Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)

Available: Command line, Option statement

Default: 0

sys18 (*integer*): Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers

Available: Command line, Option statement

By default GAMS accepts floating-point numbers with arbitrarily many digits and converts them to correctly-rounded double-precision values. This option selects a backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers (see also the [offDigit](#) dollar control option).

Default: 0

Value	Meaning
0	Use modern scheme for reading floating-point numbers
1	Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers

sys19 (*integer*): Disable permutation on Column Generation (aka execute this as pre-GAMS 36)

Available: Command line, Option statement

Default: 0

sysDir (*string*): GAMS system directory where GAMS executables reside

Available: Command line

This option sets the GAMS system directory. It is useful if there are multiple systems installed on the machine or when GAMS is called from an external system like Visual Basic.

sysIdent (*real*): Solver identification number

Available: Attribute statement (use after solve)

sysIncDir (*string*): SysInclude directory

Synonym: SDIR

Available: Command line

This option specifies the name of the directory to be used by GAMS for [sysinclude](#) files that do not have a full path specification. An absolute or relative path may be specified. If this option is not set, it will be set to the GAMS system directory.

Note that if this option is set, the default system include directory will not be searched.

Attention

Only *one* directory may be set with the option `sDir`. Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

```
> gams myfile sdir mydir
```

Note that GAMS will search for any referenced [sysinclude](#) file in the directory `mydir`.

sysOut (*bool or string*): Solver Status file reporting option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls whether additional solver generated output (the solver status file) is included in the listing file. Note that the contents of the solver status file are useful for debugging or to get additional information about a solver run. Normally, only those messages flagged by the solver as destined for the listing file will be listed. If the solver crashes or encounters any unexpected difficulties, the contents of the solver status file will be automatically sent to the listing file.

Note that the boolean values (`off: 0` and `off: 1`) are deprecated, they are only relevant for backward compatibility. The table below gives the boolean values and the associated meaning.

String Value	Meaning
off	Suppress additional solver generated output
on	Include additional solver generated output

Default: Off

sysVer (*real*): Solver version

Available: Attribute statement (use after solve)

tabIn (*integer*): Tab spacing

Available: Command line

This option sets the tab spacing. By default, tabs are not allowed in GAMS. However, the most common setting is 8. As a result, the tabs are at columns 1, 9, 17, ... and the intermediate columns are replaced by blanks.

Default: 8

Value	Meaning
0	Tabs are not allowed
1	Tabs are replaced by blanks
n	Tabs are 1, n+1, 2n+1,.. (default: n=8)

tFormat (*boolean*): Time format

Synonym: TF

Available: Command line

This option controls the time format in the listing file. The three date formats correspond to the various conventions used around the world. For example, the time 7:45~PM will be written as 19:45:00 with the default **tf** value of zero and as 19.45.00 with **tf**=1.

Default: 0

Value	Meaning
0	Time as hh:mm:ss
1	Time as hh.mm.ss

threads (*integer*): Number of threads to be used by a solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of threads (and thereby the number of processors) to be used by a solver. If the number is greater than the number of available processors, it will be reduced to the number of processors available. Note that a value of zero implies the number of threads used will be equal to the number of processors available.

Default: 1

Value	Meaning
0	Use number of available processors
n	Use n threads
minus_n	Number of processors to leave free for other tasks

threadsAsync (*integer*): Limit on number of threads to be used for asynchronous solves (solveLink=6)

Available: Command line, Option statement

Default: -1

Value	Meaning
0	Use number of available processors
n	Use n threads
minus_n	Number of processors to leave free for other tasks

timer (*integer*): Instruction timer threshold in milli seconds

Available: Command line

This option specifies an instruction timer threshold in milli seconds. That means that only details about internal GAMS intructions that took more than n milli seconds are echoed to the log.

Default: 0

Value	Meaning
0	Interpreted as +inf, no details echoed
n	Echo all details about internal GAMS instructions that took more than n milli seconds to the log

tolInfeas (*real*): Infeasibility tolerance for an empty row of the form a.. 0*x =e= 0.0001;

Available: Attribute statement (use before solve)

This option specifies the infeasibility tolerance for an empty row of the following form:

a.. 0*x =e= 0.0001;

If the option is not set, a tolerance of 10 times the machine precision will be used. Empty rows that fail this infeasibility check will be flagged with the listing file message **Equation infeasible due to rhs value.**

tolInfRep (*real*): This attribute sets the tolerance for marking infeasible in the equation listing

Available: Attribute statement (use before solve)

This option sets the tolerance for marking an equation **infeasible** in the equation listing. Note that the default value is 1.0e-13.

Default: 1.0E-13

tolProj (*real*): Tolerance for setting solution values to a nearby bound when reading a solution

Available: Attribute statement (use before solve)

When a solution is returned from a solver, equation and variable level values that are very close to their lower or upper bounds are projected or moved to that bound, and a count of the projections/moves made is included in the solution report's **REPORT SUMMARY**. This option controls the relative tolerance used in testing for closeness: project if $\text{abs}(\text{level} - \text{bound}) < \text{tolproj} * (1 + \text{abs}(\text{level}))$. For MCP models, this projection is also applied to the variable marginal values. In this case the projection count is not incremented and the test is an absolute and not a relative test: project if $\text{abs}(\text{marginal}) < \text{tolproj}$.

Default: 1.0E-08

trace (*string*): Trace file name

Available: Command line

This option specifies the [trace file](#) name and causes a trace file to be written. Note that if a previous trace file of the same name already exists, then all new data output will be appended. Therefore, users should be careful to delete all old versions of the trace file if the a file name is reused and they do wish the new data to be appended.

traceLevel (*integer*): Modelstat/Solvestat threshold used in conjunction with action=GT

Synonym: TL

Available: Command line

Default: 0

traceOpt (*integer*): Trace file format option

Available: Command line

This option specifies the format of the [trace file](#). Note that several different types of trace files may be created, depending on what output information is desired.

Default: 0

Value	Meaning
0	Solver and GAMS step trace
1	Solver and GAMS exit trace
2	Solver trace only
3	Solver trace only in format used for GAMS performance world
5	Gams exit trace with all available trace fields

tryInt (*real*): Whether solver should make use of a partial integer-feasible solution

Available: Attribute statement (use before solve, reset by solve statement)

Signals the solver to make use of a partial or near-integer-feasible solution stored in current variable values to get a quick integer-feasible point. The exact form of implementation depends on the solver and may be partly controlled by solver settings or options. See the solver manuals for details.

tryLinear (*real*): Examine empirical NLP model to see if there are any NLP terms active. If there are none the default LP solver will be used

Available: Attribute statement (use before solve)

If this option is set to 1, empirical NLP models will be examined to determine if there are any active NLP terms. If there are none, the default LP solver will be used. The procedure also checks to see if QCP and DNLP models can be reduced to an LP; MIQCP and MINLP can be solved as a MIP; RMIQCP and RMINLP can be solved as an RMIP. Note that the default value is zero.

user1..5 (*string*): User string N

Synonym: U1

Available: Command line

This option permits users to enter a text for up to 5 user-defined options. The [double dash](#) parameters supersede these parameters.

warnings (*integer*): Number of warnings permitted before a run terminates

Available: Command line

This option specifies the maximum number of allowable warnings, before the run terminates.

Default: ∞

workDir (*string*): Working directory

Synonym: WDir

Available: Command line

This option sets the working directory. This option is useful when GAMS is called from an external system like Visual Basic. If it is not specified, the working directory will be set to the directory [curDir](#).

workFactor (*real*): Memory Estimate multiplier for some solvers

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace to allocate for problem solution relative to the solver-computed estimate. For example, setting the value to 2 will double the memory estimate. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect. Note that in cases where both options [workfactor](#) and [workSpace](#) are specified, the value for [workSpace](#) will take precedence.

Default: 1

workSpace (*real*): Work space for some solvers in MB

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace in Megabytes to allocate. If it is not specified by the user, the solver will estimate the size. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect, or it may be used as a memory limit.

xSave (*string*): Creates a compressed [work file](#)

Synonym: XS

Available: Command line

This option specifies the name of a [save file](#) written in ASCII format in older GAMS systems (versions older than 21.7), in order for the save file to be platform dependent and may be moved to machines with different operating systems.

In GAMS systems from release 22.3 and newer this option has the effect that compressed save files are written.

xSaveObfuscate (*string*): Creates a compressed [obfuscated work file](#)

Synonym: XSO

Available: Command line

zeroRes (*real*): The results of certain operations will be set to zero if $\text{abs}(\text{result}) \leq \text{ZeroRes}$

Available: Command line

This option specifies the threshold value for internal rounding to zero in certain operations.

Default: 0

zeroResRep (*boolean*): Report underflow as a warning when $\text{abs}(\text{results}) \leq \text{ZeroRes}$ and result set to zero

Available: Command line

This option causes GAMS to issue warnings whenever a rounding occurs because of the setting of the option [zeroRes](#).

Default: 0

Value	Meaning
0	No warning when a rounding occurs because of ZeroRes
1	Issue warnings whenever a rounding occurs because of ZeroRes

zeroToEps (*string*): Treat zero as eps

Available: Option statement

When this is set to **on**, zero values are interpreted as EPS when loading non-scalar parameters from [GDX](#) or [embedded code](#) at execution time. Also, when deriving a set from a parameter in a GDX file at execution time, set records will be created for parameter records with value 0, if **zeroToEps** is set to **on**, but not, if it is **off**.

See dollar control option [\\$onEps](#) for the compile-time equivalent.

Default: **off**

Value	Meaning
off	Treat Zero as Zero
on	Treat Zero as Eps

4.40.7 Executing an External Program

External programs may be run during a GAMS job either using the `$call`, `Execute` or `Put_utility` syntax. The `$call` procedure is executed at the moment that is encountered during compilation. The `Execute` and `Put_utility` commands causes the external program to be run during GAMS program execution. The contrast between these statements is important in two ways.

- Influence on results that can be included in a GAMS program – Anything run with `$Call` can generate files that can be included in the subsequent compilation. On the other hand files generated with `Execute` and `Put_utility` cannot be included because `$Include` operates only at compile time (unless you use [Save and Restart](#)).
- Influence on results that can be fed into the external program – Obviously when one is running an external program there is the desire to pass it data depicting results of the GAMS execution. `$Call` cannot do this as the data passed have to exist at compile time and cannot use the result of any GAMS calculations and solves in the current program. `Execute` commands on the other hand can use any data generated during a run which arise before the `Execute` and `Put_utility` command's position in the file through passage via `put` files or other mechanisms.

The big difference between the `$call` and `execute` is

- `$call`
 - can generate results to be immediately incorporated back into GAMS
 - cannot use GAMS results generated within this run because the `$Call` is executed at compile time.
- `execute` and `put_utility`
 - can cause a program to be started using results generated by the GAMS program (note such results do have to have been saved in an external file using a command like `put`)
 - cannot generate results which can be immediately reincluded into the GAMS program because new material can only be added compile time.

4.40.7.1 Execute

This command uses the syntax

```
execute[.async[NC] | .checkErrorLevel] "[=]command_to_execute"
```

to execute a program specified by `command_to_execute`. The execution occurs during the GAMS execution phase.

- The `=` will call the program directly, while without the `=` GAMS calls a shell that executes the program. When a program is executed in a shell, mechanisms like redirection (`>`) and pipe (`|`) will work.
- The `.async` suffix makes GAMS go ahead without waiting.
- The `.asyncNC` option tells the operating system to start the run a new console rather than sharing the console of the parent process allowing use of multiple processors. This is available under Windows only.
- The `.checkErrorLevel` suffix checks the [errorLevel](#) implicitly, raises an execution error and aborts the execution, if that is not 0.
- Since this occurs during execution one cannot use the compile time `$Include` to incorporate the results of that external run into the GAMS code except through a **GAMS from GAMS** approach as discussed below or through `save` and `restart` use (see the [Save Restart](#) chapter).

4.40.7.2 Asynchronous Execution

The `.async` variant of `$call` and `execute` start a job without waiting for the result. One can continue in the GAMS program and collect the return code of the job later. There are three ways to start a job asynchronously:

- `$call.async ...` (compile phase)
- `execute.async '...';` (execution phase)
- `'put_utility fx 'exec.async' / '...!'; / put_utility fx 'shell.async' / '...!';`` (execution phase)

After each of those the function `JobHandle` can be used to get the Process ID (pid) of the last job started. With `jobStatus(pid)` one could check for the status of a job. Possible return values are:

- 0: error (input is not a valid PID or access is denied)
- 1: process is still running
- 2: process is finished with return code which could be accessed by `errorLevel`
- 3: process not running anymore or was never running, no return code available

With `jobTerminate(pid)` a interrupt signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

With `jobKill(pid)` a kill signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

The model `[ASYNCEXEC]` from the GAMS Test Library demonstrates the use of this feature.

4.41 Dollar Control Options

4.41.1 Introduction

Dollar control options are used to indicate compiler directives and options. Dollar control options are not part of the GAMS language and must be entered on separate lines marked with the symbol `$` in the first column. A dollar control option line may be placed anywhere within a GAMS program and it is processed during the compilation of the program. The symbol `$` is followed by one or more options separated by spaces. Since the dollar control options are not part of the GAMS language, they do not appear on the compilation output in the listing file unless an error has been detected or the user has requested them to be shown (with the option `$onDollar`). Note that dollar control option lines are not case sensitive and a continued compilation uses the previous settings.

This chapter is organized as follows. First an overview of the dollar control options will be given in section [List of Dollar Control Options](#), where the options will be presented in groups reflecting their major functional categories. Section [Detailed Description of Dollar Control Options](#) will contain a reference list of all dollar control options in alphabetical order with detailed description for each.

We will conclude this chapter with separate sections for two important topics: [Conditional Compilation](#), [Macros in GAMS](#), [Compressing and Decompressing Files](#), and [Encrypting Files](#).

4.41.1.1 Syntax

In general, the syntax in GAMS for dollar control statements is as follows:

```
$option_name argument_list {option_name argument_list}
```

The symbol `$` in the first column indicates that this is a dollar control statement. It is followed by the name of the dollar control option `option_name` and the list of arguments `argument_list` of the option. Depending on the particular option, the number of arguments required can vary from 0 to many. More than one dollar control option may be activated in one statement. Note that in this case the symbol `$` is not repeated. Observe that some dollar control options require that they be the first option on a line.

Note

- No blank space is permitted between the character `$` and the first option that follows.
- The effect of the dollar control option is felt immediately after the option is processed.
- Dollar control options are not part of the GAMS language they instruct the compiler to perform some task. Therefore, dollar control options are not terminated with a semicolon as real GAMS language statements.

A simple example of a list of dollar control options is shown below:

```
$title Example to illustrate dollar control options
$onsymxref onsymlist
```

Note that there is no blank space between the character `$` and the option that follows. The first dollar control option `$title` sets the title of the pages in the listing file to the text that follows the option name. In the second line of the example above, two options are set: `$onSymXRef` and `$onSymList`. These options turn on the echoing of the symbol cross reference table and symbol listing in the compilation output in the listing file.

Observe that it is also permitted to place a dollar control statement in a column other than column 1. However, in this case the statement must begin with the symbols `$$`, like in this example

```
$$title Example showing that dollar control option can start in any column with an extra $ added
```

4.41.2 List of Dollar Control Options

The dollar control options are grouped into nine major functional categories affecting

- [the input comment format](#)
- [the input data format](#)
- [the output format](#)
- [reference maps](#)
- [program control](#)
- [GDX operations](#)
- [compile-time variables and environment variables](#)
- [macro definitions](#)
- [compressing and encrypting source files](#)

The following subsections briefly describe the options in each of the categories.

4.41.2.1 Dollar Control Options Affecting the Input Comment Format

Option	Description
comment	Set the comment character
eolCom	Set the end-of-line comment character(s)
inlineCom	Set the in-line comment characters
maxCol	Set the right-hand margin of the input file
minCol	Set left-hand margin of the input file
offEolCom	Turn end-of-line comments off
offInline	Turn in-line comments off
offMargin	Turn margin marking off
offNestCom	Turn nested comments off
offText	Turn text mode off
onEolCom	Turn end-of-line comments on
onInline	Turn in-line comments on
onMargin	Turn margin marking on
onNestCom	Turn nested comments on
onText	Turn text on: the following lines are comment

Note that comments in GAMS are introduced in section [Comments](#).

4.41.2.2 Dollar Control Options Affecting the Input Data Format

Option	Description
dollar	Set the 'dollar' character
offDelim	Turn delimited data statement syntax off
offDigit	Turn the number precision check off
offEmbedded	No embedded text or data allowed
offEmpty	Disallow empty data initialization statements
offEnd	Disallow alternate program control syntax
offEps	Disallow interpretation of EPS as zero
offExternalInput	End of external input section
offGlobal	Disallow inheritance of parent file settings
offIDCProtect	Allow to change external input symbols at execution time
offSuffixDLVars	Do not allow domain limited variables with suffixes in model
offUNDF	Do not allow UNDF as input
offUni	Do not allow domain violations in assignments
offWarning	Do not convert domain errors into warnings
onDelim	Turn delimited data statement syntax on
onDigit	Turn number precision check on
onEmbedded	Allow embedded text or data in set and parameter statements
onEmpty	Allow empty data initialization statements
onEnd	Allow alternate program control syntax
onEps	Interpret zero as EPS
onExternalInput	Start of external input section
onGlobal	Force inheritance of parent file settings
onIDCProtect	Protect external input symbols from being changed at execution time
onSuffixDLVars	Allow domain limited variables with suffixes in model
onUNDF	Allow UNDF as input

Option	Description
onUni	Allow domain violations in assignments
onWarning	Convert certain domain errors into warnings
use205	Language syntax of release 2.05
use225	Language syntax of release 2.25 Version 1
use999	Latest language syntax
version	Test GAMS compiler version number

4.41.2.3 Dollar Control Options Affecting the Output Format

Option	Description
double	Double-spaced listing follows
echo	Echo text to a file
echoN	Echo text to a file without ending the line
eject	Advance to next page
hidden	Ignore text and do not list
lines	Next number of lines have to fit on the page
log	Send message to the log
offDollar	Turn the listing of dollar control option lines off
offEcho	End of block echo
offExternalOutput	End of external output section
offEpsToZero	Do not interpret EPS as zero when writing to GDX
offInclude	Turn the listing of include file names off
offListing	Turn echoing input lines to listing file off
offLog	Turn line logging off
offPut	End of block put
offUpper	Following print to listing file is mixed cased
offVerbatim	Stop verbatim copy
onDollar	Turn the listing of dollar control option lines on
onEcho	Start of block echo with substitution
onEchoS	Start of block echo with substitution
onEchoV	Start of block echo without substitution
onEpsToZero	Interpret EPS as zero when writing to GDX
onExternalOutput	Start of external output section
onInclude	Include file name echoed to listing file
onListing	Input lines echoed to listing file
onLog	Reset line logging
onPut	Start of block put without substitution
onPutS	Start of block put with substitution
onPutV	Start of block put without substitution
onUpper	Following print to listing file is all upper cased
onVerbatim	Start verbatim copy if <code>dumpopt</code> \geq 10
remark	Comment line with suppressed line number
single	Single-spaced listing follows
stars	Set "****" characters in listing file
sTitle	Set subtitle and reset page
title	Set title and reset page

4.41.2.4 Dollar Control Options Affecting the Listing of Reference Maps

Option	Description
offSymList	Turn symbol list off
offSymXRef	Turn symbol cross reference listing off
offUEIList	Turn unique element listing off
offUEIXRef	Turn unique element cross reference off
onSymList	Turn symbol list on
onSymXRef	Turn symbol cross reference listing on
onUEIList	Turn unique element listing on
onUEIXRef	Turn unique element cross reference on

4.41.2.5 Dollar Control Options Affecting Program Control

Option	Description
abort[.noError]	Issue an (error) message and abort compilation
batInclude	Include file with substitution arguments
call	Execute another program during compilation
call.Async[NC]	Execute another program asynchronously during compilation
call.checkErrorLevel	Execute another program during compilation and raise error in case of problem
clear	Reset all data for an identifier to its default value
clearError[s]	Clear compilation errors
else	Else clause
elseif	ElseIf structure with case sensitive comparison
elseifE	ElseIf structure with expression evaluation
elseifI	ElseIf structure with case insensitive comparison
endif	Close ifThen/ifThenE/ifThenI control structure
error	Issue an error message
exit	Exit from compilation
funcLibIn	Load extrinsic function library
goto	Go to line with given label name
hiddenCall	Execute another program (hidden) during compilation
hiddenCall.Async[NC]	Execute another program (hidden) asynchronously during compilation
hiddenCall.checkErrorLevel	Execute another program (hidden) during compilation and raise error in case of problem
if	Conditional processing, case sensitive
ifE	If statement with expression evaluation
ifI	Conditional processing, case insensitive
ifThen	IfThen-elseif structure with case sensitive comparison
ifThenE	IfThen-elseif structure with expression evaluation
ifThenI	IfThen-elseif structure with case insensitive comparison
include	Include file
kill	Kill data connected with identifier
label	Label name as entry point from \$goto .
libInclude	Include file from library directory
offCheckErrorLevel	Do not check errorLevel automatically after \${[hidden]call}

Option	Description
offEmbeddedCode	Ends embedded code section
offFiltered	Turn behavior of \$[gdx]load* to domain checked read
offMulti	Turn redefinition of data off
offOrder	Allow lag and lead operations on dynamic or unordered sets
offRecurse	Disable recursive include files
offStrictSingleton	Take first label if data statement for singleton set has multiple elements
onCheckErrorLevel	Throw compilation error, if errorLevel is not 0 after \$[hidden]call
onEmbeddedCode	Starts embedded code section with substitution
onEmbeddedCodeS	Starts embedded code section with substitution
onEmbeddedCodeV	Starts embedded code section without substitution
onFiltered	Turn behavior of \$[gdx]load* to filtered read
onMulti	Turn redefinition of data on (merging into existing data)
onMultiR	Turn redefinition of data on (replacing existing data)
onOrder	lag and lead operations on constant and ordered sets only
onRecurse	Enable recursive include files
onStrictSingleton	Error if data statement for singleton set has multiple elements
maxGoTo	Maximum number of jumps to the same label
phantom	Define a phantom element
shift	bat/lib/sysInclude argument shift operation
stop	Stop compilation
sysInclude	Include file from system directory
terminate	Terminate compilation and execution
warning	Issue compilation warning

Note that conditional compilation in GAMS is discussed in section [Conditional Compilation](#) below.

4.41.2.6 Dollar Control Options for GDX Operations

Option	Description
gdxIn	Open GDX file for input
gdxLoad	Load symbols from specified GDX file
gdxOut	Open GDX file for output
gdxUnload	Unload symbols into specified GDX file.
load	Load symbols from previously opened GDX file
loadDC	Load symbols from previously opened GDX file - domain checked
loadDCM	Load symbols from previously opened GDX file - domain checked - merge
loadDCR	Load symbols from previously opened GDX file - domain checked - replace
loadFiltered	Load symbols from previously opened GDX file - domain filtered
loadFilteredM	Load symbols from previously opened GDX file - domain filtered - merge
loadFilteredR	Load symbols from previously opened GDX file - domain filtered - replace
loadM	Load symbols from previously opened GDX file - merge
loadR	Load symbols from previously opened GDX file - replace
offExternalInput	End of external input section
offExternalOutput	End of external output section
offFiltered	Turn behavior of \$[gdx]load* to domain checked read
onExternalInput	Start of external input section

Option	Description
onExternalOutput	Start of external output section
onFiltered	Turn behavior of <code>[\$gdx]load*</code> to filtered read
unLoad	Unload symbols into previously opened GDX file.

Note that GDX facilities and utilities are introduced in chapter [GAMS Data eXchange \(GDX\)](#).

4.41.2.7 Dollar Control Options for Compile-Time Variables and Environment Variables

Option	Description
drop	Drop a scoped compile-time variable
dropGlobal	Drop a global compile-time variable
dropLocal	Drop a local compile-time variable
dropEnv	Drop an OS environment variable
escape	Define the % escape symbol
eval	Evaluate and define a scoped compile-time variable
eval.Set	Evaluate and define a scoped compile-time variable based on a GAMS set
evalGlobal	Evaluate and define a global compile-time variable
evalGlobal.Set	Evaluate and define a global compile-time variable based on a GAMS set
evalLocal	Evaluate and define a local compile-time variable
evalLocal.Set	Evaluate and define a local compile-time variable based on a GAMS set
prefixPath	Prefix the environment variable PATH.
scratchFileName	Set a name for a temporary file in the scratch directory using the scratch file extension
setArgs	Define local compile-time variables using argument list
setComps	Unpack dotted names into compile-time variables
setDDLlist	Check double dash GAMS parameters
setDDLlist.Cont	Start list of identifiers to check double dash GAMS parameters
setEnv	Define an OS environment variable
set	Define a scoped compile-time variable
setGlobal	Define a global compile-time variable
setLocal	Define a local compile-time variable
setName	Unpack a filename into local compile-time variables
show	Show current GAMS compile-time variables, macros, and active files
showFiles	Show active input and include files
showMacros	Show current macros
showVariables	Show current GAMS compile-time variables
splitOption	Unpack a key/value pair into scoped environment variables

See also sections [Compile-Time Variables](#) and [Environment Variables in GAMS](#).

4.41.2.8 Dollar Control Options for Macro Definitions

Option	Description
macro	Preprocess macro definition

Option	Description
<code>offDotL</code>	Do not assume <code>.l</code> for variables in assignments
<code>offDotScale</code>	Assume <code>.scale</code> for variables and equations in assignments
<code>offExpand</code>	Do not expand macros when processing macro arguments
<code>offLocal</code>	Limit <code>.local</code> nesting to one
<code>offMacro</code>	Do not recognize macros for expansion
<code>onDotL</code>	Assume <code>.l</code> for variables in assignments and put statements
<code>onDotScale</code>	Assume <code>.scale</code> for variables and equations in assignments and put statements
<code>onExpand</code>	Expand macros when processing macro arguments
<code>onLocal</code>	No limit on <code>.local</code> nesting
<code>onMacro</code>	Recognize macros for expansion

Note that macros are introduced in section [Macros in GAMS](#) below.

4.41.2.9 Dollar Control Options for Compressing and Encrypting Source Files

Option	Description
<code>compress</code>	Create compressed GAMS system file
<code>decompress</code>	Decompress a GAMS system file
<code>encrypt</code>	Create an encrypted GAMS system file
<code>expose</code>	Remove all access control restrictions
<code>hide</code>	Hide objects from the user
<code>protect</code>	Protect objects from being modified by the user
<code>purge</code>	Remove the objects and all associated data

4.41.3 Detailed Description of Dollar Control Options

In this section we will describe each dollar control option in detail. Note that the dollar control options are listed in alphabetical order for easy reference. Note further, that in each entry the default value, if applicable, is given in parentheses.

`$abort[.noError]`

Syntax:

```
$abort[.noError] [text]
```

If used as `$abort`, this option will issue a compilation error and abort the compilation. It may be followed by a text.

Example:

```
$if not %system.fileSys% == UNIX
$abort We only do UNIX
```

This stops compilation if the operating system is not Unix. Running the example above on Windows will result in the compilation being aborted and the following lines in the listing file:

```

2 $abort We only do UNIX
****      $343

```

Error Messages

343 Abort triggered by above statement

This option has a variant: `$abort.noError`. If the extension `.noError` is used the compilation will be aborted as well, but there will be no error. If a save file is written, all remaining unexecuted code will be flushed. This allows effective reuse of the save file.

Note that there is also an [abort statement](#) in GAMS, it is used to terminate the execution of a program.

See also [\\$exit](#), [\\$error](#), [\\$stop](#), and [\\$terminate](#).

`$batInclude`

Syntax:

```
$batInclude external_file {arg}
```

The `$batInclude` facility performs the same task as the [\\$include](#) facility: it inserts the contents of the specified file `external_file` at the location of the call. However, in addition, the option `$batInclude` also passes on arguments `arg` which may be used inside the include file. `external_file` is the name of the batch include file, it may be quoted or unquoted. The arguments `arg` are passed on to the batch include file. These arguments are treated as character strings that are substituted by numbers inside the included file. The arguments may be single unbroken strings (quoted or unquoted) or quoted multi-part strings.

Note that the syntax has been modeled after the DOS batch facility. Inside the batch file, a parameter substitution is indicated by using the character `%` followed immediately by an integer value corresponding to the order of parameters on the list where `%1` refers to the first argument, `%2` to the second argument, and so on. If an integer value is specified that does not correspond to a passed parameter, then the parameter flag is substituted with a null string. The parameter flag `%0` is a special case that will substitute a fully expanded file name specification of the current batch included file. The flag `$$` is the current `$` symbol (see [\\$dollar](#)). Observe that parameters are substituted independent of context and the entire line is processed before it is passed to the compiler. There is one exception: parameter flags that appear in comments are not substituted.

Attention

- GAMS requires that processing the substitutions must result in a line of less than or equal to the maximum input line length.
- The case of the passed parameters is preserved, thus it may be used in string comparisons.

Example:

```
$batInclude "file1.inc" abcd "bbbb" "cccc dddd"
```

Note that `file1.inc` is included with `abcd` as the first parameter, `bbbb` as the second parameter and `cccc dddd` as the third parameter.

```

Parameter a,b,c ;
a = 1 ; b = 0 ; c = 2 ;
$batInclude inc2.inc b a
display b ;
$batInclude inc2.inc b c
display b ;
$batInclude inc2.inc b "a+5"
display b ;

```

The external file `inc2.inc` contains the following line:

```
%1 = sqr(%2) - %2 ;
```

The echo print in the corresponding listing file follows:

```
1 Parameter a,b,c ;
2 a = 1 ; b = 0 ; c = 2 ;
BATINCLUDE C:\tmp\inc2.inc
4 b = sqr(a) - a ;
5 display b ;
BATINCLUDE C:\tmp\inc2.inc
7 b = sqr(c) - c ;
8 display b ;
BATINCLUDE C:\tmp\inc2.inc
10 b = sqr(a+5) - a+5 ;
11 display b ;
```

Note that the option `$batInclude` appears three times with different arguments. GAMS is interprets the contents of the batch include file in turn as:

```
b = sqr(a) - a ;
b = sqr(c) - c ;
b = sqr(a+5) - a+5 ;
```

Note that the third call is not interpreted as `sqr(a+5)-(a+5)`, but instead as `sqr(a+5)-a+5`. The results of the display statement are shown at the end of the listing file are given below:

```
-----      5 PARAMETER b                =          0.000
-----      8 PARAMETER b                =          2.000
-----     11 PARAMETER b                =         40.000
```

Observe that the third call leads to `b = sqr(6)-1+5`, thus the final value of `b` is 40. Suppose the statement in the batch include file is modified to read as follows:

```
%1 = sqr(%2) - (%2) ;
```

With this modification the output generated by the display statement will be as follows:

```
-----      5 PARAMETER b                =          0.000
-----      8 PARAMETER b                =          2.000
-----     11 PARAMETER b                =         30.000
```

Note that the third call leads to `b = sqr(6)-6` which results in `b` taking a value of 30.

Note

The option `$batInclude` without any arguments is equivalent to the option [\\$include](#).

See also [\\$include](#), [\\$libInclude](#), [\\$sysInclude](#).

`$call`

Syntax:

```
$call [=]command
```

This option passes a `command` to the current operating system command processor and interrupts compilation until the command has been completed. If the command string is empty or omitted, a new interactive command processor will be loaded.

Example:

```
$call dir
```

This command creates a directory listing on a PC.

Note that the command string may be passed to the system and executed directly without using a command processor by prefixing the command with an '=' sign. Compilation errors will be issued if the command or the command processor cannot be loaded and executed properly.

```
$call gams trnsport
$call =gams trnsport
```

The first call will run the model `[TRANSPORT]` in a new command shell. The DOS command shell does not send any return codes from the run back to GAMS. Therefore any errors in the run are not reported back. The second call, however, will send the command directly to the system. The return codes from the system will be intercepted correctly and they will be available to the GAMS system through the [errorLevel](#) function.

Attention

- Some commands (like `copy` on a PC and `cd` in Unix) are shell commands and cannot be spawned off to the system. Using these in a system call will create a compilation error.

```
$call 'copy myfile.txt mycopy.txt'
$call '=copy myfile.txt mycopy.txt'
```

The first call will work on a PC, but the second will not. The `copy` command may be used only from a command line shell. The system is not aware of this command (Try this command after clicking Run under the Start menu in Windows. You will find that it does not work).

- One has to take special care when the first argument of the `command` contains spaces (for example an executable with absolute path), e.g.:

```
$call C:\path with spaces\gams.exe trnsport.gms
```

This would fail, since the command processor would try to call `C:\path` as the executable. So, one might think that protecting the spaces using quotes will resolve this problem:

```
$call "C:\path with spaces\gams.exe" trnsport.gms
```

However, the quotes delimit the entire `$call` command, so that `trnsport.gms` gets interpreted as new dollar control option instead of an argument for the executable. The solution is to use nested quotes: One pair to delimit the `$call` command and another one to protect the spaces of the executable like this:

```
$call "'C:\path with spaces\gams.exe" trnsport.gms'
```

It gets even more complicated if the argument contains spaces as well, e.g. if we have `my model.gms` instead of `trnsport.gms`. Another pair of quotes solves this:

```
$call "'C:\path with spaces\gams.exe" "my model.gms"'
```

See also [\\$call.Async](#), [\\$call.checkErrorLevel](#), [\\$hiddenCall](#).

`$call.Async[NC]`

Syntax:

```
$call.Async[NC] command
```

`$call.Async` works like `$call` but allows asynchronous job handling. This means users may start a job `command` without having to wait for the result, they may continue in their model and collect the return code of the job later. The function `jobHandle` may be used to get the process ID (pid) of the last job started. The status of the job may be checked using the function `jobStatus(pid)`. An interrupt signal to a running job may be sent with the function `jobTerminate(pid)`. With the function `jobKill(pid)` a kill signal may be sent to a running job.

The difference between `$call.Async` and `$call.AsyncNC` is, that the latter starts processes in a *new console*, rather than sharing the console of the parent process.

Note

On non-Windows platforms `$call.AsyncNC` and `$call.Async` are synonyms.

`$call.checkErrorLevel`

Syntax:

```
$call.checkErrorLevel [=]command
```

`$call.checkErrorLevel` works like `$call` but checks the `errorLevel` implicitly, raises a compilation error and aborts compilation, if that is not 0.

Example:

```
$call.checkErrorLevel gams trnsport
```

This is doing the same as:

```
$call gams trnsport
$ifE errorLevel<>0 $abort 'Problem calling gams trnsport'
```

`$clear`

Syntax:

```
$clear ident {ident}
```

This option resets all data for the `identifiers ident` to their default values. Note that only the following data types may be reset: sets, parameters, variables and equations. Note further, that the clearing is carried out during compile time and not when the GAMS program executes.

Example:

```
Set    i / 1*20 /;
Scalar a / 2 /;
$clear i a
display i, a;
```

The option `$clear` resets `i` and `a` to their default values: an empty set for `i` and zero for `a`. The output generated by the display statement follows:

```
----          4 SET i
                                                    ( EMPTY )
----          4 PARAMETER a                =          0.000
```

Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Both the dollar control options and the data initialization is done in the first pass, and assignments in the second, irrespective of their relative locations. This is an issue particularly with `$clear` since data can be both initialized and assigned.

```
Scalar a / 12 /;
a = 5;
$clear a
display a;
```

Note that the scalar data initialization statement is processed during compilation and the assignment statement `a = 5;` during execution. In the order that it is processed, the example above is read by GAMS as:

```
* compilation step
Scalar a /12/ ;
$clear a
* execution step
a = 5;
display a ;
```

Therefore the result is that `a` takes the value of 5. The output from the display statement is as follows:

```
----          4 PARAMETER a                      =          5.000
```

Compare also [\\$kill](#) and the execution time [option clear](#).

`$clearError[s]`

Syntax:

```
$clearError[s]
```

This option (`$clearError` and `$clearErrors` are synonyms) clears GAMS awareness of compiler errors and turn them into warning messages instead.

Example:

```
Scalar z / 11 /;
$eval x sqrt(-1)
$clearError
$log %%x%%
Display z;
```

Note that without the use of `$clearError` the program above would not continue with the execution after line 2.

`$comment (*)`

Syntax:

```
$comment char
```

This option changes the symbol indicating a single line comment from the default `*` to the single character `char`. Note that after this option is used, the new comment character `char` cannot be used in column 1 as before, since it got a special meaning. Note further, that the case of the character does not matter if it is used as a comment character. This option should be used with great care and we recommend to reset the symbol quickly to the default.

Attention

The case of the start-of-line comment character does not matter when being used.

Example:

```
$comment c
c now we use a FORTRAN style comment symbol
$comment *
* now we are back to the default
```

See also section [Comments](#).

\$compress

Syntax:

```
$compress source target
```

This option causes the file `source` to be compressed into the packed file `target`.

Example: Consider the following example where the well-known model `[TRANSPORT]` is used:

```
$call gamslib trnsport
$compress trnsport.gms t2.gms
$include t2.gms
```

The first command retrieves the file `trnsport.gms` and the second command compresses it. Note that a compressed GAMS file is treated like any other GAMS file, therefore it may be included and executed as usual. Large data files that do not change often can be compressed this way to save disk space.

The following example serves as a little utility to compress and decompress files:

```
$ifthen set decompress
$ if not set input $set input file_c.gms
$ if not exist %input% $abort No file input file %input% exist
$ if not set output $set output file.gms
$ log Decompressing %input% into %output%
$ decompress %input% %output%
$else
$ if not set input $set input file.gms
$ if not exist %input% $abort No file input file %input% exist
$ if not set output $set output file_c.gms
$ log Compressing %input% into %output%
$ compress %input% %output%
$endif
```

The program (saved to a file called `compress.gms`) can be used as follows:

```
> gams compress.gms --input myfile.gms --output myfile_c.gms
> gams compress.gms --decompress=1 --input myfile_c.gms --output myfile.gms
```

See also [\\$decompress](#). Further details are given in chapter [Compressing and Decompressing Files](#).

\$decompress

Syntax:

```
$decompress source target
```

This option causes the compressed file `source` to be decompressed into the unpacked file `target`.

Example: Consider the following example where the well-known model `[TRANSPORT]` is used:

```
$call gamslib trnsport
$compress trnsport.gms t2.gms
$decompress t2.gms t3.gms
$call diff t3.gms trnsport.gms
$if errorlevel 1 $abort t3.gms and trnsport.gms are not identical!
```

The first command retrieves the file `trnsport.gms`, the second command compresses it and the third command decompresses the compressed file. Note that the resulting file, `t3.gms`, is identical to the original file `trnsport.gms` which is tested via the `diff` program.

See also [\\$compress](#). Further details are given in chapter [Compressing and Decompressing Files](#).

\$dollar (\$)**Syntax:**

```
$dollar char
```

This option changes the current 'dollar' symbol to the single character `char`.

Note

The special `$$` substitution symbol can be used to get the current 'dollar' symbol.

Example:

```
$dollar #
#log now we can use '$$' as the '$' symbol
```

\$double**Syntax:**

```
$double
```

The lines following this option will be echoed double spaced to the [echo print](#) in the listing file.

Example:

```
Set    i / 1*2 / ;
Scalar a / 1    / ;
$double
Set    j / 10*15 / ;
Scalar b / 2    / ;
```

The resulting echo print in the listing file looks as follows:

```
1 Set i /1*2/ ;
2 Scalar a /1/ ;

4 Set j /10*15/ ;

5 Scalar b /2/ ;
```

Note that lines before the option `$double` are listed single spaced, while the lines after the option are listed with double space.

See also [\\$single](#).

`$drop`

Syntax:

```
$drop VARNAME
```

This option destroys (removes from the program) the scoped compile-time variable `VARNAME` that was defined with the dollar control option [\\$set](#).

Example:

```
$set NAME my name
$if set NAME $log Scoped compile-time variable NAME is set to "%NAME%"
$drop NAME
$if not set NAME $log Scoped compile-time variable NAME is not available anymore
```

See also [\\$set](#), [\\$dropGlobal](#), and [\\$dropLocal](#).

`$dropEnv`

Syntax:

```
$dropEnv VARNAME
```

This dollar control option destroys (removes from the program) the operating system environment variable `VARNAME`. For detailed information, see the dollar control option [\\$setEnv](#).

Example:

```
$if setEnv GDXCOMPRESS $dropEnv GDXCOMPRESS
```

See also [\\$setEnv](#), and [\\$if setEnv](#).

`$dropGlobal`

Syntax:

```
$dropGlobal VARNAME
```

This option destroys (removes from the program) the global compile-time variable `VARNAME` that was defined with the dollar control option [\\$setGlobal](#).

Example:

```

$setGlobal NAME my name
$if setGlobal NAME $log Global compile-time variable NAME is set to "%NAME%"
$dropGlobal NAME
$if not setGlobal NAME $log Global compile-time variable NAME is not available anymore

```

See also [\\$setGlobal](#), and [\\$drop](#).

\$dropLocal

Syntax:

```
$dropLocal VARNAME
```

This option destroys (removes from the program) the local compile-time variable `VARNAME` that was defined with the dollar control option [\\$setLocal](#).

```

$setLocal NAME my name
$if setLocal NAME $log Local compile-time variable NAME is set to "%NAME%"
$dropLocal NAME
$if not setLocal NAME $log Local compile-time variable NAME is not available anymore

```

See also [\\$setLocal](#), and [\\$drop](#).

\$echo

Syntax:

```
$echo text >[>] external_file
```

This option allows to write the text `text` to a file `external_file`. The text and the file name may both be quoted or unquoted. The file name is expanded using the working directory. The option `$echo` tries to minimize file operations by keeping the file open in anticipation of another `$echo` to be appended to the same file. The file will be closed at the end of the compilation or when an option [\\$call](#) or any variant of the option [\\$include](#) is encountered. The redirection symbols `>` and `>>` have the usual meaning of starting at the beginning or appending to an existing file respectively.

Example:

```

$echo > echo.txt
$echo The message written goes from the first non blank >> echo.txt
$echo 'to the first > or >> symbol unless the text is' >> echo.txt
$echo "is quoted. The input File is %gams.input%. The" >> echo.txt
$echo 'file name "echo.txt" will be completed with' >> echo.txt
$echo %gams.workdir%. >> echo.txt
$echo >> echo.txt

```

The content of the resulting file `echo.txt` is the following:

```

The message written goes from the first non blank
to the first > or >> symbol unless the text is
is quoted. The input File is C:\tmp\echoTest.gms. The
file name "echo.txt" will be completed with
C:\tmp\.

```

See also [\\$on/offEcho](#), and [\\$echoN](#).

\$echoN

Syntax:

```
$echoN text >[>] external_file
```

This option sends a text message `text` to an file `external_file` like [\\$echo](#) but writes no end of line marker so the line is repeatedly appended to by subsequent commands. The redirection symbols `>` and `>>` have the usual meaning of starting at the beginning or appending to an existing file respectively. Note that the text and the file name may be quoted or unquoted. By default the file will be saved in the working directory.

Example:

```
$echoN 'Text to be sent'           > 'aaa.txt'
$echoN 'More text'                >> aaa.txt
$echoN And more and more and more >> aaa.txt
$echo This was entered with $echo >> 'aaa.txt'
$echo This too                    >> aaa.txt
```

The created file `aaa.txt` contains the following text:

```
Text to be sentMore textAnd more and more and moreThis was entered with $echo
This too
```

See also [\\$on/offEcho](#), and [\\$echo](#).

\$eject**Syntax:**

```
$eject
```

This option advances the [echo print](#) to the next page.

Example:

```
$eject
Set      i,j ;
Parameter Data(i,j) ;
$eject
Scalar a;
a = 7;
```

The statements following the first `$eject` will be listed on one page in the echo print of the listing file and the statements following the second `$eject` will be listed on the next page.

\$else**Syntax:**

```
$ifThen[E|I] cond
...
{ $elseIf[E|I] cond
... }
[ $else
... ]
$endIf
```

This option always appears together with the option `$ifThen[E/I]`. It is followed by an instruction which is executed if the conditional expression of the matching option `$ifThen[E/I]` is not true. For an example, see section [Conditional Compilation with \\$ifThen and \\$else](#).

See also `$ifThen`, `$selfIf` and section [Conditional Compilation](#).

`$selfIf`

Syntax:

```
$ifThen[E|I] cond
...
{ $selfIf[E|I] cond
... }
[ $else
... ]
$endIf
```

This option always appears together with the option `$ifThen[E/I]`. It is followed by another condition and instruction. For an example, see section [Conditional Compilation with \\$ifThen and \\$else](#).

See also `$ifThen`, `$else`, `$selfIfE`, `$selfIfI` and section [Conditional Compilation](#).

`$selfIfE`

Syntax:

```
$ifThen[E|I] cond
...
{ $selfIf[E|I] cond
... }
[ $else
... ]
$endIf
```

This option does the same as `$selfIf` but evaluates numerical values of the control variables.

See also `$selfIf` and section [Conditional Compilation](#).

`$selfIfI`

Syntax:

```
$ifThen[E|I] cond
...
{ $selfIf[E|I] cond
... }
[ $else
... ]
$endIf
```

This option does the same as `$selfIf` but it is case insensitive.

See also `$selfIf` and section [Conditional Compilation](#).

`$encrypt`

Syntax:

`$encrypt source target`

This option causes a file to be converted into an encrypted file. Here `source` is the name of the source file to be encrypted and `target` is the name for the resulting encrypted file. Note that encryption requires the `secure` option to be licensed and is available for commercial licenses only. The command line parameter `pLicense` specifies the target license to be used for encryption. The encrypted file can only run on a system licensed with the license file used for encryption. No special action is required on the executing system since GAMS recognizes whether a file is encrypted and will process it accordingly. There is no option to *decrypt* an encrypted file, so better keep the original unencrypted file.

Further details and examples are given in chapter [Encrypting Files](#).

\$endIf

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseif[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This must option must be matched with one of the options `$ifThen`, `$ifThenE` or `$ifThenI`. For an example, see section [Conditional Compilation with \\$ifThen and \\$else](#).

See also `$ifThen` and section [Conditional Compilation](#).

\$eolCom (!!)

Syntax:

```
$eolCom char[char]
```

This option redefines and activates the end-of-line comment symbol, which may be one character or a sequence of two characters. By default, this is initialized to `!!`, but is not active. The option `$onEolCom` is used to activate the end-of-line comments. If `$eolCom` is used, `$onEolCom` is set automatically.

Example:

```
$eolCom //
Set i /1*2/ ; // set declaration
Parameter a(i) ; // parameter declaration
```

Here the character sequence `//` serves as the end-of-line-comment indicator.

Attention

It is not allowed to reset the end-of-line comment symbol to the current end-of-line comment symbol. This would cause a compilation error as in the following example:

```
$eolCom //
$eolCom //
```

Some end of line character settings can cause confusion. The widely used end of line character sequence `//` is also legal GAMS syntax in `put` statement to indicate two line breaks:

```
file fx; put fx;
put 'first line' // 'second line' //;
$eolCom //
put 'third line' // 'fourth line';
```

results in a `put` file with the following content:

```
first line

second line

third line
```

This can also confuse syntax highlighting in editors (or on this web page). Other popular end of line characters like `#` and `@` are also used as GAMS syntax, see [Controlling the Cursor On a Page](#).

See also section [Comments](#) for more about comments in GAMS.

\$error**Syntax:**

```
$error [text]
```

This option will issue a compilation error and will continue with the next line.

Example:

```
$if not exist myfile
$error File myfile not found - will continue anyway
```

Note that the first line checks if the file `myfile` exists. If the file does not exist, it will generate an error with the comment `File myfile not found - will continue anyway` and then the compilation will continue with the next line.

See also [\\$abort](#), [\\$exit](#), [\\$terminate](#), and [\\$stop](#).

\$escape**Syntax:**

```
$escape character
```

This option allows users to work with text sequences containing % without substitution.

This causes all subsequent commands of the form %symbol% to not have parameter substitution done for them. As a consequence, no parameter substitutions are performed in GAMS statements (mostly useful in display and put statements) and the outcome of such statements where %symbol% is used is just %symbol%.

Note that the effect of the option \$escape may be reversed with the option \$escape %.

Example:

```
$set tt DOIT

file it; put it;

display "first %tt%";
display "second %&tt%&";
put "display one ", "%system.date%" /;
put "display two " "%&system.date%&"/;

$escape &
display "third %tt%";
display "fourth %&tt%&";
put "display third ", "%system.date%" /;
put "display fourth " "%&system.date%&"/;

$escape %
display "fifth %tt%";
display "sixth %&tt%&";
put "display fifth ", "%system.date%" /;
put "display sixth " "%&system.date%&"/;
```

The output generated by the display statements follows:

```
----      6 first DOIT

----      7 second %&tt%&

----     12 third DOIT

----     13 fourth %tt%

----     18 fifth DOIT

----     19 sixth %&tt%&
```

The file it.put will contain the following lines:

```
display one 08/10/17
display two %&system.date%&
display third 08/10/17
display fourth %system.date%
display fifth 08/10/17
display sixth %&system.date%&
```

Note that this option was introduced to facilitate writing GAMS code (or command.com/cmd.exe batch scripts) from GAMS including unsubstituted compile-time variables. Text can also be written at compile-time without parameter substitution via option [\\$on/offEchoV](#) and at run-time via [\\$on/offPutV](#).

Note

In GAMS the escape character *follows* the character (%) that needs to be escaped. In many other languages the escape character precedes the to be escaped character.

\$eval

Syntax:

```
$eval VARNAME expression
```

This option evaluates a numerical expression at compile time and places it into a *scoped* compile-time variable. In turn the option [\\$ifE](#) may be used to do numeric testing on the value of this variable.

VARNAME is the name of a compile-time variable and **expression** is an expression that consists of constants, functions, operators and other compile-time variables with numerical values. Note that no whitespace is allowed in the expression which can be overcome by additional parentheses.

Example:

```
$eval b1 ifthen(uniform(0,1)<0.5,0,1)
$eval b2 ifthen(uniform(0,1)<0.5,0,1)
$eval b3 (%b1%)xor(%b2%)
$log b1=%b1% b2=%b2% b1 xor b2=%b3%
```

The first two lines use the **uniform** function to generate a random number between 0 and 1 and assign 0 if this number is less than 0.5 otherwise 1 via the **ifthen** function to the scoped compile-time variable **b1** and **b1**. In the third line we apply the logical **xor** operator to **b1** and **b2** and store the result in **b3**. The parentheses are required because the more natural expression **b1% xor b2%** contains spaces. In the fourth line we print the values and result to the log.

```
b1=1 b2=1 b1 xor b2=0
```

The expression are evaluated using IEEE nonstop arithmetic, so no evaluation errors are triggered as demonstrated in the following example:

```
$eval OneDividedByZero 1/0
$log 1/0=%OneDividedByZero%
```

This produces the following log:

```
1/0=+INF
```

The **\$eval** and related dollar control options give access to a reduced set of [GAMS functions](#): **abs**, **card**, **ceil**, **cos**, **errorlevel**, **exp**, **fact**, **floor**, **frac**, **gamsrelease**, **gamsversion**, **gday**, **gdow**, **ghour**, **gleap**, **gmillicsec**, **gminute**, **gmonth**, **gsecond**, **gyear**, **ifthen**, **jdate**, **jnow**, **jobhandle**, **jobkill**, **jobstatus**, **jobterminate**, **jstart**, **jtime**, **log**, **log10**, **log2**, **max**, **min**, **mod**, **numcores**, **pi**, **power**, **round**, **sameas**, **sign**, **sin**, **sleep**, **sqr**, **sqrt**, **tan**, **trunc**, and **uniform**. The available operators are **+**, **-**, *****, **/**, ****** and even **^** (integer power) which is not available in regular GAMS expression and requires the use of the function **ipower**. The comparison relations are **<**, **>**, **<=**, **>=**, **<>**, and **=**. The logical operators are **not**, **and**, **or**, **xor**, **imp**, and **eqv**.

The expression also allows the use of [dollar on the right](#). In the following example we replace the **ifthen** function by a dollar one the right:

```

$eval b1 1$(uniform(0,1)>=0.5)
$eval b2 1$(uniform(0,1)>=0.5)
$eval b3 (%b1%)xor(%b2%)
$log b1=%b1% b2=%b2% b1 xor b2=%b3%

```

Moreover, the `$eval` has access to data available at compile time. The expression can access the value of scalars and for other symbols we can use the `card` function to access the cardinality (at this point) of the symbol. Here is an example:

```

Scalar ac 'Avogadro constant' / 6.0221409e+23 /;
$eval log_ac round(log10(ac))
$log round(log10(ac))=%log_ac%
Set d / d0*d%log_ac% /;
$eval card_d card(d)
$log card(d)=%card_d%

```

Access to individual records of symbols is not possible. The [embedded code facility](#) allows access to symbol records at compile time.

The user has the possibility to hide some of the GAMS functions by symbols with the same name. In this case, the GAMS function can still be accessed, but needs to be prefixed with `system.` as in the following example:

```

Scalar pi /3/;

$eval myPi pi
$eval GAMSPi system.pi
$log myPi = %myPi%
$log GAMSPi = %GAMSPi%

```

This is the resulting output in the log:

```

myPi = 3
GAMSPi = 3.14159265358979

```

See also [\\$eval.Set](#), [\\$evalGLobal](#), [\\$evalLocal](#), [\\$ifE](#), and [\\$set](#).

`$eval.Set`

Syntax:

```
$eval.Set VARNAME SETID[. [First|Last]TE| [First|Last]TL| [First|Last]TN|TS]
```

This option evaluates an attribute of a GAMS [set](#) at compile time and places it into a *scoped* compile-time variable. `VARNAME` is the name of a compile-time variable and `SETID` is the identifier of a GAMS set. The following attributes are allowed in this context:

Attribute	Description
[First OR Last]TE	Explanatory text of the first or last element of the set <code>SETID</code>
[First OR Last]TL	Label of the first or last element of the set <code>SETID</code>
[First OR Last]TN	Set identifier with with element labels of the first or last element of the set <code>SETID</code>
TS	Explanatory text of the set <code>SETID</code> . This is also the default, if no attribute is specified

Note

- `First??` and `??` are synonyms in the table above. It always accesses the first element of the referenced set.
- `Last??` always accesses the last element of the referenced set.
- For [Singleton Sets](#) `First??`, `Last??` and `??` are synonyms.

Example:

```
Singleton Set h Greeting / Hello          'Welcome' /;
Set          p Person   / Mr.President   'Male'
              Mrs.Chancellor 'Female' /;
```

```
$eval.Set X h.TE
$log %X%
$eval.Set X p.lastTL
$log %X%
$eval.Set X p.FirstTN
$log %X%
```

This will generate the following in the log:

```
Welcome
Mrs.Chancellor
p('Mr','President')
```

See also [\\$eval](#), [\\$evalGlobal.Set](#), [\\$evalLocal.Set](#), and [\\$set](#).

\$evalGlobal

Syntax:

```
$evalGlobal VARNAME expression
```

This option evaluates a numerical expression at compile time and places it into a *global* compile-time variable. The syntax and behavior otherwise is identical to [\\$eval](#).

\$evalGlobal.Set

Syntax:

```
$evalGlobal.Set VARNAME SETID[.[First|Last]TE|[First|Last]TL|[First|Last]TN|TS]
```

This option evaluates an attribute of a GAMS [set](#) at compile time and places it into a *global* compile-time variable. The syntax and behavior otherwise is identical to [\\$eval.Set](#).

\$evalLocal

Syntax:

```
$evalLocal VARNAME expression
```

This option evaluates a numerical expression at compile time and places it into a *local* compile-time variable. The syntax and behavior otherwise is identical to [\\$eval](#).

\$evalLocal.Set

Syntax:

```
$evalLocal.Set VARNAME SETID[.[First|Last]TE|[First|Last]TL|[First|Last]TN|TS]
```

This option evaluates an attribute of a GAMS [set](#) at compile time and places it into a *local* compile-time variable. The syntax and behavior otherwise is identical to [\\$eval.Set](#).

\$exit

Syntax:

```
$exit
```

This option will cause the compiler to exit (stop reading) from the current file. This is equivalent to having reached the end of file.

Example:

```
Scalar a ;
a = 5 ;
display a ;
$exit
a = a+5 ;
display a ;
```

Note that the lines following the option `$exit` will not be compiled.

Observe that there is a difference to the dollar control option [\\$stop](#). If there is only one input file, `$stop` and `$exit` will have the same effect. If the option `$exit` occurs *within* an include file, it acts like an end-of-file on the include file. However, if the option `$stop` occurs *within* an include file, GAMS will stop reading all input.

See also [\\$abort](#), [\\$error](#), [\\$terminate](#), and [\\$stop](#).

\$expose

Syntax:

```
$expose all | ident1 ident2 ...
```

This option removes all privacy restrictions from identifiers.

With explicit identifiers the privacy restrictions are removed only for the listed identifiers and with `all` the restrictions are removed for *all* identifiers. The privacy restrictions may be set with the dollar control options [\\$hide](#) or [\\$protect](#). Note that a special license file is needed for this feature to work and that the `expose` only takes effect in subsequent restart files. For further information, see chapter [Secure Work Files](#).

\$funcLibIn

Syntax:

```
$FuncLibIn InternalLibName ExternalLibName
```

This makes extrinsic function libraries available to a model. `InternalLibName` is the internal name of the library in the GAMS code and `ExternalLibName` is the name of the shared library in the file system. See [Using Function Libraries](#) for more information.

\$gdxIn

Syntax:

`$gdxIn [GDXFileName]`

This option is used in a sequence to load specified items from a GDX file. Here `GDXFileName` denotes the name of the GDX file (with or without the extension `.gdx`) and the command opens the specified GDX file for reading. The use of `$gdxIn` without a file name closes the currently open GDX file. The command is used in conjunction with the option `$load` or one of its variants.

Example:

```
set i,j; parameters a(i), b(j), d(i,j), f;
$gdxIn mydata.gdx
$load i j a b d f
$gdxIn
```

See also `$load`, and `$gdxOut`.

`$gdxLoad`

Syntax:

`$gdxLoad GDXFileName [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]`

This option loads symbols from a specified GDX file. It basically combines `$gdxIn` and `$load` in one call. This can be particularly useful for `$(bat|lib)include` files when you want to be sure, to not interfere with potentially previously opened GDX files. For example, a `$load` after a `"$gdxLoad"` will still load the symbols from the GDX file opened before:

```
$gdxIn A.gdx
$load a b c
$gdxLoad B.gdx d
* The following $load gets the symbols e, f, and g from GDX file A.gdx
$load e f g
```

See also `$(on)[off]Filtered`, `$(on)[off]Multi`, and `$onMultiR`.

`$gdxOut`

Syntax:

`$gdxOut [GDXFileName]`

This option is used in a sequence to unload specified items to a GDX file at compile time. Here `GDXFileName` denotes the name of the GDX file (with or without the extension `GDX`) and the command opens the specified GDX file for writing. The use of `$gdxOut` without a file name closes the currently open output GDX file and initiates the actual writing of the sequence of symbols. The command is used in conjunction with the dollar control option `$unLoad`.

Example:

```
set i /i1*i3/; parameters a(i) /i1 3, i2 87, i3 1/;
$gdxOut mydata.gdx
$unLoad i a
$gdxOut
```

See also `$unLoad`, and `$gdxIn`.

`$gdxUnload`

Syntax:

```
$gdxUnload GDXFileName [sym1[,] sym2=gdxSym2[,] ...]
```

This option unloads symbols from a specified GDx file. It basically combines [\\$gdxOut](#) and [\\$unload](#) in one call. This can be particularly useful for [\\$\[bat|lib\]include](#) files when you want to be sure, to not interfere with potentially previously opened GDx files. For example, a [\\$unload](#) after a "[\\$gdxUnload](#)" will still unload the symbols to the GDx file opened before:

```
$gdxOut A.gdx
$unload a b c
$gdxUnload B.gdx d
* The following $unload puts the symbols e, f, and g into GDx file A.gdx
$unload e f g
```

\$goto**Syntax:**

```
$goto id
$label id
```

This option will cause GAMS to search for a line starting with `$label id` and then continue reading from there. This option can be used to skip over or repeat sections of the input files. In [\\$batinclude](#) files the target labels or label arguments can be passed as parameters because of the manner in which parameter substitution occurs in such files. In order to avoid infinite loops, jumps to the same label are restricted to a maximum of 100 times by default. This maximum may be changed with the option [\\$maxGoto](#).

Example:

```
Scalar a ;
a = 5;
display a ;
$goto next
a = a+5 ;
display a ;
$label next
a = a+10 ;
display a ;
```

Note that GAMS will continue from line `$label next` after reading line `$goto next`. Observe that all lines in between are ignored. Therefore the final value of `a` in the example above will be 15.

Attention

The lines `$goto` and `$label` have to be in the same file. If the target label is not found in the current file an error will be issued.

See also [\\$label](#), [\\$maxGoto](#).

\$hidden**Syntax:**

```
$hidden text
```

A line starting with this option will be ignored and will not be echoed to the listing file. This option is used to enter information only relevant to the person manipulating the file.

Example:

```
$hidden You need to edit the following lines if you want to:
$hidden
$hidden     1. Change form a to b
$hidden     2. Expand the set
```

The lines above serve as comments to the person who wrote the file. However, these comments will not be visible in the listing file and are therefore hidden from view.

Note

This option is particularly useful when the input file is [encrypted](#).

\$hiddenCall

Syntax:

```
$hiddenCall [=] command
```

This option does the same as [\\$call](#) but the statement is neither shown on the log nor the listing file.

\$hiddenCall.Async[NC]

Syntax:

```
$hiddenCall.Async [NC] command
```

This option does the same as [\\$call.Async\[NC\]](#) but the statement is neither shown on the log nor the listing file.

\$hiddenCall.checkErrorLevel

Syntax:

```
$hiddenCall.checkErrorLevel [=] command
```

This option does the same as [\\$call.checkErrorLevel](#) but the statement is neither shown on the log nor the listing file.

\$hide

Syntax:

```
$hide all | ident1 ident2 ...
```

This option hides identifiers so they cannot be displayed or computed, but they may still be used in model calculations (i.e. commands when the solve statement is executed).

With explicit identifiers the listed identifiers are hidden and with **all** all identifiers are hidden. These restrictions may be removed with the dollar control options [expose](#) or [purge](#). Note that a special license file is needed for this feature to work.

For further information, see chapter [Secure Work Files](#).

\$if**Syntax:**

```
$if [not] conditional_expression new_input_line
```

This dollar control option provides the greatest amount of control over conditional processing of the input file(s).

For more information on the `conditional_expressions` allowed, details on the `new_input_line` and examples, see section [Conditional Compilation](#) below.

See also [\\$ifE](#), [\\$ifI](#), [\\$ifThen](#).

\$ifE**Syntax:**

```
$ifE [not] conditional_expression new_input_line
```

This dollar control option does the same as the option [\\$if](#) but allows constant expression evaluation. The `conditional_expression` may take two different forms:

```
expr1 == expr2      TRUE   if (expr1-expr2)/(1+abs(expr2)) < 1e-12
expr                TRUE   if expr1 <> 0
```

Example:

```
Scalar a;
$ifE (log2(16)^2)=16      a=0; display a;
$ifE log2(16)^2 == 16    a=1; display a;
$ifE NOT round(log2(16)^2-16) a=2; display a;
$ifE round(log2(16)^2-16) a=3; display a;
$ifE round(log2(16)^2-17) a=4; display a;
```

This will create the following output:

```
----      3 PARAMETER a          =          1.000
----      4 PARAMETER a          =          2.000
----      6 PARAMETER a          =          4.000
```

See also [\\$if](#) and section [Conditional Compilation](#).

\$ifI**Syntax:**

```
$ifI [not] conditional_expression new_input_line
```

This option is working like the option [\\$if](#). The only difference is that [\\$if](#) makes comparisons involving text in a case sensitive fashion while [\\$ifI](#) is case insensitive.

See also [\\$if](#) and section [Conditional Compilation](#).

\$ifThen**Syntax:**

```

$ifThen[E|I] cond
...
{ $elseif[E|I] cond
... }
[ $else
... ]
$endif

```

This option is a form of the option `$if` that controls whether a number of statements are active. The syntax for the condition is generally the same as for the option `$if`. Like `$if`, it is case sensitive. Often it is followed by one or more of the following dollar control options: `$else`, `$elseif`, `$elseifI`, `$elseifE`. The option `$ifThen` must be matched with the option `$endif` that marks the end of the construct. An example is given in section [Conditional Compilation with \\$ifThen and \\$else](#).

Note that users may add a tag to the `$ifThen` and `$endif`. For example, `$ifThen.tagOne` has to match with `$endif.tagOne`.

Example:

```

$ifThen.one x == y
display "it1";
$elseif.one a == a
display "it2";
$ifThen.two c == c
display "it3";
$endif.two
$elseif.one b == b
display "it4";
$endif.one

```

The resulting listing file will contain the following lines:

```

----      2 it2
----      4 it3

```

Note that the first condition (`x == y`) is obviously not true and the fourth condition (`b == b`) is not tested because the second condition (`a == a`) was already true.

See also [\\$if](#), [\\$ifThenE](#), [\\$ifThenI](#), [\\$else](#), [\\$elseif](#) and section [Conditional Compilation](#).

\$ifThenE

Syntax:

```

$ifThen[E|I] cond
...
{ $elseif[E|I] cond
... }
[ $else
... ]
$endif

```

This option does the same as the option `$ifThen` but evaluates numerical values of the control variables.

See also [\\$ifThen](#) and section [Conditional Compilation](#).

\$ifThenI

Syntax:

```
$ifThen[E|I] cond
...
{ $elseIf[E|I] cond
... }
[ $else
... ]
$endIf
```

This option does the same as the option [\\$ifThen](#) but it is case insensitive.

See also [\\$ifThen](#) and section [Conditional Compilation](#).

\$include

Syntax:

```
$include external_file
```

This option inserts the contents of a specified text file at the location of the call. Note that text files that have been compressed with [Posix utility gzip](#) or have been encrypted with tool [ENDECRYPT](#) are also allowed. `external_file` is the name of the file that is included. It can be quoted or unquoted. Note that include files may be nested.

The include file names are processed in the same way like the input file. The names are expanded using the working directory. If the file cannot be found and no extension is given, the standard GAMS input extension is tried. However, if an incomplete path is given, the file name is completed using the include directory. By default, the library include directory is set to the working directory. The default directory search path may be extended with the command line parameter [InputDir](#).

Note that the start of the include file is marked and the include file is echoed to the echo print in the listing file. This reference to the include file may be omitted by using the option [\\$offInclude](#).

Example:

```
$include myfile
$include "myfile"
```

Both statements above are equivalent and the search order for the include file is as follows:

1. `myfile` in current working directory
 2. `myfile.gms` in current working directory
 3. `myfile` and `myfile.gms` (in that order) in directories specified by the command line parameter [InputDir](#).
-

Attention

The current settings of the dollar control options are passed on to the lower level include files. However, the dollar control options set in the lower level include file are passed on to the parent file only if the option [\\$onGlobal](#) is set.

Note that details on the compilation output of include files are given in section [The Include File Summary](#).

See also [\\$batInclude](#), [\\$libInclude](#), [\\$sysInclude](#).

\$inlineCom (/ * * /)**Syntax:**

```
$inlineCom char[char] char[char]
```

This option redefines and activates the in-line comment symbols. These symbols are placed at the beginning and the end of the in-line comment and are one character or a two character sequence at the beginning and the end. By default, the system is initialized to '/'*' and '*/', but is not active. The option [\\$onInline](#) is used to activate the in-line comments. If [\\$inlineCom](#) is used, [\\$onInline](#) is set automatically.

Example:

```
$inlineCom {{ }}
Set {{ this is an inline comment }} i / 1*2 / ;
```

Note that the character pairs {{ }} serve as the indicator for in-line comments.

Attention

It is not allowed to reset the option [\\$inlineCom](#) to the current symbol for in-line comments. This would cause an compilation error as in the following example:

```
$inlinecom {{ }}
$inlinecom {{ }}
```

Note

The option [\\$onNestCom](#) enables the use of nested comments.

See also section [Comments](#).

\$kill**Syntax:**

```
$kill ident {ident}
```

This option removes all data for the [identifiers](#) *ident*, only the type and dimension are retained (this means that these identifiers will be declared but not defined anymore). Note that only the data of the following data types may be removed: sets, parameters, variables and equations. Note further that the data removal is carried out during compile time and not when the GAMS program executes.

Example:

```
Set i / 1*20 /;
Scalar a /2/;
$kill i a
```

Note that the effect of the third line above is that all data from `a` and `i` is removed, so the set `i` and the scalar `a` are declared, but not initialized or assigned to. Note that after `i` and `a` have been killed, a display statement for them will trigger an error. However, new data may be assigned to identifiers that were previously killed. Thus the following statements are valid if appended to the code above:

```
Set i / i1 *i3 /;
a = 7;
```

Observe that this option needs to be distinguished from the dollar control option `$clear`, that *resets* the data to the default values.

\$label

Syntax:

```
$goto id
$label id
```

This option marks a line to be jumped to by a dollar control option `$goto`. Any number of labels may be used in files and not all of them need to be referenced. Re-declaration of a label identifier will not generate an error and only the first occurrence encountered by the GAMS compiler will be used for future `$goto` references.

Example:

```
Scalar a ;
a = 5 ;
display a ;
$goto next
a = a+5 ;
display a ;
$label next
a = a+10 ;
display a ;
```

When GAMS reaches the line `$goto next`, it continues from the line `$label next`. All lines in between are ignored. Therefore in the example above, the final value of `a` is 15.

Attention

If several dollar control options appear in one line and `label` is one of them, then `label` must be listed first.

See also `$goto`, `$maxGoto`.

\$libInclude

Syntax:

```
$libInclude external_file {arg}
```

This option is mostly equivalent to the option `$batInclude`. However, if an incomplete path is given, the file name is completed using the library include directory. By default, the library include directory is set to the directory `inclib` in the [GAMS standard locations](#). Note that the list of default directories searched may be prepended with the command line parameter `libIncDir`.

Example:

```
$libInclude abc x y
```

This call will first look for the include file `inclib/abc` in the standard locations. If this file does not exist there GAMS will look for the file `inclib/abc.gms` in the standard locations. The arguments `x` and `y` are passed on to the include file and are interpreted as explained in the detailed description of the option `$batInclude`.

See also `$include`, `$batInclude`, `$sysInclude`.

\$lines

Syntax:

```
$lines n
```

This option starts a new page in the listing file if less than `n` lines are available on the current page.

Example:

```
$hidden Never split the first few lines of the following table
$lines 5
Table io(i,j) Transaction matrix
...
;
```

This will ensure that if there are less than five lines available on the current page in the listing file before the next statement (in this case, the table statement) is echoed to it, the contents of this statement are echoed to a new page.

\$load

Syntax:

```
$load [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is preceded and succeeded by the option `$gdxIn` that open the GDX file for reading. The option `$load` loads specified items from the GDX file. Note that more than one instance of `$load` may occur. A listing of the GDX file contents will be created if the option `$load` is not followed by arguments.

Examples

Consider the following example, where `transsol` is the GDX file of the transportation model `[TRANSPORT]`

```
$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i j a b d f
$gdxIn
```

A comma between the symbols is optional. The follow example works identically:

```
$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i, j, a, b, d, f
$gdxIn
```

The \$load without any arguments produces a table of contents of the GDX container in the listing file:

```
Content of GDX C:\Users\default\Documents\gamsdir\projdir\transsol.gdx
      5 UELs
```

Number	Type	Dim	Count	Name	
1	Set	1	2	i	canning plants
2	Set	1	3	j	markets
3	Parameter	1	2	a(i)	capacity of plant i in cases
4	Parameter	1	3	b(j)	demand at market j in cases
5	Parameter	2	6	d(i,j)	distance in thousands of miles
6	Parameter	0	1	f	freight in dollars per case per thousand mile
7	Parameter	2	6	c(i,j)	transport cost in thousands of dollars per ca
8	Variable	2	6	x(i,j)	shipment quantities in cases
9	Variable	0	1	z	total transportation costs in thousands of d
10	Equation	0	1	cost	define objective function
11	Equation	1	2	supply(i)	observe supply limit at plant i
12	Equation	1	3	demand(j)	satisfy demand at market j

Symbols may be loaded with new names with the following syntax: \$load i=gdx.i j=j-gdx. The universal set may be loaded using \$load uni=*.

```
$gdxIn transsol
Sets i, jj, uni; Parameters a(i), bb(jj), d(i,jj), f;
$load i jj=j uni=* a bb=b d f
$gdxIn
display uni;
```

This results in a display of all used labels:

```
-----      5 SET uni
Seattle , San-Diego, New-York , Chicago , Topeka
```

The syntax `sym<[=]GDXSym[.dimI]` allows to load a one dimensional set from a symbol in the GDX file that has even a higher dimensionality. GAMS tries to find the set `sym` as a domain in the symbol `GDXSym` and uses the labels from this index position (with `<` the first domain set from the right and with `<=` from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix `.dimI` allows to pick a fixed index position.

In the following we work with a GDX file created by the following code:

```
set i / i1*i3 /, ii(i,i) / i1.i2, i2.i3 /;
execute_unloadDI 'ii', i, ii;
```

Now use use this GDX file to load the first and second index from `ii`:

```
set i, i1;
$gdxIn ii
* Load first index from ii as i
$load i<=ii i1<ii.dim1
display i, i1;
```

the display lists all labels from the first index of `ii`:

```
-----      5 SET i  Domain loaded from ii position 1
i1,      i2

-----      5 SET i1 Domain loaded from ii position 1
i1,      i2
```

Now we match from the right and get the second index of `ii`:

```
set i, i2;
$gdxIn ii
* Load second index from ii as i
$load i<ii i2<ii.dim2
display i, i2;
```

The resulting listing file will contain the following lines:

```
-----      5 SET i  Domain loaded from ii position 2
i2,      i3

-----      5 SET i2 Domain loaded from ii position 2
i2,      i3
```

This type of projection loading can be useful to extract the domain sets from a single parameter that is stored in a GDX file:

```
set i,j,k; parameter data(i,j,k);
$gdxIn data
$load i<data.dim1 j<data.dim2 k<data.dim3 data
```

Attention

Loading an item that was already initialized will cause a compilation error.

For example, the following code snippet will cause a compilation error:

```
Set j / 1*5 /;
$gdxIn transsol
$load j
$gdxIn
```

Note that GAMS offers variants of `$load` that do not cause a compilation error in such a case: `$loadM` and `$loadR`.

`$loadDC`

Syntax:

```
$loadDC [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is an alternative form of `$load`. It performs [domain checking](#) when items are loaded. Any domain violations will be reported and flagged as compilation errors. This is basically the opposite of `$loadFiltered`. All other features are the same as discussed under `$load`.

Example: Consider the following example where `transsol` is the GDX file of the transportation model `[TRANSPORT]`.

```

Set i, j;
Parameter b(i), a(j);
$gdxIn transsol
$load i b
$loadDC j a
$gdxIn

```

Note that in contrast to the example above, the parameter `a` is indexed over the set `i` and the parameter `b` is indexed over the set `j` in the file `transsol`. While `$load i b` does not generate an error and `b` is just empty, the option `$loadDC j a` triggers a domain violation error because in `transsol` `a` is indexed over `i` and produces a list of errors in the listing file:

```

--- LOAD a = 3:a
**** Unique domain errors for symbol a
  Dim Elements
    1 seattle, san-diego

    5 $loadDC j a
****                $649

```

\$loadDCM

Syntax:

```
$loadDCM [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *merging* as in `$loadM` and *domain checking* as in `$loadDC`.

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [TRANSPORT].

```

Set i, uni 'all labels';
Parameter abFail(i), ab(uni) 'capacity and demand';
$gdxIn transsol
$load i abFail=a
$loadDCM abFail=b
$loadDCM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;

```

Here we try to merge parameters `a` and `b` together into one parameter. The first attempt (to merge it into parameter `abFail`) would fail because of line 5 and result into a domain violation report as described with dollar control option `$loadDC`. In the second attempt we first merge the sets `i` and `j` into set `uni` and then merge the parameters `a` and `b` into `ab`. If one comments line 5 the resulting display looks as follows:

```

-----      8 SET uni  all labels
seattle ,    san-diego,    new-york ,    chicago ,    topeka

-----      8 PARAMETER ab  capacity and demand
seattle  350.000,    san-diego 600.000,    new-york  325.000
chicago 300.000,    topeka   275.000

```

\$loadDCR

Syntax:

```
$loadDCR [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *replacing* data as in [\\$loadR](#) and [domain checking](#) as in [\\$loadDC](#).

Example:

Consider the following example where `transsol` is the GDX file of the transportation model `[TRANSPORT]`.

```
Set uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadM uni=i uni=j ab=a
$loadDCR ab=b
$gdxIn
display uni, ab;
```

Here we try to read twice into the parameter `ab`. First GDX symbol `a` and `b` are read into `ab`. GDX symbol `b` is read with *replace* and hence the parameter `ab` contains the elements of `b` only.

\$loadFiltered

Syntax:

```
$loadFiltered [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is an alternative form of [\\$load](#), in particular, it works like [\\$load](#) while [\\$onFiltered](#) is set. That means, when items are loaded, [domain violations](#) are not flagged as compilation errors, but items violating the domain definition are just filtered out. This is basically the opposite of [\\$loadDC](#). All other features are the same as discussed under [\\$load](#).

Example: Consider the following example where `transsol` is the GDX file of the transportation model `[TRANSPORT]`.

```
Set i / seattle /
    j / new-york, chicago /;
Parameter a(i), b(j);
$gdxIn transsol
$loadFiltered a
$loadDC      b
$gdxIn
```

While [\\$loadFiltered a](#) does not generate an error, but just ignores the data that does not match the defined domain, [\\$loadDC b](#) triggers a domain violation error.

See also [\\$loadFilteredM](#) and [\\$loadFilteredR](#).

\$loadFilteredM

Syntax:

```
$loadFilteredM [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *merging* as in [\\$loadM](#) and domain filtering as in [\\$loadFilterd](#).

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [TRANSPORT].

```
Set i, uni 'all labels';
Parameter abFilter(i), ab(uni) 'capacity and demand';
$gdxIn transsol
$load          i abFilter=a
$loadFilteredM abFilter=b
$loadFilteredM uni=i uni=j ab=a ab=b
$gdxIn
Display uni, ab, abFilter;
```

Here we try to merge parameters `a` and `b` together into one parameter. The first attempt (to merge it into parameter `abFilter`) does not add anything, since the elements in `b` do not match the defined domain `i` (compare [\\$loadFilterd](#)). In the second attempt we first merge the sets `i` and `j` into set `uni` and then merge the parameters `a` and `b` into `ab`. The `Display` statement produces the following output:

```
----      31 SET uni  all labels

seattle  ,      san-diego,      new-york ,      chicago  ,      topeka

----      31 PARAMETER ab  capacity and demand

seattle  350.000,      san-diego 600.000,      new-york 325.000,      chicago  300.000,      topeka

----      31 PARAMETER abFilter  capacity of plant i in cases

seattle  350.000,      san-diego 600.000
```

\$loadFilteredR

Syntax:

```
$loadFilteredR [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *replacing* data as in [\\$loadR](#) and domain filtering as in [\\$loadFilterd](#).

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [TRANSPORT].

```
Set      uni      'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadFilteredM uni=i uni=j ab=a
$loadFilteredR ab=b
$gdxIn

Display uni, ab;
```

Here we try to read twice into the parameter `ab`. First GDX symbol `a` and `b` are read into `ab`. GDX symbol `b` is read with *replace* and hence the parameter `ab` contains the elements of `b` only:

```

----      31 SET uni  all labels

seattle  ,      san-diego,      new-york  ,      chicago  ,      topeka

----      31 PARAMETER ab  capacity and demand

new-york 325.000,      chicago 300.000,      topeka 275.000

```

\$loadM

Syntax:

```
$loadM [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is an alternative form of `$load`. Instead of replacing an item or causing a *symbol redefined* error if the item was already initialized it *merges* the contents. Records that would result in domain violations will be ignored.

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [TRANSPORT].

```

Set i, uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;

```

Here we merge parameters `a` and `b` together into one parameter `ab`. We first merge the sets `i` and `j` into set `uni` and then merge the parameters `a` and `b` into `ab`. The resulting display looks as follows:

```

----      6 SET uni  all labels

seattle  ,      san-diego,      new-york  ,      chicago  ,      topeka

----      6 PARAMETER ab  capacity and demand

seattle 350.000,      san-diego 600.000,      new-york 325.000
chicago 300.000,      topeka 275.000

```

\$loadR

Syntax:

```
$loadR [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is a variant of the option `$load`. With `$loadR` we can have multiple loads into the same symbols and the data stored in GAMS will be replaced with the one from the GDX container.

Example:

Consider the following example, where `transsol` is the GDX file of the transportation model [TRANSPORT]:

```

Sets i / 1*3 /
      j / 1*2 /;
$gdxIn transsol
$loadR i j
$gdxIn
display i, j;

```

The resulting listing file will contain the following lines:

```

----      6 SET i  canning plants
Seattle  ,   San-Diego

----      6 SET j  markets
New-York,   Chicago ,   Topeka

```

\$log

Syntax:

```
$log text
```

This option will send a message `text` to the log file. Recall that by default, the log file is the console. The default log file may be reset with the command line parameters [logOption](#) and [logFile](#).

Attention

- Leading blanks are ignored when the text is written out to the log file as a result of using the `$log` option.
- All special `%` symbols will be substituted before the text passed through the `$log` option is sent to the log file.

Example:

```

$log
$log      The following message will be written to the log file
$log with leading blanks ignored. All special % symbols will
$log be substituted before this text is sent to the log file.
$log This was line %system.incLine% of file %system.incName%
$log

```

The log file that results by running the lines above will contain the following lines:

```

The following message will be written to the log file
with leading blanks ignored. All special % symbols will
be substituted before this text is sent to the log file.
This was line 5 of file C:\tmp\logTest.gms

```

Note that `%system.incLine%` is replaced by 5 which is the line number where the string replacement was requested. Note further that `%system.incName%` is substituted with the name of the file completed with the absolute path. Observe that the leading blanks on the second line of the example are ignored.

\$macro

Syntax:

```
$macro name(arg1,arg2,arg3, ...) macro_body
```

This option defines a macro in GAMS. Here **name** is the name of the macro, **arg1, arg2, arg3, . . .** are the arguments and **macro.body** defines what the macro should do. The macro names follow the rules for [identifiers](#). The macro **name** cannot be used for other symbols. For further details and examples, see section [Macros in GAMS](#) below.

\$maxCol (80001)

Syntax:

```
$maxCol n
```

This option restricts the valid range of input columns at the *right* margin. Note that all input after column **n** is treated as comment, therefore it is ignored.

Example:

```
$maxCol 30
Set    i / vienna, rome /;    set definition
Scalar a / 2.3                /;  scalar definition
```

Observe that the text strings **set definition** and **scalar definition** are treated as comments and are ignored since they begin on or after column 31.

Any changes in the margins via **\$maxCol** or **\$minCol** will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option **\$minCol 20 maxCol 110** will trigger the following message:

```
NEW MARGINS: 20-110
```

Note

- GAMS requires that the right margin set by **\$maxCol** is greater than 15.
- GAMS requires that the right margin set by **\$maxCol** is greater than the left margin set by [\\$minCol](#).

See also [\\$on/offMargin](#) and section [Comments](#).

\$maxGoto 100

Syntax:

```
$maxGoto n
```

This option sets the maximum number of jumps to the same label and is used in the context of the options [\\$goto](#) and [\\$label](#). Once the maximum number is reached a compilation error is triggered. Such a limit has been implemented to avoid infinite loops at compile time.

Example:

```
Scalar a / 1 /;
$maxGoto 5
$label label1
a = a+10;
display a ;
$goto label1
```

Note that a compilation error is triggered if **\$goto label1** is called for the fifth time.

\$minCol (1)

Syntax:

```
$minCol n
```

This option restricts the valid range of input columns at the *left* margin. Note that all input before column *n* is treated as comment, therefore it is ignored.

Example:

```
$minCol 30
Set definition          Set    i / vienna, rome /;
Scalar definition      Scalar a / 2.3          /;
```

Observe that the text strings `set definition` and `scalar definition` are treated as comments and are ignored since they are placed before column 30.

Any changes in the margins via the option `$maxCol` or `$minCol` will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option `$minCol 20 maxCol 110` will trigger the message:

```
NEW MARGINS: 20-110
```

Attention

GAMS requires that the left margin set by the option `$minCol` is smaller than the right margin set by the option `$maxCol`.

See also [\\$on/offMargin](#) and section [Comments](#).

`$[on][off]CheckErrorLevel` (`$offCheckErrorLevel`)**Syntax:**

```
$onCheckErrorLevel
$offCheckErrorLevel
```

If the option `$onCheckErrorLevel` is active, the `errorLevel` is checked implicitly after `$call` and `$hiddenCall`. A compilation error is triggered and the compilation is aborted if it is not 0. With `$offCheckErrorLevel`, this is not done, but one can do it explicitly. So, with `$onCheckErrorLevel` `$call` behaves like `$call.checkErrorLevel` and `$hiddenCall` behaves like `$hiddenCall.checkErrorLevel`.

`$[on][off]Delim` (`$offDelim`)**Syntax:**

```
$onDelim
$offDelim
```

This option controls whether data in table statements may be entered in delimited format. As delimiter one can use `"."`, `" "`, or `"TAB"`.

Example:

```
Sets plant 'plant locations' / NEWYORK, CHICAGO, LOSANGELES /
      market 'demands' / MIAMI, HOUSTON, PORTLAND /;
```

```
Table dist(plant,market)
$onDelim
,MIAMI,HOUSTON,PORTLAND
NEWYORK,1300,1800,1100
CHICAGO,2200,1300,700
LOSANGELES,3700,2400,2500
$offDelim
;
```

```
Display dist;
```

The resulting listing file will contain the following output:

```
-----      12 PARAMETER dist

                MIAMI      HOUSTON      PORTLAND

NEWYORK      1300.000      1800.000      1100.000
CHICAGO      2200.000      1300.000        700.000
LOSANGELES   3700.000      2400.000      2500.000
```

\$(on)[off]Digit (\$onDigit)

Syntax:

```
$onDigit
$offDigit
```

Historically, GAMS has run on widely different platforms where even the floating-point arithmetic varied. To ensure the precision specified in the GAMS input didn't exceed what could be stored and computed with as GAMS ran, we limited the precision (i.e. the number of significant digits used for numbers) that could be specified in the GAMS source. This limit could be relaxed by using the `$offDigit` control.

Modern computers all support IEEE double-precision arithmetic, and GAMS uses this internally. It's a well-accepted and familiar standard, and the current behavior - to convert the decimal value in the GAMS source into the nearest double-precision value, regardless of the number of digits in the GAMS source - is what is generally expected. There is a limit (currently 40) on the number of digits treated as potentially significant: digits beyond this point are quietly treated as zero.

The `$offDigit` control remains useful for changing how GAMS handles numbers with very large or small magnitude. With `$onDigit`, GAMS throws compiler warnings/errors for these values. With `$offDigit`, GAMS quietly converts them to UNDF or EPS, respectively.

Example:

```
scalar aboveTheLimit / 222e299 /;
scalar tiny / 1.0e-275 /;
scalar tinier / 1.0e-285 /;
$offdigit
scalar uberTheLimit / 222e299 /;
scalar klein / 1.0e-275 /;
scalar kleiner / 1.0e-285 /;
```

The resulting listing file will contain the following lines:

```

1 scalar aboveTheLimit / 222e299 /;
****                               $106
2 scalar tiny / 1.0e-275 /;
****                               $595
3 scalar tinier / 1.0e-285 /;
****                               $594
5 scalar uberTheLimit / 222e299 /;
6 scalar klein / 1.0e-275 /;
7 scalar kleiner / 1.0e-285 /;
Error Messages
106 abs(number) out of range
    abs(number) must be less than 1E300
    $offdigit can be used to replace large numbers with UNDF
594 Exponent very very small - rejected
    $offdigit can be used to replace with EPS
595 Exponent very small
    $offdigit can be used to quietly accept very small values

```

`$(on)[off]Dollar` (`$offDollar`)

Syntax:

```

$onDollar
$offDollar

```

This option controls the echoing of dollar control option lines in the listing file.

Example:

```

$hidden This line will not be displayed
$onDollar
$hidden This line will be displayed
$offDollar
$hidden This line will not be displayed

```

The compilation output of the resulting listing file will contain the following lines:

```

2 $onDollar
3 $hidden This line will be displayed

```

Note that all lines between the option `$onDollar` and the option `$offDollar` are echoed in the listing file. Note further that the effect of this option is immediate: the line `$onDollar` is echoed in the listing file, while the line `$offDollar` is not.

`$(on)[off]DotL` (`$offDotL`)

Syntax:

```

$onDotL
$offDotL

```

This option activates or deactivates the automatic addition of the attribute `.L` to variables on the right-hand side of assignments and in `put` statement. It is most useful in the context of macros. For further information, see section [Macros in GAMS](#) below.

Example:

Consider the following code snippet which can be added to the end of the `[TRANSPORT]` model:

```
$onDotL
file fx; put fx;
loop((i,j),
      put / x(i,j)
);
$offDotL
file fx; put fx;
loop((i,j),
      put / x(i,j)
);
```

This is the generated output:

```
50.00
300.00
0.00
275.00
0.00
275.00
x('seattle','new-york')
x('seattle','chicago')
x('seattle','topeka')
x('san-diego','new-york')
x('san-diego','chicago')
x('san-diego','topeka')
```

First, we see the `level` for each `x` record. After setting `$offDotL` we are back at the default which means, that the `.tn` attribute is used implicitly.

`$(on)[off]DotScale ($offDotScale)`

Syntax:

```
$onDotScale
$offDotScale
```

This option activates or deactivates the automatic addition of the attribute `.Scale` to variables and equations on the right-hand side of assignments and in `put` statements. As with `on/offDotL` It is most useful in the context of macros. For further information, see section [Macros in GAMS](#) below.

`$(on)[off]Echo[S][V]`

Syntax:

```

$onEcho[S|V] >[>] external_file
text
{text}
$offEcho

```

This option is used to send one or more lines of `text` to an file `external_file`. The text and the file name may be quoted or unquoted. The external file is not closed until the end of the compilation or when the option `$call` or any variant of the option `$include` is encountered. Note that the redirection symbols `>` and `>>` have the usual meaning: `>` creates a new file and writes to it or - in case there exists already a file with the respective name - overwrites the existing file and `>>` appends to a file. Note further that parameter substitutions are permitted with `$onEcho`. The option `$onEcho` has two more variants: `$onEchoS` and `$onEchoV`. `$onEchoS` allows parameter substitutions like `$onEcho`, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended `S`. The option `$onEchoV` does not allow parameter substitutions but writes the text verbatim.

Example:

```

$set it TEST
$onEchoS > externalfile1.txt
send %it% to external file
line 2 to send
$offEcho

```

```

$onEchoV > externalfile2.txt
send %it% to external file
line 2 to send
$offEcho

```

The `externalfile1.txt` will contain the following lines:

```

send TEST to external file
line 2 to send

```

The `externalfile2.txt` will contain these lines:

```

send %it% to external file
line 2 to send

```

Observe that in the first case `%it%` is substituted with `TEST`, but in the second case there is no substitution.

Note that by default the external file will be placed in the current working directory if there is no path specified.

See also options `$echo`, and `$echoN`.

`$[on][off]Embedded` (`$offEmbedded`)

Syntax:

```

$onEmbedded
$offEmbedded

```

This option enables or disables the use of embedded values in parameter and set data statements. If enabled, the explanatory text for set elements is concatenated with blank separators. For parameters, the embedded values get multiplied.

Example:

```

Set k / a,b /
    l / a /;
Set      i(k,l) / a.a 'aaaa cccc dddd'
          b.a 'bbbb cccc dddd' /;
Parameter m(k,l) / a.a 12
              b.a 24 /;

$onEmbedded
Set      j(k,l) / (a aaaa, b bbbb).(a cccc) dddd /;
Parameter n(k,l) / (a 1,   b 2) .(a 3) 4 /;

```

Note that the explanatory text of the set elements in `i` and `j` as well as the values of the parameters `m` and `n` are identical.

`$(on)[off]EmbeddedCode[S][V]`

Syntax:

```

$onEmbeddedCode[S|V] Python: [arguments]
Python code
{Python code}
$offEmbeddedCode {symbol[<[=]embSymbol[.dimX]]}

```

This option is used to execute one or more lines of Python code while GAMS stays alive. The Python code has access to GAMS symbols and can read and change them.

Note that parameter substitutions are permitted with `$onEmbeddedCode`. The option `$onEmbeddedCode` has two more variants: `$onEmbeddedCodeS` and `$onEmbeddedCodeV`. `$onEmbeddedCodeS` allows parameter substitutions like `$onEmbeddedCode`, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended `S`. The option `$onEmbeddedCodeV` does not allow parameter substitutions but passes the code verbatim to the Python interpreter. The optional `arguments` given to `$onEmbeddedCode[S|V]` can be accessed in the Python code.

`$offEmbeddedCode` can be followed by a GAMS symbol or a list of GAMS symbols. If GAMS symbols are specified they get updated in the GAMS database after the Python code got executed. The syntax `symbol[<[=]embSymbol[.dimX]]` allows to load a one dimensional set from a symbol which was set in the embedded code that has even a higher dimensionality (here we call `<[=]` the projection operator). GAMS tries to find the set `symbol` as a domain in the symbol `embSymbol` and uses the labels from this index position (with `<` the first domain set from the right and with `<=` from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix `.dimX` allows to pick a fixed index position (`X` needs to be replaced by the desired index position).

Example:

```

Set cc      / "France - Paris", "France - Lille", "France - Toulouse"
             "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
             "USA - Washington DC", "USA - Houston", "USA - New York",
             "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /

country / system.empty /
city    / system.empty /
mccCountry(cc,country)
mccCity(cc,city);

```

```

$onEmbeddedCode Python:
mccCountry = []
mccCity = []
country = set()

```

```

city = set()
for cc in gams.get("cc"):
    r = str.split(cc, " - ", 1)
    mccCountry.append((cc,r[0]))
    mccCity.append((cc,r[1]))
    country.add(r[0])
    city.add(r[1])
gams.set("country",list(country))
gams.set("city",list(city))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode country city mccCountry mccCity

```

```

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry ,mccCity;

```

This will be in the listing file:

```

----      28 SET country

```

```

Spain   ,      USA      ,      France ,      Germany

```

```

----      28 SET city

```

```

Washington DC,      Toulouse      ,      Berlin      ,      Munich
Houston      ,      Madrid      ,      New York      ,      Seville
Paris      ,      Bilbao      ,      Lille      ,      Bonn
Cordoba

```

```

----      28 SET mccCountry

```

```

France - Paris      .France
France - Lille      .France
France - Toulouse   .France
Spain - Madrid      .Spain
Spain - Cordoba     .Spain
Spain - Seville     .Spain
Spain - Bilbao      .Spain
USA - Washington DC.USA
USA - Houston       .USA
USA - New York      .USA
Germany - Berlin    .Germany
Germany - Munich    .Germany
Germany - Bonn      .Germany

```

```

----      28 SET mccCity

```

```

France - Paris      .Paris
France - Lille      .Lille
France - Toulouse   .Toulouse
Spain - Madrid      .Madrid
Spain - Cordoba     .Cordoba
Spain - Seville     .Seville
Spain - Bilbao      .Bilbao
USA - Washington DC.Washington DC
USA - Houston       .Houston

```

```

USA - New York      .New York
Germany - Berlin   .Berlin
Germany - Munich   .Munich
Germany - Bonn     .Bonn

```

Using the projection operator the same task could be done like this:

```

Set cc      / "France - Paris", "France - Lille", "France - Toulouse"
           / "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
           / "USA - Washington DC", "USA - Houston", "USA - New York",
           / "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
country / system.empty /
city    / system.empty /
mccCountry(cc,country)
mccCity(cc,city);

```

`$onEmbeddedCode` Python:

```

mccCountry = []
mccCity = []
for cc in gams.get("cc"):
    r = str.split(cc, " - ", 1)
    mccCountry.append((cc,r[0]))
    mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode country<mccCountry city<mccCity mccCountry mccCity

```

```

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry ,mccCity;

```

See also chapter [Embedded Code Facility](#) for more details.

`$[on][off]Empty` (`$onEmpty`)

Syntax:

```

$onEmpty
$offEmpty

```

Setting `$onEmpty` allows empty data statements for list or table formats. Note that by default, empty data statements will cause a compilation error.

Example:

```

Set      i      / 1,2,3 / ;
Set      j(i)   /      / ;
Parameter x(i)  "empty parameter" / / ;
Table    y(i,i) "headers only"
         1  2  3
;
$onEmpty
Set      k(i)   / / ;
Parameter xx(i) "empty parameter" / / ;
Table    yy(i,i) "headers only"
         1  2  3
;

```

The resulting listing file will contain the following lines:

```

1 Set      i      / 1,2,3 / ;
2 Set      j(i) /      / ;
****
3 Parameter x(i)  "empty parameter" / / ;
****
4 Table    y(i,i) "headers only"
5          1    2    3
6          ;
****
7          $460
8 Set      k(i) / / ;
9 Parameter xx(i) "empty parameter" / / ;
10 Table   yy(i,i) "headers only"
11         1    2    3
12        ;

```

Error Messages

```

460 Empty data statements not allowed. You may want to use $ON/OFFEMPTY
462 The row section in the previous table is missing

```

Empty data statements are most likely to occur when data is being entered into the GAMS model by an external program. This problem may be overcome with the option `$onEmpty`.

Note

The empty data statement may only be used with symbols which have a known dimension. If the dimension is also derived from the data, the option `$phantom` should be used to generate 'phantom' set elements.

The option `$onEmpty` in conjunction with the option `$onMulti` and the [save and restart feature](#) may be used to set up a model and add data later.

`$(on)[off]End` (`$offEnd`)

Syntax:

```

$onEnd
$offEnd

```

This option offers an alternative syntax for [flow control statements](#). The option `$onEnd` causes the following words to be regarded as keywords: `do`, `endLoop`, `endIf`, `endFor` and `endWhile`. They are used to close the language constructs `loop`, `if`, `for` and `while` respectively.

Example:

Note

The standard syntax is given as an end-of-line comment.

```

Set      i      / 1*3 /;
Scalar   cond / 0 /;
Parameter a(i) / 1 1.23, 2 2.65, 3 1.34/;

$eolCom //
$onEnd

loop i do                                // loop (i,
  display a;                             //   display a;

```

```

endLoop;                                // );

if (cond) then                          // if (cond,
  display a;                            //   display a;
else                                     // else
  a(i) = a(i)/2;                        //   a(i) = a(i)/2;
  display a;                            //   display a;
endIf;                                  // );

for cond = 1 to 5 do                    // for (cond = 1 to 5,
  a(i) = 2 * a(i);                      //   a(i) = 2 * a(i);
endFor;                                 // );

while cond > 3 do                       // while (cond > 3,
  a(i) = a(i) / 2;                      //   a(i) = a(i) / 2;
  cond = cond-1;                        //   cond = cond-1;
endWhile;                               // );

```

Observe that the alternative syntax is more in line with the syntax used in some of the popular programming languages.

Attention

Setting the option `$onEnd` will make the alternative syntax valid, and at the same time it will make the standard syntax invalid. Therefore the two forms of the syntax will never be valid simultaneously.

`$(on)[off]EolCom ($offEolCom)`

Syntax:

```

$onEolCom
$offEolCom

```

This option acts as a switch to control the use of end-of-line comments. Note that by default, the end-of-line comment symbol is set to `!!` but the processing is disabled.

Example:

```

$onEolCom
Set      i    /1*2/ ; !! set declaration
Parameter a(i)      ; !! parameter declaration

```

Observe that after the option `$onEolCom` has been specified, comments may be entered on the same line as GAMS code.

Note

The option `$eolCom` automatically sets `$onEolCom`.

See also section [Comments](#).

`$(on)[off]Eps ($offEps)`

Syntax:

```
$onEps
$offEps
```

This option is used to interpret zero values as **EPS** when non-scalar parameters, variable attributes, or equation attributes are defined or loaded (e.g. from [GDX](#) or [embedded code](#)) at compile time. This can for example be useful if the value of zero is overloaded with existence interpolation.

See option [zeroToEps](#) for the execution-time equivalent.

Example 1:

Consider the following example where zero values are defined for a one dimensional parameter, once under `$onEps` and `$offEps`.

```
Set      i      / one, two, three, four /;
Parameter a(i) /
$onEps
      one      0
$offEps
      two      0
      three    EPS /;
Display a ;
```

The outcome generated by the display statement follows:

```
----      8 PARAMETER a

one  EPS,      three EPS
```

Note that only those entries specifically entered as 0 are treated as **EPS**.

Example 2:

Consider the following example where zero values are loaded from a [GDX](#) file, once under `$offEps` (default) and `$onEps` (derived from test library model `[ZEROTOEPS1]`).

```
Set s,t;
Parameter p(s<,t<)
      pOnEps(s,t);
$gdxIn zeropar.gdx
$onText
P looks like this:
      t1      t2      t3
s1 0          0.843267
s2 0.224053  0.349831  0
s3          0          5
$offText
$load p
$onEps
$load pOnEps=p
display p, pOnEps;
```

The outcome generated by the display statement follows:

```

-----      15 PARAMETER p
              t1          t2          t3

s1              0.843
s2      0.224    0.350
s3                          5.000

-----      15 PARAMETER pOnEps
              t1          t2          t3

s1      EPS      0.843
s2      0.224    0.350      EPS
s3              EPS      5.000

```

Example 3:

Consider the following example where zero values are loaded from [embedded Python code](#), once under \$offEps (default) and \$onEps (derived from test library model [ZEROTOEPS1]).

```

Set s / s1*s3 /;
Parameter pEC(s)
      pECOnEps(s);
$onEmbeddedCode Python:
p = [('s1',1), ('s3',0)]
gams.set('pEC',p)
$offEmbeddedCode pEC
$onEps
$onEmbeddedCode Python:
p = [('s1',1), ('s3',0)]
gams.set('pECOnEps',p)
$offEmbeddedCode pECOnEps

display pEC, pECOnEps;

```

The outcome generated by the display statement follows:

```

-----      14 PARAMETER pEC

s1 1.000

-----      14 PARAMETER pECOnEps

s1 1.000,    s3  EPS

```

\$[on][off]EpsToZero (\$offEpsToZero)

Syntax:

```

$onEpsToZero
$offEpsToZero

```

This option is used to write EPS values as zero when parameters, or variable and equation levels get written to **GDX** at compile time.

See option [EpsToZero](#) for the execution-time equivalent.

Example:

Usually GAMS squeezes out 0 values when writing to GDX. To get them written anyway, one can define them as EPS (e.g. by using `$onEps`) and set `$onEpsToZero`:

```
Set      i      / zero, one, two /;
$onEps
Parameter a(i) / zero    0
                one     1
                two     2  /;

$onEpsToZero
$gdxUnload 'zero.gdx' a
```

`$(on)[off]Expand ($offExpand)`

Syntax:

```
$onExpand
$offExpand
```

This option changes the processing of macros that appear in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch `$onExpand` enables the recognition and expansion of macros in the macro argument list and `$offExpand` will restore the default behavior.

Example:

```
variable x(*,*);
$macro f(i) sum(q, x(i,q))
$macro equ(x) equation equ_&x; equ_&x.. &x =e= 0;
equ(f(i))
```

The macro expansion of the code above will result in an equation definition that reads as follows:

```
equation equ_f(I); equ_f(i).. f(i) =e= 0;
```

If we compile the code under `$onExpand` the argument `f(i)` is expanded before the macro `equ()` gets expanding resulting in the following (incorrect) code:

```
equation equ_sum(q, x(i,q)); equ_sum(q, x(i,q)).. sum(q, x(i,q)) =e= 0;
```

For further information, see section [Macros in GAMS](#) below.

`$(on)[off]ExternalInput ($offExternalInput)`

Syntax:

```
$onExternalInput
$offExternalInput
```

`$onExternalInput` and `$offExternalInput` mark the beginning and end of a well defined section in which data is loaded implicitly from an external data source, namely from a GDX file specified by the command line parameter [IDCGDXInput](#).

Note

- If none of the command line parameters `IDCGDXInput`, `IDCGenerateGDXInput`, `IDCJSON`, `IDCGenerateJSON`, or `IDCGenerateGDX` is set, nothing - but a few checks for consistency - will happen by setting `$onExternalInput` and `$offExternalInput`.
- If at least one of the before mentioned command line parameters is set, an additional license check will be triggered: Without the `MIRO Connector License` not more than 5 indexed symbols can be declared as external input or `external output`.

For symbols, which are declared, while `$onExternalInput` is active, data in data statements of the declaration is ignored. Instead, the data is loaded from the GDX file specified by `IDCGDXInput`. Also for those symbols, if they are referenced with `$load*` or `$offEmbeddedCode` while `$onExternalInput` is active, the data is loaded from the GDX file specified by `IDCGDXInput` instead of the defined data source and symbol renaming as well as the projection operator are ignored in this case.

In addition, the following dollar control options are ignored, while `$onExternalInput` is active and `IDCGDXInput` is set:

- `$batInclude`
- `$call`
- `$call.Async[NC]`
- `$call.checkErrorLevel`
- `$gdxIn`
- `$hiddenCall`
- `$hiddenCall.Async[NC]`
- `$hiddenCall.checkErrorLevel`
- `$include`
- `$libInclude`
- `$onEmbeddedCode[S|V]` (including the following embedded code until `$offEmbeddedCode` is hit)
- `$sysInclude`

Example:

Lets look at a modified version of the simple example presented [here](#):

```
Set
```

```
  i 'canning plants'
  j 'markets';
```

```
$onExternalInput
```

```
$call mdb2gms I=Sample.accdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
Parameter d(i<,j<) 'distance in thousands of miles' /
```

```
$include distances.inc
```

```
/;
```

```
$offExternalInput
```

```
display d;
```

Without setting a command line parameter, this runs in the same way as described in the other chapter, so by default, setting `$onExternalInput` and `$offExternalInput` does not make much of a difference. Now, lets run it with `IDCGDXInput` being set to `transsol`, which is a GDX file generated by running the transportation model `[TRANSPORT]`. There will be some new messages in the log:

```

--- GDxin=transsol.gdx
--- Distances1.gms(7) 2 Mb
--- Ignoring $call in externalInput section
--- Distances1.gms(9) 2 Mb
--- Ignoring $include in externalInput section

```

First, we notice, that the file `transsol.gdx` will be opened for input. This happens implicitly with `$onExternalInput`. Then, both the `$call` as well as the `$include` lines were ignored, since we do not want to query the data source explicitly defined in the model, but the GDX file defined by `IDCGDXInput`. Note, that the data statement in the declaration of `d` is actually empty when we ignore the `$include` statement. While `$onExternalInput` this does not lead to an error, but behaves as if `$onEmpty` was set. Looking at the output of the `display` statement in the `1st` file, one can see that the expected data was loaded:

```

----      13 PARAMETER d  distance in thousands of miles

                new-york      chicago      topeka

seattle          2.500          1.700          1.800
san-diego        2.500          1.800          1.400

```

If any of the options `IDCGDXInput`, `IDCGDXOutput`, `IDCJSON` or their `Generate` versions, e.g. `IDCGenerateGDXInput`, has been set, a MIRO connector license is required.

See also `$[on][off]ExternalOutput`.

`$[on][off]ExternalOutput` (`$offExternalOutput`)

Syntax:

```

$onExternalOutput
$offExternalOutput

```

`$onExternalOutput` and `$offExternalOutput` mark the beginning and end of a well defined section in which data is written implicitly to an external data file, namely to a GDX file specified by the command line parameter `IDCGDXOutput` or `IDCGenerateGDXOutput`.

Note

- If none of the command line parameters `IDCGDXOutput`, `IDCGenerateGDXOutput`, `IDCJSON`, `IDCGenerateJSON`, or `IDCGenerateGDX` is set, nothing - but a few checks for consistency - will happen by setting `$onExternalOutput` and `$offExternalOutput`.
- If at least one of the before mentioned command line parameters is set, an additional license check will be triggered: Without the `MIRO Connector License` not more than 5 indexed symbols can be declared as external output or `external input`.

Example:

This is a slightly modified code snippet of the transportation model `[TRANSPORT]`:

```

...
$onExternalOutput
Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

```

Variable

```

x(i,j) 'shipment quantities in cases'

```

```
$offExternalOutput
  z      'total transportation costs in thousands of dollars';
```

Positive Variable x;

Equation

```
$onExternalOutput
  cost      'define objective function'
$offExternalOutput
  supply(i) 'observe supply limit at plant i'
  demand(j) 'satisfy demand at market j';
...

```

Without setting a command line parameter, this runs in the same way as the original model, so by default, setting `$onExternalOutput` and `$offExternalOutput` does not make much of a difference. Now, let's run it with `IDCGDXOutput` being set to `transOut.gdx`. This generates the file `transOut.gdx` with the following content:

Entry	Name	Type	Dim	Records	Text	i ↗	j ↗	Level	Marginal	Lower	Upper	Scale
1	c	Parameter	2	6	transport cost in ...	seattle	new-york	50	0	0	+INF	1
3	cost	Equation	0	1	define objective ...	seattle	chicago	300	0	0	+INF	1
2	x	Variable	2	6	shipment quanti...	seattle	topeka	0	0.036	0	+INF	1
						san-diego	new-york	275	0	0	+INF	1
						san-diego	chicago	0	0.009	0	+INF	1
						san-diego	topeka	275	0	0	+INF	1

So, this implicit generation of the output file is basically equivalent to the following explicit statement:

```
execute_unload 'transOut.gdx', c, x, cost;
```

If any of the options `IDCGDXInput`, `IDCGDXOutput`, `IDCJSON` or their `Generate` versions, e.g. `IDCGenerateGDXInput`, has been set, a MIRO connector license is required.

See also `$(on)[off]ExternalInput`.

`$(on)[off]Filtered` (`$(on)Filtered`)

Syntax:

```
$(on)Filtered
$(off)Filtered
```

This dollar control option controls how GAMS loads data from GDX with `gdxLoad`, `$load`, `$loadR`, and `$loadM`. With `$(on)Filtered` the `$load*` calls behave like `$loadFiltered*` calls. With `$(off)Filtered` the `$load*` calls behave like `$loadDC*` calls. This dollar control option also controls how GAMS loads symbols on the `$offEmbeddedCode` line. With `$(on)Filtered` data is read filtered while `$(off)Filtered` triggers a domain check of the data. The `gams.set` Python function allows to overwrite the setting of this dollar control option with the argument `domCheck=DomainCheckType.CHECKED` or `domCheck=DomainCheckType.FILTERED`.

`$(on)[off]Global` (`$(off)Global`)

Syntax:

```
$onGlobal
$offGlobal
```

When an [include file](#) is inserted, it inherits the dollar control options from the higher level file. However, the dollar control option settings specified in the include file do not affect the higher level file. This convention is common among most scripting languages or command processing shells. In some cases, it may be desirable to break this convention. This option allows an include file to change the options of the parent file as well.

Example:

```
$include 'inc.inc'
$hidden after first call to include file
$onGlobal
$include 'inc.inc'
$hidden after second call to include file
```

The file `inc.inc` contains the following lines:

```
$onDollar
$hidden text inside include file
```

The the echo print of the resulting listing file follows:

```
INCLUDE      D:\GAMS\INC.INC
   2  $onDollar
   3  $hidden text inside include file
INCLUDE      D:\GAMS\INC.INC
   7  $onDollar
   8  $hidden text inside include file
   9  $hidden after second call to include file
```

Note that the dollar control option [\\$onDollar](#) inside the include file does not affect the parent file until [\\$onGlobal](#) is set. The text following the option [\\$hidden](#) is then echoed to the listing file.

`$(on)[off]IDCProtect` (`$onIDCProtect`)

Syntax:

```
$onIDCProtect
$offIDCProtect
```

This controls if symbols which are declared as [external input](#) can be changed at execution time. With `$onIDCProtect` external input symbols are protected from being changed; `$offIDCProtect` allows it.

The initial state of this can be set with the command line parameter [IDCProtect](#).

`$(on)[off]Include` (`$onInclude`)

Syntax:

```
$onInclude
$offInclude
```

This option controls the listing of the expanded include file name in the listing file.

Example:

```
$include 'inc.inc'
$offInclude
$include 'inc.inc'
```

We assume that the file `inc.inc` contains the following lines:

```
$onDollar
$hidden Text inside include file
```

The resulting listing file will contain the following lines:

```
INCLUDE      C:\tmp\inc.inc
  2  $onDollar
  3  $hidden Text inside include file
  6  $onDollar
  7  $hidden Text inside include file
```

Note that the include file name is echoed the first time the include file is used. However, the include file name is not echoed after `$offInclude` has been set. Also, the [include file summary](#) and the creation of an [Expanded Include File](#) is suppressed if `$offInclude` is set.

`$(on)[off]Inline` (`$(offInline)`)

Syntax:

```
$onInline
$offInline
```

This option acts as switch to control the use of in-line comments. Note that by default, the in-line comment symbols are set to the two character pairs `/*` and `*/` but the processing is disabled. In-line comments may span several lines till the end-of-comment characters are encountered.

Example:

```
$onInline
Set i /* The default comment symbols are now
      active. These comments can continue
      to additional lines till the closing
      comments are found. */ / i1*i3 / ;
```

Note

- The option `$inlineCom` automatically sets `$onInline`.
- *Nested* in-line comments are illegal unless the option `$onNestCom` is set.

See also section [Comments](#).

`$(on)[off]Listing` (`$(onListing)`)

Syntax:

```
$onListing
$offListing
```

This option controls the echoing of input lines to the compilation output of the listing file. Note that suppressed input lines do not generate entries in the symbol and reference sections that appear at the end of the compilation output. Lines with errors will always be listed.

Example:

```
Set i /0234*0237/
    j /a,b,c/      ;
Table x(i,j) "very long table"
    a  b  c
0234  1  2  3
$offListing
0235  4  5  6
0236  5  6  7
$onListing
0237  1  1  1
;
```

The resulting listing file will contain the following lines:

```
1 Set i /0234*0237/
2   j /a,b,c/      ;
3 Table x(i,j) very long table
4     a  b  c
5 0234  1  2  3
10 0237  1  1  1
```

Note that the lines in the source file between the options `$offListing` and `$onListing` are not echoed to the listing file.

Note

For some projects the listing file can become huge and can take significant time to be written. This time can be saved by setting `$offListing` at the beginning of the input file and `$onListing` just before the parts one is interested in, or not at all, if one does not look at the listing file anyway.

`$(on)[off]Local ($onLocal)`

Syntax:

```
$onLocal
$offLocal
```

The suffix `.local` attached to the name of a controlling set will use an *implicit alias* within the scope of the indexed operation or on the left-hand side of an assignment statement. This feature is particularly useful in the context of nested macros.

Example:

```
Set i /1*3/; alias(i,j);
Parameter xxx(i,j) / 1.1 1, 2.2 2, 3.3 3, 1.3 13, 3.1 31 /;
display xxx;

Parameter p(i);
p(i.local) = sum(j, xxx(i,j));
display p;
```

Note that in the assignment statement the set `i` on the right-hand side is controlled by `i.local` on the left-hand side. Thus we have the following values for the two parameters:

```

----      3 PARAMETER xxx
          1          2          3
1         1.000                13.000
2                2.000
3        31.000                3.000

----      7 PARAMETER p
1 14.000,   2 2.000,   3 34.000

```

In the example above, the suffix `.local` appeared one time on the left-hand side. The option `$onLocal` allows the suffix `.local` to appear more than one time attached to the same symbol. Consider the following example that extends the example above:

```

Parameter g(i,i);
g(i.local-1,i.local) = xxx(i,i);
display g;

```

Note that in the assignment statement of `g` the suffix `.local` attached to the set `i` appears two times on the left-hand side. The question arises whether the reference to the set `i` on the right-hand side refers to the first or the second instance of `.local` on the left-hand side. The assignment statement may alternatively be written in the following way using an *explicit* alias statement:

```

alias (i,i1,i2);
g(i1-1,i2) = xxx(i2,i2);

```

Thus it becomes clear that the symbol on the right-hand side refers to the controlling index that enters last (here the second one). The output generated by the display statement follows:

```

----      10 PARAMETER g
          1          2          3
1         1.000      2.000      3.000
2         1.000      2.000      3.000

```

Observe that the multiple use of the suffix `.local` on the same symbol is considered an error with the option `$offLocal`.

Note that it is also allowed to combine the original index with an index suffixed with `.local`. Consider the following alternative formulation:

```

g(i.local-1,i) = xxx(i,i);

```

Note that in this case the index suffixed with `.local` takes precedence and the reference of `i` on the right-hand side refers to the index `i.local` even though `i` is entered last. Observe that this statement even works with `$offLocal` as the suffix `.local` appears only once.

See also section [Macros in GAMS](#) below.

`$(on)[off]Log` (`$onLog`)

Syntax:

```

$onLog
$offLog

```

This option acts as a switch that controls logging information about the line number and memory consumption during compilation. This is scoped like the option `$on/offListing` applying only to included files and any subsequent included files but reverting to the setting `$onLog` in the parent files (if it was not changed there as well).

Example:

```
Set i /i1*i20000000/;
$include inc.inc
Set l /l1*l20000000/;
```

The file `inc.inc` looks like this:

```
Set j /j1*j20000000/;
$offLog
Set k /k1*k20000000/;
```

The generated log will contain the following lines:

```
--- test.gms(1) 1602 Mb  5 secs
--- test.gms(2) 1602 Mb
--- .inc.inc(1) 3122 Mb  6 secs
--- test.gms(3) 6161 Mb 14 secs
```

Note that the first line of both the parent and the include file got logged, but not the third line of the include file, after `$offLog` was set. The last line of the parent file got logged again.

`$[on][off]Macro ($onMacro)`

Syntax:

```
$onMacro
$offMacro
```

Enables or disables the expansion of macros defined by `$macro`.

Example:

```
$macro oneoverit(y) 1/y
$offMacro
y = oneoverit(x1);
display y;
```

causes an error because the macro `oneoverit` in line 3 can not be expanded.

`$[on][off]Margin ($offMargin)`

Syntax:

```
$onMargin
$offMargin
```

This option controls margin marking, that means if margins set by the options `$minCol` and `$maxCol`, should be marked in the `lst` file.

Example:

```

$onmargin mincol 20 maxcol 51
Now we have      Set      i "plant" / US, UK /; This defines I
turned on the    Scalar    x      / 3.145 /; A scalar example.
margin marking.  Parameter a, b;      Define some
                                           parameters.
$offmargin

```

The lst file will contain this:

```

 2 Now we have      |Set      i "plant" / US, UK /; |This defines I
 3 turned on the    |Scalar    x      / 3.145 /; |A scalar example.
 4 margin marking.  |Parameter a, b;      |Define some
 5                  |                |parameters.

```

Note that any statements between columns 1 and 19 and any input beyond column 52 are treated as comments. These margins are marked with | on the left and right.

See also section [Comments](#).

\$(on)[off]Multi (\$offMulti)

Syntax:

```

$onMulti
$offMulti

```

This option controls multiple data statements or tables. By default, GAMS does not allow data statements to be redefined. If this option is activated the second or subsequent data statements are merged with entries of the previous ones. Note that all multiple data statements are performed before any other statement is executed.

Note

- There is also [\\$onMultiR](#), which behaves similarly, but replaces existing data instead of merging into it. Compare the example here and there to see the difference.
- When [\\$onMulti](#) is active [\\$load](#) behaves like a [\\$loadM](#).

Example:

Consider the following slice of code. The list after the end of line comment describes the complete content of the symbol x after the data statement has been processed:

```

$eolCom //
Set i / i1*i10 /;
Parameter x(i) / i1*i3 1 / // /i1 1,i2 1,i3 1/
$onMulti
Parameter x(i) / i7*i9 2 / // /i1 1,i2 1,i3 1,i7 2,i8 2,i9 2/
Parameter x(i) / i2*i6 3 / // /i1 1,i2 3,i3 3,i4 3,i5 3,i6 3,i7 2,i8 2,i9 2/
Parameter x(i) / i3*i5 0 / // /i1 1,i2 3,i6 3,i7 2,i8 2,i9 2/
$offMulti
display x;

```

Note that the repeated parameter statements would have resulted in a compilation error without the presence of the option [\\$onMulti](#). The result of the display statement in the listing file follows:

```

----          8 PARAMETER x

1 1.000,      2 3.000,      6 3.000,      7 2.000,      8 2.000,      9 2.000

```

Note that `x("i1")` is assigned the value of 1 with the first data and is not affected by any of the subsequent data statements. `x("i3")` on the other hand is reset to 3 by the third data statement and wiped out with 0 in the fourth data statement.

Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option `$onMulti` since it allows data initializations to be performed more than once. See section [GAMS Compile Time and Execution Time Phase](#) for details.

Consider the following example:

```
Scalar a /12/;
a=a+1;
$onMulti
Scalar a /20/;
display a;
```

Note that the two `scalar` data initialization statements and the option `$onMulti` are processed before the assignment statement `a=a+1`. As a result, the final value of `a` will be 21. The output of the display statement follows:

```
-----          5 PARAMETER a                      =          21.000
```

Observe that the option `$onEmpty` in conjunction with the option `$onMulti` and the [save and restart feature](#) may be used to set up a model and add data later. See example in section [Advanced Separation of Model and Data](#) for details.

`$onMultiR|offMulti ($offMulti)`**Syntax:**

```
$onMultiR
$offMulti
```

This option controls multiple data statements or tables. By default, GAMS does not allow data statements to be redefined. If this option is activated the second or subsequent data statements replace the previous ones. Note that all multiple data statements are performed before any other statement is executed.

Note

- There is also `$onMulti`, which behaves similarly, but *merges* into existing data instead of replacing it. Compare the example here and there to see the difference.
- In contrast to `$onMulti`, `$onMultiR` also allows to redefine an equation and a [macro](#).

Example:

Consider the following slice of code. The list after the end of line comment describes the complete content of the symbol `x` after the data statement has been processed:

```
$eolCom //
Set i / i1*i10 /;
Parameter x(i) / i1*i3  1 /  // /i1 1,i2 1,i3 1/
$onMultiR
Parameter x(i) / i7*i9  2 /  // /i7 2,i8 2,i9 2/
Parameter x(i) / i2*i6  3 /  // /i2 3,i3 3,i4 3,i5 3,i6 3/
Parameter x(i) / i3*i5  0 /  // ( ALL          0.000 )
$offMulti
display x;
```

Note that the repeated parameter statements would have resulted in a compilation error without the presence of the option `$onMultiR`. The result of the display statement in the listing file follows:

```
-----          9 PARAMETER x
( ALL          0.000 )
```

Note

- When using a redefinition with `$onMultiR` to remove elements from a set, which was used as domain of another symbol, also the dependent symbol gets reduced. This can happen through data statements, but also with `$clear` and `$load/$loadDC`.
- When `$onMultiR` is active `$load` behaves like a `$loadR`.

Example:

```
Set i          / i1*i5 /;
Parameter p(i) / #i 3 /;

$onMultiR

Set i          / i3*i6 /;
Display p;
```

Looking at the output from the `Display` statement one can see, that the entries for `i1` and `i2` were removed by the second definition of `i`:

```
-----          7 PARAMETER p
i3 3.000,      i4 3.000,      i5 3.000
```

Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option `$onMultiR` since it allows data initializations to be performed more than once. See section [GAMS Compile Time and Execution Time Phase](#) for details.

Consider the following example:

```
Scalar a /12/;
a=a+1;
$onMultiR
Scalar a /20/;
display a;
```

Note that the two `scalar` data initialization statements and the option `$onMultiR` are processed before the assignment statement `a=a+1`. As a result, the final value of `a` will be 21. The output of the display statement follows:

```
-----          5 PARAMETER a          =          21.000
```

Observe that the option `$onEmpty` in conjunction with the option `$onMultiR` and the [save and restart feature](#) may be used to set up a model and add data later. See example in section [Advanced Separation of Model and Data](#) for details.

\$_[on][off]NestCom (\$offNestCom)**Syntax:**

```
$onNestCom
$offNestCom
```

This option controls nested in-line comments. It makes sure that the open-comment and close-comment characters match.

Example:

```
$inlineCom { } onNestCom
  { nesting is now possible in comments { braces
    have to match } }
```

See also [\\$inlineCom](#), [\\$onInline](#) and section [Comments](#).

\$_[on][off]Order (\$onOrder)**Syntax:**

```
$onOrder
$offOrder
```

[Lag and lead operations](#) and the [ord](#) function require the referenced set to be [ordered](#) and constant. In some special cases users might want to use those operations on dynamic and/or unordered sets. The option [\\$on/offOrder](#) has been added to locally relax the default requirements. The use of this option comes with a price, the system will not be able to diagnose odd and incorrect formulations and data sets.

Example:

```
Set      t1      / 1987, 1988, 1989, 1990, 1991 /
          t2      / 1983, 1984, 1985, 1986, 1987 /;
Parameter p(t2);
$offOrder
p(t2) = ord(t2);
display t2,p;
```

Without the [\\$offOrder](#) the compilation of the line `p(t2) = ord(t2);` would have triggered a compilation error. The ordinal numbers assigned here are probably not what one expects. The element 1987 gets ordinal number 1 although it seems to be last last in the set. The ordinal numbers are assigned in the order the set is stored internally in GAMS. This order is also used when displaying the set `t2`:

```
-----      6 SET t2
1987,      1983,      1984,      1985,      1986

-----      6 PARAMETER p
1987 1.000,      1983 2.000,      1984 3.000,      1985 4.000,      1986 5.000
```

\$_[on][off]Put[S][V]

Syntax:

```
File myputfile;
put myputfile;
$onPut[S|V]
text
{text}
$offPut
```

The pair `$onPut[S|V]` - `$offPut` causes a block of text to be placed in a [put file](#) at run-time. This is one of the few dollar control options that operate at run time. The `$` in the first column usually indicates action at compile time.

Note that parameter substitutions are not permitted with `$onPut`. The option `$onPut` has two more variants: `$onPutS` and `$onPutV`. `$onPutS` allows parameter substitutions while the option `$onPutV` does not allow parameter substitutions, like `$onPut`, so it is just a synonym which makes it more obvious that the text is written verbatim with the appended `V`.

Example:

```
$set it TEST
File myputfile;
put myputfile;
$onPutS
Line 1 of text "%it%"
Line 2 of text %it%
$offPut
```

This code generates the put file `myputfile.put` with the following content:

```
Line 1 of text "TEST"
Line 2 of text TEST
```

Note that the [compile-time variable](#) `%it%` was replaced by `TEST`. However, if the option `$onPutV` is used instead, then `%it%` will not be substituted:

```
$set it TEST
File myputfile
put myputfile
$onPutV
Line 1 of text "%it%"
Line 2 of text %it%
$offPut
```

The resulting file `myputfile.put` will contain the following lines:

```
Line 1 of text "%it%"
Line 2 of text %it%
```

`$(on)[off]Upper ($offUpper)`**Syntax:**

```
$onUpper
$offUpper
```

GAMS code echoed to the listing file is written in upper case after `$onUpper`. The default of mixed code echoing is restored with `$offUpper`.

Note

The default case of the echo print can be set using the command line option [case](#).

Example:

Set

```
i 'Canning plants' / seattle, san-diego /
j 'Markets'         / new-york, chicago, topeka /;
```

\$onupper

Parameter

```
a(i) 'Capacity of plant i in cases'
      / seattle    350
      san-diego   600 /
```

\$offupper

```
b(j) 'Demand at market j in cases'
      / new-york   325
      chicago     300
      topeka      275 /;
```

The generated listing file looks like this:

```
1 Set
2   i 'Canning plants' / seattle, san-diego /
3   j 'Markets'       / new-york, chicago, topeka /;
4
5
6 PARAMETER
7   A(I) 'CAPACITY OF PLANT I IN CASES'
8       / SEATTLE    350
9       SAN-DIEGO   600 /
10
11
12  b(j) 'Demand at market j in cases'
13     / new-york   325
14     chicago     300
15     topeka      275 /;
```

\$[on][off]Recurse (\$offRecurse)

Syntax:

```
$onRecurse
$offRecurse
```

This option controls whether it is permitted for a file to include itself.

Example:

The following GAMS program result in a recursive inclusion of the program itself:

```
$onRecurse
$include "%gams.input%"
```

Note that the maximum include nesting level is 40 and if it is exceeded an error is triggered.

In the following example that prints a string and then the reverse string the nesting level is less than 40 and one get some kind of recursion at compile time:

```

$onEchoV > reverse.gms
$ifthen %1=%3+1
  put ' '
$ exit
$endif
loop(map(chars,code)$(code.val=ord("%2",%1)), put chars.tl:0);
$eval posPlus1 %1+1
$batInclude reverse %posPlus1% %2 %3
loop(map(chars,code)$(code.val=ord("%2",%1)), put chars.tl:0);
$offEcho

set chars / A*Z /, code / 65*90 /, map(chars,code) / #chars:#code /;
file fx /''/; put fx;
$onRecurse
$batInclude reverse 1 RACECAR 7
put /;
$batInclude reverse 1 LAGER 5

```

The log will print the following lines:

```

--- Starting execution: elapsed 0:00:00.067
RACECAR RACECAR
LAGER REGAL
*** Status: Normal completion

```

`$(on)[off]StrictSingleton` (`$(onStrictSingleton)`)

Syntax:

```

$onStrictSingleton
$offStrictSingleton

```

If the option `$(onStrictSingleton)` is active, a compilation error is triggered if a data statement for a [singleton set](#) contains more than one element. After activating the option `$(offStrictSingleton)` GAMS will take the *first* element of a singleton set that was declared with multiple elements as the valid element, the other elements are disregarded and there is no error. The option to control this behavior at runtime is [strictSingleton](#).

Example:

The *first* element is not always the one that appears in the data statement first as the following example shows:

```

set i /1,2/
$offStrictSingleton
singleton set ii(i) /2,1/;
display ii;

```

The set `ii` contains the element 1 because it is the first in the GAMS label order as the display statements shows:

```

----      4 SET ii
1

```

`$(on)[off]SuffixDLVars` (`$(offSuffixDLVars)`)

Syntax:

```
$onSuffixDLVars
$offSuffixDLVars
```

This option controls if it is allowed to use suffixes on [variables with limited domains](#) in a model. By default this is not allowed but this can be changed by setting `$onSuffixDLVars`.

Example:

```
Set n          / n1*n100 /
    t          / t1*t10  /
    sub(n,t) / #n:#t   /;

Variable z, x(n,t);
Equation obj;

x.up(n,t) = uniformInt(7,13);
obj.. z =e= sum((n,t),x(n,t)/x.up(n,t));

Model m / all, x(sub) /;
Solve m min z use lp;
```

This causes the following error by default:

```
*** Problem in Model Generation: Variable "x" appears with suffix "Up".
*** Error at line 12: Cannot use domain limited variables with suffix in model - use $onSuffixDLVars
```

The purpose is to make the user aware of the fact, the she uses `x.l`, which would also be affected by the domain restriction of `x(sub)` in the model statement. So, if the user made sure, that this is all intended, setting `$onSuffixDLVars` before the solve statements overcomes this error. Though, with the example given here, this would actually lead to a "division by zero" error, since some `x.up` were excluded leaving a 0 as divisor.

See also related command line parameter [SuffixDLVars](#).

`$[on][off]SymList` (`$offSymList`)

Syntax:

```
$onSymList
$offSymList
```

This option controls whether the symbol listing map appears in the compilation output of the listing file. The symbol listing map contains the complete listing of all symbols that have been defined and their explanatory text. The entries are in alphabetical order and grouped by symbol type.

Example:

The symbol listing map generated by running `[TRANSPORT]` with `$onSymList` is as follows:

Symbol Listing

SETS

```
i          canning plants
j          markets
```

PARAMETERS

a	capacity of plant i in cases
b	demand at market j in cases
c	transport cost in thousands of dollars per case
d	distance in thousands of miles
f	freight in dollars per case per thousand miles

VARIABLES

x	shipment quantities in cases
z	total transportation costs in thousands of dollars

EQUATIONS

cost	define objective function
demand	satisfy demand at market j
supply	observe supply limit at plant i

MODELS

transport

This serves as a simple description of the symbols used in a model and may be used in reports and other documentation. For further information, see section [The Symbol Listing Map](#).

`$(on)[off]SymXRef ($offSymXRef)`

Syntax:

`$onSymXRef`
`$offSymXRef`

This option controls the following:

- Collection of cross references for symbols like sets, parameters, variables, acronyms, equations, models and put files.
- Symbol cross reference report of all collected symbols in the compilation output of the listing file. For details, see section [The Symbol Reference Map](#).
- Listing of all referenced symbols and their explanatory text by symbol type in listing file. This listing may also be activated with the option [\\$onSymList](#).

Example:

```
$onSymXRef
Set i / 1*6 /, k;
$offSymXRef
Set j(i) "will not show" / 1*3 /;
$onSymXRef
k('1') = yes;
```

The resulting listing file will contain the following symbol reference map and symbol listing map:

SYMBOL	TYPE	REFERENCES			
i	SET	declared	2	defined	2
k	SET	declared	2	assigned	6

SETS

i
k

Note that the set j does not appear in these listings because the listing was deactivated with the option `$offSymXRef` in line 3 of the code above.

`$(on)[off]Text`**Syntax:**

```
$onText
$offText
```

The pair `$onText` - `$offText` encloses comment lines. Line numbers in the compiler listing are suppressed to mark skipped lines.

Example:

```
* Standard comment line
$onText
Everything here is a comment
until we encounter the closing $offText
like the one below
$offText
* Another standard comment line
```

The echo print of the resulting listing file will contain the following lines:

```
1 * Standard comment line
   Everything here is a comment
   until we encounter the closing $offText
   like the one below
7 * Another standard comment line
```

Attention

GAMS requires that every `$onText` has a matching `$offText` and vice versa.

See also section [Comments](#).

`$(on)[off]UEIList ($offUEIList)`**Syntax:**

```
$onUEIList
$offUEIList
```

This option controls the complete listing of all set elements that have been entered in the compilation output of the listing file. For details see section [The Unique Element Listing Map](#).

Example:

The unique element listing in the listing file generated by running the model `[TRANSPORT]` with `$onUEList` follows:

Unique Element Listing

Unique Elements in Entry Order

```
1 seattle      san-diego    new-york     chicago     topeka
```

Unique Elements in Sorted Order

```
1 chicago     new-york     san-diego    seattle     topeka
```

Note that the sorted order is not the same as the entry order. For more information, see section [Ordered and Unordered Sets](#).

`$(on)[off]UEIXRef ($offUEIXRef)`

Syntax:

```
$onUEIXRef
$offUEIXRef
```

This option controls the collection and listing of cross references of set elements in the compilation output. For more information, see section [The Unique Element Listing Map](#).

Example:

```
Set i "set declaration" / one, two, three /, k(i);
$onUEIXRef
k('one') = yes;
$offUEIXRef
k('two') = yes;
$onUEIXRef
k('three') = yes;
```

The resulting listing file will contain the following unique element reference report:

Unique Element Listing

ELEMENT	REFERENCES	
one	index	3
three	index	7

Note that the element `two` does not appear in this listing because the listing was deactivated with the option `$offUEIXRef` in line 4 of the code above.

`$(on)[off]UNDF ($offUNDF)`

Syntax:

```
$onUNDF
$offUNDF
```

This option controls the use of the special value `UNDF` which indicates a result is undefined. For details see section [Extended Range Arithmetic](#). By default, `UNDF` is not permitted to be used in assignments. This may be changed with the option `$onUNDF`.

Example:

```
Scalar x;
$onUNDF
x = UNDF;
Display x;
```

The output of the display statement follows:

```
-----      4 PARAMETER x                =                UNDF
```

Note that an error would have been triggered without the use of `$onUNDF`. The option `$offUNDF` will return the system to the default, where `UNDF` may not be used in assignments.

\$(on)[off]Uni (\$offUni)**Syntax:**

```
$onUni
$offUni
```

This controls whether the compiler checks the referential integrity (see section [Domain Checking](#)) of the code. This is an essential part of good GAMS programming and it is highly recommend to declare symbols with proper domains. With the universe as a domain the compiler does not help the user with easy-to-make mistakes, like swapping indexes, `a(i,j)` versus `a(j,i)`. By default something like this would generate an error, if `a` was declared as `a(i,j)`. Such an error could be ignored, by setting `$onUni`, which can be useful in few situations, when accessing a symbol with a set that is not the domain or a subset of the domain. For example, we could read data of a union of sets that already exist. We could use the universe as the domain for that symbol, but perhaps we need to protect the referential integrity of this symbol too.

Example:

```
Set      fruit   / apple, pear /
         veggie  / carrot, pea /
         produce / #fruit, #veggie /;
Parameter produceCalories(produce) "per 100g" / apple 52, pear 57, carrot 41, pea 81 /
         fc(fruit) "calories per 100g"
         vc(veggie) "calories per 100g";

$onUni
fc(fruit) = produceCalories(fruit);
vc(veggie) = produceCalories(veggie);
$offUni
display fc, vc;
```

So when assigning `fc` we only access `produceCalories` with `fruit`. We could reverse the order of declaration of `fruit`, `veggie` and `produce` and use a proper subdomain, but sometimes data flow and input don't allow that.

Attention

When the GAMS compiler operates under \$onUni it treats all symbols as being declared over the universe. So all domain checking is gone. We can set elements in a symbols that normally can't be entered. This can also lead to strange effects:

```

set          i / 1*2 /
            j / a,b /;
parameter pi(i);
$onuni
pi(j) = 1;
$offuni
* We will see elements from j in pi
Display pi;
* The following should only clear the i-elements from pi, but it clears the
* entire symbol, because GAMS knows it's doing this to the entire domain and
* takes a shortcut.
pi(i) = no;
Display pi;

```

[\$on][off]Verbatim**Syntax:**

```

$onVerbatim
$offVerbatim

```

These options are used in conjunction with the GAMS command line parameter [DumpOpt](#) to suppress the input preprocessing for input lines that are copied to the dmp file. This feature is mainly used to maintain different versions of related models in a central environment.

Note

- The options \$on/offVerbatim are only recognized for DumpOpt ≥ 10 and apply only to lines in the file between the two options
- If \$onVerbatim is active, DumpOpt = 11 behaves like DumpOpt = 21 (comments are kept)

Observe that the use of the options [\\$goto](#) and \$on/offVerbatim are incompatible and may produce unexpected results.

Example:

```

$set f 123
$log %f%
$onVerbatim
$log %f%
$offVerbatim
$log %f%

```

The corresponding dmp file will contain the following lines:

```

$log 123
$onVerbatim
$log %f%
$offVerbatim
$log 123

```

See also command line parameter [DumpOpt](#).

\$(on)[off]Warning (\$offWarning)**Syntax:**

```

$onWarning
$offWarning

```

This option acts as a switch for data domain checking. In some cases it may be useful to accept domain errors in data statements that are imported from other systems and report warnings instead of errors. Data will be accepted and stored, even though it is outside the domain.

Attention

- This switch effects three types of domain errors usually referred to as error numbers 116, 170 and 171, see example below.
- This may have serious side effects and we recommend to exercise great care when using this feature.

Example:

```

Set i      / one, two, three /
$onWarning
  j(i) / four, five /
  k      / zero /;
Parameter x(i) "Messed up Data" / one 1.0, five 2.0 /;
x('six') = 6;
x(j) = 10;
x('two') = x('seven');
j(k) = yes;
$offWarning
display i,j,x;

```

Note that the set j, although specified as a subset of i, contains elements not belonging to its domain. Similarly, the parameter x contains data elements outside the domain of i. The skeleton listing file that results from running this code follows:

```

1 Set i      / one, two, three /;
3      j(i) / four, five /
****          $170 $170
4      k      / zero /;
5 Parameter x(i) "Messed up Data" / one 1.0, five 2.0 /;
****          $170
6 x('six') = 6; x(j) = 10; x('two') = x('seven');
****          $170          $116,170
7 j(k) = yes;
****          $171
9 display i,j,x;

```

Error Messages

```

116 Label is unknown
170 Domain violation for element
171 Domain violation for set

```

```
**** 0 ERROR(S)    7 WARNING(S)
```

```
E x e c u t i o n
```

```

----      9 SET i
one ,    two ,    three

----      9 SET j
four,    five,    zero

----      9 PARAMETER x Messed up Data
one 1.000,    four 10.000,    five 10.000,    six 6.000

```

Observe that the domain violations are marked like normal compilation errors but are only treated as warnings and it is permitted to execute the code.

For an introduction to domain checking in GAMS, see section [Domain Checking](#).

\$phantom id

Syntax:

```
$phantom id
```

This option is used to designate *id* as a *phantom* set element. Syntactically, a phantom element is handled like any other set element. Semantically, however, it is handled like it does not exist. This is sometimes used to specify a data template that initializes the phantom records to default values.

Example:

```

$phantom null
Set i / null /
     j / a, b, null /;
display i,j;

```

The output generated by the display statement is shown below:

```

----      4 SET i
                                                    ( EMPTY )

----      4 SET j
a,      b

```

Note that `null` does not appear in the listing file.

Attention

Statements that assign values to phantom labels are ignored.

Consider the following extension to the previous example:

```

Parameter p(j) / a 1, null 23 /;
display p;

```

The output generated by the display statement is shown below:

```

----      6 PARAMETER p
a 1.000

```

The system attribute `system.empty` is an implicitly defined phantom element. The following code works even without specifying `$phantom`:

```
Set i / system.empty /
    j / a, b, system.empty /;
display i,j;
```

Another way to specify empty data statements makes use of `on/offEmpty`. The following example produces the same data as the data statement with the phantom label. In contrast to the example we `$phantom` we need to provide the dimensionality of the symbol `i` explicitly via the `(*)`:

```
$onEmpty
Set i(*) / /
    j / a, b /;
display i,j;
```

`$prefixPath`

Syntax:

```
$prefixPath directoryPath
```

This option augments the search path in `PATH` environment variable. The effect is that the text `directoryPath` is added to the beginning of the search path.

Example:

```
$log %sysenv.PATH%
$prefixPath C:\somewhereelse\anotherpath
$log %sysenv.PATH%
```

The log contains the following two relevant lines:

```
C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\System32\WindowsPowerShell\v1.0\
C:\somewhereelse\anotherpath;C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\
```

The option `setEnv` and `sysEnv.VARNAME%` allow to modify system environment variables but the length of the environment variable value is limited in GAMS to 255 characters. The `PATH` environment variable is often much longer and therefore this special `$prefixPath` option exists.

This works on all platforms but the path separator depends on the operating system (`;` for Windows and `:` for Unix).

`$protect`

Syntax:

```
$protect all | ident1 ident2 ...
```

This option creates a privacy setting: it freezes all values of identifiers with the result that modifications are no longer allowed but the parameters may still be used in model calculation (for example, equation definitions). Here `ident1` and `ident2` are specific [GAMS identifiers](#) previously defined in the program and the keyword `all` denotes all identifiers.

Note that this option is mainly used in the context of [secure work files](#). The privacy restrictions may be removed with the options `$expose` or `$purge`.

\$purge**Syntax:**

```
$purge all | ident1 ident2 ...
```

This option removes the identifiers and all associated data in a privacy setting. With explicit identifiers the listed [identifiers](#) are removed, and with **all** all identifiers are removed.

Note that this option is used in the context of [secure work files](#). A special license file is needed for this feature to work, the removal only takes effect in the restart files.

\$remark**Syntax:**

```
$remark text
```

This option performs a parameter substitution and writes a comment **text** to the compilation output of the listing file. Note that the line numbers of the comment are suppressed.

Example:

```
$set it TEST
$remark Write %it% to the listing file
```

The resulting listing file will contain the following line:

```
Write TEST to the listing file
```

\$scratchFileName**Syntax:**

```
$scratchFileName VARNAME [fileStem]
```

This option establishes or redefines the content of a *scoped* compile-time variable that is accessible in the code where the command appears and all code included therein. Here **VARNAME** is any user chosen variable name; **fileStem** is optional and used to built the name for a file in the [scratch directory](#) with a [scratch extension](#) (unless an extension is set explicitly). If it is omitted, the system will make up a random file name.

So,

```
$scratchFileName fn abc
```

is equivalent to

```
$set fn %gams.scrDir%abc.%gams.scrExt%
```

Example:

```
* Set fileStem explicitly
$scratchFileName fn1 abc
$log %fn1%
```

```
* Omit fileStem
$scratchFileName fn2
$log %fn2%
```

The log will show:

```
C:\Data\t m p\225a\abc.dat
C:\Data\t m p\225a\__sFN__-0_313342928588555.dat
```

See also [\\$set](#) and section [Compile-Time Variables](#).

\$set

Syntax:

```
$set VARNAME text
```

This option establishes or redefines contents of a *scoped* compile-time variable that is accessible in the code where the command appears and all code included therein. Here `VARNAME` is any user chosen variable name; `text` is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that *scoped* compile-time variables may be destroyed (removed from the program) with the option [\\$drop](#).

Note that in contrast to the option [\\$eval](#) the option `$set` does not evaluate the expression at compile time.

Note that GAMS allows *scoped*, *local* and *global* compile-time variables to be defined with the same name and therefore in some cases needs to prioritize. When referencing a compile-time variable via `VARNAME%` a *local* variable hides *scoped* and *global* variables and a *scoped* variable hides the *global* variable as the following example demonstrates.

Example:

```
$setLocal myvar this is a local variable
$set myvar this is a scoped variable
$setGlobal myvar this is a global variable
$log %myvar%
$dropLocal myvar
$log %myvar%
$drop myvar
$log %myvar%
```

The log will look as follows:

```
this is a local variable
this is a scoped variable
this is a global variable
```

If one wants to set a compile-time variable in an include file that is visible to the program after the `$include` one need to use `$setglobal`:

```
$onEchoV > setvar.gms
$setArgs varname varvalue
$setglobal %varname% %varvalue%
$offEcho
$batInclude setvar MYVAR one
$log %MYVAR%
```

The log will show

```
one
```

An inventory of all defined compile-time variables and their type (local, scoped, and global) is available with the option `$show`.

See also `$setGlobal`, `$setLocal`, and section [Compile-Time Variables](#).

`$setArgs`

Syntax:

```
$setArgs id1 id2 id3 ...
```

With this option parameters that may be substituted are defined as GAMS compile-time variables. Note that `$setArgs` may only be used in external files that are included with the option `$batInclude`, `$libInclude`, and `$sysInclude`.

Example:

```
Scalar a /2/, b /4/, c /5/;
$batInclude test3 a b c
```

The file `test3.gms` contains the following lines:

```
Scalar x;
x = %1 + %2 * %3 ;
display x;
$setArgs aa bb cc
x = %aa% - %bb% * %cc% ;
display x;
x = %1 + %2 * %3 ;
display x;
```

The option `$setArgs` allows the `batInclude` file to use the more descriptive compile-time variables `aa%` instead of `%1`, `bb%` instead of `%2` and `cc%` instead of `%3`. Note that the use of `%1`, `%2` etc. is still allowed. The program listing looks as follows:

```
1  Scalar a /2/, b /4/, c /5/;
BATINCLUDE C:\Users\default\Documents\gamside\projdir\test3.gms
3  Scalar x;
4  x = a + b * c ;
5  display x;
7  x = a - b * c ;
8  display x;
9  x = a + b * c ;
10 display x;
```

and the output generated by the display statements follows:

```
----      5 PARAMETER x          =      22.000
----      8 PARAMETER x          =     -18.000
----     10 PARAMETER x          =      22.000
```

See also `$set`, `$batInclude`.

`$setComps`

Syntax:

```
$setComps perioddelimstring id1 id2 id3 ...
```

This option establishes or redefines compile-time variables so they contain the components of a period delimited string.

Here `perioddelimstring` is any period delimited string like the set specification of a multi-dimensional parameter, `id1` is the name of a scoped compile-time variable that will contain the name of the set element in the first position, `id2` is the name of a scoped compile-time variable that will contain the name of the set element in the second position and `id3` is the name of a scoped compile-time variable that will contain the name of the set element in the third position. The items may be recombined back into the original filename string by using `%id1%.%id2%.%id3%`.

Example:

```
$setComps period.delim.string id1 id2 id3
$log id1=%id1%
$log id2=%id2%
$log id3=%id3%
$set name %id1%.%id2%.%id3%
$log name=%name%
```

The resulting log file will contain the following lines:

```
id1=period
id2=delim
id3=string
name=period.delim.string"
```

See also [\\$set](#).

`$setDDLlist[.Cont]`

Syntax:

```
$setDDLlist.Cont id1 id2 ...
$setDDLlist      id3 id4 id5 ...
```

This option causes GAMS to look for misspelled or undefined double dash GAMS parameters.

Example: Consider the following example where three double dash GAMS parameters are defined on the command line:

```
> gams mymodel.gms --one=11 --two=22 --three=33 --four=44
```

The corresponding GAMS file follows:

```
$log %one%
$log %two%
$setDDLlist three
$log %three%
$log %four%
```

Note that the option `$setDDLlist three` checks if all double dash parameters have been used so far except for `three`. An error is triggered because `four` has not been used so far, the log file will contain the following:

```
*** 1 double dash variables not referenced
    --four=44
```

`$setDDLlist.Cont` can be used to define a list of parameters to be checked over multiple lines. So, the following two examples do the same thing:

```
$setDDLlist one two three four

$setDDLlist.Cont one
$setDDLlist.Cont two three
$setDDLlist      four
```

Note

`$setDDLlist.Cont` does not do anything without a `$setDDLlist` statement.

See also section [Double Dash Parameters](#).

`$setEnv`

Syntax:

```
$setEnv VARNAME value
```

This option defines an operating system environment variable. Here `VARNAME` is a user chosen environment variable name and `value` may contain text or a number. Note that system environment variables are destroyed (removed from the program) with the option `$dropEnv` or when GAMS terminates.

Example:

```
$ondollar
$set env this is very silly
$log %env%
$setenv verysilly %env%
$log %sysenv.verysilly%
$if not "%env%"=="%sysenv.verysilly%" $error "$setEnv did not work"

$dropenv verysilly
$if setenv verysilly $error should not be true
```

The following output is echoed to the log file:

```
--- Starting compilation
this is very silly
this is very silly
```

See also `$dropEnv` and section [Environment Variables in GAMS](#).

`$setGlobal`

Syntax:

```
$setGlobal VARNAME text
```

This option establishes or redefines contents of a *global* compile-time variable that is accessible in the code where the command appears and all code included therein and all parent files. Here `VARNAME` is any user chosen variable name; `text` is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that global compile-time variables may be destroyed (removed from the program) with the option `$dropGlobal`.

The difference between local, scoped, and global compile-time variable is explained with the option `$set`.

See also `$set`, `$setLocal`, `$dropGlobal` and section [Compile-Time Variables](#).

`$setLocal`

Syntax:

```
$setLocal VARNAME text
```

This option establishes or redefines contents of a *local* compile-time variable that is accessible only in the code module (source file) where it is defined. Here `VARNAME` is any user chosen variable name; `text` is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that local compile-time variables may be destroyed (removed from the program) with the option `$dropLocal`.

The difference between local, scoped, and global compile-time variable is explained with the option `$set`.

See also `$set`, `$setGlobal`, `$dropLocal` and section [Compile-Time Variables](#).

`$setNames`

Syntax:

```
$setNames file filepath filename fileextension
```

This option establishes or redefines three scoped compile-time variables so they contain the drive subdirectory, filename and extension of a file named with full path. Here `file` is any filename, `filepath` is the name of a scoped compile-time variable that will contain the name of the subdirectory where the file is located, `filename` is the name of a scoped compile-time variable that will contain the root name of the file and `fileextension` is the name of a scoped compile-time variable that will contain the extension of the file.

Example:

```
$setNames "%gams.input%" filepath filename fileextension
$set name %filepath%filename%fileextension%
$log %name%
```

The log will show

```
C:\Users\default\Documents\gamside\projdir\
Untitled_1
.gms
C:\Users\default\Documents\gamside\projdir\Untitled_1.gms
```

Note that `file` is separated into its three components placing `C:\Users\default\Documents\gamside\projdir\` into `filepath`, `Untitled_1` into `filename` and `.gms` into `fileextension`. The three items may be recombined back into the original filename by using `filepath%filename%fileextension%` as shown in the example.

If the file is missing a path, name, or extension the corresponding variable is defined but remains empty as demonstrated in the following example:

```
$onEchoV > showfileparts.gms
$setNames "%1" filepath filename fileextension
$log path=%filepath%
$log name=%filename%
$log ext=%fileextension%
$offEcho
$batInclude showfileparts "C:\tmp\"
$batInclude showfileparts "Untitled_1"
$batInclude showfileparts "Untitled_1.gms"
$batInclude showfileparts "Untitled_1.gms.txt"
```

The log shows:

```

--- Untitled_1.gms(7) 2 Mb
path=C:\tmp\
name=
ext=
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(8) 2 Mb
path=
name=Untitled_1
ext=
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(9) 2 Mb
path=
name=Untitled_1
ext=.gms
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(10) 2 Mb
path=
name=Untitled_1.gms
ext=.txt

```

Note that if a file contains multiple `.` the last one will be assigned to the `fileextension` as shown in the example with `Untitled_1.gms.txt`.

\$shift

Syntax:

```
$shift
```

This option is similar to the `command.com/cmd.exe shift` operator (see en.wikipedia.org/wiki/COMMAND.COM:_Bat). It shifts the order of all parameters passed once to the *left*. This effectively drops the lowest numbered parameter in the list.

Example:

```

Scalar a, b, c ; a = 1 ;
$batInclude inc.inc a b c
display a, b, c ;

```

The batch include file `inc.inc` follows:

```

%2 = %1 + 1 ;
$shift
%2 = %1 + 1 ;

```

The resulting listing file will contains the following echo print:

```

1 Scalar a, b, c ; a = 1 ;
BATINCLUDE C:\Users\default\Documents\gamsdir\projdir\inc.inc
3 b = a + 1 ;
5 c = b + 1 ;
6 display a, b, c ;

```

Note that in the first statement in the include file, `%1` is the first argument in the `$batInclude` call and in this case it is interpreted as `a`. `%2` is the second argument in the `$batInclude` call and is interpreted as `b`. This leads to the overall assignment being interpreted as `b=a+1`. The dollar control option `$shift` shifts the arguments to the left. As a result, `%1` is interpreted as `b`, and `%2` is interpreted as `c`. This leads to the second assignment being interpreted as `c=b+1`.

Therefore the outcome generated by the `display` statement in the input file is as follows:

```

-----      6 PARAMETER a          =          1.000
              PARAMETER b          =          2.000
              PARAMETER c          =          3.000

```

See also [\\$batInclude](#).

\$show

Syntax:

```
$show
```

This option causes current values of the compile-time variables plus a list of the [macros](#) and active input and include files to be shown in the compilation output, where "active" means, that `$show` was either directly in that file or that file is a parent that includes the file with `$show`.

Example:

```

$set it 1
$setLocal yy
$setGlobal gg what
$include myinclude
$macro addx(x) x+x
$show

```

The file `myinclude.gms` follows:

```

$set inincs
$setLocal inincsl
$setGlobal inincsg
$macro multx(x) x*x
$show

```

The resulting listing file will contain the following *environment reports* in the compilation output:

```

----- Begin of Active File List
Level Type          Line  Filename
-----
      1 INCLUDE          5  C:\Users\default\Documents\gamside\projdir\myinclude.gms
      0 INPUT           4  C:\Users\default\Documents\gamside\projdir\Untitled_1.gms
----- End of Active File List

----- Begin of Compile-time Variable List
Level SetVal          Type      Text
-----
      1 inincsl          LOCAL
      1 inincs          SCOPED
      0 yy              LOCAL
      0 it              SCOPED    1
      0 gg              GLOBAL    what
      0 inincsg          GLOBAL
----- End of Compile-time Variable List

----- Begin of Macro List
$macro multx(x) x*x
----- End of Macro List

```

and

```

---- Begin of Active File List
Level Type          Line  Filename
-----
      0 INPUT              6  C:\Users\default\Documents\gamside\projdir\Untitled_1.gms
---- End of Active File List

---- Begin of Compile-time Variable List
Level SetVal                Type      Text
-----
      0 yy                    LOCAL
      0 it                    SCOPED    1
      0 gg                    GLOBAL    what
      0 inincsg                GLOBAL
---- End of Compile-time Variable List

---- Begin of Macro List
$macro multx(x)  x*x
$macro addx(x)  x+x
---- End of Macro List

```

Note that only the macros and the item defined with the option `$setGlobal` in the included file carries over.

If one needs only parts of this report, the dollar control options `$showFiles`, `$showMacros` and `$showVariables` can be used.

See also section [Compile-Time Variables](#).

`$showFiles`

Syntax:

```
$showFiles
```

This option prints the active files to the lst file as described at [\\$show](#).

`$showMacros`

Syntax:

```
$showMacros
```

This option prints a list of [macros](#) to the lst file as described at [\\$show](#).

`$showVariables`

Syntax:

```
$showVariables
```

This option prints a list current values of the compile-time variables to the lst file as described at [\\$show](#).

`$single`

Syntax:

\$single

The lines following this option will be echoed single spaced in the compilation output. Note that this is the default. The option is only useful as a switch to deactivate the option [\\$double](#).

Example:

```
Set    i / 1*2 / ;
Scalar a / 1    / ;
$double
Set    j / 10*15 / ;
Scalar b / 2    / ;
$single
Set    k / 5*10 / ;
Scalar c / 3    / ;
```

The echo print in the resulting listing file will look as follows:

```
1 Set i / 1*2 / ;
2 Scalar a /1/ ;

4 Set j / 10*15 / ;

5 Scalar b /2/ ;
7 Set k / 5*10 / ;
8 Scalar c /3/ ;
```

Note that lines between the options [\\$double](#) and [\\$single](#) are listed double spaced, while the lines after the option [\\$single](#) revert back to being listed single spaced.

See also [\\$double](#).

\$splitOption**Syntax:**

```
$splitOption KEYVALPAIR optname optvalue
```

Establishes or redefines two scoped compile-time variables so they contain the name and value of an option key/value pair specified in various formats. **KEYVALPAIR** is a string formatted as `-opt=val` or `-opt val` (instead of `-` one can also use `/`). **optname** is the name of a scoped compile-time variable that will contain the name of the option and **optvalue** is the name of a scoped compile-time variable that will contain the value of the option. This is useful in particular in combination with [batInclude](#) files.

Example:

```
$onechoV > myinclude.gms
* Default values for named arguments
$setGlobal a1 1
$setGlobal a2 2
$setGlobal a3 nothing
$setGlobal positionalArgs
$label ProcessNamedArguments
$ splitOption "%1" key val
$ if x%key%==x $goto FinishProcessNamedArguments
$ ifThenI.NamedArguments %key%==a1
$   setGlobal a1 %val%
$   elseifI.NamedArguments %key%==a2
```

```

$   setGlobal a2 %val%
$   elseifI.NamedArguments %key%==a3
$   setGlobal a3 %val%
$   else.NamedArguments
$   error Unkown named argument "%key%"
$   endif.NamedArguments
$   shift
$goto ProcessNamedArguments
$label FinishProcessNamedArguments
$setGlobal positionalArgs %1 %2 %3
$offEcho
$batInclude myinclude "-a3=some things" -a2=3.14 i j k
$log Using named arguments a1:>%a1%< a2:>%a2%< a3:>%a3%< positionalArgs:>%positionalArgs%<

```

Now when calling this piece of code as a `batInclude` one can specify optionally some named arguments (in any order) right after the name of the `batInclude` file and before the positional arguments as demonstrated by the log output:

```
Using named arguments a1:>1< a2:>3.14< a3:>some things< positionalArgs:>i j k<
```

`stars (****)`

Syntax:

```
$stars char[char][char][char]
```

This option is used to redefine the `****` marker in the GAMS listing file. By default, important lines like those that denote errors and the solver and model status are prefixed with `****`. A new marker consists of one to four characters.

Example:

```
$stars ***
garbage
```

The resulting listing file follows:

```

      2 garbage
****          $140
**** $36,299 UNEXPECTED END OF FILE (1)

```

Error Messages

```

36 '=' or '..' or ':=' or '$=' operator expected
    rest of statement ignored
140 Unknown symbol
299 Unexpected end of file

```

\$sTitle

Syntax:

```
$sTitle text
```

This option sets the subtitle in the page header of the listing file to `text`. Note that the next output line will appear on a new page in the listing file.

Example:

```
$sTitle Data tables for input/output
```

See also [\\$title](#).

\$stop

Syntax:

```
$stop [text]
```

This option stops program compilation without creating an error. Note there is a difference to the option [\\$exit](#). If there is only one input file, [\\$stop](#) and [\\$exit](#) will have the same effect. In an [include file](#) the option [\\$exit](#) acts like an end-of file on the include file. However, the option [\\$stop](#) in an include file will cause GAMS to stop reading all input but continue the execution phase of the so far compiled program. The text followed by [\\$stop](#) is ignored.

Example:

```
$ifthen not set EXPORTEXCEL
$ stop No export to Excel
$else
$ call gdxrw ...
$endif
```

See also [\\$abort](#), [\\$error](#), [\\$exit](#), and [\\$terminate](#).

\$sysInclude

The syntax of this dollar control option is equivalent to the syntax of [\\$batinclude](#):

Syntax:

```
$sysinclude external_file arg1 arg2 ...
```

However, if an incomplete path is given, the file name is completed using the system include directory. By default, the system include directory is set to the GAMS system directory. Note that the default directory may be reset with the command line parameter [sysIncDir](#).

Example:

The only relevant include file in the GAMS system directory is `mpsgeset` for MPSGE models, see for example [\[HARMGE\]](#):

```
$sysInclude mpsgeset KAMIYA
```

Note that this call will first look for the include file `[GAMS System Directory]/mpsgeset`. If this file does not exist, it will look for `[GAMS System Directory]/mpsgeset.gms`. The argument `KAMIYA` is passed on to the include file and are interpreted as explained for the dollar control option [\\$batInclude](#).

Consider the following example:

```
$sysInclude C:\Users\default\Documents\mpsgeset KAMIYA
```

This call will first look specifically for the include file `C:\Users\default\Documents\mpsgeset` and next for `C:\Users\default\Documents\mpsgeset.gms`.

See also [\\$batInclude](#).

\$terminate

Syntax:

```
$terminate [text]
```

This option terminates compilation and also does not execution to program compiled so far without giving an error.

Example:

```
$if set JUSTTERMINATE $terminate
```

See also [\\$abort](#), [\\$error](#), [\\$exit](#), and [\\$stop](#).

\$title**Syntax:**

```
$title text
```
