- **Create a solver option file:** via either the Studio menu or the project context menu in project explorer.
 - From the Studio menu, choose **File > New...** then enter a valid solver option file name and suffix into the file dialog. choosing **Add new file** by right clicking on project name in project explorer brings up the same file dialog for entering a valid solver option file name and suffix (See how to set different suffix values for solver option file from [optFile](#) parameter).
 - From the project context menu, right clicking on project name in project explorer and choosing **Add new solver option file** brings up a list of solver names. Selecting a solver name from the list brings up a file dialog with the selected solver name as file name and the default option file suffix name **opt** (See how to set different suffix values for solver option file from [optFile](#) parameter).
- **Open an existing solver option file:** via either the Studio menu or project context menu in project explorer.
 - From the Studio menu, choose **File > Open...** and select **Option Files** or **All Files** in the file dialog and then select a solver option file.
 - From the project context menu, right click on project name then choose **Add Existing file** then choose **Option Files** or **All Files** in the open file dialog and then select a solver option file.
 - In case a solver option file is already opened with solver option editor, the file can be reopened in text editor by choosing **Reopen File As Text** from the file context menu in project explorer.
 - It is possible to open the solver option file in either solver option editor or text editor.
 - * In case a solver option file has already been opened in solver option editor, choosing **Reopen File As Text** from the file context menu in project explorer closes the solver option editor and reopens the file in the text editor. Note that **Open As Text** button in the left pane editor performs the same function.
 - * In case a solver option file is already opened in text editor, choosing **Reopen File using Solver Option Editor** from the file context menu in project explorer closes the text editor and reopens the file in the solver option editor.
 - * In case a file is already listed under the project entry but not yet opened, choosing **Open File** from the project context menu opens the file in the solver option editor; however, choosing **Open File As Text** from the project context menu opens the file in the text editor.
- **Save a solver option file:** activated by choosing either **File > Save** menu or **Ctrl - S** shortcut. Choosing **File > Save As** menu or **Ctrl - S** shortcut brings up a file dialog to choose a file with different name to be saved as (See also how to set different suffix values for solver option file from [optFile](#) parameter).

6.13.2.6.2 Navigating the contents When a component of the solver option editor in focus, it is possible to perform further actions (see section [Summary of Actions and Shortcuts](#) for the list of actions and shortcuts). Clicking the component area will bring the component into focus or in selection. In addition to using mouse to navigate the solver option editor components, it is also possible using keyboard. Press **Tab** key navigates the components of the solver option editor. For example, when left pane editor is in focus, pressing **Tab** navigates from the left pane editor, to the right pane option group box, to the right pane Search box, and to the right pane definition browser in the describing order. When the left

pane editor is in focus, press **Up**, **Down**, **Left**, and **Right** keys to navigate the left pane editor table. When the right pane browser is in focus, press **Up** and **Down** to navigate the definition entries, press **Right** to expand/show the enumerated entries of the definition, and press **Left** to collapse/hide the enumerated entries of the definition.

There is a connection between an option entry in the left pane editor and a definition entry in the right pane browser. When navigating the solver option editor, it is possible to identify this connection from both the left pane editor and the right pane browser.

- From the left pane editor, right click on the selected entry and choose **show option definition** from the context menu. The entry in the right pane browser that contains the definition of the selected entry is highlighted and selected. When a cell or a row is already selected the shortcut **Ctrl + F1** delivers the same behavior.

- From the right pane browser, click or select on an entry. All entries in the left pane editor will be highlighted and selected if the definition has already been added. Otherwise there will be no selection in the left pane editor.

More editing actions can be performed on both the left pane editor and the right pane browser (See [Editing the Contents](#) for details).

6.13.2.6.3 Editing the Contents The followings describe actions that can be performed when editing the contents:

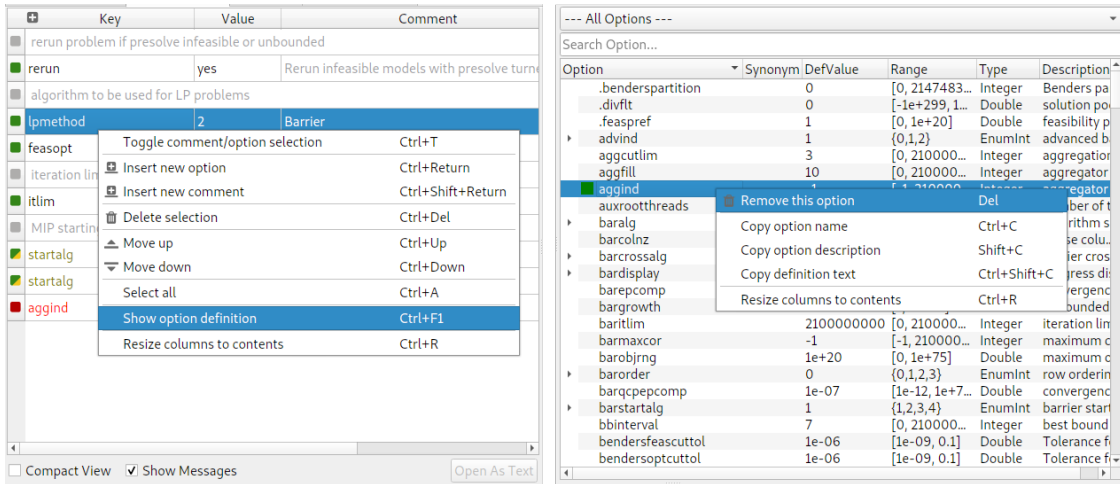

Figure 6.17 actions to be performed via the left pane editor and the right pane editor

- **Edit option key, value, and comment:** This action performs in the left pane editor.
 - when the cell in the left pane editor is selected, double click on the cell or press platform-dependent edit key (eg. F2) in order to edit option key, value, or comment (if available). A drop-down list suggests possible option keys and option values as when possible. Press **Enter** to confirm the edit and press **Esc** to cancel the edit.

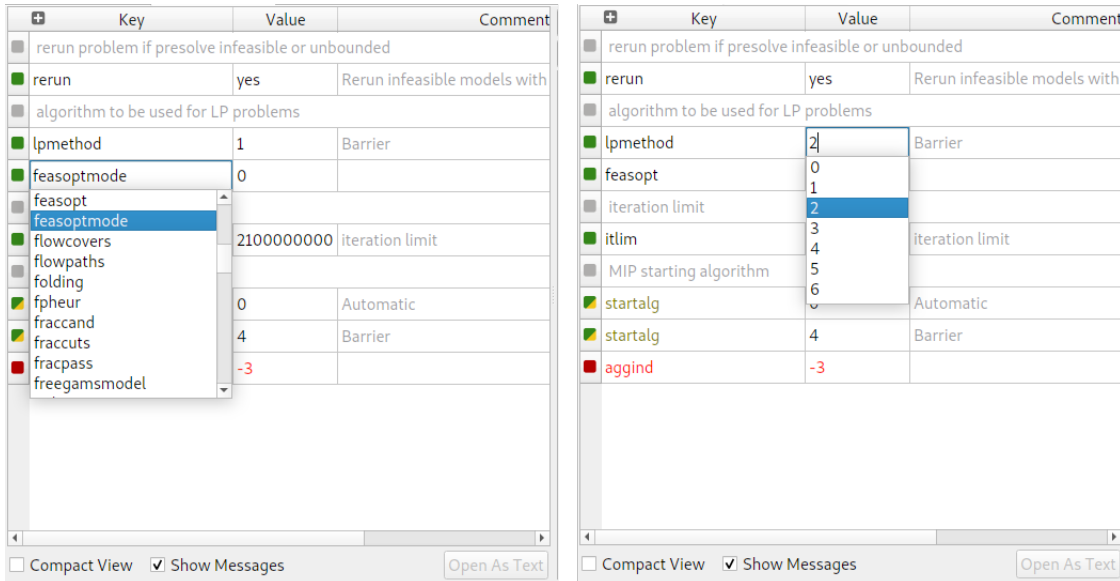

Figure 6.18 Drop-down lists suggest possible keys (left) and values (right)

- **Add new option:** This action appends a new option entry as the last entry of the left pane editor. There are several ways to add a new option entry.
 - click on the plus icon in the header of the left pane editor, a new option entry with dummy option key [KEY], option value [VALUE], and option comment [comment] (if available) is appended as the last entry.
 - it is also possible to add new option from the the right pane browser. Select the definition entry in the right pane browser that has not been added/inserted into the left pane editor (a solid checkbox in front of the entry is not marked), double click or right click on the selection

then choose **add this option**. A new option entry with the option key and default value of this definition will be added as the last entry in the left pane editor. and dummy option value [VALUE] is appended as the last entry.

- **Insert new option and comment:** It is possible to perform this action from the left pane editor and from the the right pane browser and there are several ways to insert a new option or a comment entry.
 - right click on the selected entry in the left pane editor and choose **insert new option** from the context menu. A new option entry with dummy option key [KEY], option value [VALUE], and option comment [comment] (if available) will be inserted before the selected entry. When a cell or a row is already selected the shortcut **Ctrl - Return** delivers the same behavior.
 - right click on the selected entry in left pane editor and choose **insert new comment** from the context menu. A new option entry with dummy text [COMMENT] will be inserted before the selected entry. When a cell or a row is already selected the shortcut **Ctrl - Shift - Return** delivers the same behavior.
 - double click on a definition entry in right pane browser.
 - * In case this definition has not yet been added/inserted (a checkbox in front of the entry is not marked), a new option entry with the option key, default value, and comment (if available) of this definition will be added as the last entry in the left pane editor. When there is a selection on a cell or a row the shortcut **Return** delivers the same behavior.
 - * In case this definition has already been added/inserted (a checkbox in front of the entry is marked), by default the studio option editor will ask for overriding existing option if there is an option from the same definition that has already been added/inserted into the left pane editor. A pop-up message box appears and offers three alternatives: either to **replace existing entry**, or to **add new entry**, or to **abort**. **Replace existing entry** will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition. **Add new entry** will add a new option entry with the option key and default value of this definition into the left pane editor. **Abort** will cancel the action. See section [override existing option](#) on how to suppress this default behavior.

When double clicking an enumerated value entry of the definition a new option entry will be added with the option key of the parent entry and the selected enumerated value.

- drag a definition entry from the right pane browser and drop in the left pane editor.
 - * In case this definition has not yet been added/inserted (a checkbox in front of the entry is not marked), a new option entry with the option key, default value, and comment (if available) of this definition will be dropped before the position of selected entry in the left pane editor.
 - * In case this definition has already been added/inserted (a checkbox in front of the entry is marked), by default the studio option editor will ask for overriding existing option if there is an option from the same definition that has already been added/inserted into the left pane editor. A pop-up message box appears and offers three alternatives: either to **replace existing entry**, or to **add new entry**, or to **abort**. **Replace existing entry** will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition. **Add new entry** will insert a new option entry with the option key and value of this definition before the position of selected entry in the left pane editor. **Abort** will cancel the action. See section [override existing option](#) on how to suppress this default behavior.

See also section [Settings](#) on how to insert a new option together with a comment from the definition.

- **Toggle comment/option:** This action performs in the left pane editor, turning an option entry into a comment entry and turning a comment entry into an option entry.
 - select the option entry and right click on the selection, then choose **toggle comment/option selection** from the context menu. In case of an option entry this action turns the entry into a comment entry (shown in grey color). In case of a comment entry this action turns the entry into an option entry (shown in either green or red color depending on whether or not

there is an error). When a cell or a row is already selected the shortcut **Ctrl - *** delivers the same behavior. Clicking on the color box in front of the entry row also delivers the same behavior, even without a selection.

- **Move up and down:** These two actions perform in the left pane editor, changing the order of the option and comment entries.
 - to move an entry up in the left pane editor: select the option entry and right click on the selection, then choose **move up** from the context menu. The selected option entry will be moved one position up the option entry table. When a cell or a row is already selected the shortcut **Ctrl - Up** delivers the same behavior.
 - to move an entry up in the left pane editor: select the option entry and right click on the selection, then choose **move down** from the context menu. The selected option entry will be moved one position down the option entry table. When a cell or a row is already selected the shortcut **Ctrl - Down** delivers the same behavior.
- **Deleted option:** It is possible to perform this action from the left pane editor and from the the right pane browser.
 - from the left pane editor, select the option entry and right click on the selected, then choose **delete selection**. The selected option entry will be deleted from the option entry table. When there is a selection on a cell or a row the shortcut **Ctrl - Delete** delivers the same behavior.
 - from the right pane browser, select the definition entry that has already been add/inserted into the left pane editor (a checkbox in front of the entry is marked) and right click on the selection then choose **remove this option**. All entries in the left pane editor defined by this definition will be deleted from the option entry table. When there is already a selection on a definition row the shortcut **Delete** delivers the same behavior.
- **Show option definition:** This action performs in the left pane editor. Right click on the left pane of the option editor and choose **Show option definition**. The option definition entry on the right pane will be highlighted. The shortcut **Ctrl - F1** delivers the same behavior.
- **Show all options of the same definition:** This action performs in the left pane editor. Right click on the left pane of the extended editor and choose **Show all options of the same definition**. All option entries on the left pane will be highlighted. The shortcut **Shift - F1** delivers the same behavior.

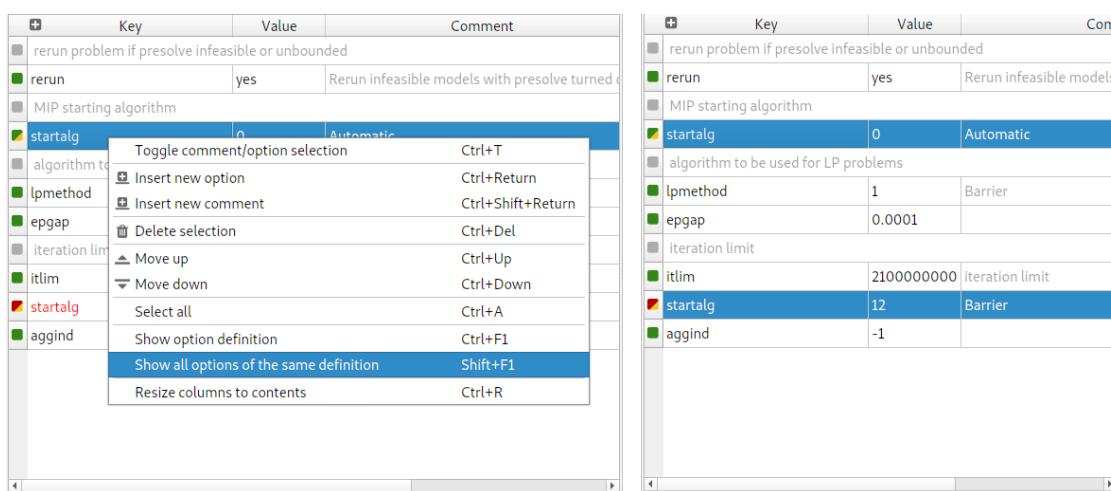

Figure 6.19 All entries of the same option are highlighted

6.13.2.6.4 Compact View Compact View of the solver option editor allows to view and edit solver option without comments. Comments in a solver option file are not interpreted by either GAMS or the solver but used for documentation purpose. As the contents of the solver option file grows larger with several comment lines, it can be difficult to see which options eventually will be interpreted. To this end, the compact view becomes useful to hide all comments and show only non-comment lines. In the right pane editor, mark **Compact View** checkbox to activate the compact view and unmark the checkbox to deactivate the compact view. The comment entry is shown again once the compact view is deactivated.

Note that the result of some actions are not visible when in compact view. For example, action **toggle comment/option selection** when performed on an option row entry, turning the entry into a comment entry and therefore hidden from the compact view. Action **delete selection** when performed on an option row entry, removing the content entry and therefore no longer visible hidden from the compact view.

Some editing actions that can change the order of the contents are suppressed. These actions are **insert new option**, **insert new comment**, **move up**, and **move down**. Nevertheless adding or inserting option from the right pane are allowed, but a comment that has been inserted with the option (if set) are not visible in compact view. See also section [Settings](#) on how to insert a new option together with a comment from the definition.

6.13.2.6.5 Settings The setting tab allows to configure the behavior when inserting new option from definition and deleting option. The setting can be accessed by opening the Settings dialog (**File > Settings**) and switching to the **Misc.** tab. These configurations are:

- **Override existing option.** This behavior allows Studio to override existing option when an option entry has been added or inserted from the right pane browser. In case there are more than one entry of the same option, Studio will pop-up a message box to offer three alternatives: either to **replace existing entry**, or to **add new entry**, or to **abort**.
 - *Replace existing* entry will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition.
 - *Add new entry* will add or insert a new option entry with the option key and default value of this definition into the left pane editor.
 - *Abort* will cancel the action.

By default this behavior has been set. In the Settings dialog, unmark the checkbox in front of the text *overriding existing option* to suppress the behavior and mark to enable the behavior.

- **Add option description as comment above.** This behavior allows Studio to add option description as additional comment entry above an option entry that has been added or inserted from the right pane browser. The description has been taken from the option definition in the right pane browser. By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text *add option description as comment above* to enable the behavior and unmark the checkbox to suppress the behavior.
- **add option description as end of line comment** This behavior allows Studio to add option description as additional end-of-line comment of an option entry that has been added or inserted from the right pane browser. The end of line comment is only available when the solver defines valid end of line characters. The end-of-line comment column will be shown in the solver option editor only when available (there is definition of end-of-line comment characters for a solver option file). By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text *add option description as end of line comment* to enable this behavior and unmark the checkbox to suppress the behavior.
- **delete all immediate comments above** This behavior allows Studio to delete all immediate comments (if there is any) above when deleting an option. By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text *delete all immediate comments above* to enable this behavior and unmark the checkbox to suppress the behavior.

6.13.2.6.6 Summary of Actions and Shortcuts Actions and their shortcuts that can be performed via the left pane of solver option editor are:

Action	Shortcut	macOS	Description
Toggle option/comment selection	Ctrl - *	Command - *	Toggle between option and comment
Insert new option	Ctrl - Return	Command - Return	Insert a new option
Insert new comment	Ctrl - Shift - Return	Ctrl - Shift - Return	Insert a new comment
Delete selection	Ctrl - Delete		Delete the selected option/comment
Move up	Ctrl - Up	Command - Up	Move the selected option/comment up for 1 row
Move down	Ctrl - Down	Command - Down	Move the selected option/comment down for 1 row
Select all	Ctrl - A	Command - A	Select all options
Show option definition	Ctrl - F1	Command - F1	Show definition of this selected option in the right pane
Show all options of the same definition	Shift - F1		Show all options of the same definition defined in the right pane
Resize columns to contents	Ctrl - R	Command - R	Resize the columns in the left pane to contents

Actions and their shortcuts that can be performed via the right pane of solver option editor are:

Action	Shortcut	macOS	Description
Option Search	Ctrl - F	Command - F	Jump to the focus to the Option Search input field
Add this option	Return	Return	Add option in the left pane from the selected definition
Remove this option	Delete		Remove option defined by this definition from the left pane
Copy option name	Ctrl - C	Command - C	Copy option key from this selected definition
Copy option description	Shift - C	Shift - C	Copy option description from this selected definition
Copy definition text	Ctrl - Shift - C	Command - Shift - C	Copy option text from this selected definition
Resize columns to contents	Ctrl - R	Command - R	Resize the columns in the right pane to contents

6.13.2.7 GAMS Configuration Editor

The GAMS Configuration Editor is used to view and edit a [GAMS Configuration File in YAML Format](#). The editor shows the two configuration sections: command line parameters (`commandLineParameters`), and operating system environment variables (`environmentVariables`), in different tabs of the editor.

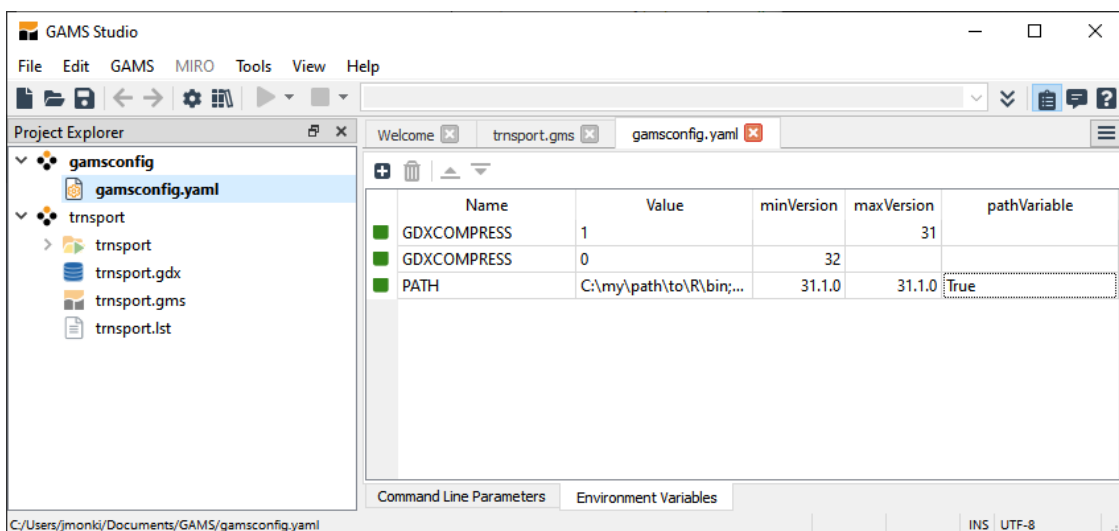

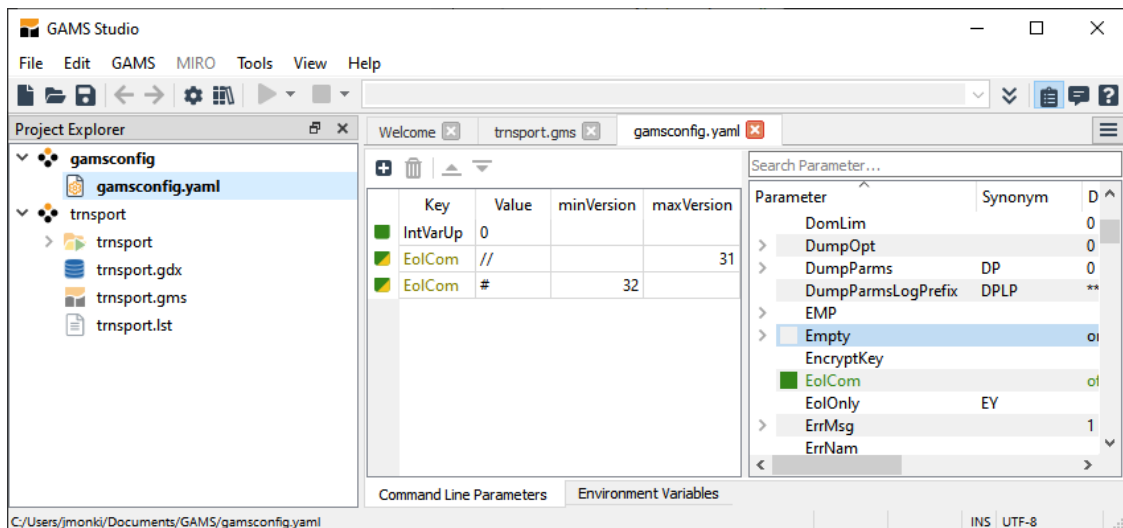

Figure 6.20 Contents of `gamsconfig.yaml` shown in GAMS Configuration Editor

Note that GAMS Configuration editor does not show the contents of the third section: external solver configuration (`solverConfig`) if exists. However, the contents in this section will be written out to the file when saving the file via the editor. It is possible to use **Reopen File as Text** from **Project Explorer** context menu to reopen and edit the file contents in text editor when the file is already opened in the GAMS Configuration Editor and use **Open File as Text** from **Project Explorer** context menu to open the file in text editor when the file is not yet opened in any editor. See the syntax of `gamsyconfig.yaml` file from [GAMS Configuration File in YAML Format](#).

GAMS will process a sequence of `gamsconfig.yaml` files from different locations (see the location of GAMS Configuration file from [The GAMS Configuration in YAML Format](#) and the order of precedence for command line parameters from [Order of Precedence for Options](#)). Studio can create a new `gamsconfig.yaml` file at the default user-specific location and open the file in the editor when the file at the location does not exist. This can be done by choosing **GAMS > Default GAMS Configuration**. In case the file already exists at the default location, choosing **GAMS > Default GAMS Configuration** will not override the `gamsconfig.yaml` in the default user-specific location but open the file in the editor.

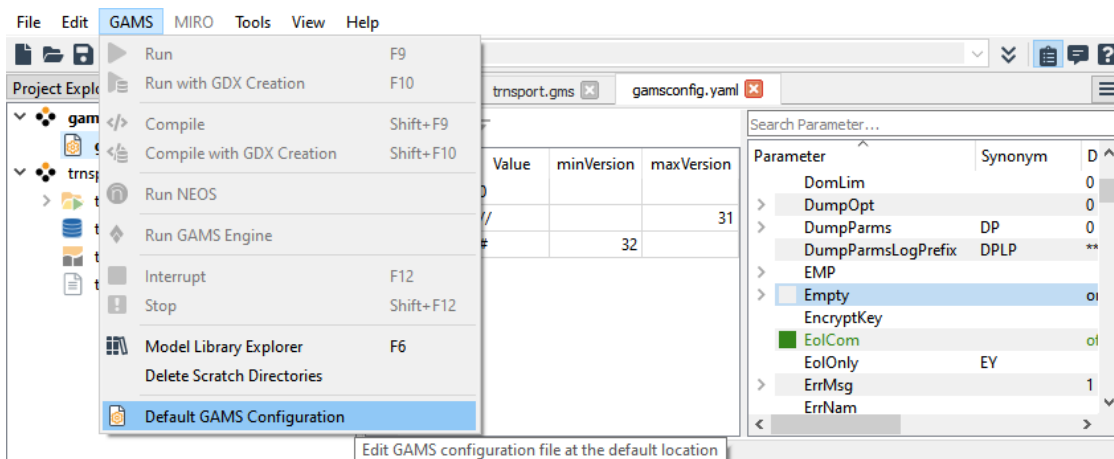

Figure 6.21 Menu entry point to create/open gamsconfig.yaml file from default location

It is possible to save the gamsconfig.yaml file into different location using File > Save As....

6.13.2.8 Tab Browser

The Tab Browser is accessible with a button next to the main tab bar or via the shortcut **Ctrl - 4**. It opens a list of all open files and features a search input field. When opening the tab browser, the search field is already focused. Typing updates the list in real time. The **Enter** key selects the first item in the list and opens it. It is also possible to use arrow up/down to navigate the list and select an item with **Enter**. The filter supports wildcard syntax.

6.13.2.9 Navigation History

The Navigation History records a navigation history event each time the cursor is moved in some kind of text file opened in the Studio central widget. This allows the user to quickly jump back (and forward again) to text passages that were recently edited. To reduce clutter some events are set to overwrite the previous event. This happens when the cursor is moved by only a single position in either direction, so that when a user jumps through text or types something only the latest position will be put into the history. The idea behind this is to make it easier and more convenient to jump to positions that actually matter. Using the navigation history is not limited to a single file. It is easy to jump between two or more files to go back and review recent changes. If a file was closed in the meantime it will be reopened when navigating through the history. This includes even files that were completely removed from Studio. When such a file is reopened through the Navigation History feature, due to technical limitations, the affiliation of the file to its previous project is lost. Please note that after navigating back in the history all "future" history events will be deleted and overwritten if the user creates new history events.

Action	Shortcut	macOS	Alternative Shortcut
Go Back	Alt - Left Arrow	Ctrl - [Mouse Button 4
Go Forward	Alt - Right Arrow	Ctrl -]	Mouse Button 5

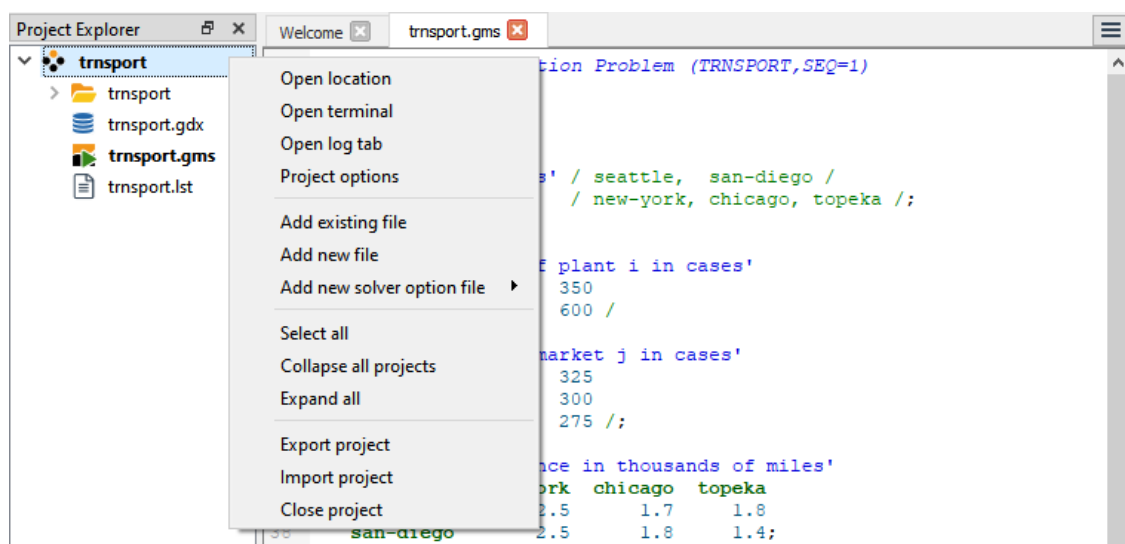

6.13.3 Further Studio Widgets

6.13.3.1 Project Explorer

The Project Explorer organizes the files opened in Studio into projects. Each project has its own base directory. All files associated to the project are organized in a hierarchical tree structure of folders relative to this base directory. A projects tooltip tells the location of the project in the file system. To support faster detection there are several icons for different file types:

- The runnable GAMS files (currently supported `.gms` and `.inc`) are listed with GAMS icon,
- the main GAMS file assigned to the project additionally contains a green play symbol,
- GDX files (`.gdx`) have an database icon,
- Reference files (`.ref`) are shown with a reference nodes on a sheet,
- editable files (e.g. `.txt`) contain a pen on a sheet,
- read-only files (e.g. `.log`) contain lines on a sheet.

The tooltip of a file or folder entry tells the location in the file system. The file location, the project location, and the folder location can be explored using the default file system explorer via the context menu "Open location". Selecting "Open terminal" opens the systems terminal in the location of the selected file, project, or folder. The context menu of a `.gdx` file provides a special entry "Open in GDX Diff" that opens the specific [GDX Diff Dialog](#).

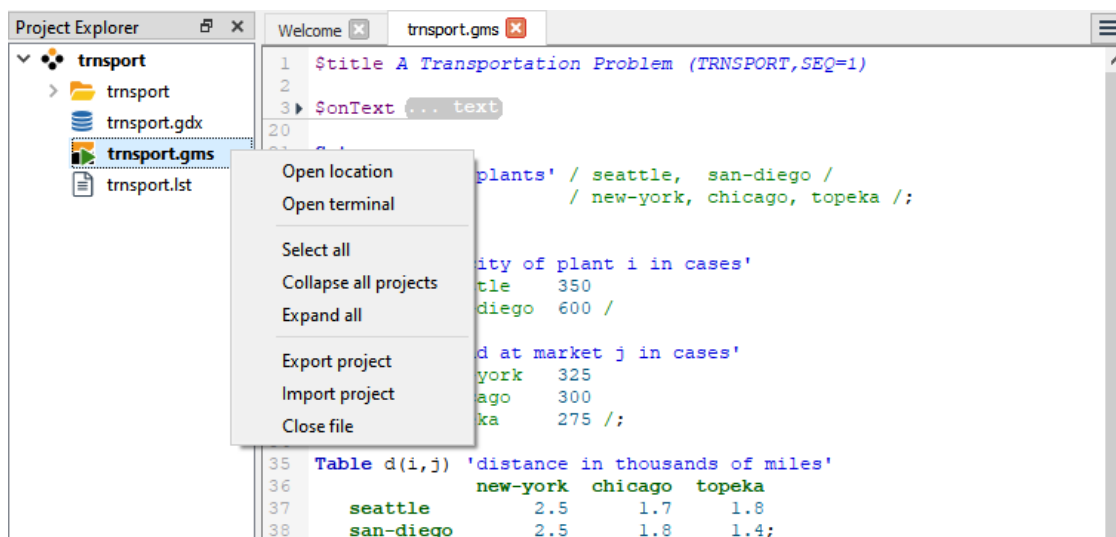

Figure 6.22 Project Explorer and its context menu

An empty project can be created by selecting **New Project** from the **File** menu or the context menu in the Project Explorer. A file dialog opens to select the project folder. The project gets the name of that folder. If a project with that name already exists, **Studio** looks for a number to append until the projects name is unique. Additionally a project is created automatically when opening a file. The projects name and location is determined by the name and location of the opened file. One project may contain multiple runnable GAMS files but only one runnable GAMS file is set as the main file, marked with a green arrow overlay. By default the first runnable GAMS file in a project is considered the main file. The tooltip of a project also tells the location of the folder and the name of the current main file. Additionally the name of the recently created output file (.lst) is shown after the first run. The main file can be changed to other runnable GAMS file in a project via the context menu "Set as main file". The project base directory remains unchanged if the runnable GAMS file is changed.

The main file of the active project will be executed when pressing F9 or clicking the execute button (see how to set GAMS parameters and execute the main file in [Quick Access Toolbar and GAMS Parameter Editor](#)). To better recognize the active project, the current file and its project are in bold text and the icons of other projects are slightly dimmed. After executing the main file, the generated listing file (.lst) is added to its project and the output view (see [Process Log](#)) is opened. A clickable log line in the process log may add the corresponding file into the project and open the file in the [Central Widgets](#) area. Users can manually add more files to a project by right-clicking and choosing either "Add existing file" or "Add new file" from the context menu. Additionally Drag and Drop from the systems file explorer is supported.

Files can also be removed from a project and projects can be removed from Project Explorer via the two actions "Close file" and "Close project" from the context menu. The action "Close project" closes the project and all files in the project if opened as well as removes all file entries and the project entry from the Project Explorer without actually touching the files on the file system. The action "Close files in this folder" closes all files in this folder and it's subfolders. The action "Close file" closes the file if opened and removes the file entry from the project. In case the closed file is the only entry in a folder, the folder is also closed accordingly. In contrast a project can be empty during the current session but an empty project isn't restored on **Studio** restart. In case there are unsaved changes a message popup will appear, asking the user how to proceed.

Next to each project there is a cog wheel button that opens the **Project options** page. It contains these actions:

- Name: defines the name of the project

- Working directory: defines the default directory where the main GAMS file associated to the project will be executed
- Base directory: defines the directory from where the folders to each file of the project are generated. Changing this will update the folder structure to all files of this project.
- Main GMS file: informs about the current main GMS file.

The changed Project Options can be applied by selecting **File > Save** or pressing **Ctrl - S**.

It is possible to select multiple items in the project explorer. A selection always contains items of one kind, files or projects never both depending on the first selected item. Folders in this case count as multiple file selection. The context menu then addresses all selected items.

A project can be 'exported' using the context menu to a 'GAMS Studio Project' with the suffix `.gsp`. The files assigned to the project are referenced relatively to the projects base directory. Therefore it is highly recommended to export the project to the base directory itself to keep its consistency. The relative paths allows to share the project along with its other files. When a project file is 'imported' into GAMS Studio, the base directory is set to the location of the project file. Starting from this directory Studio expects the other files of this project.

Selected files can be dragged to another project. By dropping them they are moved to the destination project. If a folder is empty after this action its representation is removed from the project. Pressing the **Ctrl** key creates a copy of the file-reference in that project (no file copy). If the project already contains a specific file it is just ignored.

Actions like rename, move, or delete from file system are currently not supported but will be added in the future.

Note

For long-time users of the classic [GAMS IDE](#) the section about the differences between [IDE projects and Studio projects](#) might be of particular interest.

6.13.3.2 Process Log

After starting a GAMS process the LogViewer is opened to view the process **Log**. Usually the **Log** stays at the bottom to keep tracking the latest log lines. The tracking can be paused by clicking on the up arrow of the vertical scrollbar. To continue tracking drag the scrollbar to the bottom.

The **Log** usually contains links of different kinds:

- compilation errors (red): Links to the `.gms` file where the error occurred. Additionally contains a link to the listing file (`.lst`) at the beginning of the line (blue).
- listing links: Links to a specific line in the listing file
- file link (green): Links to a file without line numbers such as `.gdx` or `.ref`

Clicking on a link takes the focus to that file (and line). Double-clicking in the **Log** looks for the nearest link to the listing file and takes the focus there. Files that were not part of the current project are added when they are opened by link.

For general messages there is the **System Log** stacked together with all **Process Logs**. It keeps track of **Studio** related messages not originated from a specific GAMS run.

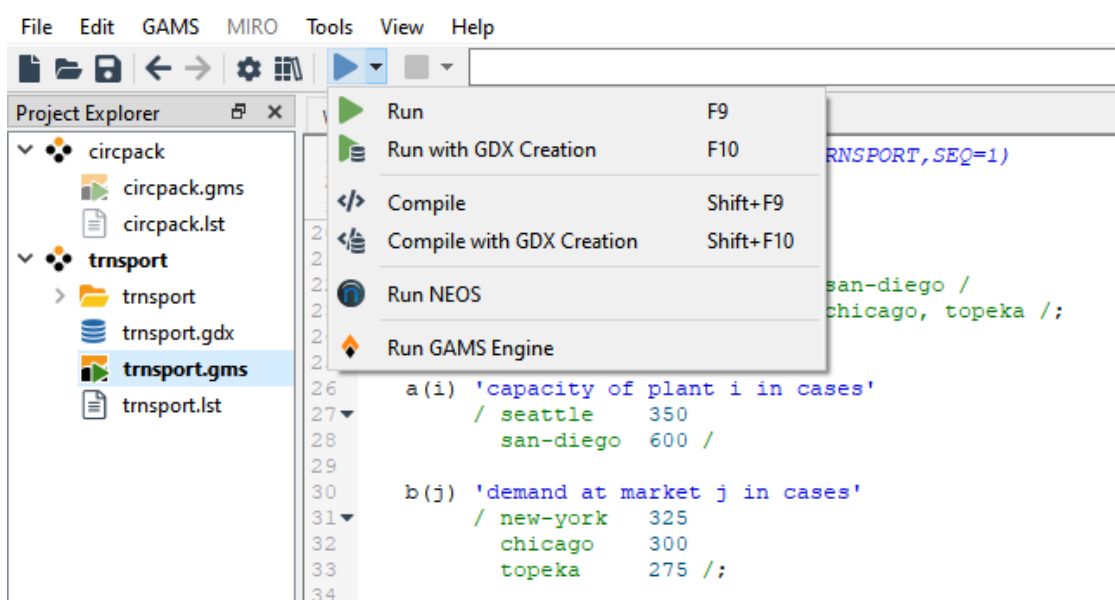

6.13.3.3 Quick Access Toolbar and GAMS Parameter Editor

The toolbar contains two parts: a quick access section and GAMS Parameter editor to customize how GAMS is executed the model (see [The GAMS Call and Command Line Parameters](#)).

The quick access section contains icons for performing common File actions like *New*, *Open*, and *Save*, as well as accessing *Settings* dialog, *Model Library Explorer* dialog, *Project Explorer* view, *Process Log*, and *Help* view.

The GAMS Parameter Editor provides a way to control and customize the execution of a GAMS model. The editor displays the parameters of the project of the file that is currently opened in [Central Widgets](#) (see also [Project Explorer](#) for project and its runnable files). The parameters can be typed into a combobox and the execution of a GAMS model can be carried out using the following pre-customized execution commands:

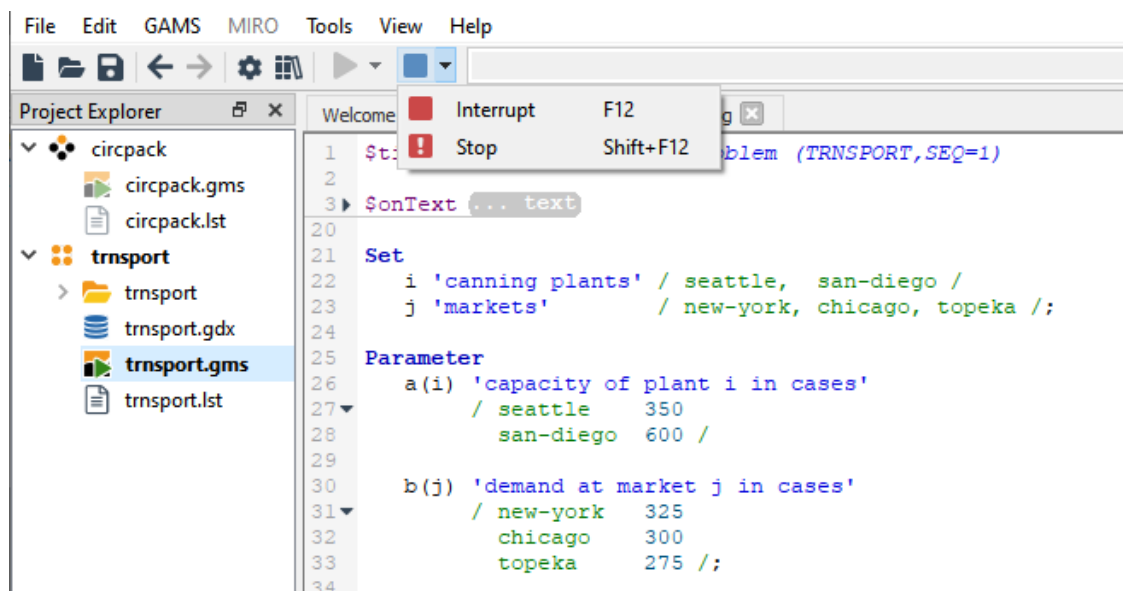

- **Run:** Choose Run or press F9 to compile and execute GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the default parameter `action=CE` (Compile and Execution).
- **Run with GDX Creation:** Choose Run with GDX Creation or press F10 to compile and execute GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two parameters `action=CE` and `gdx=default`.
- **Compile:** Choose Compile or press Shift - F9 to compile GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the parameter `action=C` (CompileOnly).
- **Compile with GDX Creation:** Choose Compile with GDX Creation or press Shift - F10 to compile GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two parameters `action=C` and `gdx=default`.
- **Run NEOS:** Choose Run NEOS to compile GAMS statements in the main runnable file locally and pass the execution to the [NEOS](#) server.

- **Run GAMS Engine:** Choose **Run GAMS Engine** to compile GAMS statements in the main runnable file locally and pass the execution to the **GAMS Engine** server.

The pre-customized execution command will operate on the main file (marked with a little green arrow over the regular icon) of the active project (see how to manage the main file in section [Project Explorer](#)). In case GAMS parameters have been set they will be appended to the pre-customized commands. Just like the GAMS Terminal, when there are identical parameters with different values the last one "wins" and overwrites the previous ones. Thus it is possible for a user to change and override GAMS Studio default parameters, which can possibly lead to problems if done incorrectly. In this case Studio prints out a warning message, informing users about potential problems. To debug what Studio does the full GAMS call parameters will be printed to the system log. After execution, the parameters will be added into the project history. All files in a project share one parameter history. The previous GAMS parameters can be recalled from the project history via the drop-down menu of the combobox. Switching the file opened in [Central Widgets](#) will activate the different project history only when the project of the newly opened file is different from the project of the file before the switch.

The parameters `curDir` and `workDir` behave slightly differently in Studio compared to the terminal. When using one of these parameters on the command line GAMS expects the `gms` file to be in the given folder. In Studio the path to the input file is always given as an absolute one. Therefore, there is no need to use the `inputDir` parameter to make the `gms` file accessible to GAMS if it is not in the specified working directory.

The GAMS Parameter Editor provides a way to either interrupt or stop the currently running job when an execution of a GAMS model is in progress (indicating with animated icon over the project folder icon in [Project Explorer](#)) :

- **Interrupt:** Click the **Interrupt** button or press **F12** to send an interrupt request to the running job in order to perform a graceful stop and collect an incumbent result back from the execution if the solver supports this feature. The command is enabled when there is a job that is currently running in the project and disabled when there is no currently running job in the project.
- **Stop:** Click the **Stop** button or press **Shift - F12** to send a request to stop the running job immediately. The command is enabled when there is a job that is currently running in the project and disabled when there is no currently running job in the project.

The Extended GAMS Parameter Editor allows to configure the GAMS parameters. The extended parameter editor is shown when the Show button next the parameter combobox is clicked or with the shortcut **Ctrl - Alt - 3**. The editor can be hidden when the button is clicked again. When shown, the GAMS parameters from the parameter combobox will appear as a list of entries in the left pane of the extended parameter editor, each entry contains the **Key** and **Value**.

Note that the GAMS parameter combobox will be disabled when the extended parameter editor is shown and all editing has to be done in the extended parameter editor.

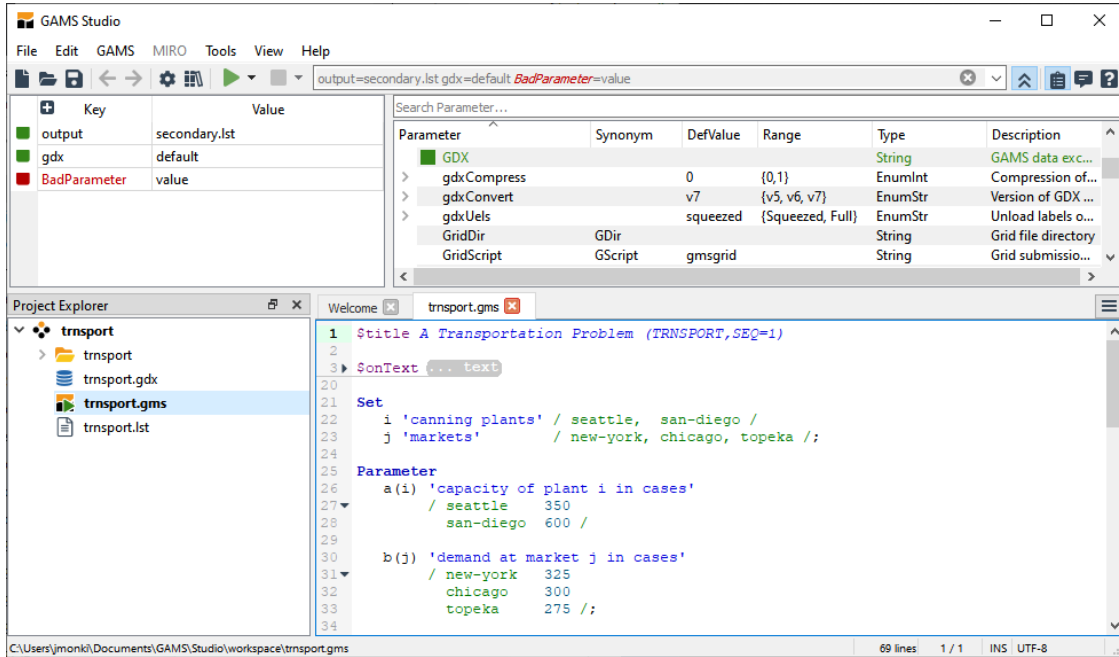

Figure 6.23 Extended GAMS Parameter Editor is shown when the button next to parameter combobox is clicked

The right pane of the extended editor displays the list of all valid parameter definitions, each contains **Parameter Name**, **Synonym**, **Default Value**, **Type**, and **Description**. The parameter definition entry with enumeration type (**EnumStr** or **EnumInt**) can be expanded to show all enumerated values of the parameter by clicking the bullet in front of the parameter entry, clicking the bullet again will hide all enumerated values of the parameter. Above the list of all valid parameter definitions is a search box (with placeholder text **Search Parameter...**) to allow a simple search through all parameter definitions. As a search keyword has been typed into the search box the results will be displayed in the list below. The search will perform on all fields of parameter definitions including enumerated values.

The parameter editor displays potential parameter errors in red color both in the combobox and in the left pane of the extended editor. When hovering a mouse over the error key or value, a tooltip with more detailed explanation of the error appears.

Figure 6.24 Parameter key turns red with pop-up tooltip when there is a potential error

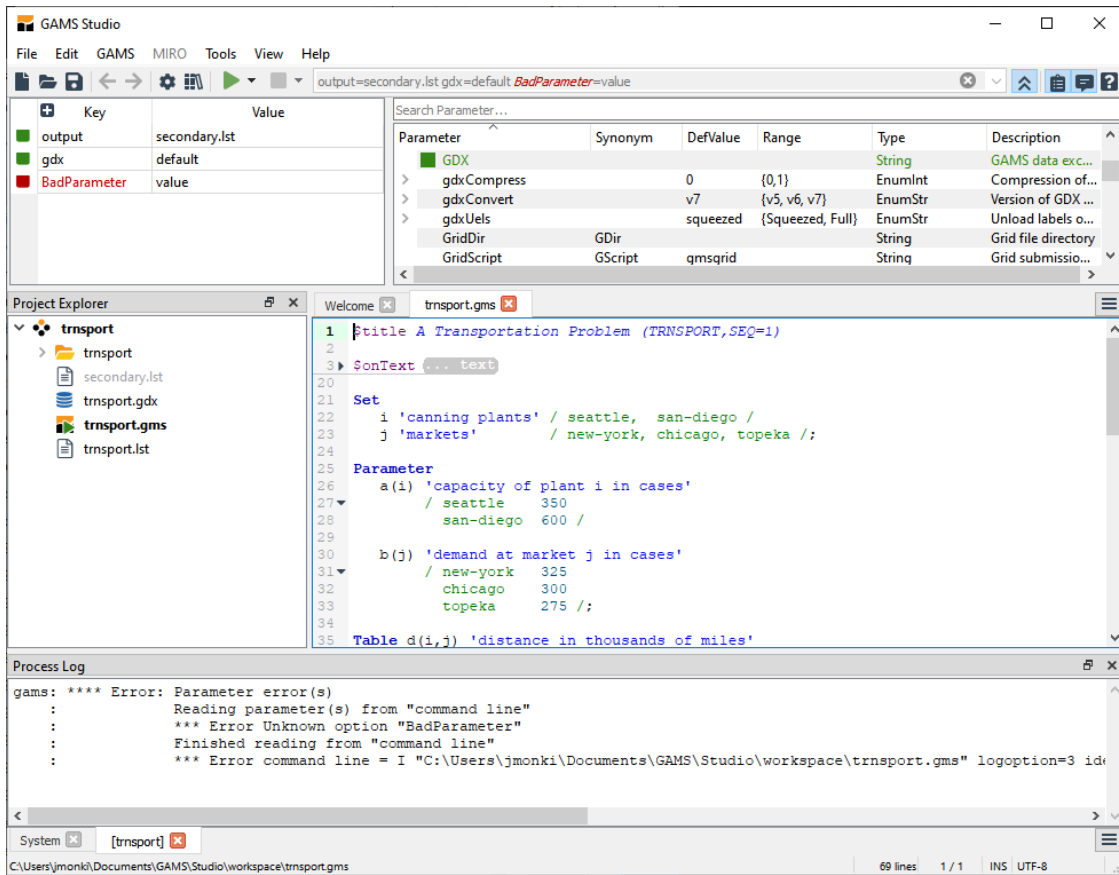

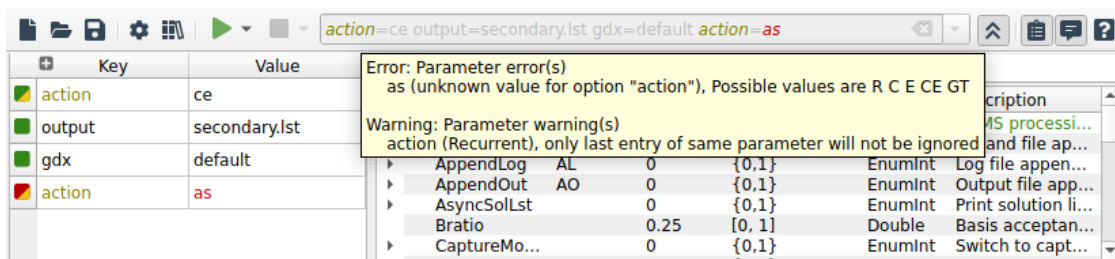

Figure 6.25 Process Log reports parameter errors when running the model with an unknown option parameter

When there are several entries of the same parameter, all other entries except the last entry will be ignored when gams executes the model. In such case, the combobox of parameter editor displays a warning in yellow and the icon in front of the parameter in the extended editor turns half-yellow in combination of another color, red or green, depending of whether or not there is a potential error.

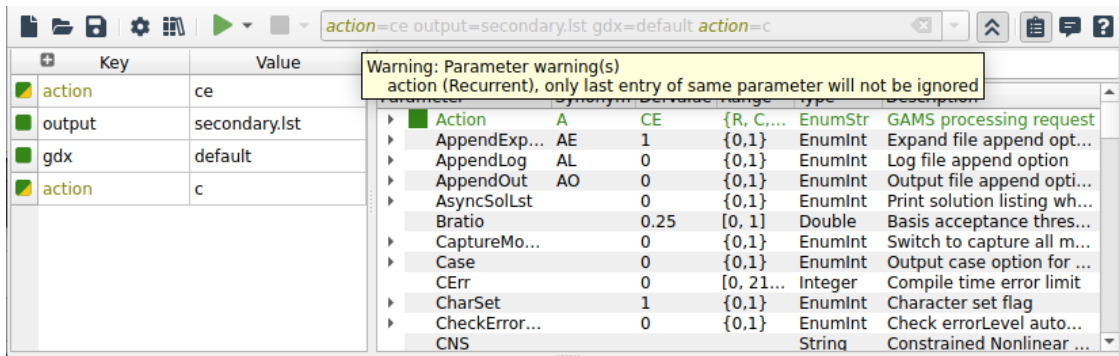

Figure 6.26 Parameter key turns yellow and the pop-up tooltip indicating a warning

See [edit parameter key and value](#) on how to edit parameter key and value that contains an error or a warning. See [show all parameters of the same definition](#) on how to locate all entries of the same parameter.

The followings describes all editing actions that can be performed via the extended parameter editor:

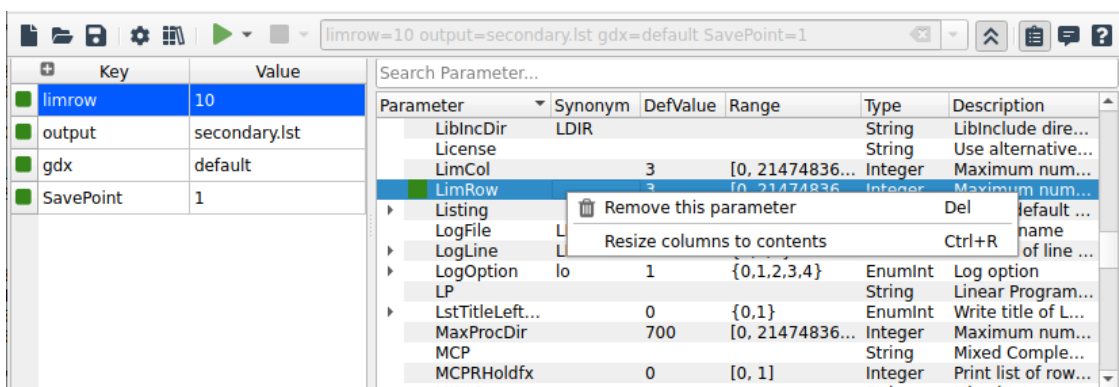

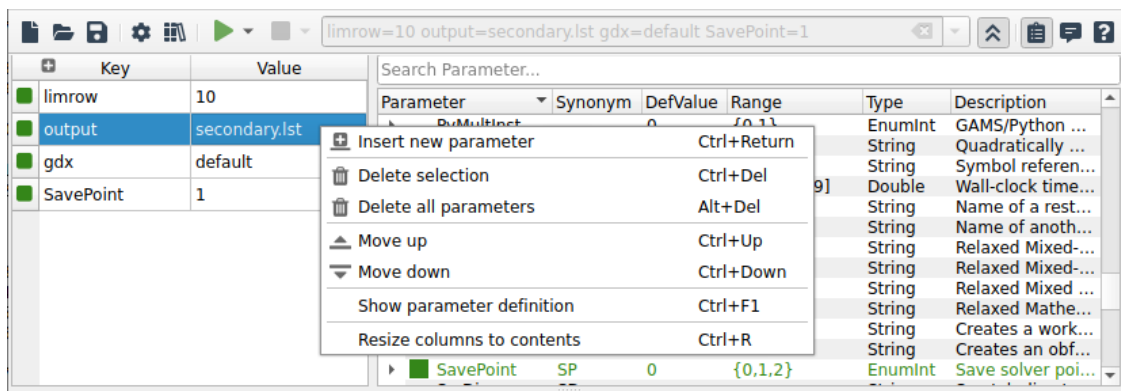

Figure 6.27 A number of actions that can be performed via the context menus of Extended Parameter Editor

- **Edit parameter key and value:** double click on key cell to edit Key and on value cell to edit Value of the entry. A drop-down list will suggest possible keys and values when possible. Press **Enter** to confirm the edit and press **Esc** to cancel the edit.

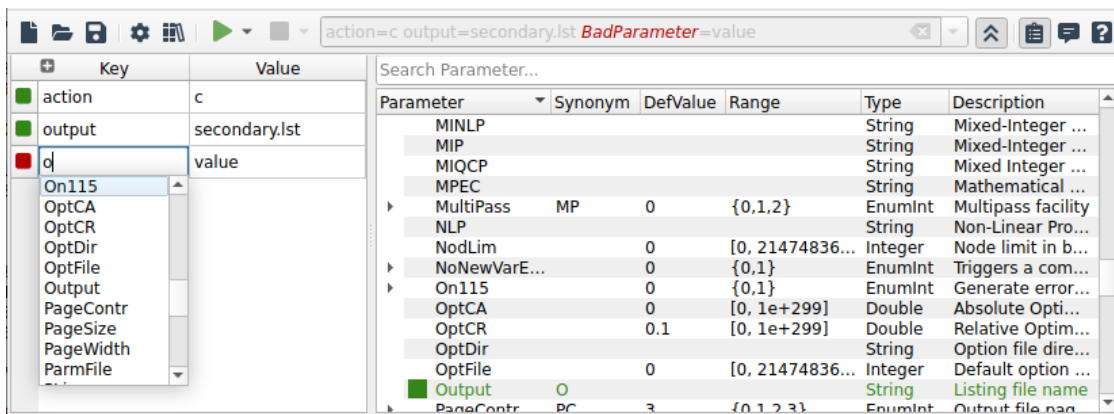

Figure 6.28 GAMS Parameter editor shows a drop-down list of all possible parameters started with 'o'

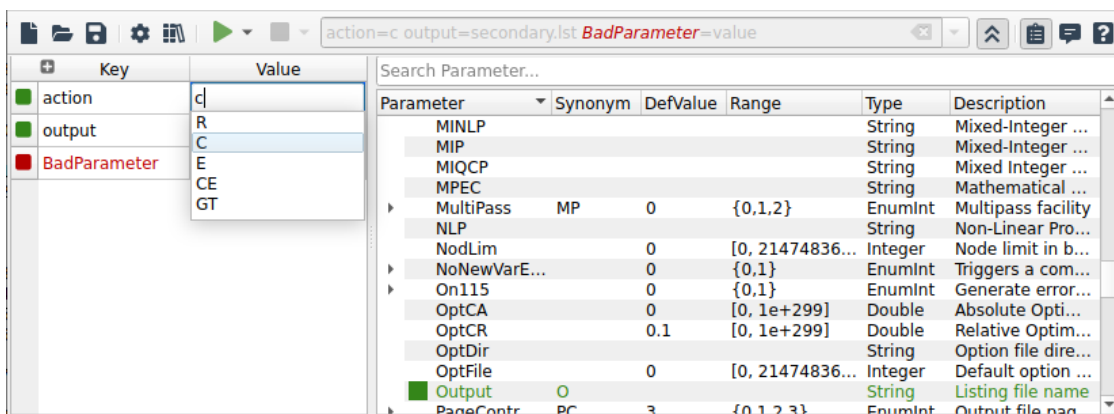

Figure 6.29 GAMS Parameter editor shows a drop-down list of all enumerated values of parameter 'action'

- **Add new parameter:** there are several ways to add a new parameter via extended parameter editor.
 - right click on the left pane of the parameter editor and choose **add new parameter** from the pop-up context menu
 - right click on the selected parameter entry of the parameter table and choose **add new parameter** from the pop-up context menu
 - click on the add new parameter button next to Key table header in the left pane

A new entry will be added at the end of parameter entry table with dummy parameter key [KEY] and dummy parameter value [VALUE]. See [edit parameter key and value](#) on how to edit parameter key and Value.

It is also possible to add a new parameter from the right pane of the parameter editor by double clicking at the definition entry in the right pane. The selected definition entry will be added as a new parameter entry at the end of table in the left pane. In case of double clicking an enumerated value entry of a parameter definition the definition entry will be added as a new parameter with the selected enumerated value. Otherwise the default value of the entry will be added.

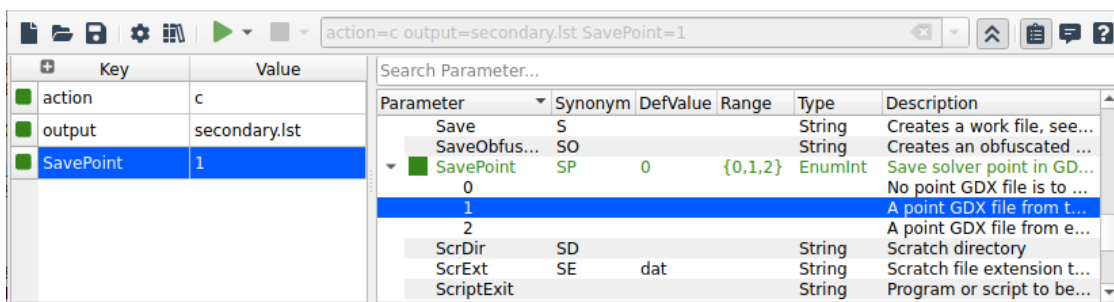

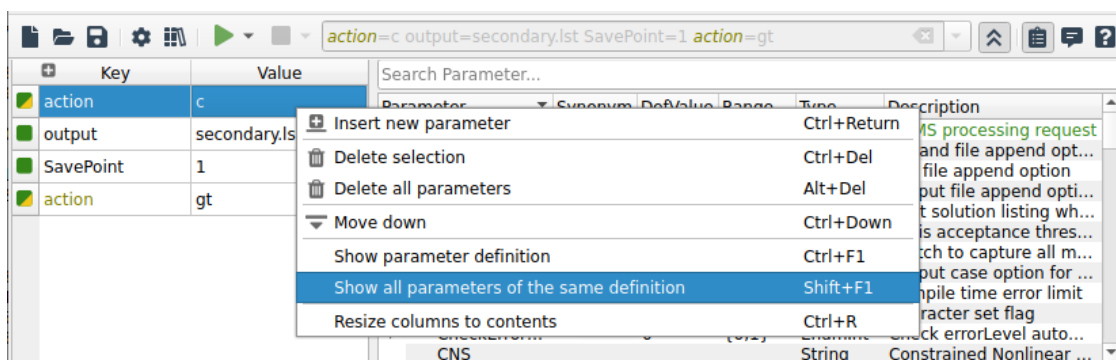

Figure 6.30 Parameter with enumerated value added by double clicking at the selected entry in the right pane

- **Insert new parameter:** right click on the selected entry and choose **insert new parameter**. A new entry will be inserted before the selected entry with dummy parameter key [KEY] and dummy parameter value [VALUE]. See [edit parameter key and value](#) on how to edit parameter key and value.
- **Move up:** right click on the selected entry and choose **Move Up**. The selected entry will be moved one position up the table. This action will change the order of parameters.
- **Move down:** right click on the selected entry and choose **Move Down**. The selected entry will be moved one position down the table. This action will change the order of parameters.
- **Delete selection:** right click on the selected entry and choose **Delete Selection**. The selected entry will be deleted from the table.
- **Delete all parameters:** right click on the left pane of the extended editor and choose **Delete all Parameters**. All entries will be deleted from the table.
- **Show parameter definition:** right click on the left pane of the extended editor and choose **Show parameter definition**. The parameter definition entry on the right pane will be highlighted.
- **Show all parameters of the same definition:** right click on the left pane of the extended editor and choose **Show all parameters of the same definition**. All parameter entries on the left pane will be highlighted.

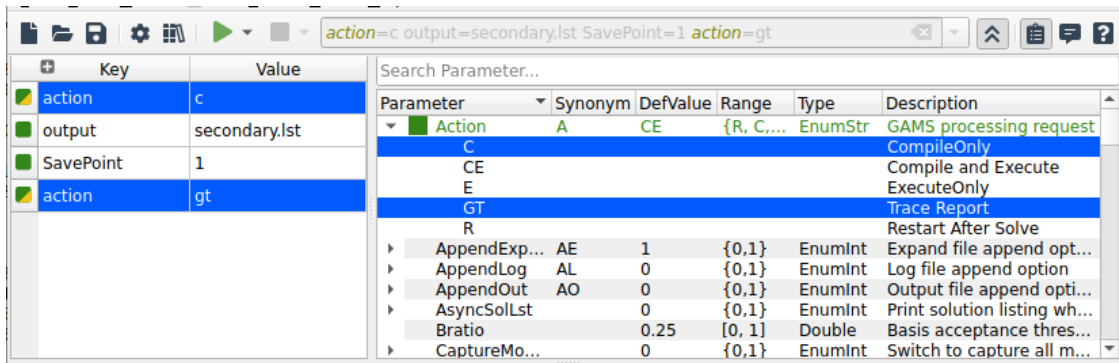

Figure 6.31 All entries of the same parameter are highlighted

- **Resize columns to contents:** right click on the left or right pane of the extended editor and choose **Resize columns to contents**. All columns will be resized according to their contents.
- **Add this parameter:** right click on the right pane of the extended editor and choose **Add this parameter**. The parameter with default value (if defined) of the selected definition will be added as the last entry on the left pane of the extended parameter editor. This action in the context menu is enabled only when there is no entry of this parameter on the left pane. Note that a double click on the definition will also perform add this parameter action. Performing the action on the parameter definition that has already been added will pop-up a dialog indicating that the parameter exists on the left pane and prompting for one of the followings:
 - replace existing entry If there is only one entry or replace the first entry and delete other entries if there is more than one entry, or
 - add new entry of the same definition, or
 - show details of all entries of the same parameter, or
 - abort the action

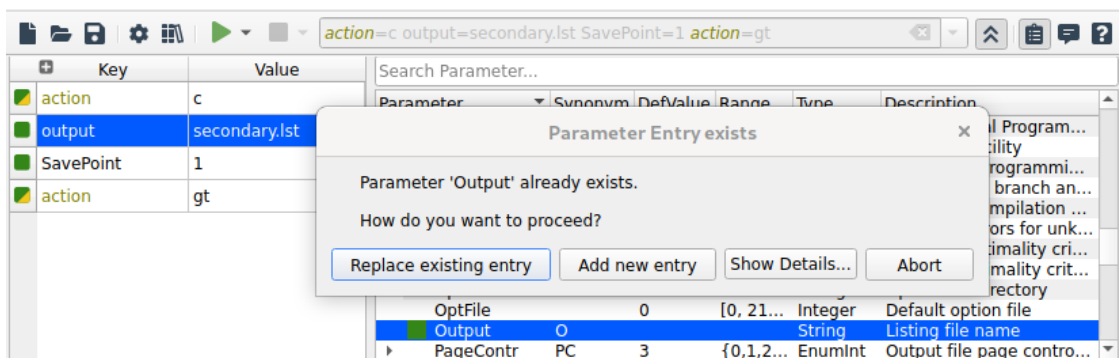

Figure 6.32 A pop-up dialog when adding the definition parameter that has already been added

- **Remove this parameter:** right click on the right pane of the extended editor and choose **Remove this parameter**. The parameter of the selected definition will be deleted from the left pane of the extended parameter editor. This action in the context menu is enabled only when there is an entry of this parameter definition on the left pane. In case there are multiple entries of the same parameter, all entries on the left pane will be deleted.

Press **F1** on a parameter entry in the extended parameter editor will activate the [The GAMS Call and Command Line Parameter](#) help page containing the detailed description of the GAMS parameter.

6.13.3.3.1 Summary of Actions and Shortcuts Actions and their shortcuts that can be performed via Toolbar and GAMS parameter editor are:

Action	Shortcut	macOS	Description
New	Ctrl - N	Command - N	Open new file dialog
Open	Ctrl - O	Command - O	Open file open dialog
Save	Ctrl - S	Command - S	Save the current file. If the file does not exist on disk open the save file dialog
Settings	F7	Command - ,	Open the Settings dialog
Model Library	F6	F6	Open the Model Library Explorer dialog
Run	F9	F9	Run main file of current project with GAMS
Run with GDX Creation	F10	F10	Run main file of current project with GAMS and create a GDX file
Compile	Shift - F9	Shift - F9	Compile main file of current project with GAMS without execution
Compile with GDX Creation	Shift - F10	Shift - F10	Compile main file of current project with GAMS and create a GDX file without execution
Interrupt	F12	F12	(Gracefully) Interrupt currently running GAMS job
Stop	Shift - F12	Shift - F12	Stop currently running GAMS job
Show extended parameter	Shift - Ctrl - 3	Control - Option - 3	Open the extended GAMS parameter editor
Project explorer	Ctrl - 1	Command - 1	Open Project Explorer
Process Log	Ctrl - 5	Command - 5	Open Process Log
Help	F1	F1	Open the GAMS Help .

Actions and their shortcuts that can be performed via the left pane of the extended GAMS parameter editor are:

Action	Shortcut	macOS	Description
Insert new parameter	Ctrl - Return	Ctrl - Return	Insert a new parameter
Delete selection	Ctrl - Delete		Delete the selected parameter
Delete all parameters	Alt - Delete		Delete all parameters
Move up	Ctrl - Up	Command - Up	Move the selected parameter up for 1 row
Move down	Ctrl - Down	Command - Down	Move the selected parameter down for 1 row
Select all	Ctrl - A	Command - A	Select all parameters
Show parameter definition	Ctrl - F1		Show definition of this selected parameter in the right pane
Show all parameters of the same definition	Shift - F1		Show all options of the same definition defined in the right pane
Resize columns to contents	Ctrl - R	Command - R	Resize the columns in the left pane to contents

Actions and their shortcuts that can be performed via the right pane of the extended GAMS parameter editor are:

Action	Shortcut	macOS	Description
Parameter Search	Ctrl - F	Command - F	Jump to the focus to the Parameter Search input field
Add this parameter	Return	Return	Add option in the left pane from the selected definition
Remove this parameter	Delete		Remove option defined by this definition from the left pane
Resize columns to contents	Ctrl - R	Command - R	Resize the columns in the right pane to contents

6.13.3.4 Integrated Help

The Help View is designed to integrate the navigation of the GAMS documentation into GAMS Studio. Press F1 or choose **Help > GAMS Documentation** or check **View > Help** to start the Help View and browse the documentation. The start page of the Help View is the main document page available in the GAMS distribution that has been used to run GAMS Studio. See [Home](#) on how to always navigate back to the start page of the document. Alternatively, choose **Help > Studio Documentation** to directly jump the to start of the GAMS Studio documentation. Click Close button or uncheck **View > Help** to dismiss the Help View. GAMS Studio will remember the last viewed page along with its browsing history until GAMS Studio is restarted.

The Help View starts in docking state for the first time and can be docked around the editor in the central widgets area by either dragging the view to the desired location. Studio will remember last state of the Help View before it was closed.

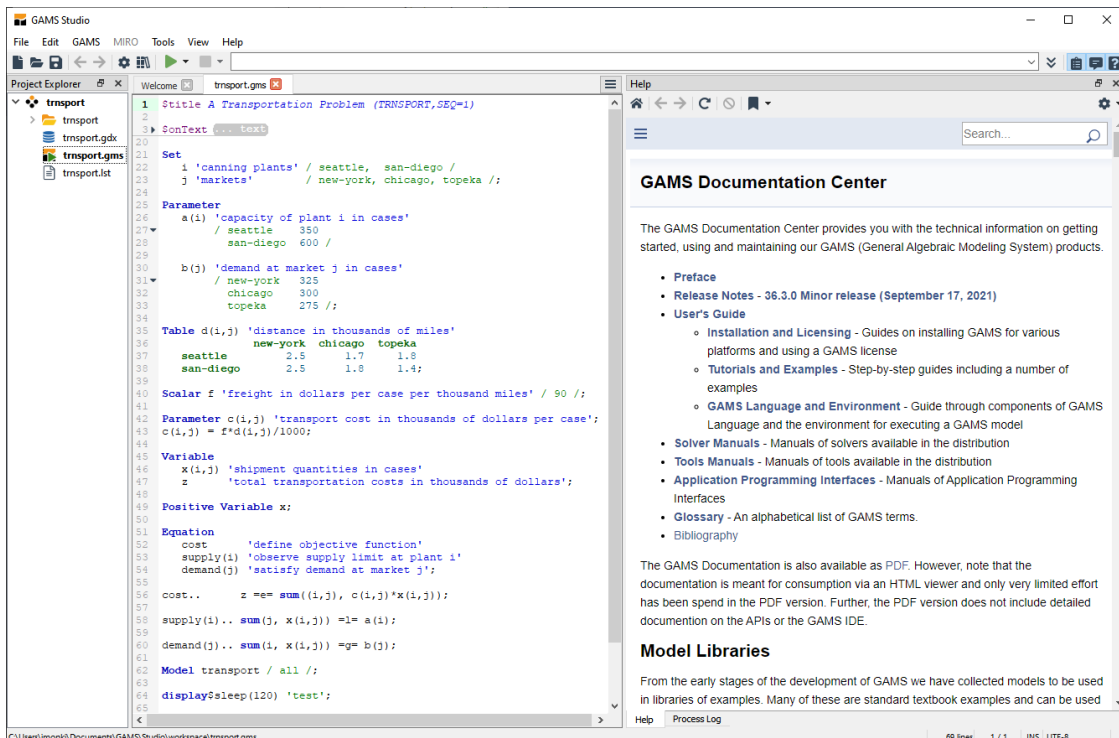

Figure 6.33 Help View when docked to the right of Code Editor

The Help View can also be floated by double clicking the title part of the Help View. Dragging or double clicking the title of the Help View again will dock the Help View.

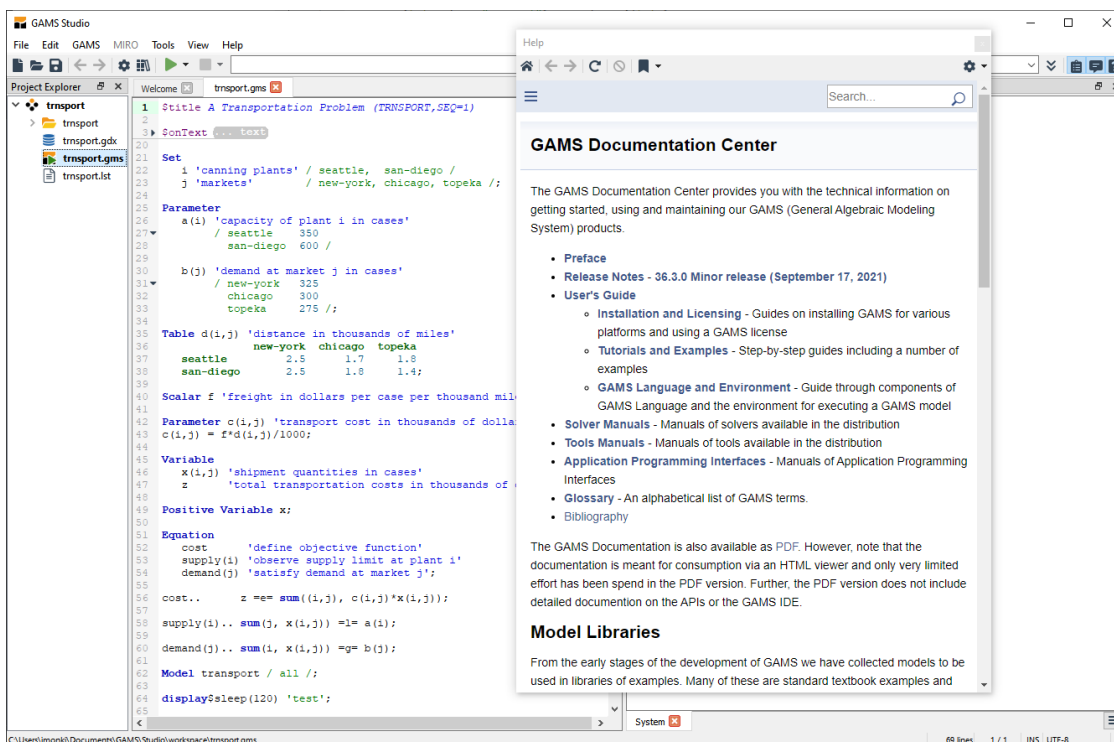

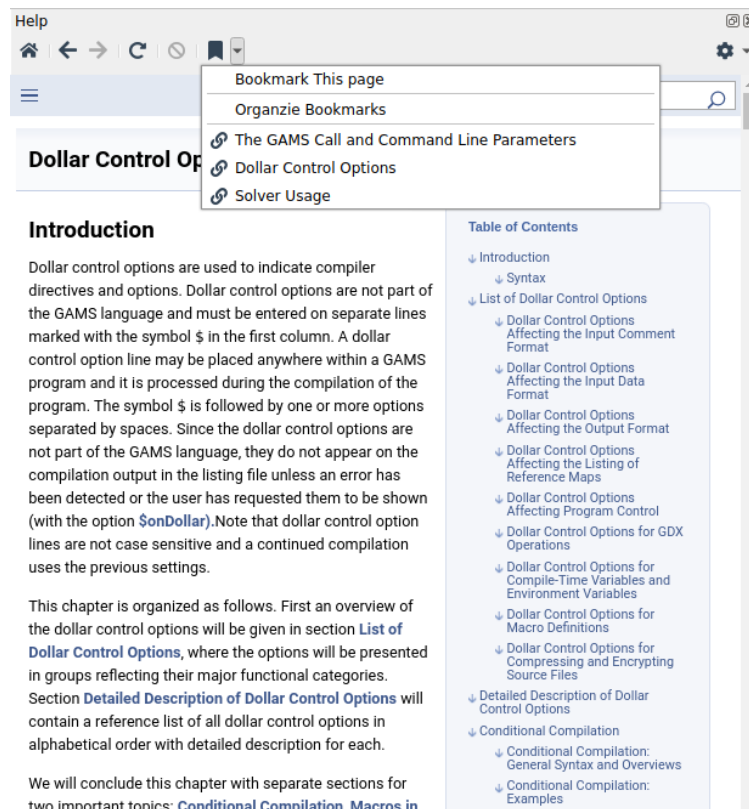

Figure 6.34 Help View when floated

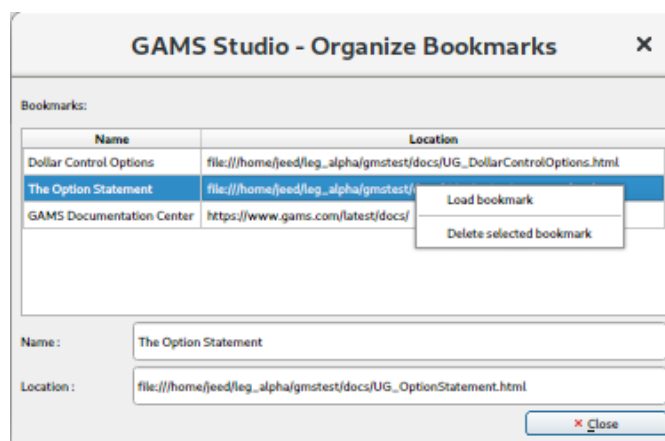

Note that the Help View does not offer the full browsing features of a web browser. Though the help view offers a [Open this page in Default Web Browser](#) button to use the full features of a web browser.

An overview of Help features:

- **Home:** Start the start help page [`GAMSDir`]/docs/index.html
- **Back:** Back to previous page
- **Forward:** Go to next page
- **Reload:** Reload the content of this page
- **Stop:** Stop loading the content of this page
- **Bookmarks:**
 - **Bookmark this page:** Store the title of the page as the name of bookmark together with its location. The entry of the bookmark will appear below the [Organize Bookmarks](#) section. Click on an entry to jump to the page that has been bookmarked.

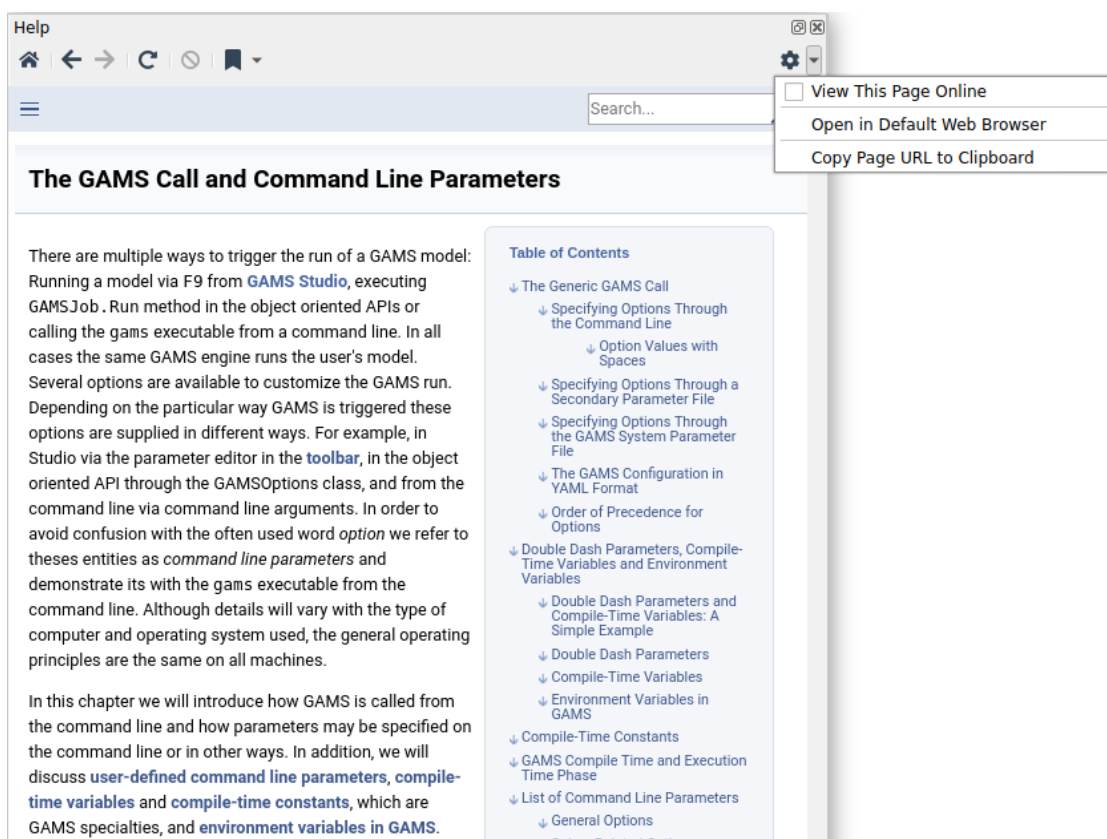

- **Organize Bookmarks:** Open the bookmark dialog to edit or delete a bookmark entry. Right click on the selected entry in the bookmark table, then either load the selected bookmark in the Help View, or delete the selected bookmark. The selected bookmark Name and Location can be edited from the lower part of the bookmark dialog and press **Enter**. Press **Esc** to cancel the edit. Click close button to dismiss the bookmark dialog.

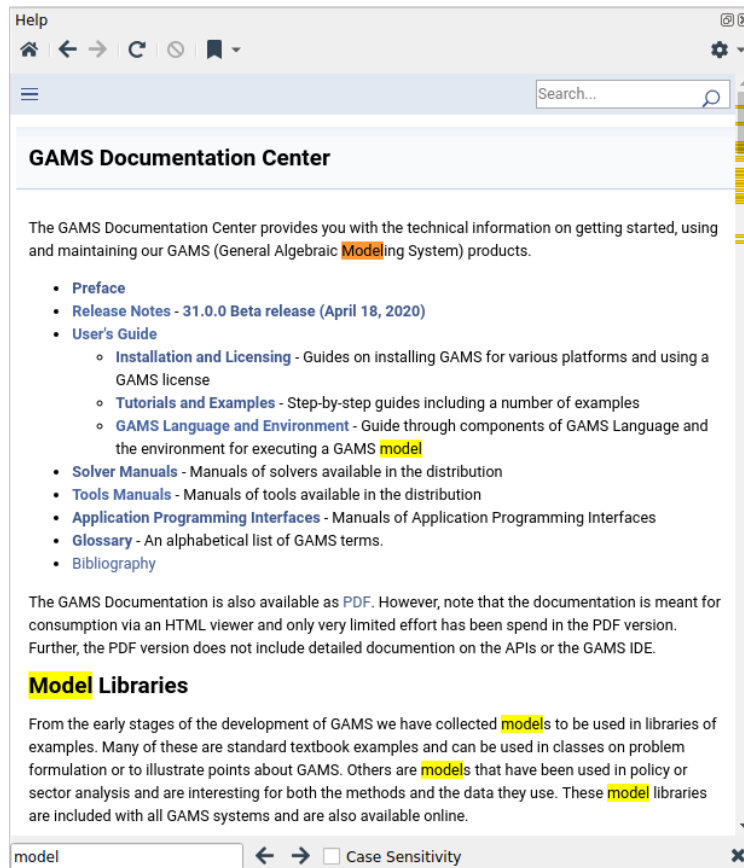

- **Zoom In:** Zoom in the page to increase the font size. Press **Ctrl - +**, or **Ctrl - Mousewheel Up** or choose **View > Zoom In** menu to zoom in the page.
- **Zoom Out:** Zoom out the page to reduce the font size. Press **Ctrl - -**, or **Ctrl - Mousewheel Down** or choose **View > Zoom Out** menu to zoom out the page.
- **Reset Zoom:** Reset the font size of the page to its original size. Press **Ctrl - 0** or choose **View > Reset Zoom** menu to reset zoom in the page.
- **Help Option :**
 - **View This Page Online :** Browse the same documentation on GAMS website. This, for example, allows to use more sophisticated search functionalities across all GAMS documentation of version 38.0 or to browse different version of documentation, or to browse the GAMS website from the Help View.

- **Open in Default Web Browser** : Browse the same document in default web browser. As the help view does not offer the full features of a web browser, this allows to browse the documentation using the full web browser features in default web browser.

- **Copy page URL to Clipboard** : Copy of the current page's URL to the clipboard. This, for example, help to see the URL of the currently viewed page of the document.

- **Find in page...** : Press **Ctrl - F** or choose **Edit > Search** menu to activate a search at the bottom area of the Help View. Type in a word to be found in the page. The word found in the page will be highlighted as it has been typed in and the number of found occurrences will be highlighted in the scrollbar of the Help View. Click **previous button** to find the previous occurrence, and click **next button** or press **Enter** to find the next occurrence. Check **Case Sensitivity box** to find a word case sensitively. Highlighting the word stays as the document is navigated from page to page until the keyword is clear or the search is dismissed or the Help View is closed or invisible. Click the close button or press **Esc** to dismiss the search.

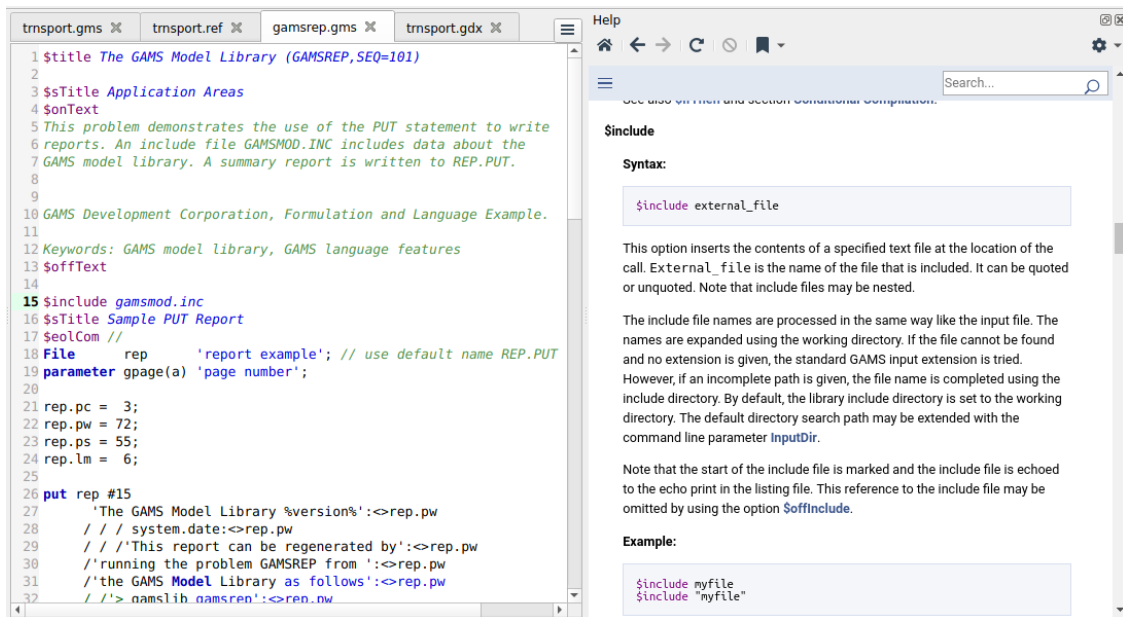

Help on Specific widgets

It is possible to jump directly from different widgets ([Welcome Page](#), [Code Editor](#), [Listing Viewer](#), [GDX Viewer](#), [Reference File Viewer](#), and [Solver Option Editor](#)) to the related part of the document.

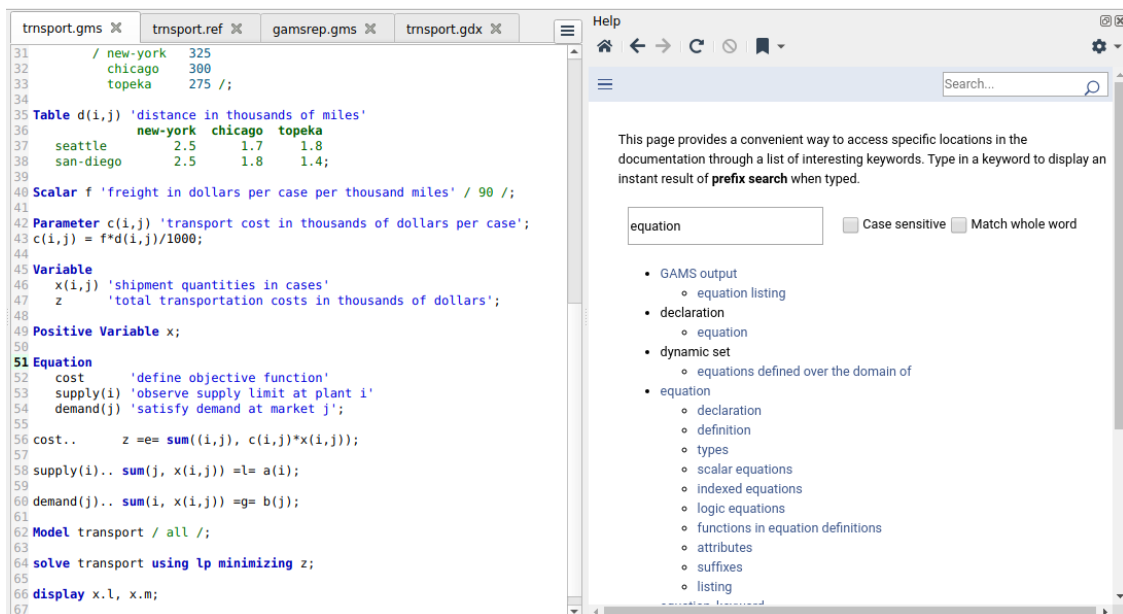

From [Welcome Page](#), [Listing Viewer](#), [GDX Viewer](#), and [Reference File Viewer](#), press **F1** will activate the [GAMS Studio](#) page and jump to the section corresponding to the widget. From [GAMS Parameter Editor](#), press **F1** on a parameter entry in the extended parameter editor will activate the [The GAMS Call and Command Line Parameters](#) help page containing the detailed description of the GAMS parameter. From [Solver Option Editor](#), press **F1** on an option entry in the editor will activate the related solver page containing the detailed description of the option.

From [Code Editor](#), it is possible to jump to the document page that describes [Dollar Control Options](#) or to the index page that lists entries related to [Data Types and Definitions](#) and [Language Items](#) in [Code Editor](#), as well as from the parameter editor to the GAMS parameter described in [The GAMS Call and Command Line Parameters](#) :

- Press **F1** on a [Dollar Control Option](#) within the editor will activate the page [Dollar Control Options](#) in the Help View and jump to the corresponding dollar control option described in [Dollar Control Options](#) chapter.

- Press F1 on a keyword in [Data Types and Definitions](#) or in [Language Items](#) within the editor to activate the **Index** Page in the Help View that lists the index entries related to the keyword.

- Press F1 on a parameter entry within the extended parameter editor to activate the help page displaying the detailed description of the GAMS parameters in [The GAMS Call and Command Line Parameters](#).

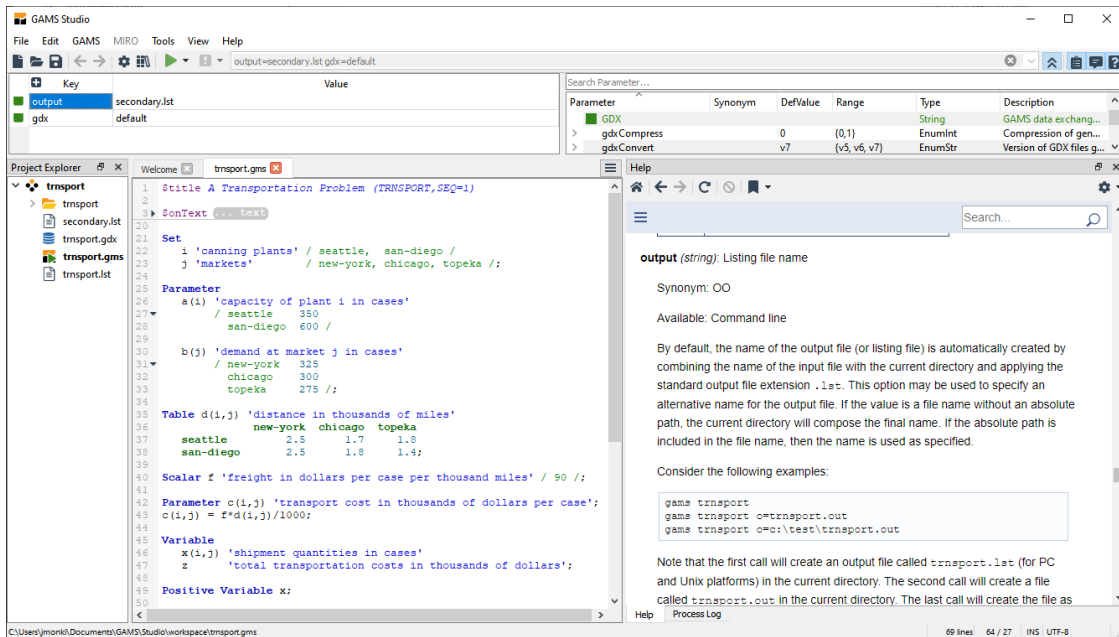

Figure 6.35 Help View when press F1 on parameter entry 'output' in extended parameter editor

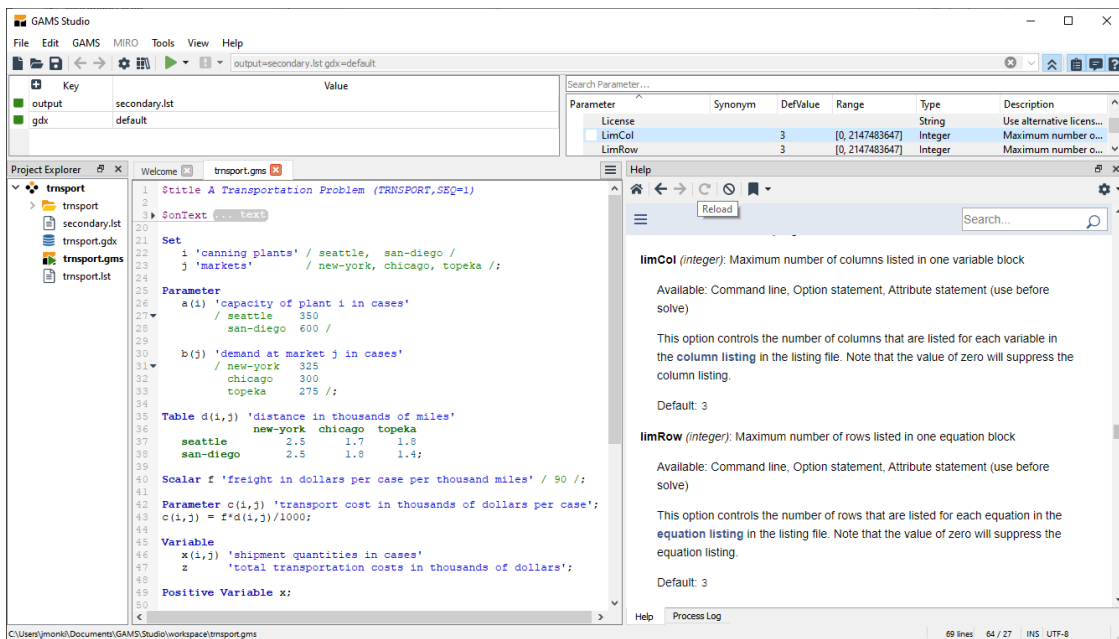

Figure 6.36 Help View when press F1 on parameter definition entry 'LimRow' in extended parameter editor

Action	Shortcut	macOS	Description
Zoom In	Ctrl- + or Ctrl - Wheel Up	Command - + or Command - Wheel Up	Zoom in the page to increase the font size
Zoom Out	Ctrl- - or Ctrl - Wheel Down	Command - - or Command - Wheel Down	Zoom out the page to reduce the font size
Reset Zoom	Ctrl - 0	Command - 0	Reset the font size of the page to its original size

Action	Shortcut	macOS	Description
Search	Ctrl - F	Command - F	Jump to the help search box to search for a keyword in the current page

6.13.3.4.1 Summary of Actions and Shortcuts

6.13.4 MIRO

GAMS Studio can be used to develop models for [GAMS MIRO](#). Please go to the [GAMS MIRO documentation](#) to learn more about the features and workflow of the MIRO integration.

6.13.4.1 GAMS MIRO Shortcuts

Action	Shortcut	macOS	Description
Run base mode	F8	F8	Run main file of current project with MIRO in Base Mode
Run configuration mode	Shift - F7	Shift - F7	Run MIRO configuration mode

6.13.5 NEOS

GAMS Studio can remotely execute models on the [NEOS server](#). The model is compiled locally before the compilation object is send to NEOS. Note that a GDX file can be created but always has the name `out.gdx`. On running a dialog pops up to enable further setup:

- "Email" - The email to submit a job. It can be predefined by setting `NEOS_EMAIL` in the [GAMS User Configuration](#) or by defining the environment variable `NEOS_EMAIL`.
- "Create a GDX file" - Create a GDX file even if the Command line parameter is not set.
- "Short priority" - The execution may start earlier and provides intermediate log output, but it is limited to an execution time of five minutes.
- "Long priority" - The execution may start later and provides no intermediate log output, but it is not limited in execution time.

The selections of the dialog are stored to the settings. To reveal the Terms of Use after checked **Don't show Terms of Use again** there is a checkbox in **Settings > Misc**.

The results of the remotely executed model are placed into a sub-folder named by the base name of the model. The log output of the remote execution has a different background color which can be configured in the settings dialog (Default Text, 3rd color). Links in the remote execution log output are replaced by their local counterpart.

6.13.6 GAMS Engine

GAMS Studio can remotely execute models on your own **GAMS Engine server**. The model is compiled locally before the compilation object is send to GAMS Engine. Additional files can be send to the server by creating a file with the name of the model and the extension ".efi" (for "External Files"). Each line in this file addresses an additional file.

On running a dialog pops up asking the user to log in. If already logged in before and the login is still valid this first page is skipped.

- *Login page*
 - "Url" - The URL to your GAMS Engine server
 - "User" - The username to login
 - "Password" - The password to login

On changing the URL, **Studio** tries directly to access the server and requests version information. On success it gets the GAMS Engine version placed to the right and the version of the GAMS installation on the server to the left. If the local GAMS version is newer the command line parameter "previousWork=1" will be added automatically if no "previousWork" is already present. The entries of the dialog (excluding the password) are stored to the settings. Further configuration can be done in the settings dialog.

Being logged in, the submit page allows to setup the remote job:

- *Submit page*
 - "Namespace" - The **namespace** to be used on the server
 - "Create a GDX file" - Creates a GDX file even if the command line parameter is not set

To get back to the login page click the "Logout" Button. The job is submitted to the GAMS Engine server on clicking "OK". To always run the same setup, the "OK, don't ask" can be selected. For this Studio session the job is always submitted directly without showing this dialog. To see the dialog again, use **Ctrl-Click** on the Engine icon, or click on "Settings > Remote > Reactivate Dialog".

The results of the remotely executed model are placed into a sub-folder named by the base name of the model. The log output of the remote execution has a different background color which can be configured in the settings dialog (Default Text, 3rd color). Links in the remote execution log output are replaced by their local counterpart.

6.13.7 Dialogs and Actions

6.13.7.1 GAMS Licensing

The GAMS Licensing dialog is part of the GAMS Studio Help menu. It provides information about the used GAMS as well as available solvers, which lists the solver licenses and their capabilities. Furthermore, the dialog can be used to install a GAMS license. To do so the steps below have to be applied.

1. Copy the GAMS license to the clipboard
2. Open GAMS Studio and click on Help > GAMS Licensing
3. A messages box shows up if a GAMS license has been found on the clipboard. If 'Yes' is clicked the new license will be installed and presented via the GAMS Licensing dialog; otherwise the old license is shown.

Studio will also detect a license on the clipboard when it starts. If a license is detected the same message box will show up like if the GAMS Licensing dialog is used.

6.13.7.2 Check for Update

Check if a more recent version of GAMS or GAMS Studio is available for download (and can be used with the present license) and report the results. The information shown uses the current license file for this.

6.13.7.3 Search and Replace

Action	Shortcut	macOS	Description
Open/Focus Search Dialog	Ctrl - F	Command - F	Opens the search dialog or focusses it if it is already open, if Text is selected it will automatically be entered as a search term
Find next	F3 or Enter	F3 or Enter	Jumps to the next match that fits all search criteria
Find previous	Shift - F3	Shift - F3	Jumps to the previous match
Find All	Shift - Enter	Shift - Enter	Starts a search, opens the page of search results and jumps to the first hit
Close Dialog	Esc	Esc	Closes the search dialog. On second press any highlights of results will be removed

Pressing the **Ctrl - F** opens the Search and Replace window. If text is selected it will be pasted into the search field. Users can search specific files with it and do text replacement operations. Depending on which file type is openend in the editor, the search widget changes to visualize which actions are available. Due to technical limitations **.gdx** files cannot be searched, also replacing in read-only file types (e.g. **.lst** or **.ref**) is deactivated. For reasons of performance the search stops when reaching 50000 search results. This is visualized in all places where the number of matches is shown by showing "50000+" as the results number, indicating that there might be more results.

Figure 6.37 Search window in its default configuration

In the first row of the search widget from left to right the following items are located: Search field, which takes the search term and saves a list of recent searches. Next to it there is a "Find All" button which starts a search in a user defined scope. In the output pane of studio a table containing all matches will open. Items can be double clicked to perform a jump to the result. Information about the file, the location of the match, plus some context information are also shown. Right of "Find All" there are the find previous occurrence and find next occurrence buttons located, labeled "<" and ">" respectively. These will find and highlight the next word matching the search criteria either before or after the current text cursor position.

The next row houses items related to the replace functionality. Most of these are deactivated for files that are opened in read-only mode (e.g. **.lst**). First comes the replace input field where users can input the

text which replaces the search term. "Replace All" replaces all matches *in the currently selected scope* after a pop-up is shown asking the user whether the replacement of **n** occurrences of **X** with **Y** is intended. In this pop-up the user can also decide to start a search instead, opening the results page showing all occurrences of the would-be replace action. The next button is "Replace" and works similarly to Find Next. On the very first click it selects the next match, without replacing anything. On the next click it replaces the current selection with the replacement term and jumps to the next match in the same file, selecting it. Users can use this to click through a file, replacing words while keeping an overview over what is actually changed. Both replacement actions can be undone by pressing either the undo button or hotkey **Ctrl** - **Z**. The button "Clear" on the far right clears all highlighted results and both text fields. A shortcut to clear all results is to press the **Esc** key in the [Code Editor](#).

The last row contains options to narrow down a search. "Whole Words" excludes partial hits from matches. For example, when searching for "in" with the option checked only the word "in" is found but no occurrences in "information". "Case Sensitivity" sets if the case of letters in the search term matters. Reminder: The GAMS language is case insensitive, so this option can actually lead to incomplete results, depending on for what it is used. "Use Regex" activates an advanced search term interpretation mode and stands for *Regular Expressions*. When activated, instead of a single search term users can specify a pattern that matches an array of different words. [Click here](#) for further information about regular expressions.

The "File Pattern" drop-down menu can be used to filter the files to be searched. Using a wildcard syntax patterns of filenames can be specified. The drop-down menu comes with a few default options for GAMS specific file types but can also be used to enter own patterns. Comma-separated lists of patterns are also supported. Right next to it is another, non-editable drop down menu which works like a simpler filter. The scope of the search can be set here with five options available:

- "This File" limits the search to the currently active file and is the default. File patterns are ignored for this option.
- "This Project" searches all files that belong to the same project as the currently opened file. This are all children of the same project in the [Project Explorer](#).
- "Selection" searches the text selected in the current file. The search dialog will give feedback if no selection is present. To remove the search selection press either **Esc** or the "Clear" button. Keep in mind that starting a new search moves the search selection to the currently selected text.
- "Open Tabs" searches all files currently opened in Studio (except GDX files).
- "All Files" searches all files that appear in the Project Explorer and are searchable.

Tooltips are available for most items in the search window and contain further information like keyboard shortcuts.

6.13.7.3.1 Workflow Tips

- Edit a file, hit **Ctrl** - **F** to open the search widget. The search field is focused automatically so you can start typing your search term. Pressing the **Enter** key is a shortcut for Find Next. Press **Enter** again or **F3** to step through all matches. Press **Shift** - **F3** to step backwards. Make changes to you document, press **Ctrl** - **F** again to re-focus the search widget without having to pick up the mouse.
 - Enter a search term, and then **Shift** - **Enter** to trigger "Find All". This will open a list of results.
 - The **Esc** key will close the search widget. Pressing **Esc** again will clear all highlighted search results.
 - Use project or file prefixes when working with projects with many files. Use search filters to only search relevant files.
-

6.13.7.4 Model Library Explorer

The Model Library Explorer is used to search the different **model libraries** provided by GAMS and to retrieve their models in a convenient way. It can be opened either by choosing *GAMS > Model Library Explorer* from the menu, by using the shortcut F6 or by clicking the corresponding icon in the [Quick Access Toolbar](#).

Every library is presented in a separate tab. The search facility in the upper part of the Model Library Explorer allows for dynamic filtering of all model libraries simultaneously using a wildcard syntax. As the search string is entered, the results are applied to the tabs representing the different libraries. If there are no more results on the selected model library tab, the first non-empty tab is automatically selected. This is undone as soon as the originally selected model library contains results again. The parenthesis enclosed numbers indicate the number of models found for the specific library and the current search input. For a more sophisticated search syntax select the **Regular Expression** checkbox next to the search input.

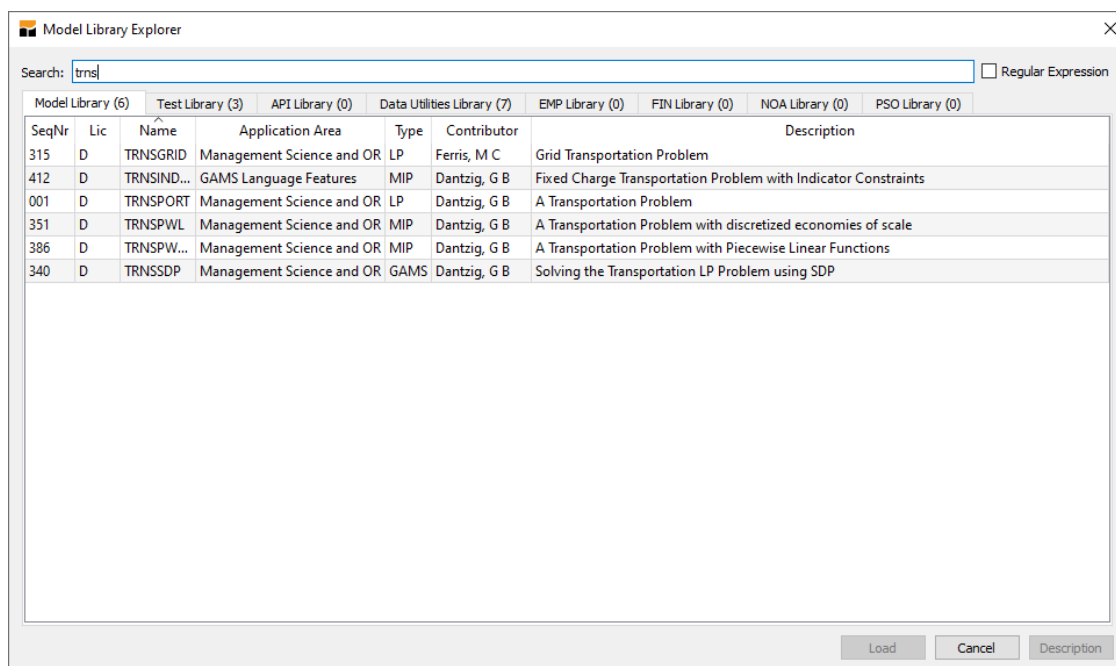

Figure 6.38 Searching for trns in the Model Library Explorer

Beside a short description, several models have a longer and more detailed description available. Selecting a model and clicking on the **Description** button in the lower right corner opens a pop-up dialog showing further information about the model. A model can be opened either by clicking on the **Load** button, by double clicking or by selecting the model and pressing the **Enter** key.

6.13.7.4.1 User Libraries Additionally to the model libraries distributed by GAMS, it is possible to access user defined model libraries by providing a GLB file along with the corresponding files belonging to the models in the library. The Model Library Explorer looks into a specific location for user defined model libraries. This location can be accessed or changed by opening the Settings dialog (**File > Settings**) and switching to the **Misc.** tab. The **Arrow** button will show the location where the Model Library Explorer tries to find user defined model libraries, the **Folder** button allows to change the location. Adding a new library is done by copying the required files into a subdirectory in this location. See [Creating a User Library](#) on how to create a custom model library. Newly added libraries require a restart of the Model Library Explorer to become visible.

6.13.7.5 Settings

The GAMS Studio settings dialog can be accessed via the *File > Settings* menu entry or with the hotkey F7. Users can change certain aspects of Studio like behavior or appearance. Settings are categorized loosely on five tab pages.

6.13.7.5.1 General page On the "General" tab users control general settings of Studio. Some additional hints:

- "Default GAMS Studio workspace". This path is used as a default location for models imported from the [Model Library Explorer](#).
- "Automatically save modified files before running GAMS" is an option that saves all modified files when the user starts a GAMS run. Thereby, previously unsaved changes will be incorporated into that GAMS execution without the need to go through all files and make sure that changes were saved manually.
- "Open .lst file after running GAMS" automatically puts the generated lst file into the foreground after each GAMS run.
- "Jump to first compilation error" is an automatism that aims to make working with Studio a little easier. When compilation errors occur, the editor and the log both jump to the first error detected if this option is activated. This also applies when the option *Open .lst file after running GAMS* is activated. Studio then opens the lst file generated and jumps to the first error in it. If you navigate back to the gms file, the view has also moved to the first error found.
- "Open file in current project by default" switches the menu *File > Open (Ctrl-O)* to always open a file in the current project, even if it exists in another project. The alternative open (*Ctrl-Shift-O*) is changed to *File > Open in new project...*
- "Open file finds or creates new project" switches the menu *File > Open (Ctrl-O)* to find the file in any project and open it. If not found, a new project is created. The alternative open (*Ctrl-Shift-O*) is changed to *File > Open in current project...*
- At the bottom of this tab there is a section to backup all settings. When pressing the **Export** button a dialog pops up, asking for a filename. This name can be chosen freely and the file can then be copied to a USB stick for sharing, or just be saved for later. This is handy if you are planning a fresh install or want to copy your personal settings to a different machine. The button **Import** is used to load a saved settings file. These settings are applied immediately and the settings dialog will be closed automatically.

6.13.7.5.2 Editor & Log page The "Editor & Log" tab contains many self explanatory appearance options. Most notably font settings which are shared between editor and log.

- "Enable auto-indentation" activates smart line break behavior. When pressing the **Enter** key a line break is inserted and the indentation of the line of origin is copied instead of moving the cursor to the first column.
 - "Highlight word under cursor without selection" changes the highlighting behavior of word occurrences. While the default behavior highlights other occurrences of the same word when double clicking or selecting a word, activating this option changes the behavior so that every time there is a word under the text cursor, all of its occurrences will be highlighted. Only full words and no partial matches are highlighted.
 - "Tab stop size" lets the user decide how many tabs will be inserted when pressing the Tab-key. GAMS Studio always replaces inserted tabs with spaces.
-

- "Fold DCO blocks on open" folds all foldable blocks of the types "Text", "Echo", "Put", and "Fold"
- "Clear process log before GAMS execution" empties the log before running a gms file. If deactivated old log output is kept but colored in a lighter gray so users are still able to identify that they are looking at an old run instead of the most current one. One can also decide if the log should be written to disk as well and if so, how many old versions of the same log should be kept on disk as backup. Note, that in addition to this log file written by Studio, one can instruct GAMS itself to write a log file using the GAMS parameter `logOption`, which could cause a file naming clash.

6.13.7.5.3 Colors page The "Colors" tab enables you to configure several colors. Studio provides two fixed themes: the "dark" theme and the "light" theme. Depending on the your operating system, this can be selected by the system and/or manually. You can use this to set Studio to use a darker color palette for when you like to work in the dark and don't like to get blinded by bright windows.

```

1 title A Transportation Problem (TRANSPORT,SEQ=1)
2
3 SonText (... text)
20
21 Set
22 i 'canning plants' / seattle, san-diego /
23 j 'markets' / new-york, chicago, topeka /;
24
25 Parameter
26 a(i) 'capacity of plant i in cases'
27 / seattle 350
28 san-diego 600 /;
29
30 b(j) 'demand at market j in cases'
31 / new-york 325
32 chicago 300
33 topeka 275 /;
34
35 Table d(i,j) 'distance in thousands of miles'

39
40 Scalar f 'freight in dollars per case per thousand miles' / 90 /;
41
42 Parameter c(i,j) 'transport cost in thousands of dollars per case';
43 c(i,j) = f*d(i,j)/1000;
44
45 Variable
46 x(i,j) 'shipment quantities in cases'
47 z 'total transportation costs in thousands of dollars';

```

Figure 6.39 Studio using a dark theme

The fixed themes can't be modified, modifying a value implicitly creates a copy of the theme where the changed value is applied. After copying a theme, the new user theme can be adapted to your needs. Additionally these user themes can be exported and imported to a file each.

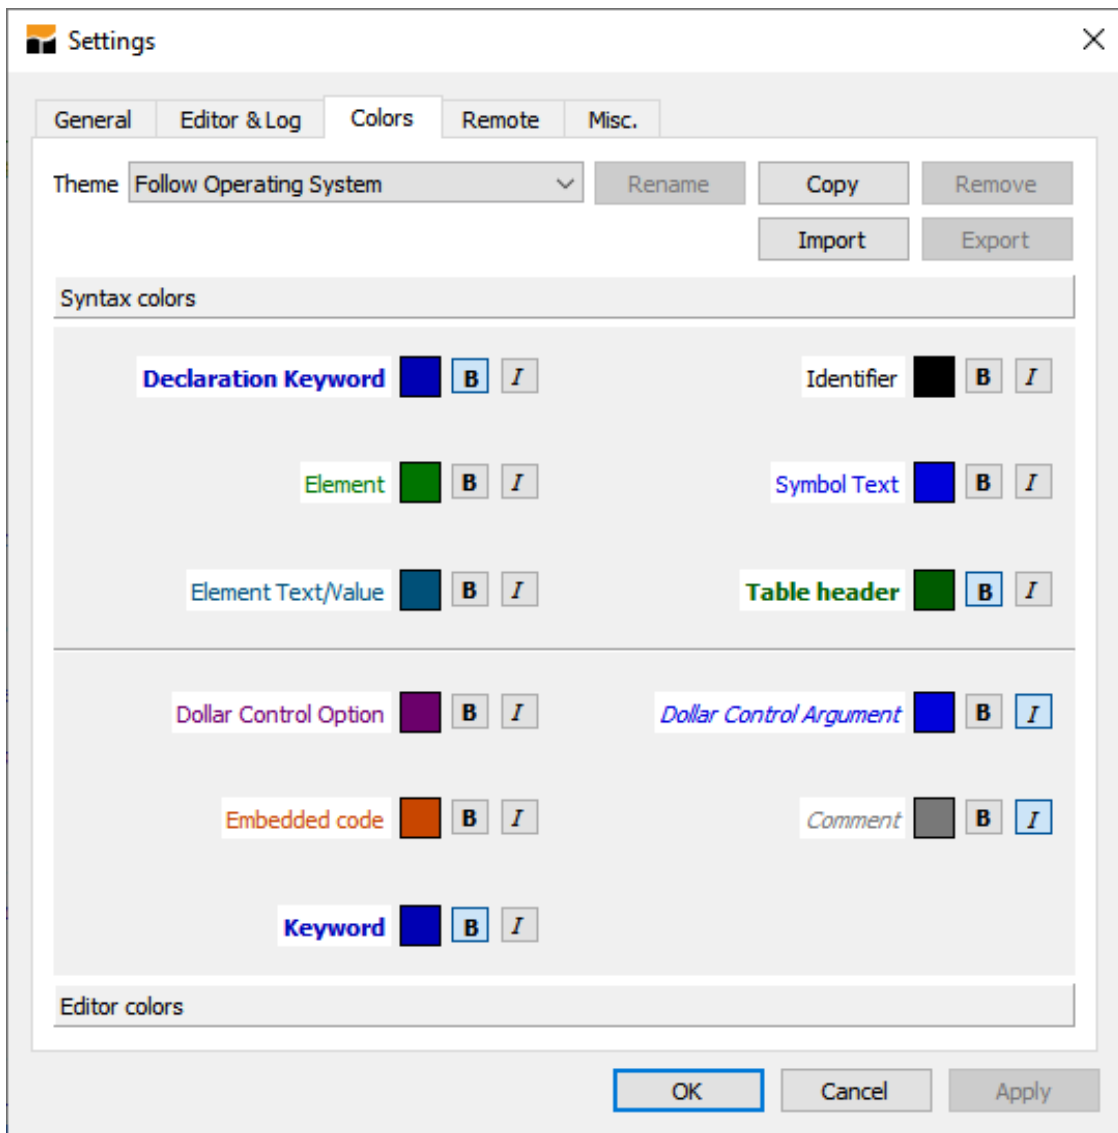

Figure 6.40 Color Settings

The colors are listed in two sections:

- On the "Syntax colors" page you can define a *text color* and the attributes *bold* and *italic*.
- The "Editor colors" page allows to change the colors of *text*, *background*, and *second background* (for blinking). The very first entry on this page, the "Default Text", is the base of the syntax colors.

6.13.7.5.4 Remote page The "Remote" tab is used to set various remote settings.

- In the MIRO section the location of your local MIRO installation can be defined.
- The checkbox "Always agree to NEOS" allows to hide the "Terms Of Use" in the submission dialog of NEOS.
- In the GAMS Engine section it can be defined if a login token should be stored to the settings to stay logged in on restarting Studio. The next line allows to define how long the login is valid.
- If the dialog has been switched invisible by clicking "OK, don't ask", the button "Reactivate dialog" switches it on again.

6.13.7.5.5 Misc page The "Misc" tab contains some lesser common settings.

- "GAMS source file extensions" allows to add own file extensions that **Studio** counts as *runnable GAMS*. File types added here can be executed, set as main file, and are assigned to the [GAMS Syntax Highlighter](#). The field accepts a comma separated list of file extensions.
- "Auto-reload extensions" Specific extensions that should be *reloaded automatically* can be added here. Files of that type are reloaded into the editor if changed externally. If they also were changed internally, a dialog asks how to proceed. The field expects a comma separated list of file extensions.
- "User model library" shows the folder that is used to find user generated model libraries, see [User Libraries](#). This folder can be changed to a custom location. Up to 10 locations are stored in the history. To remove the current entry from the history use the trash-bin button. The arrow-button opens the file browser in the current folder.
- "Reset History" clears the list of last files used on the [Welcome Page](#)
- "Reset Window" resets the appearance of Studio if something went wrong.
- The next group contains a list of options for the [Solver Option Editor](#).

6.13.7.6 Delete scratch directories

GAMS creates working folders for running processes in your working directory. Normally these are automatically removed when a run finishes. However, if a run was interrupted sometimes these working directories remain. That in itself is not a problem as GAMS will pick a new name for the next run if the default name for the working directory is already taken. To automatically clean up the user workspace, Studio offers an action to do this. In the menu under **GAMS > Delete scratch directories** the user has the possibility to remove unwanted, autogenerated directories. Before deleting anything, there will be a popup asking the user for confirmation and also showing the path of the directory that will be cleaned. If the user choses "Yes", all directories that start with 225 followed by one or two letters will be deleted in the given path, which is usually the default workspace. This action is automatically triggered when GAMS has exhausted the pool of possible scratch directory names, but not without asking the user for confirmation first. To avoid any potential errors this action should only be triggered if there are no running GAMS jobs at the moment.

6.13.7.7 Full Screen & Distraction Free Mode

Especially small devices suffer from sparse screen real estate. Studio comes with a few features to make the most of the space that is available on your machine.

The Full Screen mode is activated by pressing **Alt-Enter** on Windows and Linux systems, while on macOS the shortcut is **Command-Control-F**. This enlarges Studio over the whole screen, covering the taskbar and other operating system specific items. The same shortcuts also exit Full Screen mode.

As an alternative, there is also the Distraction Free mode. Some users want to keep their taskbar so with the shortcuts **Ctrl-Alt-Enter** on Windows and Linux or **Cmd-Option-Enter** on macOS hide all Studio widgets and enlarge the central widget to the size of the studio window. You can use this to get the log-, file- and help view out of the way and concentrate writing. Pressing the shortcut again brings everything back. Running your GAMS modell in the Distraction Free mode will also open the log, so you are not missing out on anything.

Action	Shortcut	macOS
Enter/Exit Full Screen	Alt - Enter	Command - Control - F
Enter/Exit Distraction Free Mode	Ctrl - Alt - Enter	Command - Option - Enter

6.13.7.8 GDX Diff

The GDX Diff dialog serves as a graphical interface to the command line tool [GDXDIFF](#). It compares the data of two GDX files and writes the differences to a third GDX file. The dialog can be opened by choosing **Tools > GDX Diff** from the menu.

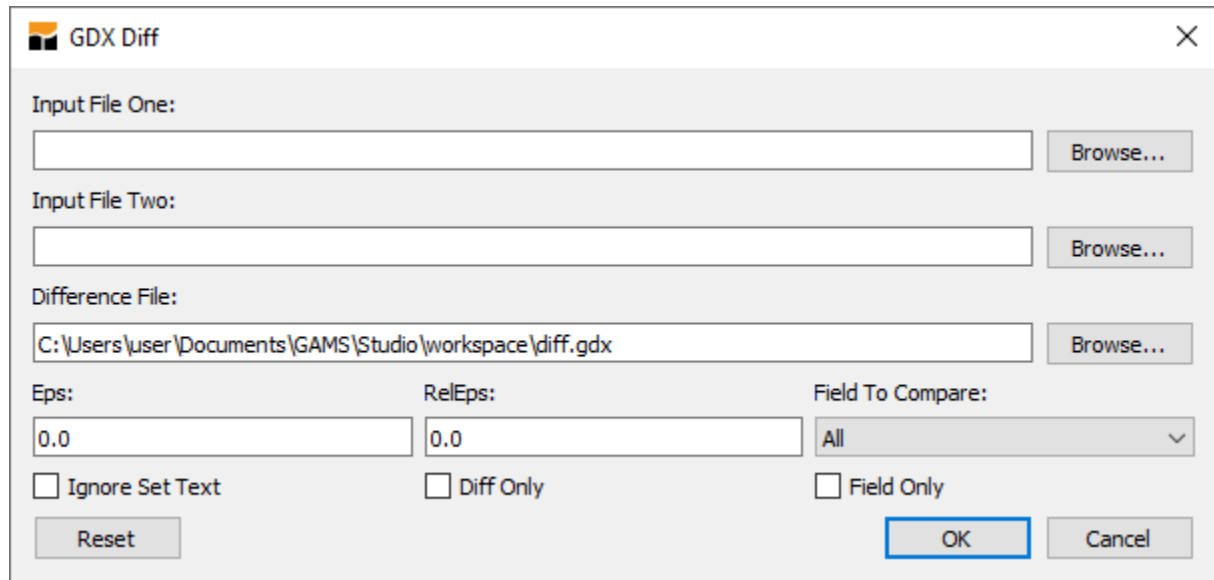

Figure 6.41 GDX Diff dialog

The dialog consists of two parts. The upper part is used to specify the two GDX files for the comparison. The resulting GDX difference file is determined automatically as long as no manual changes have been applied. The default schema for the resulting GDX difference file is the location of the first input GDX file and the file name `diff.gdx`. The difference file will be updated whenever the first input is modified to an existing file. If the GDX Diff dialog gets opened and does not contain a valid first input file, the most recently used directory is used as the location for the resulting difference file instead.

The lower part of the dialog contains different options that can be used in order to control the behavior of the comparison:

- **Eps:** Absolute difference for comparisons. If the difference between two values exceeds Eps, a difference will be reported. Default is 0.0.
- **RelEps:** Relative difference for comparisons. If the value of RelEps is exceeded, a difference will be reported. Default is 0.0.
- **Field To Compare:** The specified subfield is the only field used for deciding if a variable or equation is different. List of possible values:
 - **All:** All fields
 - **L:** Level
 - **M:** Marginal
 - **Lo:** Lower Bound
 - **Up:** Upper Bound
 - **Prior**
 - **Scale**

- **Ignore Set Text:** Allows to ignore explanatory text of set elements.
- **Diff Only:** Differences for variables and equations will be written as parameters. Each parameter will have an additional index which is used to store the field name. Only fields that are different will be written. This option can not be used in combination with **Field Only**.
- **Field Only:** Used in combination with **Field To Compare**. The variables and equations will be written as parameters for the selected subfield. This option can not be used in combination with **Diff Only** and it requires a value for **Field To Compare** other than **All**.

As soon as the OK button is clicked, a validation check on the given input is performed and the two input files are compared. If the specified difference file is already open in a [GDX Viewer](#), the corresponding tab remains open while the underlying GDX file is detached. As soon as the file was updated, the GDX Viewer is reinitialized. In case the GDX file was not open already it gets opened in a new tab. The **Cancel** button closes the dialog and stops a process that has not been finished yet. The dialog needs to be kept open for longer running comparisons of large input files. The **Reset** button can be used to reset the whole dialog to its default state which also enables the automatic pre-population of the difference file path in case it has been disabled before due to a manual change.

The GDX Diff dialog also has an integration in the context menu of the [Project Explorer](#). As soon as either exactly one or two GDX files are selected, the context menu contains an entry for opening the GDX Diff dialog with the file(s). If only one file is selected, the input field that is empty is populated with the corresponding file path. If both fields are filled, the first input file path gets overwritten. In case of two selected GDX files, both input fields get overwritten.

6.13.8 Terminal

GAMS Studio is able to open a native terminal via the main menu **Tools > Terminal** or the shortcut **CTRL - T**. Alternatively, a terminal can be opened by right clicking on any entry of the "Project Explorer" and selecting **Open terminal**. The terminal points to the workspace of the current project. On macOS the terminal location is always the user's home directory.

6.13.9 Command Line Options

GAMS Studio can be started with additional command line options that change the behavior or trigger certain functionality at start up time. The syntax for starting GAMS Studio from the command line is

```
studio [options] [files]
```

While **files** is one or more files to be opened by GAMS Studio, the following **options** can be supplied:

- **-, -h, --help** : Displays the help.
 - **-v, --version** : Displays version information.
 - **--ignore-settings** : Ignore settings files. Studio will load with default settings without writing them.
 - **--reset-settings** : Reset all settings to default. Studio will load with default settings and save them.
 - **--reset-view** : Reset studio visually without resetting settings. Useful when a widget got lost or studio started on a disconnected monitor.
 - **--gams-dir path_to_gams** : Point Studio to a specific GAMS installation.
-

6.13.10 General Shortcuts

This section lists any shortcuts that are global to Studio. Shortcuts for more specific areas are mentioned in their corresponding section.

6.13.10.1 Studio Workflow Shortcuts

Shortcut	macOS	Description
Ctrl - 1	Command - 1	Set focus to the project explorer. After that the arrow keys can be used for file navigation.
Ctrl - 2	Command - 2	Set focus to main editor.
Ctrl - 3	Command - 3	Set focus to the command line option input field.
Ctrl - 4	Command - 4	Opens the tab browser which has a list of all open tabs. Focus is on an input field that can be used to filter tabs. Pressing Return opens the highlighted file.
Ctrl - 5	Command - 5	Set focus to log widget.
Shift - Ctrl - 3	Control - Option - 3	Opens and closes extended command line option editor.
Ctrl - Tab		Toggles through the open tabs of the central widget from left to right.
Ctrl - Shift - TAB		Toggles through the open tabs of the central widget from right to left.
Alt - Return	Command - Control - F	Full Screen
Ctrl - Shift - T	Command - Shift - T	Restore recently closed tab
Ctrl - Shift - W	Command - Shift - W	Close all tabs
Ctrl - W	Command - W	Close current tab. Alternatively, a tab can be closed by clicking the middle mouse button.
Ctrl - Q	Command - Q	Close GAMS Studio

6.13.10.2 Studio Dialogs

Shortcut	macOS	Description
F1	F1	Open the GAMS Help . If the word under the cursor is a GAMS keyword a search in the documentation document will be started
F6	F6	Open GAMS Model Library Explorer
F7	Command - ,	Open Studio Settings
Ctrl - F	Command - F	Open search and replace widget
Ctrl - G	Command - G	Goto specific line number
Ctrl - N	Command - N	Open new file dialog
Ctrl - O	Command - O	Open file open dialog
Ctrl - Shift - O	Command - Shift - O	Open file dialog to open the file(s) in the current (a new) project
Ctrl - P	Command - P	Open print dialog
Ctrl - S	Command - S	Save the current file. If the file does not exist on disk open the save file dialog
Ctrl - Alt - S	Command - Option - S	Open save as dialog
Ctrl - Shift - S	Command - Shift - S	Save all open files. Open save file dialog if needed

Shortcut	macOS	Description
Ctrl - T	Command - T	Open a terminal for the current project location. On macOS the terminal points to the users home directory

6.13.10.3 Studio Recovery

Shortcut	macOS	Description
Ctrl - F2	Command - F2	Reset Studio to default visual settings (window position and -size, widget position and -visibility) Useful when a widget got lost or studio started on a disconnected monitor.

6.13.11 System Requirements

Compared to most of the GAMS system, GAMS Studio has some additional system requirements, which depend on the platform used. Also, additional information about technical requirements are listed at the [GAMS Studio GitHub Wiki](#).

6.13.11.1 Linux

The Linux version of GAMS Studio is distributed as [AppImage](#) and requires glibc 2.27 as well as [FUSE](#) to be installed.

The GAMS Studio AppImage was tested and it was verified that it worked for the following Linux distributions (which are all under maintenance). All Linux distributions are under constant development and updates may change the behavior of the AppImage. Please check the [Studio issue page](#) if you encounter any issue.

- Arch
- CentOS 8
- Debian 10
- Debian 11
- Fedora 35
- openSUSE Leap 15.3
- openSUSE Tumbleweed
- Ubuntu 18.04 LTS
- Ubuntu 20.04 LTS

Other flavors might work as well, but were not tested. If you experience problems with a particular Linux distribution, please let us know.

6.13.11.2 macOS

macOS has some special platform requirements related to finding GAMS. Below the steps are listed which are used to link GAMS Studio to GAMS.

- GAMS Studio is going to find GAMS in `/Applications/**` and `/Users/username/Applications/**` if it is part of a GAMS folder. It is required that GAMS Studio gets copied via **Finder** to its target location. This is the case if the GAMS installer is used or if the GAMS Studio DMG is open and GAMS Studio gets copied from there.
- If GAMS Studio could not find GAMS like described previously then it will search `/Applications/**` for a valid GAMS installation, i.e. a GAMS installation which has the minimum required GAMS version or higher.
- GAMS Studio will check the `$PATH` to find GAMS. In almost all cases this will not work on macOS.
- In case of special needs the path to GAMS can be set explicitly by starting GAMS Studio with the command line argument `--gams-dir`.

6.13.11.3 Windows

There are dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio, please run the appropriate installer for these libraries called `vc redistrib_x64.exe`, which can be found in the GAMS installation folder at `[GAMS system]\studio`.

6.13.12 Comparing GAMS Studio and GAMSIDE

As mentioned [above](#), the classic **GAMS IDE** has been shipped with the GAMS system for many years and is still the workhorse for many GAMS programmers. So it is still around and an alternative to GAMS Studio, especially since it has features, which are not available in GAMS Studio (yet), but it also lacks some features which are available in GAMS Studio. The following table gives a compact overview about most of the differences.

GAMSIDE only	GAMS Studio only
Supported Platforms	
- Windows	- Windows
	- Linux
	- Mac OS
GDX Viewer	
- Creating charts	- Filtering (both, symbols and data, labels and values)
- Writing to Html/Excel	- Sorting by numerical value
- Heat-map functionality (aka Data Colors)	- Option to change display format of numerical values
Editor	
- Fixed encoding (ISO 8859-1)	- Allow change of encodings and use UTF-8 by default
- Spell checker	- Block edit
- Open same file in different buffers	- Help integration (pressing F1 on a keyword opens the relevant index page of the documentation)
- Recognize URLs and open them in the browser	- Tooltips for compilation errors

GAMSIDE only	GAMS Studio only
- Different set of keyboard shortcuts	- Navigation history
	- Code Completion
	- "Smart typing": Automatic insertion of closing character for brackets and quotes
	- Distraction Free Mode
	- Code Folding
	- Open <code>\$(bat/lib)include</code> files directly from editor
Execution	
- IDE Projects	- Studio Projects (see below for details)
- Set default options for the IDE only	- Interactive editor for the GAMS User Configuration
- Use different GAMS versions	- Interactive editor of GAMS command line parameters
- Use alternative license	- Option to jump to first error automatically
- Execute program based on extension	- Option to run with GDX creation automatically (F10 vs. F9)
- Solver selection menus	- Integration of GAMS MIRO
	- Option to not write log to disk
	- Remote execution on NEOS Server for Optimization
	- Remote execution with GAMS Engine
Other	
- Text Diff	- Welcome page
- Script recording	- Project Explorer
- Find in Files (in given folders; independent of open files in the IDE)	- Reference File Viewer allows to jump to all references etc. and not just the first one
- Email file	- Filtering in Model Library Explorer (all model libraries at the same time)
- Save test files in UNIX format	
- Link to McCarl chm	- Allow to switch between light, dark or custom themes
- 32-bit application	- 64-bit application

6.13.12.1 GAMSIDE Projects vs. GAMS Studio Projects

With the GAMSIDE one always started with creating a "Project". This mainly defined a directory used to execute the models added to it (so, it is used to implicitly define the [workDir](#) when starting GAMS). When starting the IDE for the first time, one is asked to create a new project. For example, one creates this in directory **a**. After adding models **a/a.gms** and **b/b.gms** both get executed in the project directory **a**, meaning that data sources are expected in **a** (or relative to it) and also output files are generated in **a**, and not necessarily at the location of the **gms** file.

When starting GAMS Studio for the first time, it starts with an empty [Project Explorer](#). Opening a new file creates a new Project per default. Studio Projects do not know about a specific folder (meaning, in contrast to the GAMSIDE, Studio does **not** set the [workDir](#) implicitly). If a model gets executed, it gets executed at its location. So, if ones opens **a/a.gms** and **b/b.gms**, by default, Studio will create two projects: **a** and **b**. When **a** is started input files are expected in directory **a** and output files get generated in **a**. When **b** is started input files are expected in directory **b** and output files get generated in **b**. If one has structured the models so that they rely on the "GAMSIDE way" to execute a model, one can just set [workDir](#) explicitly when starting the model.

It is also possible to have multiple files in one project. For example, one could add `b.gms` to project `a` by drag'n'drop in the Project Explorer. Now, the concept of the "main file" of projects becomes important: While the GAMSIDE always executed the currently active `.gms` file, GAMS Studio always executes the main file of the currently active project. So, in our example, you can look at `a.lst` and press F9 to rerun `a.gms` (the GAMSIDE would not run anything in this case). After adding `b.gms` to project `a`, one would also execute `a.gms` by pressing F9 while looking at `b.gms`. If you want to execute `b.gms` instead, you can make it the main file of the project. For this, right-click in the Project Explorer at `b.gms` and select "Set as main file". Note that the green arrow indicating the main file of a project in the Project Explorer switches from `a.gms` to `b.gms`. As a reminder: Projects do not know a particular working directory. Pressing F9 after switching the main file will execute `b.gms` in folder `b`.

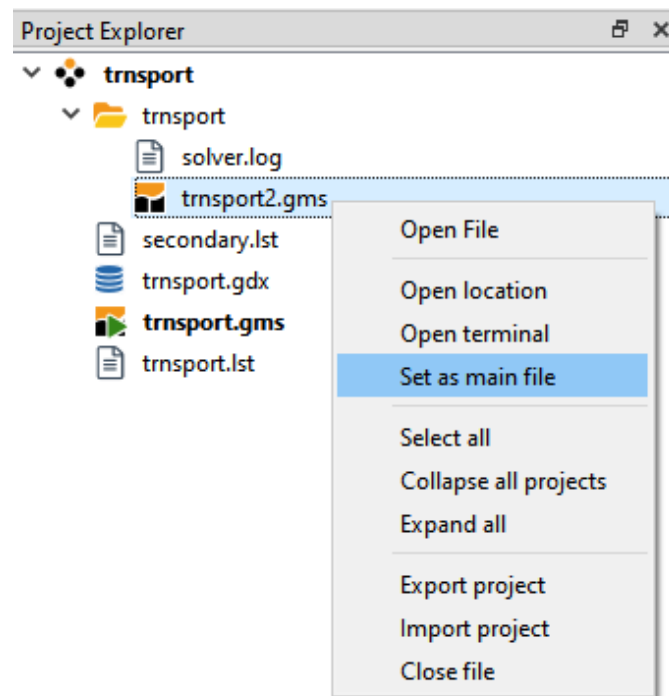

Figure 6.42 Switching the main file

6.14 GDX2ACCESS

6.14.1 Overview

GDX2ACCESS is a tool to dump the contents of a GDX file to an MS Access file (MDB or ACCDB format). Every identifier gets its own table in the database.

6.14.2 Usage

```
gdx2access inputFile {options}
```

The `.gdx` file extension of the `inputFile` can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

6.14.3 Options

Options are specified in an **INI** file and not directly on the command line. By default, the file `gdx2access.ini` located in the same directory as `gdx2access.exe` is consulted. If this file is not available, the program will continue using default settings (listed in the tables below).

It is also possible to tell the program to use a different INI file. This is done by using an extra argument of the form `@iniFile`. If you want to dump the contents of `myFile.gdx` to an MS Access file according to the options specified in a file called `myIniFile.ini`, run the following code:

```
gdx2access myFile.gdx @myIniFile.ini
```

In this case, the program will not read `gdx2access.ini` located in the same directory as `gdx2access.exe`, but rather `myIniFile.ini` in the current directory.

The INI file can contain two sections: `[settings]` and `[debug]`. A complete INI file with all possible settings looks like:

```
[settings]
smdir=c:\tmp
inf=1.0e100
mininf=-1.0e100
eps=0.0
na=0.0
undf=0.0
scalarTable=1
etFlag=1
dbVersion=9
[debug]
method=5
thresholdCount=5
keepFiles=1
```

Note that the values above are not the default values for some options!

Section `[settings]`

Below some short descriptions for the options in the `[settings]` section:

Option	Default	Description
<code>smdir</code>	<code><windowstemp></code>	Directory for temporary scratch files.
<code>inf</code>	<code>1.0e100</code>	The value used for GAMS special value <code>+INF</code> . See also the example Special value mapping .
<code>mininf</code>	<code>-1.0e100</code>	The value used for GAMS special value <code>-INF</code> . See also the example Special value mapping .
<code>eps</code>	<code>0.0</code>	The value used for GAMS special value <code>EPS</code> . See also the example Special value mapping .
<code>na</code>	<code>0.0</code>	The value used for GAMS special value <code>NA</code> . See also the example Special value mapping .
<code>undf</code>	<code>0.0</code>	The value used for GAMS special value <code>UNDEF</code> . See also the example Special value mapping .

Option	Default	Description
scalarTable	0	Possible values: 0 or 1. When set to 1, scalars of the same type are combined in a single table. The names for these tables are fixed: <code>ScalarParameter</code> , <code>ScalarEquation</code> and <code>ScalarVariable</code> . See also the example Special value mapping .
etFlag	0	Possible values: 0 or 1. When set to 1, include the text strings for sets containing element texts. See also the example Writing Explanatory Text to Database .
dbVersion	0	Specify the format of the output database. See also the example Writing Explanatory Text to Database . 0: Create database using current default format. 9: Create a database in the Microsoft Access 2000 (.mdb) file format. 10: Create a database in the Microsoft Access 2002-2003 (.mdb) file format. 12: Create a database in the Microsoft Office Access 2007 (.accdb) file format.

Section [debug]

Below some short descriptions for the options in the [debug] section:

Option	Default	Description
method	5	Select an algorithm to insert data into the Access database. 1: Write a CSV file and use the TransferText action to read this into Access. This is fast, but does not always work when non-US language settings are used. 2: Use recordset.add to add records. This is slow, but does not use intermediate files. 3: Write a tab delimited file with a complete file specification (schema.ini) and use the ISAM Text driver to import the data. This is fast and should work in international settings. 4: For small data use method=2 and for larger data items use method=1. 5: For small data use method=2 and for larger data items use method=3.
thresholdCount	5	When to change between algorithms while using method=4 or method=5. The default is 5 records.
keepFiles	0	Possible values: 0 or 1. When set to 1, the program will not delete intermediate scratch files.

6.14.4 Examples

6.14.4.1 Intro

Suppose we want to write the data of the `[transport]` model from the GAMS model library after solving to an MS Access data file. First of all, we solve the model by running the following command. Note that we will save the complete symbol table to a GDX file called `transport.gdx` by adding the command line option `gdx=transport`.

```
gams trnsport.gdx=trnsport lo=2
```

The option `lo=2` causes GAMS to save the log to an external file (in this case `trnsport.log`), instead of writing it to the screen. In order to get an idea about the data at this point, we use the [GDXDUMP](#) tool to display the contents of the GDX file by running the following command:

```
gdxdump trnsport.gdx symbols
```

By adding the `GDXDUMP` option `symbols`, we will only display the table of contents (shown below) rather than all data stored in `trnsport.gdx`.

```
* GDX dump of trnsport.gdx
* Library in use : C:\GAMS23.3
* Library version: GDX Library      Nov  1, 2009 23.3.3 WIN 14596.15043 VIS x86/MS Windows
* File version   : GDX Library      Nov  1, 2009 23.3.3 WIN 14596.15043 VIS x86/MS Windows
* Producer      : GAMS Base Module Nov  1, 2009 23.3.3 WIN 14929.15043 VIS x86/MS Windows
* File format   :      7
* Compression   :      0
* Symbols       :     12
* Unique Elements:      5
  Symbol Dim Type Explanatory text
  1 a          1 Par capacity of plant i in cases
  2 b          1 Par demand at market j in cases
  3 c          2 Par transport cost in thousands of dollars per case
  4 cost       0 Equ define objective function
  5 d          2 Par distance in thousands of miles
  6 demand     1 Equ satisfy demand at market j
  7 f          0 Par freight in dollars per case per thousand miles
  8 i          1 Set canning plants
  9 j          1 Set markets
 10 supply     1 Equ observe supply limit at plant i
 11 x          2 Var shipment quantities in cases
 12 z          0 Var total transportation costs in thousands of dollars
```

Once we have a GDX file, we can use `GDX2ACCESS` to create a MDB or an ACCDB file. Versions of Microsoft Office prior to version 2007 use the file extension `.mdb`, while version 2007 and later versions use the file extension `.accdb`. We write all the data stored in the GDX file `trnsport.gdx` to `trnsport.mdb` resp. `trnsport.accdb` by running the following code:

```
gdx2access trnsport.gdx
```

Note that we do not referenced an INI file in the previous command in order to specify the options, i.e. `GDX2ACCESS` will consult the file `gdx2access.ini` located in the same directory as `gdx2access.exe` or, if the file does not exist, the tool will continue using the default settings (see [Options](#)). The information written to the log is shown below, including the identifiers of the symbols which are written to `trnsport.accdb` and the elapsed time per symbol and in total.

```
GDX Access      ALFA 23Mar10 23.4.0 WIN 16693.16738 VS8 x86/MS Windows
Creating C:\GAMS support\settext\temp1.accdb with Access: 0.48 seconds
Using temp directory C:\Users\Paul\AppData\Local\Temp\
  i.  Insert:  0.00 seconds
  j.  Insert:  0.00 seconds
  a.  Insert:  0.00 seconds
```

```

    b.   Insert:  0.00 seconds
    d.   Dump:   0.00 seconds  Load:  0.05 seconds
    f.   Insert:  0.00 seconds
    c.   Dump:   0.00 seconds  Load:  0.05 seconds
    x.   Dump:   0.00 seconds  Load:  0.03 seconds
    z.   Insert:  0.00 seconds
    cost. Insert:  0.00 seconds
    supply. Insert: 0.02 seconds
    demand. Insert: 0.02 seconds
Renaming C:\GAMS support\settext\temp1.accdb -> trnsport.accdb
Total elapsed time: 0.92 seconds

```

The resulting ACCBD, opened with MS Access, is shown in [Figure 1](#) (limited to the parameter `c` on the left and the variable `x` on the right).

As can be seen, every identifier is stored in its own table. For parameters like `c`, the value is stored in a column named `value`, while variables like `x` and equations have the columns `level`, `marginal`, `lowerbound` and `upperbound`. A possible additional field (scale for NLP's, priority for MIP's, stage for stochastic problems) is not exported. If needed, you can assign such a quantity to a parameter in GAMS before writing the GDX file. The complete process shown here can be automated as demonstrated in [Example 1](#).

If no domain information is available for a symbol (like `B` in the code below), each index position gets a column and will be labeled automatically with `dim1`, `dim2`, etc. If domain information is available, the columns will use that information but keeping the names unique (like `A` in the code below). The small example below shows how the index positions are made unique using the (relaxed) domain information by adding an ascending number to the identifier.

```

Set i / i1*i5 /;
Alias (i,j,k);

Parameter A(i,i,i) 'domain informations, but the column name would not be unique';
A(i,j,k) = uniform(0,1);

Parameter B 'no domain information' / i1.i1 1, i1.i2 2, i2.i1 3, i2.i2 4 /;

execute_unload 'AB.gdx', A, B;
execute '=gdx2access AB.gdx';

```

The resulting database file, opened with MicroSoft Access, is shown in [Figure 2](#) (parameter `A` on the left, parameter `B` on the right).

6.14.4.2 Example 1 - Dumping the Contents of `trnsport.gdx`

This example will solve the `[trnsport]` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Access and MS Access is launched to inspect the results. This is a small example that should run very quickly.

```

execute '=gamslib trnsport';
execute '=gams trnsport lo=3 gdx=trnsport';
execute '=gdx2access trnsport.gdx';
$libInclude win32 shellExecute trnsport.accdb

```

Note: the equal signs in front of the external programs indicate we don't go through a shell (e.g. command.com or cmd.exe). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the '=', such errors go undetected and the GAMS model will continue.

The command `$libInclude win32 shellExecute trnsport.accdb` will launch Access to view the AC-CDB file. This assumes that the version of Access installed is a version as recent as version 2007. Earlier versions will generate a database with the extension .mdb and the shellExecute command needs to be changed as follows:

```
* view generated file create
$libInclude win32 shellExecute trnsport.mdb
```

The complete example is also part of the GAMS Data Utilities Library, see model [[GDX2ACCESSExample1](#)] for reference.

6.14.4.3 Example 2 - Writing Explanatory Text to Database

In this example, we write a few sets to a GDX file; two of the sets written have explanatory text for set elements. We use the option `etFlag` to get this text saved in the Access database file along with the corresponding set elements. Without using the option, only the set tuples are saved in the database.

Running this example on a machine with Access 2007 or a later version installed will create a database with the .accdb file extension that cannot be read by an older version of Access. We use the `dbVersion` option to save the database in the MDB format. Both options must be specified in an user defined INI file within the settings section, see `howToWrite.ini` in the code below.

```
Set
  i      / i1 'one', i2 'two', i3 'three', i4 'four' /
  j      / j1*j4 /
  ij(i,j) / i1.j1 'red', i2.(j2,j3) 'green', i3.(j1,j2) 'blue' /;

$gdxOut example2.gdx
$unload i j ij
$gdxOut

$onEcho > howToWrite.ini
[settings]
etFlag=1
dbVersion=10
$offEcho

$call =gdx2access example2.gdx @howToWrite.ini%
```

When we open the database and inspect the table created from the set `ij`, we see the explanatory texts stored along with the corresponding set elements. The column containing the explanatory text will be labeled with `SetText` automatically. The column headers can be renamed as demonstrated in [Example 5 - Renaming Fields](#).

The complete example is also part of the GAMS Data Utilities Library, see model [[GDX2ACCESSExample2](#)] for reference.

6.14.4.4 Example 3 - Dumping a large Table to Database

This is an artificial example where we generate a large identifier in GAMS: a parameter with a million elements. This parameter will be dumped to an MS Access Database afterwards. Note that the GDX2ACCESS execution will last several seconds. The resulting database file has approximately 36MB of size.

```
Set i / i1*i1000 /;
Alias (i,j);
Parameter p(i,j);
p(i,j) = uniform(-100,100);
execute_unload 'example3.gdx', p;
execute '=gdx2access example3.gdx';
```

The complete example is also part of the GAMS Data Utilities Library, see model [[GDX2ACCESSExample3](#)] for reference.

6.14.4.5 Example 4 - Special Value Mapping

To store special values like +INF, -INF, EPS, NA and UNDF in a numeric field in the database, GDX2ACCESS uses a mapping. This mapping can be changed by using an INI file (for the default values, see [Options](#) resp. the comments in the second code below). We will define a scalar for each special value in GAMS in order to demonstrate the [scalarTable](#) option in addition. By default, every scalar will be written to a new table. By activating the [scalarTable](#) option in the INI file, all scalars will be stored together in a single table.

```
$onEcho > howToWrite.ini
[settings]
inf=1
mininf=2
eps=3
na=4
undf=5
scalarTable=1
$offEcho
```

The usage of our previously customized INI file howToWrite.ini is indicated by the argument @howToWrite.ini within the execute statement.

```
$onUndf
Scalar
  pInf      / inf /
  mInf      / -inf /
  epsilon   / eps /
  notAvail  / na /
  undefined / undf /;
```

```
* save scalars in scalars.mdb in a single table named ScalarParameter using
* the scalarTable option
* special values are translated to default values:
* INF -> 1.0e100
* -INF -> -1.0e100
* EPS,NA,UNDF -> 0
```

```
execute_unload 'scalars.gdx', pInf, mInf, epsilon, notAvail, undefined;
execute 'gdx2access scalars.gdx @howToWrite.ini';
```

Note the \$onUndf command in order to enter Undf values directly within the definition of the scalars. When we view the generated GDX file in the GAMS IDE or GAMS Studio, the special values are shown (note that the figure shows a parameter actually instead of five single scalars for a more compact presentation):

Viewing the resulting table in Access shows how the mapping for special values was applied (i.e. the GAMS special values have been substituted by our customized values defined in the INI file):

Note that the table will be named `ScalarParameter` automatically.

The complete example is also part of the GAMS Data Utilities Library, see model [`GDX2ACCESSExample4`] for reference.

6.14.4.6 Example 5 - Renaming Fields

GDX2ACCES will use names like `i`, `j`, `dim1`, `dim2`, `value` etc. for the column headers in the resulting database file. In some cases, this may not be convenient, e.g. when more descriptive field names are required. In the following model, we will show how a small script in VBscript[1] can handle this task. The script will rename the columns `i`, `j`, and `Value` in table `c` to `ifrom`, `jto`, and `transportcost`. At first, the data is defined and dumped to an MicroSoft Access database. The VBscript named `access.vbs` is written at compile time and later executed at execution time in order to rename the column headers.

Set

```
i 'canning plants' / seattle, san-diego /
j 'markets' / new-york, chicago, topeka /;
```

Parameter

```
a(i) 'capacity of plant i in cases'
    / seattle 350
    san-diego 600 /

b(j) 'demand at market j in cases'
    / new-york 325
    chicago 300
    topeka 275 /;
```

Table d(i,j) 'distance in thousands of miles'

	new-york	chicago	topeka
seattle	2.5	1.7	1.8
san-diego	2.5	1.8	1.4;

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';

```
c(i,j) = f*d(i,j)/1000;
```

* export to gdx file.

```
execute_unload 'c.gdx', c;
```

* move to access database

* column names are i and j

```
execute '=gdx2access c.gdx';
```

```

* rename columns
execute '=cscript access.vbs';

* view results
$libInclude win32 shellExecute c.accdb

$onEcho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"
set oa = CreateObject("Access.Application")
set oDAO = oa.DBEngine
Wscript.Echo "DAO Version: " & oDAO.version
Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name
Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name
' rename fields
oTable.Fields.Item("i").name = "ifrom"
oTable.Fields.Item("j").name = "jto"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"
oDB.Close
Wscript.Echo "Done"
$offEcho

```

The resulting ACCBD, opened with MS Access, is shown in [Figure 6](#) (parameter *c* before executing the VBScript on the left, parameter *c* after renaming the column headers on the right).

The complete example is also part of the GAMS Data Utilities Library, see model [[GDX2ACCESSEExample5](#)] for reference.

6.15 GDX2HAR and HAR2GDX

GDX2HAR and HAR2DX are translation Tools for GDX and HAR Files.

Author

Date

August, 2003 (revised July, 2007)

Source of this document: <http://www.mpsge.org/gdxhar/index.html>

The purpose of this document is to provide an overview of GDX2HAR and HAR2GDX translation tools. The GDX2HAR and HAR2GDX programs efficiently translate between HAR and GDX file formats, and their operation is straightforward. The examples covered in this document have been designed to illustrate potential difficulties which may arise and how these issues can be addressed.

6.15.1 Syntax

6.15.1.1 Syntax for GDX2HAR

```
gdx2har GDX_file_prefix [.gdx] [HAR_file_prefix [.har]] [/s]
```

Comments:

- `gdx2har.exe` is a Windows console application which runs on 32-bit versions of MSWindows (Win95 or later).
- The program requires `gdxiomh.dll` to be located in the same folder as `gdx2har.exe`.
- When only a single file is specified, the output file is `GDX_file_prefix.HAR`.
- Any (and all) single dimensional sets and all parameters in the GDX file are written to the HAR file. Variables, equations and multi-dimensional sets (tuples) in the GDX file are ignored.
- Sets in the GDX file are written as sets in the HAR file. Parameters from the GDX file are written as coefficients in the HAR file.
- The `/s` switch invokes strict enforcement of translation syntax. When this switch is specified, warning messages result in program termination without generation of any output.
- Warning messages are generated when incompatible features are encountered in the translation process, including names or set labels with more than 12 characters or other non-conforming syntax. (Set labels in GEMPACK may not begin with a numeric symbol).

Making sense of `gdx2har` requires some understanding of the underlying file formats. GAMS stores values for parameter matrices in GDX files using a *sparse matrix* format, so that a table like

	USA	France
Agriculture	411	87
Services	2831	365
SweetCorn	11	0
Truffles	0	68
Durian	0	0

is stored in a GDX file in a binary format corresponding to the following list:

```
"Agriculture" "USA"    411
"Agriculture" "France"  87
"Services"    "USA"    2831
"Services"    "France"  365
"SweetCorn"   "USA"    11
"Truffles"    "France"  68
```

The key point is that zero elements are not stored in the GDX format, and nor is explicit information about the domain of parameters as declared in the GAMS program which produced the GDX file. To work around this problem, GDX2HAR uses two strategies to infer the domain of a parameter:

1. GDX2HAR scans the descriptive text of parameters in the GDX file to see if an *explicit* header and domain have been provided. This information is identified by its enclosure in double square brackets, e.g.

PARAMETER OUTPUT(i,r) Base year production [[Y:I*R]]

The HAR information enclosed in double square brackets consists of the header key ("Y" in this example) and the domain defined with dimension sets separated by 's. The maximum length of a header key is 4 characters.

2. In the absence of explicit declaration in the descriptive text, GDX2HAR examines the labels of nonzero array elements which are stored in a GDX file to see if they correspond to a declared set. If the row or column set does not correspond to a set stored in the GDX file, a new set is created to define the coefficient domain in the HAR file. In the above example, if the GDX file contained sets defined as

```
GOODS = [Agriculture,Services,SweetCorn,Truffles,Durian]
```

and

```
REGIONS = [USA,France]
```

The GDX2HAR program would then correctly infer that the column set is REGIONS, but it would **not** conclude that the row set is GOODS. It would instead declare a new set

```
SET1 = [Agriculture,Services,SweetCorn,Truffles]
```

with which to dimension the data table in the HAR file. As illustrated in this example, the translation process can be problematic which parameters in the GDX file are not explicitly declared.

6.15.1.2 Syntax for HAR2GDX

```
har2gdx HAR_file_prefix [.har] [GDX_file_prefix [.gdx]] [/s]
```

Comments:

- `har2gdx.exe` is a Windows console application which run on 32-bit versions of MSWindows (Win95 or later).
- The program requires `gdxiomh.dll` to be located in the same folder as `gdx2har.exe`.
- When only a single file is specified, the output file is `HAR_file_prefix.GDX`.
- All sets and coefficients in the HAR file are written to the GDX file as sets and parameters, respectively.
- The `/s` switch invokes strict enforcement of translation syntax. When this switch is specified, warning messages result in program termination without generation of any output.

6.15.2 GDX2HAR Examples

6.15.2.1 Example 1: Default operation

This example shows how a GDX file can be written by a GAMS program and the results then transferred into a HAR file. In the small GAMS example two sets and three parameters are defined. The program output is then written to the GDX file. Set and parameter names are shorter than 12 characters and conform to GEMPACK syntax rules, so the translator retains all same names in the HAR file. In this case, set and parameter names have fewer than 4 characters, so the HEADER identifiers in the HAR file are identical to the GAMS names.

GDX2HAR infers domains of the parameters from the array elements, which are all non-zero in this case.

```

Set
  i / a, b, c /
  j / red, green, blue /;

Parameter
  x      'Scalar value'      / 1.5 /
  y(i)   'Vector of values' / a 10.2, b 1.3, c 1.5 /
  z(i,j) 'Matrix of random values';

z(i,j) = uniform(0,1);

```

This program may be stored as `ex1.gms` and then run from the command line as

```
gams ex1.gdx=ex1
```

If the program is executed from the GAMS IDE a GDX file can be generated by adding `gdx=ex1` to the Additional Parameters box in the File/Options/Execute dialogue. The resulting GDX file can be opened in the GAMS IDE and appears as follows:

The GDX file can be translated into HAR format with the command:

```
gdx2har ex1 >ex1.log
```

As specified here, GDX2HAR program output (including warning messages) is written to `ex1.log`:

```

Running program: C:\GAMS21.0\GDX2HAR.EXE
Input file: H:\gdxhar\examples\ex1.gdx
Output file: H:\gdxhar\examples\ex1.har
Deleted existing file: H:\gdxhar\examples\ex1.har
Loaded GDX library: C:\GAMS21.0\gdxiomh.dll
Above is DLL version: _GAMS_GDX_V228_2003-05-07
GDX file was produced by:
  GAMS Rev 134 May 1, 2003 WIN.00.NA 21.0 134.000.041.VIS P3PC
  Using GDX library: _GAMS_GDX_V228_2003-05-07
GDX file contains 5 symbols and 6 set elements.
Reading GDX set "i".
Reading GDX set "j".
Reading GDX array "x".
Reading GDX array "y".
Reading GDX array "z".
Finished OK; created file: H:\gdxhar\examples\ex1.har

```

The resulting HAR file can be examined using the [VIEWHAR](#) utility:

Note that the HAR file contains the five items from the source GDX file as well as two additional sets named `OGEL` and `NGEL`. These sets are always provided to provide a consistent report in the event that set labels may have been translated.

6.15.2.2 Example 2: Missing sets are constructed.

In this example, sets are not written to the GDX file. GDX2HAR then generates the sets based on the nonzero patterns of the parameters. This example illustrates how a GDX file can be written and translated into HAR format within a GAMS program.

```

Set
  i / a, b, c /
  j / red, green, blue /;

Parameter
  x      'Scalar value'      / 1.5 /
  y(i)   'Vector of values' / a 10.2, b 1.3, c 1.5 /
  z(i,j) 'Matrix of random values';

z(i,j) = uniform(0,1);

execute_unload 'ex2.gdx', x, y, z;
execute 'gdx2har ex2 > ex2.log';

```

The resulting HAR file appears as follows:

The sets titled `Set1` and `Set2` have been introduced by GDX2HAR and are stored in the HAR file under headers `S1` and `S2`. GDX2HAR has inferred that `y` and `z` share the common dimension `set1`, but does not know that `set1` was called "i" in the GAMS program.

6.15.2.3 Example 3: Zeros can create problems.

If one element of the `w` vector is zero, GDX2HAR does not assume that the coefficient is defined over set "i". Instead GDXHAR introduces a new set to define the domain.

```

Set i / a, b, c /;

Parameter w(i) 'Vector of values' / a 10.2, c 1.5 /;

execute_unload 'ex3.gdx', i, w;
execute 'gdx2har ex3 > ex3.log';

```

Above, the set `Set1` contains only 2 members, `a` and `c`, corresponding to non-zero elements of `w`.

6.15.2.4 Example 4: EPS can be used to define a domain.

The GAMS language includes a special value `EPS`, standing for "epsilon," a infinitesimally small but nonzero number. When `EPS` is added to every element of an array over a given domain, then when that array is written to the GDX file the zeros become visible. The `EPS` values which are stored in the GDX file appear as a true zero in the translated HAR output file.

```

Set i / a, b, c /;

Parameter w(i) 'Vector of values' / a 10.2, c 1.5 /;

execute_unload 'ex3.gdx', i, w;
execute 'gdx2har ex3 > ex3.log';

* Add eps to create zeros which are "visible" in the
* GDX file:
w(i) = w(i) + eps;

execute_unload 'ex4.gdx', i, w;
execute 'gdx2har ex4 > ex4.log';

```

6.15.2.5 Example 5: Explicit declaration of HAR coefficients.

As an alternative to adding EPS to all parameter values, the header and coefficient domain may be specified in the GAMS declaration of a parameter. The HAR declaration is provided within double square quotes, [[]].

In this example the GAMS parameter is 12 characters in length. This name may be used in the HAR file to define the coefficient, but it may not be used as the header. (Headers are limited to four characters.) It is possible to define a specific header and domain within the descriptor text of the GAMS parameter.

```

Set
  i / a, b, c /
  j / red, green, blue /;

Parameter zs_long_name(i,j) 'Param with header and domain [[z:i*j]]';

* Note that missing rows are not a problem when the domain is explicitly
* specified:
zs_long_name(i,j) = uniform(0,1);
zs_long_name("b",j) = 0;

display zs_long_name;
execute_unload 'ex5.gdx', i, j, zs_long_name;
execute 'gdx2har ex5 > ex5.log';

```

6.15.2.6 Example 6: Long names are truncated

In GAMS, a set or parameter may have as many as 31 characters. GDX2HAR truncates such names to 12 characters.

```

Parameter GAMS_name_with_31_characters_OK 'A long GAMS identifier' / 1.5 /;

execute_unload 'ex6.gdx', GAMS_name_with_31_characters_OK;
execute 'gdx2har ex6 > ex6.log';

```

In this example GDX2HAR generates the following HAR file:

But issues the following warning message:

```

**** Warning: To conform with GEMPACK rules, GDX symbol
      GAMS_name_with_31_characters_OK was converted to GAMS_name_wi

```

6.15.2.7 Example 7: The GAMS symbol table controls set sequencing

Attention to the GAMS symbol table is needed if set sequences in the HAR file are to be in a particular order. Consider the following GAMS program:

```
Set
  r 'Selected South American countries' / ARG, BRA, COL, PER, BOL, URG /
  e 'Selected energy goods'           / OIL, COL, GAS, ELE           /;

display e;

Parameter d(e,r) 'Energy demands';
d(e,r) = uniform(0,1);

execute_unload 'ex7.gdx', r, e, d;
execute 'gdx2har ex7 > ex7.log';
```

Note that the listing file output of this program presents set *e* is a ordered in a sequence which differs from the declared sequence:

```
-----      5 SET e  Selected energy goods
COL,      OIL,      GAS,      ELE
```

The point is that GAMS orders all output rows and columns in accordance with the sequencing of the *global symbol table*. This aspect of GAMS carries over into HAR file generation. In this example, the order in which set *e* is displayed in the listing file is the same as the order in which the rows are sorted in the GDX and HAR files:

One way to control the global symbol table in a GAMS program is to declare a *fictive* set at the top of a program in which set elements are defined in the preferred sequence. For example, in the case of the previous program, the following declaration would produce the desired sequence of both sets R and E in the HAR file:

```
Set
  symbols                / ARG, BRA, OIL, COL           /
  r 'Selected South American countries' / ARG, BRA, COL, PER, BOL, URG /
  e 'Selected energy goods'           / OIL, COL, GAS, ELE           /;
```

This produces a consistent ordering of both sets *r* and *e*, but this type of work-around may not always be possible. (See example 9 below.)

6.15.2.8 Example 8: Set elements may be truncated or revised.

Restrictions in GEMPACK on the length of set elements and the use of embedded blanks enforced by GDX2HAR. Also, GEMPACK does not allow for set elements to begin with a digit.

```
Set
  c / 'New York', 'San Francisco', 'Los Angeles' /
  t / 2000*2010 /;

execute_unload 'ex8.gdx', c, t;

execute 'gdx2har ex8 > ex8.log';
```

With this example GDX2HAR produces the following warning message:

```
**** Warning: To conform with GEMPACK requirements,
    the following GDX set elements were changed:

New York became NewYork
San Francisco became SanFrancisco
Los Angeles became LosAngeles
2000 became A2000
2001 became A2001
2002 became A2002
2003 became A2003
2004 became A2004
2005 became A2005
2006 became A2006
2007 became A2007
2008 became A2008
2009 became A2009
2010 became A2010
Reading GDX set "c".
Reading GDX set "t".
**** Warning: Some GDX set elements were changed.
There were 2 warnings.
```

GDX2HAR also alters identifiers to assure that they remain unique, for example, after truncation to 12 letters.

6.15.3 HAR2GDX Examples

6.15.3.1 Example 9: GlobalSet is provided by HAR2GDX to sequence the GAMS symbol table.

HAR2GDX constructs a symbol table which, where possible, provides properly sequenced arrays in the resulting GDX file. A simple example illustrates how this works. In the source HAR file there are two sets, COM and HAR. COM consists of [Cereals, OtherCrops, Power, Services], and IND contains [Agriculture, Nuclear, CoalFired, Services]. The HAR file contains a single numeric matrix, MAKE, which appears in VIEWHAR as follows:

When the HAR file ex9.har (from href="examples.zip" > examples.zip) is translated by HAR2GDX, the resulting GDX file contains three sets and one parameter array. The sets include COM and IND, as well as a GlobalSet which is inserted to provide a means of sorting the ata arrays into proper sequence. By virtue of the HAR2GDX global symbol table, the translated MAKE array appears in the GDXVIEWer as follows:

If, however, the global symbol table is ignored when the data is read into a GAMS program, as in the example:

```
Set
  COM(*) 'Set of commodities'
  IND(*) 'Set of industries';

$gdxIn make.gdx
$load com ind

Parameter make(com,ind) 'Make matrix';
$load make
display make;
```

Then the program develops a global symbol table in which set IND is ordered differently than in the source HAR file. The reason is that GAMS constructs a symbol table sequentially, so if COM is read before IND, then Services is introduced prior to Agriculture, Nuclear, and CoalFired:

```

----      11 PARAMETER make   Make matrix

           Services  Agricultu~    Nuclear    CoalFired

Cereals           7.000
OtherCrops        4.000
Power              2.000        14.000
Services          29.000

```

On the other hand, if GlobalSet is read first, then the GAMS set order (in this example) is identical to the HAR file order:

```

Set
  GlobalSet(*) 'Set provided by GDX2HAR to order symbol table'
  COM(*)       'Set of commodities'
  IND(*)       'Set of industries';

$gdxIn make.gdx
$load globalset com ind

Parameter make(com,ind) 'Make matrix';
$load make
display make;

```

```

----      12 PARAMETER make   Make matrix

           Agricultu~    Nuclear    CoalFired    Services

Cereals          7.000
OtherCrops       4.000
Power            2.000        14.000
Services                    29.000

```

6.15.3.2 Example 10: Some GEMPACK datasets cannot be represented in GAMS without reordering sets.

The following is an example of a HAR file which cannot be translated to GAMS without reordering sets. Within ex10.har the sets IND and COM in this example are, respectively, [A,B,C,D] and [D,C,B,A]:

The HAR file can be translated to GDX, but this produces the following error message:

```

**** Warning: Inconsistent order: elements "D" and "C" in set COM
**** Warning: Inconsistent order: elements "C" and "B" in set COM
**** Warning: Inconsistent order: elements "B" and "A" in set COM

```

This message means that HAR2GDX was unable to construct a global symbol table which is ordered consistently with both HAR sets COM and IND. The translated data appears as:

Within the GDX file both COM and IND will be ordered [A,B,C,D], and the elements of X are displayed in that order. Notice that values for particular array elements are translated correctly, e.g. X("A","B") = 14 in both HAR and GDX files.

6.15.4 Concluding Remarks

GDX2HAR and HAR2GDX efficiently translate between HAR and GDX file formats. Although the examples above concentrate on potential problems, in practice both programs are generally easy to use. To avoid problems:

- if you are using GAMS to prepare a GDX file for translation to HAR, remember that GDX files do not naturally contain information about array domains – the sets over which the array is defined. To assist GDX2HAR, you should store associated sets in the GDX file and include domain information and a suggested header key in the "explicit text" description of each GAMS array declaration, as in example 5 above.
- if you are using GEMPACK to prepare a HAR file for translation to GDX, avoid creating sets which share common elements that are ordered differently. If you follow this rule, the GAMS user can use GlobalSet (prepared by HAR2GDX) to ensure that GAMS orders set elements in the same way as GEMPACK. See example 9 above.
- Try to use names (for arrays, sets and set elements) which are legal in both GEMPACK and GAMS. Identifiers of maximum length 10 with first character one of [A..Z,a..z] and remaining characters in [A..Z,a..z,0..9] will translate most smoothly.

6.16 GDX2SQLITE

A Tool to dump GDX contents into SQLite database file

Author

Erwin Kalvelagen

Date

November 30, 2015

6.16.1 Introduction

GDX2SQLITE.EXE is a tool to dump the complete contents of a GAMS GDX file (see [GAMS Data eXchange \(GDX\)](#)) into a SQLite database file (the website <http://www.sqlite.org/> contains a wealth of information on SQLite).

A SQLite database is stored in a single file so it can be easily e-mailed or otherwise transmitted. The main advantages of using SQLite over other single file database systems such as MS Access is that SQLite is free and in the public domain and that it does not impose a 2 GB file size limit. For some large data sets this size limit present in MS Access and DBF database files causes problems. Another useful format is CSV files, but typically several CSV files are needed to store a data set stored in a GDX file. Many programs support reading SQLite database files, either through a native database access driver or via a standard ODBC interface. In summary: SQLite is a useful export format for GAMS solution data sets.

6.16.2 Usage

'GDX2SQLITE' is a command line tool that is best called from within a GAMS program using the \$call or Execute statement, e.g.:

```
execute_unload "results.gdx", yield, price;  
execute "gdx2sqlite -i results.gdx -o results.db";
```

The following options are available:

Options	Description
<code>-i gdxinputfile</code>	Specifies the input GDX file. Typically this is a file with a .gdx extension
<code>-o sqloutputfile</code>	Specifies the output SQLite database. Typically this file has a .db extension.
<code>-debug</code>	This is an optional flag that will cause gdx2sqlite to print additional debugging information.
<code>-expltext</code>	This optional flag will export explanatory text for set elements.
<code>-append</code>	Don't delete the database file before processing. This will allow adding new symbols in new tables. We will not allow adding data to existing tables.
<code>-small</code>	Write data strings in a separate table. A user-friendly SQL VIEW is created to hide the complexities of the joins.
<code>-fast</code>	Try to speed up writing the data using some non-standard pragmas. Using both <code>-small</code> <code>-fast</code> will write the data most efficiently.
<code>-varchar</code>	String columns will have the type <code>VARCHAR(255)</code> instead of <code>TEXT</code> .

An example of explanatory text is:

```
Set cty / AFG 'Afghanistan'
          AGO 'Angola'
          ALB 'Albania'    /;
```

In GAMS set elements have a maximum length of 63 characters. Explanatory text has a maximum length of 255 characters.

6.16.3 How data is stored

6.16.3.1 Gams issues

GAMS does not store zero values (or default records for variables and equations). Such non-existing records will not be exported to the GDX file and to the database either. To force a zero to be exported, set it to EPS in GAMS. E.g.:

```
p(i)$p(i)=0 = EPS;
```

In case of doubt you are encouraged to inspect the GDX file.

6.16.3.2 Sets

n-dimensional sets are stored as tables with n text columns. In case the option `-expltext` is used, another column may be added with explanatory text.

GAMS	SQLite
<pre>Set month / jan, feb, mar / year / 2013, 2014 / date(year,month) /(2013,2014).(jan,feb,mar) /; execute_unload "sets.gdx"; execute "gdx2sqlite -i sets.gdx -o sets.db";</pre>	<pre>sqlite>select * from month; month ----- jan feb mar sqlite>select * from year; year ----- 2013 2014 sqlite>select * from date; year month ----- ----- 2013 jan 2013 feb 2013 mar 2014 jan 2014 feb 2014 mar</pre>
<pre>Set month / jan 'january' feb 'fabruary' mar 'march' /; execute_unload "sets.gdx"; execute "gdx2sqlite -i sets.gdx -o sets.db -expltext";</pre>	<pre>sqlite>select * from month; month expltext ----- ----- jan january feb fabruary mar march</pre>

6.16.3.3 Parameters

n-dimensional parameters will have n index columns plus a value column. Scalars are collected in a separate table.

GAMS	SQLite
<pre>Set i / i1*i4 /; Parameter p(i); p(i) = uniform(0,1); Scalar s1 / 10 / s2 / 20 /; execute_unload "data.gdx"; execute "gdx2sqlite -i data.gdx -o data.db";</pre>	<pre>sqlite>select * from p; i value ----- ----- i1 0.171747132 i2 0.843266708 i3 0.550375356 i4 0.301137904 sqlite>select * from scalars; name value ----- ----- s1 10.0 s2 20.0</pre>

6.16.3.4 Variables and Equations

n-dimensional variables and equations have besides n index columns also columns for the level, the lower and upper-bound and the marginal. Scalars are collected in the tables scalarvariables and scalarequations. Note that INF and -INF are mapped to 1.0e100 and -1.0e100. The special value EPS is exported as zero. To be complete: UNDEF, NA and acronyms are exported as NULLs.

GAMS	SQLite
<pre>Set i / i1*i4 /; Positive Variable x(i); x.l(i) = uniform(0,1); Variable z; z.m = 1; execute_unload "data.gdx"; execute "gdx2sqlite -i data.gdx -o data.db";</pre>	<pre>sqlite>select * from x; i level lo up marginal ----- ----- i1 0.171747132 0.0 1.0e+100 0.0 i2 0.843266708 0.0 1.0e+100 0.0 i3 0.550375356 0.0 1.0e+100 0.0 i4 0.301137904 0.0 1.0e+100 0.0 sqlite>select * from scalarvariables; name level lo up marginal ----- ----- z 0.0 -1.0e+100 1.0e+100 1.0</pre>

6.16.3.5 Fixing up names

A database table is not allowed to have columns with the same name. If a name clash is detected new names may be invented.

GAMS	SQLite
<pre>Set i / i1*i4 /; Parameter p(i,i); p(i,i) = 1; execute_unload "data.gdx"; execute "gdx2sqlite -i data.gdx -o data.db";</pre>	<pre>sqlite>select * from p; i i2 value ----- ----- i1 i1 1.0 i2 i2 1.0 i3 i3 1.0 i4 i4 1.0</pre>

6.16.3.6 Speeding up writing data

With the `-small` option we write data in a slightly different format. Instead of using strings for the GAMS indices we write integers. The integers can be looked up in a separate table UEL\$ where the GAMS UELS (Unique Elements) are stored. We export an SQL view for each symbol to hide the complexities of the joins needed to replace the integers by strings.

For more information see: <http://yetanothermathprogrammingconsultant.blogspot.com/2014/06/big-data-cube>

The `-fast` option will set some SQLite pragmas that can speed up the inserts. Basically they will give up some consistency in case the program crashes, in which case the created database may be invalid.

For more information see: <http://yetanothermathprogrammingconsultant.blogspot.com/2014/07/a-little-bit->

6.16.4 SQLite Browsers and compatible software

6.16.4.1 SQLite3.exe

From the distribution on <http://www.sqlite.org/download.html> a command line tool is available that functions as shell for SQLite. An example session can look like:

```

C:\projects\impact3\sqlite>sqlite3.exe data.db
SQLite version 3.8.0.2 2013-09-03 17:11:13
Enter ".help" for instructions
Enter SQL statements terminated with a ";"
sqlite> .schema
CREATE TABLE [i]([i] TEXT);
CREATE TABLE [p]([i] TEXT,[i2] TEXT,[value] REAL);
sqlite> select * from p;
i1|i1|1.0
i2|i2|1.0
i3|i3|1.0
i4|i4|1.0
sqlite> .quit

C:\projects\impact3\sqlite>

```

6.16.4.2 SQLite Studio

A visual front-end can be downloaded from <http://sqlitestudio.pl/>.

6.16.4.3 SQLite Database Browser

Another visual browser is available from <http://sqlitebrowser.sourceforge.net/>.

6.16.4.4 SQLite and R

The statistical software R can conveniently use SQLite data, and can be called from a GAMS environment as follows:

```

$onText
Get data from GAMS into R via SQLite
$offText

$set IMPACTPATH      c:\projects\impact3\impact_3\IMPACTv3.0
$set SCRIPT          script.R
$set RPATH           "C:\Program Files\R\R-3.0.2\bin\R.exe"
$set DB              mapdata.db

Set cty;
$gdxIn %IMPACTPATH%\GDXs\Sets.gdx
$load cty

display cty;

Set maps / data1 'uniform random data between 0 and 1'
          data2 'uniform random data between 0 and 2' /;

Parameter mapdata(cty,maps);
mapdata(cty,"data1") = uniform(0,1);
mapdata(cty,"data2") = uniform(0,2);

execute_unload "mapdata.gdx";
execute "gdx2sqlite -i mapdata.gdx -o %DB% -expltext";

```

```

execute '%RPATH%' --vanilla < %SCRIPT%';

$onEcho > %SCRIPT%
if (!require(RSQLite)) {
  install.packages("RSQLite", repos="http://cran.r-project.org")
  library(RSQLite)
}

sqlite<-dbDriver("SQLite")
db <- dbConnect(sqlite,"%DB%")
dbListTables(db)

maps<-dbGetQuery(db,"select * from maps")
maps

mapdata<-dbGetQuery(db,"select * from mapdata")
mapdata
$offEcho

```

6.16.4.5 SQLite and Python

Python has built-in support for SQLite:

```

import sqlite3

db = sqlite3.connect("turkey.db")

c = db.execute("select * from yield1")
for row in c:
    print row

db.close()

```

6.16.4.6 SQLite ODBC Driver

ODBC is a database access layer for Windows. It allows many Windows programs that need to talk to databases to do this in a database independent manner. The SQLite ODBC driver can be downloaded from: <http://www.ch-werner.de/sqliteodbc/>.

6.16.4.7 SQLite and Excel

Excel can read SQLite database files through ODBC.

6.16.4.7.1 Import as Table To import a table from a SQLite database perform the following steps:

1. Select the Data tab and choose Get External Data From Other Sources
 2. Choose the Data Connection Wizard
 3. Choose ODBC DSN
 4. Select SQLite3 Datasource
-

5. Enter the name and path of the database file and press OK.
6. Choose a table from the database.
7. Give this selection a name.
8. Choose Import as Table

The result is a table:

6.16.4.7.2 Import as Pivot Table The same steps can be used to import as Pivot Table. This way we can easily create summary reports, such as:

6.17 GDX2VEDA

Translates a GDX file into the **VEDA** format.

6.17.1 Usage

```
gdx2veda gdx vdd [run]
```

gdx

GAMS GDX file

vdd

VEDA Data Definition file

run

VEDA Run identifier (optional)

The VEDA data file name and run identifier are either taken from the gdx file name or specified with the run name. Use "token with blanks" if needed.

6.17.2 Examples

This example dumps the gdx symbols:

```
gdx2veda mygdx
```

This example prints usage and example:

```
gdx2veda
```

To print [more detailed help message](#):

```
gdx2veda --help
```

Add .csv to the run name to write in csv format

6.17.3 Detailed Help Message

6.17.3.1 VDD file Summary

```
[DataBaseName]
myveda

[Dimensions] cube dimensions
long_name tuple_element1 tuple_element2 ...

[DataEntries] data for the cube
long_name gams_name tuple_element1 tuple_element2 ...

[DimensionText] for generating .vde file (only for data in [DataEntries])
gams_set tuple_element1 tuple_element2 ...

[DimensionTextAll] for generating .vde file (also for data not in [DataEntries])
gams_set tuple_element1 tuple_element2 ...

[SubSets] for generating .vds file
sub_name gams_name tuple_element1 tuple_element2 ...

[ParentDimension] defines parent-child structure
parent_tab child_tab1 child_tab2 ...

[ParentDimensionTextAll] .vde file definitions with parent-child structure
2d_gams_set parent_tab child_tab
2d_gams_set child_tab parent_tab

[ParentSubSets] .vds file definitions with parent-child structure
sub_name 2d_gams_set parent_tab child_tab
sub_name 2d_gams_set child_tab parent_tab

[Options]
TupleSeparator "string" use a different separator symbol between tuple elements
ShowAllSeparators      don't squeeze unnecessary separators
RelaxDimensionAll      relax strict dimensionality checks in DimensionText(All) sections.
ValueDim n             if n=2 write PV/DV value pairs for VEDA
SetsAllowed dim1 dim2 .. write SetsAllowed specification line to VEDA .vd file
Scenario scenarioSet   specify the scenario set; a record with expl text goes to .vde
Format veda/csv        specify the format of the data files
Not-0 attribute ...    don't write records with zero values for these attributes

[SpecialValues]
EPS "string"          value to be used for EPS
INF "string"          value to be used for +INF
MINF "string"         value to be used for -INF
NA "string"           value to be used for NA
UNDEF "string"        value to be used for UNDEF
```

<myveda>

is usually the application name which will be displayed on the top of the VEDA splash screen.
When a new VEDA database is created, a new folder with this name will appear:

```
...veda\database\mayveda_date_time.
```

Where data and time are the creation time stamp.

<tab_name>

corresponds to the tabs of your VEDA screen

Lines starting with * and empty lines are ignored. Blanks, commas and tabs are delimiters, blanks before and after delimiters are ignored. Quotes around data items are optional. The input data is NOT case sensitive.

6.17.3.2 Veda Data Definition file

Example of a Veda Data Definition file:

```
* Transport model

[DataBaseName]
myveda

[Dimensions]
* tab-name indices
Plants      i
Warehouses  j
Links       ii jj

[DataEntries]
* veda_attribute gams_name tab1 tab2 ... for gams index 1, 2, ...
"x(i,j) duals" x.m      i Warehouses
Shipments     x.l      i j
SupplyPrice   supply.m i
DemandPrice   demand.m j
TransportCost c        i j
Distance      d        ii jj
Supply        a        i
Demand        b        j
TotalCost     z.l
SupplyNodes   i        i
DemandNodes   j        j
Rate          f

[DimensionText]
* gams_set tab
i i

[DimensionTextAll]
* gams_set tab
j j

[SubSets]
* sub_name gams_name tab
i1 ic Plants
i1 id i
```

Notes:

The long name from the [Dimensions] section can be used as a macro that expands to the tuples it defines. E.g. "Links" is identical to "ii jj".

In the [DataEntries] section a literal tuple element can be defined as /element/.

When ValueDim=2, the [DataEntries] section can contain X.LM entries, indicating both .L and .M needs to be written as a pair.

6.18 GDX2XLS

A Tool to convert GDX data to MS Excel spreadsheets

Author

Erwin Kalvelagen

Date

June 10, 2005; December 6, 2006

This document describes the `GDX2XLS` utility which allows to convert data stored in a GDX file into Excel spreadsheets.

6.18.1 Overview

Note

The Windows GAMS distribution contains several tools to exchange data with MS-Excel: `GDX2XLS`, `GDXXRW`, `XLS2GMS`, and `XLSDUMP`. While we continue to include all four tools in our distribution, only `GDXXRW` is under active development. Therefore, we strongly recommend using `GDXXRW` for data exchange with Excel.

`GDX2XLS` is a tool to dump the complete contents of a GDX file to an MS Excel spreadsheet file (`.xlsx` or `.xls` file). Every identifier gets its own sheet in the `.XLSX` file. Excel 2007 or more recent versions will default to an `xlsx` file; versions before that default to the `.xls` file format. For instance when we save the results of the `transport` model from the model library:

```
C:\tmp>gamslib transport
Model transport.gms retrieved
```

```
C:\tmp>gams transport gdx=transport lo=2
```

```
C:\tmp>gdxdump transport.gdx symbols
Symbol Dim Type Records Explanatory text
1 a      1 Par      2 capacity of plant i in cases
2 b      1 Par      3 demand at market j in cases
3 c      2 Par      6 transport cost in thousands of dollars per case
4 cost   0 Equ      1 define objective function
5 d      2 Par      6 distance in thousands of miles
6 demand 1 Equ      3 satisfy demand at market j
7 f      0 Par      1 freight in dollars per case per thousand miles
8 i      1 Set      2 canning plants
9 j      1 Set      3 markets
10 supply 1 Equ      2 observe supply limit at plant i
11 x     2 Var      6 shipment quantities in cases
12 z     0 Var      1 total transportation costs in thousands of dollars
```

```
C:\tmp>
```

The example shows how we copy the `transport.gms` model from the model library, and then solve it. The option `gdx=filename` will save the complete symbol table to a GDX file. The option `lo=2` tells GAMS to save the log to a file (in this case `transport.log`) instead of writing it to the screen. The `gdxdump` will display the contents of the GDX file (the option `symbols` will only display the table of contents, rather than all data)

Once we have a GDX file we can use `GDX2XLS` to create an `.XLSX` file:

```
C:\tmp>gdx2xls transport.gdx
GDX2XLS          34.1.0 r644dbd9 Released Jan 29, 2021 WEI x86 64bit/MS Window
Output file: C:\tmp\transport.xlsx
C:\tmp>
```

The resulting XLSX file, opened with MS Excel is shown in [Figure 1](#). The first page is the Table of Contents page with all identifiers sorted alphabetically. When clicking on variable `x`, the sheet shown in [Figure 2](#) is displayed.

The table of contents can be reached again by clicking on the TOC link in the top left corner. The complete process shown here can be automated as is shown in section [Model gdx2xls1: import transport.gdx](#). As can be seen, every identifier is stored in its own sheet. Index positions get a column with labels showing their domains, or `dim1`, `dim2`, etc. if domain information is not available. By default scalar quantities are collected in a single sheet called `scalar`.

6.18.2 AutoFilter

By default the exported tables are organized in `AutoFilter` tables. This will allow you to easily make selections and sort the results.

It is possible to set filters for different columns. Only the rows that meet the criteria will be shown. The columns used in the filter can be recognized by having a blue arrow instead of a black one in the drop down menu header.

Sorting can also be performed on multiple columns: e.g. first sort on one column, then sort on a second column.

The autofilter generation can be turned off using an option in the `.ini` file.

6.18.3 Options

6.18.3.1 Default ini file

Options are specified in an `.INI` file. By default, the file `gdx2xls.ini` located in the same directory as `gdx2xls.exe` is consulted. If this file is not available, the program will continue using default settings.

6.18.3.2 Custom ini file

It is also possible to tell the program to use a different .ini file. This is done by using an extra argument of the form @inifile. An example would be:

```
C:\TMP> gdx2xls myfile.gdx @myinifile.ini
```

In this case the program will not read `gdx2xls.ini` located in the same directory as `gdx2xls.exe` but rather `myinifile.ini` in the current directory.

The ini file can contain two sections: `[settings]` and `[colors]`. A complete ini file with all possible settings looks like:

```
[settings]
inf=INF
mininf=-INF
eps=EPS
na=NA
undf=INDF
scalarsheet=1
tableformatting=1
toc=1
sorttoc=1
autofilter=1
freezeheader=1
indexformat=
valueformat=

[colors]
header=17
body=19
italics=48

[xmlcolors]
link=#0000FF
header=#9999FF
body=#FFFFCC
italics=#969696
```

6.18.3.3 Settings section

A complete description for the `[settings]` section is:

[settings]	Description
inf	Special values may need to be mapped to numeric values so the values can be used in formula's etc. This setting will specify the value for the GAMS INF quantity. The default is the string INF.
mininf	This is the mapped value for -INF. The default is -INF.
eps	This is the mapped value to be used for EPS. The default is EPS.
na	This is the mapped value to be used for NA. The default is NA.
undf	This is the mapped value to be used for UNDF. The default is UNDF.

[settings]	Description
scalarsheet	When this parameter is set to 1, GDX2XLS will generate a separate sheet to collect scalar parameters, scalar equations and scalar variables. This can reduce the number of sheets created with just a single data item. The name of the sheet is fixed: <code>scalar</code> . By default this option is turned on.
tableformatting	If this option is turned on, extra table formatting is used (adding colors, etc.) to make the tables look better. If this is not needed, this option can be turned off. Default: <code>tableformatting=0</code> .
toc	Whether or not to add a <code>{Table of Contents}</code> sheet. Default is to generate such a table.
sorttoc	Whether or not to sort the table of contents alphabetically. If turned off, the table will be displayed in the order in which the identifiers appear in the GDX file. Default is to sort.
autofilter	Automatically generate <code>AutoFilter</code> enabled tables in Excel.
freezeheader	Keep headers fixed so they don't scroll off the screen.
indexformat	Custom format for index columns. By default this is an empty string.
valueformat	Custom format for value columns. By default this is an empty string.

An example of setting special values can be found in section [Model gdx2xls4: special value mapping](#).

6.18.3.4 Colors section

A complete description for the `[colors]` section is:

[colors]	Description
header	The colorindex to be used as background for table headers. Default is 17.
body	The colorindex to be used as background for table bodies. Default is 19.
italics	The colorindex to be used for the font when writing explanatory text. The default is light grey (color index 48).

The `[xmlcolors]` section is used to specify colors in the XML file to be generated.

6.18.3.5 Custom formats

The format strings consists of four pieces:

```
[format for $x>0$];[format for $x<0$];[format for $x=0$];[format for strings]
```

An example given in the Excel help is:

```
#,###.00_);[Red](#,###.00);0.00;"sales "@
```

The codes used here have the following meaning:

Formatting Characters	Description
# (number sign)	displays only significant digits and does not display insignificant zeros.

Formatting Characters	Description
, (comma)	To display a comma as a thousands separator or to scale a number by a multiple of one thousand, include a comma in the number format.
0 (zero)	displays insignificant zeros if a number has fewer digits than there are zeros in the format.
_ (underscore)	To create a space the width of a character in a number format, include an underscore, followed by the character. For example, when you follow an underscore with a right parenthesis, such as _), positive numbers line up correctly with negative numbers that are enclosed in parentheses.
[color]	One of [Black], [Blue], [Cyan], [Green], [Magenta], [Red], [White], [Yellow].
@ (at sign)	Include an at sign (@) in the section where you want to display any text entered in the cell.

Additional formatting characters include:

Formatting Characters	Description
? (question mark)	adds spaces for insignificant zeros on either side of the decimal point so that decimal points align when formatted with a fixed-width font, such as Courier New. You can also use ? for fractions that have varying numbers of digits.
condition	Conditions can be specified as follows: [Red] [<=100] ; [Blue] [>100].
exponent	To display numbers in scientific format, use exponent codes in a section, for example, E-, E+, e-, or e+.

A useful format is:

```
[settings]
valueformat=#.????
```

which aligns numbers on the decimal point and depicts zero's as dots just as the listing file is doing.

6.18.4 Examples

6.18.4.1 Model.gdx2xls1: import trnsport.gdx

This example will solve the `trnsport.gms` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a small example that should run very quickly.

```
$onText
Test of GDX2XLS. Dumps all symbols of
trnsport.gms to trnsport.xlsx.
$offText

execute '=gamslib trnsport';
execute '=gams trnsport lo=3 gdx=trnsport';
execute '=gdx2xls trnsport.gdx';
$libInclude win32 shellExecute trnsport.xlsx
```

Notes: the equal signs in front of the external programs indicate we don't go through a shell (e.g. `command.com` or `cmd.exe`). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the '=' such errors go undetected and the GAMS model will continue.

The command `$libInclude win32 shellExecute trnsport.xlsx` will launch Excel to view the .XLSX file.

6.18.4.2 Model gdx2xls2: import indus89.gdx

This example will solve the `indus89.gms` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a fairly large GDX file, with many identifiers, resulting in many sheets in the workbook.

```
$onText
Test of GDX2XLS. Dumps all symbols of
indus89.gms to indus89.xlsx. This takes
longer as there is a large number of symbols.
$offText

execute '=gamslib indus89';
execute '=gams indus89 lo=3 gdx=indus89';
execute '=gdx2xls indus89.gdx';
$libInclude win32 shellExecute indus89.xlsx
```

6.18.4.3 Model gdx2xls3: a large table

This is an artificial example where we generate a large identifier in GAMS: a parameter with as many elements as the number of rows that Excel can handle.

```
$onText
Test of GDX2XLS. Single symbol with 65536-3=65533 records.
Maximum rows that XLS can handle is 65536; an XLSX file allows for slightly more than a million rows
$offText

Set i / i1*i65533 /;

Parameter p(i);
p(i) = uniform(-100,100);
execute_unload 'test.gdx', p;

execute '=gdx2xls test.gdx';
$libInclude win32 shellExecute test.xlsx
```

If you create a spreadsheet with too many rows, the XLSX file writer will return OLE error 800A03EC. When generating an XML file, an error will occur when Excel loads the file.

6.18.4.4 Model gdx2xls4: special value mapping

To store special values like INF, EPS, NA in a numeric field in the database, GDX2XLS uses a mapping. This mapping can be changed using an INI file.

```

$onText
Test of GDX2XLS.
Check special value mapping.
$offText

$onEcho > m.ini
[settings]
inf=1.0e100
mininf=-1.0e100
eps=0.0
na=#NA!
undef=#UNDF!
$offEcho

Parameter p(*) / i1 inf, i2 -inf, i3 eps, i4 na /;
p('i5') = 1/0;
display p;

* save parameter p in p.xlsx
* special values are translated to default values:
execute_unload "p.gdx", p;
execute '=gdx2xls p.gdx';
$libInclude win32 shellExecute p.xlsx

* save parameter p in q.xls using new mapping
* INF -> 1.0e100 (numeric)
* -INF -> -1.0e100 (numeric)
* EPS -> 0.0 (numeric)
* NA -> #NA! (string)
* UNDF -> #UNDF! (string)
*
execute_unload "q.gdx", p;
execute '=gdx2xls q.gdx @m.ini';
$libInclude win32 shellExecute q.xlsx

```

Numeric values are important if you want Excel being able to operate on these numbers.

6.18.4.5 Model gdx2xls8: custom format

We use a custom value format to color the different values $x < 0$, $x = 0$, $x > 0$ differently. Also align on the decimal point.

```

$onText
GDX2XLS example: use of custom format
$offText

$onEcho > mexls.ini
[settings]

```

```
valueformat=[Blue]#.????;[Red]-#.????;[Green]0.????;[Magenta]
$offEcho

execute '=gamslib mexls';
execute '=gams mexls lo=3.gdx=mexls';
execute '=gdx2xls mexls.gdx @mexls.ini';
$libInclude win32 shellExecute mexls.xlsx
```

6.18.4.6 Model gdx2xls9: custom format 2

This uses the more useful custom format `valueformat=#.????` (see [Figure 7](#)).

```
$onText
GDx2XLS example: use of custom format
$offText

$onEcho > align.ini
[settings]
valueformat=#.????
$offEcho

execute '=gamslib mexls';
execute '=gams mexls lo=3.gdx=mexls';
execute '=gdx2xls mexls.gdx @align.ini';
$libInclude win32 shellExecute align.xlsx
```

6.19 GDXCOPY

GDx files from different GAMS version can possibly be incompatible. A current GAMS system can read all older GDx file formats. The GDXCOPY utility provides a mechanism to convert GDx files to a format that different GAMS systems can read.

6.19.1 Usage

```
gdxcopy option inFile outDir
```

or

```
gdxcopy option -Replace inFile
```

The first form copies the converted files to a directory; the second form replaces the original file(s).

inFile

Single file or a file pattern with `.gdx` file extension.

outDir

The output directory.

Instead of converting the files explicitly using the GDXCOPY utility, files can also be converted by using the environment variable `GDxCONVERT` with values `V5`, `V6` or `V7`. The values specified will be used together with the value of the environment variable `GDxCOMPRESS` to call GDXCOPY as soon as a GDx file is created.

The values of the environment variables can also be set using the GAMS parameters `GDxCONVERT` and `GDxCOMPRESS`.

Option:

Option	Target format
-V5	Version 5
-V6U	Version 6 uncompressed
-V6C	Version 6 compressed
-V7U	Version 7 uncompressed
-V7C	Version 7 compressed

A current GAMS system can always handle older GDX file formats. The GDXCOPY utility provides a mechanism to convert GDX files to a prior format, so an older GAMS system can read these files.

Notes:

- Version 7 formatted files were introduced with version 22.6 of GAMS; version 6 formatted files were introduced with version 22.3 of GAMS. Prior versions used version 5.
- Some features introduced in version 7 of the GDX file format cannot be represented in older formats.

Feature	Action taken
Dimension > 10	Symbol is ignored
Identifier longer than 31 characters	Truncated to 31 characters
Unique element longer than 31 characters	Truncated to 31 characters
Domain of a symbol	Domain is ignored
Aliased symbol	Symbol is entered as a set
Additional text for symbol	Additional text is ignored

- The Macintosh Intel-based system (DII) which was introduced with GAMS 22.6 does not support GDX conversion into formats version 6 and version 5.

6.19.2 Example

In the example below we convert all GDX files to a compressed format for version 6.

```
dir
 1,219 t1.gdx
 1,740 t0.gdx
889,973 i.gdx
 1,740 pv.gdx
894,672 bytes

gdxcopy -v6c *.gdx newdir
dir newdir
 1,219 t1.gdx
 1,219 t0.gdx
203,316 i.gdx
 1,219 pv.gdx
206,973 bytes
```

6.20 GDXDIFF

The GDXDIFF tool compares the data of symbols with identical name, type and dimension in two GDX files and writes the differences to a third GDX file. A summary report will be written to standard output.

6.20.1 Usage

```
gdxdiff file1 file2 {difffile} {options}
```

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. GDXDIFF requires two parameters, the file names of two GDX files. An optional third parameter is the name of the GDX difference file. Without the third parameter, the difference file will be difffile.gdx in the current directory.

difffile = *fileName* (default = difffile.gdx)

An optional name of the GDX difference file.

6.20.2 Options

The following options can be used when calling GDXDIFF:

Option	Default	Description
Eps	0.0	Epsilon for comparison (absolute).
RelEps	0.0	Epsilon for comparison (relative).
field	all	Specify a single subfield (1 , m , up , lo , prior , scale) of a variable or equation to be compared.
fldOnly	disabled	Write variables and equations as parameters for the selected subfield.
id	all	Define specific identifiers of the GDX files to be compared.
diffOnly	disabled	Controls if differences of variables and equations will be written as parameters or not.
cmpDefaults	disabled	Enables the comparison of default values.
cmpDomains	disabled	Enables the comparison of symbol domains.
matrixFile	disabled	Enables the comparison of GAMS matrix files in GDX format.
ignoreOrder	disabled	Ignores UEL order of input files to reduce size of output file.
setDesc	Y	Control if associated text of matching set elements is compared.

Some more detailed remarks on the options:

Eps = *value* (default = 0.0)

Absolute difference for comparisons; see also [Comparing numeric values](#). If the difference between two values exceeds **Eps**, a difference will be reported. The valid range is

RelEps = *value* (default = 0.0)

Relative difference for comparisons; see also [Comparing numeric values](#). If the value of **RelEps** is exceeded, a difference will be reported.

field = *fieldName* (default = all)

The specified subfield is the only field used for deciding if a variable or equation is different. *FieldName* is one of the following: **l**, **m**, **up**, **lo**, **prior**, **scale** or **all**.

fldOnly (disabled by default)

Used in combination with the [field](#) option; The variables and equations will be written as parameters for the selected subfield. This option cannot be used in combination with [diffOnly](#) and requires [field](#) being set to an actual field name but not to **all**.

id = *identifier* (default = all)

Limits the comparison to one or more symbols; symbols not specified will be ignored. Multiple identifiers can be specified as: **id=id1 id=id2** or as **id="id1 id2"**. When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

diffOnly (disabled by default)

Differences for variables and equations will be written as parameters; each parameter will have an additional index which is used to store the field name. Only fields that are different will be written. This option cannot be used in combination with **fldOnly**.

cmpDefaults

Enables the comparison of default values. When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

cmpDomains (disabled by default)

Enable the comparison of symbol domains. Note that the difference are not listed in particular in the diff file. When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

matrixFile

This activates a special mode to compare GAMS matrix files in GDX format. This is mostly done for internal use. When using GDXDIFF from the menu bar in the GAMS IDE (Utilities), this option is not available.

ignoreOrder

By default, GDXDiff preserves the UEL order of the input files. If this is set, this is disabled so that records in the output file could show up in a different order than in the input files. Doing this, the output file can be reduced in size.

setDesc = *boolean* (default = Y)

Enable or disable the comparison of associated texts for set elements.

Criterion for comparing numeric Values

The use of [Eps](#) and [RelEps](#) is best described by the code fragment below.

```
AbsDiff := Abs(V1 - V2);
if AbsDiff <= EpsAbsolute
then
  Result := true
else
  if EpsRelative > 0.0
  then
    Result := AbsDiff / (1.0 + DMin(Abs(V1), Abs(V2))) <= EpsRelative
  else
    Result := false;
```

Interpreting the Labels in the diff file

Only symbols with the same name, type and dimension will be compared. Tuples with different values are written to the GDX difference file, and a dimension is added to describe the difference using the following labels:

- `ins1` indicates that the tuple only occurs in the first file.
- `ins2` indicates that the tuple only occurs in the second file.
- `dif1` indicates that the tuple occurs in both files; contains the value from the first file.
- `dif2` indicates that the tuple occurs in both files; contains the value from the second file.

6.20.3 Examples

6.20.3.1 Compares two GDX Files and writes the Differences to a third GDX File

In the following example, the `[transport]` model is solved twice with different capacity data. GDX files are saved for each run, and compared afterwards using `GDXDIFF`. The shipments variable is loaded into a new variable used for a display statement. We introduce four new unique elements that are used in the difference file.

```
* solve and write to unmodified.gdx before manipulating the data
solve transport using lp minimizing z;
execute_unload 'unmodified.gdx', a, x;

* manipulate the data and solve again, write to modified.gdx
a('seattle') = 1.2*a('seattle');
solve transport using lp minimizing z;
execute_unload 'modified.gdx', a, x;

execute 'gdxdiff unmodified modified diff file > %system.nullfile%';

* Declare symbols to hold the data for differences
Set difftags / dif1, dif2, ins1, ins2 /;
Variable xdif(i,j,difftags);
Parameter adif(i,difftags);

execute_load 'diff file' adif=a, xdif=x;
display a, xdif.l;
```

The display statement generates the following output in the listing file:

```

----      101 PARAMETER a  capacity of plant i in cases

seattle   420.000,    san-diego 600.000

----      101 VARIABLE xdif.L

                                dif1      dif2

seattle .new-york      50.000      120.000
san-diego.new-york    275.000      205.000

```

Alternatively, one can open the diff file in the GAMS IDE or GAMS Studio to display the differences.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXDIFFExample16\]](#) for reference.

6.21 GDXDUMP

GDXDUMP is a tool to write scalars, sets, parameters (tables), variables and equations from a GDX file formatted as a GAMS program with data statements to standard output, GMS or CSV files. To write to a file, use the output redirection '>' provided by the operating system or the [output](#) option of GDXDUMP.

6.21.1 Usage

```
gdxdump filename {options}
```

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

6.21.2 Options

The table summarizes the options of GDXDUMP. Running GDXDUMP without any arguments will write the sets, parameters, scalars etc. to standard output formatted as a GAMS program with data statements.

Option	Default	Description
output	none	Specify the output filename.
version	disabled	Writing version information only.
symp	none	Specify a single identifier to be written from the GDX.
UelTable	none	Write all unique elements in the GDX to a single set.
delim	if format=normal: period if format=csv: comma	Specify a delimiter to separate elements in the output.
decimalSep	period	Specify a decimal separator.
noHeader	disabled	Suppress writing the header information.
header	none	Specify a new header when writing to CSV.

Option	Default	Description
noData	disabled	Only write the headers of the symbols.
CSVAllFields	disabled	Controls the writing of subfields of a variable or equation to CSV.
CSVSetText	disabled	Controls the writing of set element text to CSV.
symbols	disabled	Generate an alphabetical list of all symbols in the GDX file.
symbolsAsSet	disabled	Write some basic information for all symbols in the GDX as set.
symbolsAsSetDI	disabled	Write some basic information including domain information for all symbols in the GDX as set.
domainInfo	disabled	Generate an alphabetical list of all symbols in the GDX file that includes domain information.
setText	disabled	Show the set text (aka the associated text) in the GDX file.
format	normal	Specify the output file format.
dFormat	normal	Specify the numerical format in the output file.
cDim	N	Controls the writing of the column header when using the CSV format.
filterDef	Y	Controls the writing of default values.
EpsOut	EPS	String to be used when writing the value for 'Epsilon'.
NaOut	NA	String to be used when writing the value for 'Not Available'.
pInfOut	+Inf	String to be used when writing the value for 'Positive Infinity'.
mInfOut	-Inf	String to be used when writing the value for 'Negative Infinity'.
UndfOut	Undf	String to be used when writing the value for 'Undefined'.
ZeroOut	0	String to be used when writing the value for 'Zero'.

Some more detailed remarks on the options:

output = *fileName* (default=none)

Write the output to a file. The .gms resp. the .csv file extension must be added when writing to GMS resp. CSV.

This option is demonstrated in [Writing GDX to CSV](#).

-version (disabled by default)

Synonym: -v

Write version information only and terminate; all other options will be ignored.

symp = *identifier* (default=none)

Specify a single identifier in the GDX file to be written to standard output, GMS or CSV. When writing to CSV, one must specify the **symp** option.

This option is demonstrated in [Writing GDX to standard output and to GMS](#).

UelTable = *identifier* (default=none)

Write all unique elements found in the GDX file to a set using the identifier specified as the name for the set.

This option is demonstrated in [Writing GDX to standard output and to GMS](#).

delim = [period, comma, tab, blank, semiColon] (if format=normal: default=period, if format=csv: default=comma)

Selects a different delimiter to separate unique elements; period is the default when writing to standard output or GMS, while comma is the default when writing to CSV.

This option is demonstrated in [Writing GDX to CSV](#).

decimalSep = [period, comma] (default=period)

Specify a decimal separator.

This option is demonstrated in [Writing GDX to CSV](#).

noHeader (disabled by default)

Suppress the header information when writing a single symbol; only the data for the symbol will be written, not its declaration. The option is ignored when writing all symbols. When writing to CSV, the header row can be suppressed by enabling **noHeader**.

This option is demonstrated in [Adding double Quotes to an user defined Header when writing to CSV](#).

header = *string* (default=none)

The string supplied replaces the default header written by the program to a CSV file. If an empty header is desired, the string can be empty; such a string can be written using two single quotes (header=""), while in general it is best to enclose the string with double quotes.

This option is demonstrated in [Writing GDX to CSV](#) and [Adding double Quotes to an user defined Header when writing to CSV](#).

noData (disabled by default)

Only write the headers for the symbols; no data is written. The option is ignored when writing to CSV.

CSVAllFields (disabled by default)

When writing a variable or equation to CSV, all fields (level, marginal, lower, upper, and scale) will be written. Without this option, only the level will be written. When writing a set the option control the writing of the element text.

This option is demonstrated in [Writing GDX to CSV](#).

CSVSetText (disabled by default)

When writing a set to CSV, the set element text will be written as the last column in the CSV file in addition to the set elements. Without this option, only the set elements will be written.

This option is demonstrated in [Writing GDX to CSV](#).

symbols (disabled by default)

Generate an alphabetical list of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in [Writing GDX to standard output and to GMS](#).

symbolsAsSet (disabled by default)

Generate a set declaration where the data represents basic information (symbol identifier, dimension, type, explanatory text) of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in [Writing GDX to standard output and to GMS](#).

symbolsAsSetDI (disabled by default)

Generate a set declaration where the data represents basic information (symbol identifier, dimension, type, domain information) of all symbols in the GDX file (not valid when writing to CSV).

domainInfo (disabled by default)

Generate an alphabetical list of all symbols in the GDX file that includes domain information (not valid when writing to CSV). The column `DomInf` can have the following values:

- `N/A` - The function to get the type of domain information is not available
- `None` - No domain was specified (domain is the universe)
- `Relaxed` - The domain is relaxed, i.e. the identifiers shown do not necessarily represent one dimensional sets
- `Regular` - Regular domain; the identifiers shown are one dimensional sets

This option is demonstrated in [Writing GDX to standard output and to GMS](#).

setText (disabled by default)

Show the set text (aka the associated set text or the set element text) in the GDX file (not valid when writing to CSV).

GDX allows a string of text to be associated with each element of a set. The universe of such strings stored for use in any particular GDX file (i.e. the set text list) can be shown with this option.

format = [normal, gamsbas, CSV] (default=normal)

Change the output format and the symbols written.

When using the gamsbas format, the program will not write the declarations for the symbols and only write the Level and Marginal assignment statements for the variables, and the Marginal assignment statements for equations.

The CSV format adds column headers to the output. By enabling the `cDim` option the unique elements of the last dimension of the symbol will be used as column headers for the values. If domain information is available, the column headers will be made unique if overlapping names have been used for the names of the index positions. If no domain information is available, the index names used will be of the form `dim1, dim2, ...`

In order to run `GDXDUMP`, one must specify a single symbol using the `symb` option when writing to CSV.

The gamsbas and CSV format is demonstrated in [Writing GDX to standard output and to GMS](#) resp. [Writing GDX to CSV](#).

dFormat = [normal, hexponential, hexBytes] (default=normal)

Specify the numerical format in the output file.

cDim = [Y, N] (default = N)

Can be used when writing a CSV file; when enabled, the unique elements of the last dimension will be used as column headers for the values.

This option is demonstrated in [Writing GDX to CSV](#).

filterDef = [Y, N] (default = Y)

When enabled, default values will be filtered and not written. This option is enabled by default. For example, if the Level field (.L) of a variable is zero, the value will not be written.

EpsOut = *string* (default = EPS)

String to be used when writing the value for 'Epsilon'.

NaOut = *string* (default = NA)

String to be used when writing the value for 'Not Available'.

pInfOut = *string* (default = +Inf)

String to be used when writing the value for 'Positive Infinity'.

This option is demonstrated in [Writing GDX to CSV](#).

mInfOut = *string* (default = -Inf)

String to be used when writing the value for 'Negative Infinity'.

UndfOut = *string* (default = Undf)

String to be used when writing the value for 'Undefined'.

zeroOut = *string* (default = 0)

String to be used when writing the value for 'Zero'.

Note that GDX files can also be viewed using the GAMS IDE or GAMS Studio.

6.21.3 Examples

To demonstrate the features of GDXDUMP in the [Writing GDX to standard output and to GMS](#) and [Writing GDX to CSV](#) examples, we execute the model `transport.gms` ([\[TRANSPORT\]](#) from [GAMS Model Library](#)) initially to create the GDX file `transport.gdx` by using the GDX command line option. Afterwards, some important features of GDXDUMP are demonstrated.

```
gams transport.gdx=transport
```

The figure shows the symbol listing of the GDX file in total and the variable `x` in particular, since those data is used quite often in the following examples:

All subfields of the variable `x` are shown in the next figure:

6.21.3.1 Writing GDX to standard output and to GMS

In this example, we will demonstrate the effect of some basic features of GDXDUMP.

While we write to standard output in the most sections of this example, one can also write the GDX file contents into a GAMS file using the following command to redirect the output:

```
gdxdump trnsport.gdx > GDXContents.gms
```

Alternatively, the `output` option can be used to specify an output filename.

Option symbols

This listing shown above can also be written to standard output by using the `symbols` option of GDXDUMP:

```
gdxdump trnsport symbols
```

The GDXDUMP program writes the following output (except for the numbering and the records column, the content is identical compared to the figure):

	Symbol	Dim	Type	Records	Explanatory text
1	a	1	Par	2	capacity of plant i in cases
2	b	1	Par	3	demand at market j in cases
3	c	2	Par	6	transport cost in thousands of dollars per case
4	cost	0	Equ	1	define objective function
5	d	2	Par	6	distance in thousands of miles
6	demand	1	Equ	3	satisfy demand at market j
7	f	0	Par	1	freight in dollars per case per thousand miles
8	i	1	Set	2	canning plants
9	j	1	Set	3	markets
10	supply	1	Equ	2	observe supply limit at plant i
11	x	2	Var	6	shipment quantities in cases
12	z	0	Var	1	total transportation costs in thousands of dollars

Option domainInfo

We use the `domainInfo` option to write some basic information including domain information (column DomInf) to standard output:

```
gdxdump trnsport domainInfo
```

The GDXDUMP program writes the following output:

SyNr	Type	DomInf	Symbol
3	Par	Regular	a(i)
4	Par	Regular	b(j)
7	Par	Regular	c(i, j)
10	Equ	None	cost
5	Par	Regular	d(i, j)
12	Equ	Regular	demand(j)
6	Par	None	f
1	Set	None	i(*)
2	Set	None	j(*)
11	Equ	Regular	supply(i)
8	Var	Regular	x(i, j)
9	Var	None	z

Check the `domainInfo` option explanation linked above to get a full list of possible values for `DomInf` and their interpretation. In this example, the symbol dimensions were not specified (`none`) or they are defined on the one dimensional sets `i` and `j` (`regular`).

Option `symbolsAsSet`

Using the `symbolsAsSet` option one can write the information displayed by enabling the `symbols` option to a set declaration:

```
gdxdump trnsport symbolsAsSet
```

The GDXDUMP program writes the following:

```
alias (Symbol, Dim, Type, *)
set   gdxitems(Symbol,Dim,Type)  Items in the GDX file /
"i".1."Set" "canning plants",
"j".1."Set" "markets",
"a".1."Par" "capacity of plant i in cases",
"b".1."Par" "demand at market j in cases",
"d".2."Par" "distance in thousands of miles",
"f".0."Par" "freight in dollars per case per thousand miles",
"c".2."Par" "transport cost in thousands of dollars per case",
"x".2."Var" "shipment quantities in cases",
"z".0."Var" "total transportation costs in thousands of dollars",
"cost".0."Equ" "define objective function",
"supply".1."Equ" "observe supply limit at plant i",
"demand".1."Equ" "satisfy demand at market j"
/;
```

Option `symp`

One can write a single identifier from the GDX using the `symp` option:

```
gdxdump trnsport.gdx symp=x
```

The default output includes the declaration header and a data statement when writing a set or parameter. When writing a variable, the output includes the level and marginal subfields:

```
positive Variable x(i,j) shipment quantities in cases /
'seattle'. 'new-york'.L 50,
'seattle'. 'chicago'.L 300,
'seattle'. 'topeka'.M 0.036,
'san-diego'. 'new-york'.L 275,
'san-diego'. 'chicago'.M 0.009000000000000001,
'san-diego'. 'topeka'.L 275 /;
```

Note the default values are not written (for instance, zero values of the level or lower bound subfields are missing).

Option `UelTable`

Using the `UelTable` option one can write a set (named `allUELS` in this example) containing all unique elements of the GDX file:

```
gdxdump trnsport output=allUELS.gms UelTable=allUELS
```

The following set declaration will be part of the output file allUELS.gms:

```
Set allUELS /
  'seattle' ,
  'san-diego' ,
  'new-york' ,
  'chicago' ,
  'topeka' /;
```

Format gamsbas

Using the [format](#) option one can write a variable or equation in the gamsbas format, i.e. there will be no declaration of the symbol and the level and marginal subfields will be written as assignments.

```
gdxdump transport format=gamsbas
```

GDXDUMP writes the following to standard output:

```
x.L ('seattle'. 'new-york') = 50 ;
x.L ('seattle'. 'chicago') = 300 ;
x.M ('seattle'. 'topeka') = 0.036 ;
x.L ('san-diego'. 'new-york') = 275 ;
x.M ('san-diego'. 'chicago') = 0.009000000000000001 ;
x.L ('san-diego'. 'topeka') = 275 ;

z.L = 153.675 ;
cost.M = 1 ;
supply.M ('seattle') = Eps ;
demand.M ('new-york') = 0.225 ;
demand.M ('chicago') = 0.153 ;
demand.M ('topeka') = 0.126 ;
```

6.21.3.2 Writing GDX to CSV

Next we specify CSV as the output [format](#) and demonstrate some simple features available when writing to CSV.

Writing to CSV

One can write to a CSV file by running the following command:

```
gdxdump transport.gdx output=varX.csv symb=x format=csv
```

By doing this, the level subfield of the variable `x` is written as a list to the file `varX.csv` specified in the [output](#) statement. The header row contains the domain set identifiers `i` and `j` of `x` and the field "Val":

```
"i","j","Val"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275
```

Option cDim

Using the [cDim](#) option one can write the data as a table since the right most dimension is used as the column header:

```
gdxdump trnsport.gdx symb=x format=csv cDim=y
```

We did not specify an output file in this case, so the data will be written to standard output formatted as CSV:

The GDXDUMP program writes the following:

```
"i","new-york","chicago","topeka"
"seattle",50,300,0
"san-diego",275,0,275
```

Note the elements new-work, chicago and topeka are written to the header row, since they are elements of the most right dimension j.

Customizing the output: CSVAllFields, header, decimalSep, delim, pInfOut etc.

In this section, all subfields of the variable `x` are written to CSV and the representation is customized. The writing of subfields is enabled by [CSVAllFields](#). In addition, the [header](#) option is used to overwrite the default header (as seen in the two previous paragraphs). For instance, we want to replace `i` with the term 'canning plants', `j` with the term 'markets' and "Val" with the term 'shipment quantities in cases', while we are fine with the default column labels for the level, marginal etc. subfields, but they will be overwritten, too. Therefore, we must specify them again manually in the [header](#) option. For some reason, the field separator is changed from comma (default) to semicolon and the decimal separator from period (default) to comma using the [delim](#) and [decimalSep](#) options. One can define the string written to CSV for special values of GAMS like +INF by using the corresponding option [pInfOut](#), which might be useful for further processing of the CSV file.

```
gdxdump trnsport format=csv output=varX.csv symb=x CSVAllFields header="canning plants;markets;shipment quantities in cases;Level;Marginal;Lower;Upper;Scale"
```

GDXDUMP creates the following output:

```
canning plants;markets;shipment quantities in cases;Level;Marginal;Lower;Upper;Scale
"seattle";"new-york";50;0;0;1E+100;1
"seattle";"chicago";300;0;0;1E+100;1
"seattle";"topeka";0;0,036;0;1E+100;1
"san-diego";"new-york";275;0;0;1E+100;1
"san-diego";"chicago";0;0,009000000000000001;0;1E+100;1
"san-diego";"topeka";275;0;0;1E+100;1
```

Note that the fields in the header are not enclosed by double quotes. This problem is addressed in the next section [Adding double Quotes to an user defined Header when writing to CSV](#).

Customizing the output: CSVSetText

The set element text is the *value* of a set element. Often this is left out when defining sets, but for descriptive models often set element text is provided. When dumping a set to a CSV file the set element text is not written to the CSV file by default. The option `CSVSetText` enables the writing of the text. The model `mexss.gms` (`[MEXSS]` from [GAMS Model Library](#)) has a set `i` of steel plants with set element text

```
Set i 'steel plants' / ahmsa      'altos hornos - monclova'
                        fundidora 'monterrey'
                        sicartsa  'lazarro cardenas'
                        hylsa     'monterrey'
                        hylsap    'puebla'                /;
```

When we create a GDX file and dump set `i` as CSV with defaults via the following commands

```
gamslib mexss
gams mexss a=c.gdx=mexss
gxdump mexss format=csv output=setI.csv symb=i header="steel_plants"
```

GDXDUMP creates the following output:

```
steel_plants
"ahmsa"
"fundidora"
"sicartsa"
"hylsa"
"hylsap"
```

If we add `CSVSetText`

```
gamslib mexss
gams mexss a=c.gdx=mexss
gxdump mexss format=csv output=setI.csv symb=i CSVSetText header="steel_plants,real_name"
```

GDXDUMP creates the following output:

```
steel_plants,real_name
"ahmsa","altos hornos - monclova"
"fundidora","monterrey"
"sicartsa","lazarro cardenas"
"hylsa","monterrey"
"hylsap","puebla"
```

6.21.4 Adding double Quotes to an user defined Header when writing to CSV

This sections describes a possible workaround for the following problem: Suppose one wish to write a parameter or variable from GDX to CSV, but with a non default header containing double quotes. For this purpose, one might try to use the `header` option of `GDXDUMP` to specify an user defined header. Though, there is no way to add double quotes enclosing the single fields using the `header` option, but this is a quite common standard in CSV files (for instance, if the fields contain reserved characters).

Initially, define the header you want to write to the CSV file and redirect the line to your final CSV file (which will be created at this point, an already existing file will be overwritten!). Note the double quotes enclosing the field content. Adding the single quotes is necessary in order to run the following statement from GAMS IDE (however, they will not be written to the file), while they must be omitted when using the command prompt.

```
$echo '"canning plants","markets","shipment quantities in cases"' > quotedHeader.csv
```

Afterwards, call `GDXDUMP` by specifying the GDX file, the single symbol `x` we want to write, the output format CSV and redirect the output to the file `quotedHeader.csv`:

```
$call gdxdump trnsport.gdx symb=x format=csv noHeader >> quotedHeader.csv
```

Appending the output of the recent `GDXDUMP` call to the already existing file `quotedHeader.csv` adds the data of `x` to the file and creates the following CSV file (note that one must prevent `GDXDUMP` to write the default header by using the command `noHeader`):

```
"canning plants","markets","shipment quantities in cases"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275
```

6.22 GDXMERGE

The program `GDXMERGE` combines multiple GDX files into a single GDX file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.

6.22.1 Usage

```
gdxmerge filepattern1 filepattern2 .... filepatternN {options}
```

Each file pattern represents a file name or a wildcard representation using `?` and `*`. A parameter of the form `@filename` will process the commands from the text file specified. The result of the `GDXMERGE` execution will be written to a file called `merged.gdx`, unless this default is overwritten by the output option.

The `.gdx` file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

6.22.2 Options

The following options can be specified:

id = *<ident1>*, *<ident2>*... (default = none)

Only merge the symbols **ident1**, **ident2**, ...

exclude = *<ident1>*, *<ident2>*... (default = none)

Merge all symbols except for **ident1**, **ident2**, ...

big = *<integer>*

The size for big symbols.

strict = true|false (default = false)

The program terminates with an error (non-zero return code) if input files specified cannot be found or a file pattern results in no files. An already existing output file also triggers an error if strict is set to true.

output = *fileName* (default = merged.gdx)

The optional output file name.

All symbols with matching type and dimension will be merged. By specifying the parameter **id=ident1** the merge process will only be performed for the identifier(s) specified, while **exclude=ident1** indicates that all symbols should be merged except for the ones specified in the **exclude** list. Note that the two options **id** and **exclude** are mutually exclusive.

By default, the program reads all GDX once and stores all data in memory before writing the merged.gdx file. The **big** parameter is used to specify a cutoff for symbols that will be written one at a time. Each symbol that exceeds the size will be processed by reading each GDX file and only process the data for that symbol. This can lead to reading the same GDX file many times, but it allows the merging of large data sets. The formula used to calculate the cutoff is:

$$\text{dimension} * \text{totalNumberOfElements}.$$

The calculated value is doubled for variables and equations.

In addition to the symbols written, a set is added to the GDX file representing all the files processed during the merge operation. The name of the set is **Merged_set.1**, and is made unique by changing the number. The explanatory text for each set element contains the date and time of the GDX file processed.

Note

- The file merged.gdx, or the file specified with the output parameter, will never be used in a merge operation even if the name matches a file pattern.
- Symbols with dimension 20 cannot be merged, because the resulting symbol will have dimension 21 which exceeds the maximum dimension allowed by GAMS.

6.22.3 Examples

6.22.3.1 Merging several GDX Files

In this example, we solve the `[transport]` model from the GAMS Model Library using different LP solvers. After each run, we write all symbols to a GDX file and merge the files into one file. The variable `X` is read from the merged file and displayed.

```
$call gamslib transport
$call gams transport lp=cplex gdx=cplex
$call gams transport lp=xpress gdx=xpress
$call gams transport lp=conopt gdx=conopt
$call gams transport lp=minos gdx=minos
$call gams transport lp=snopt gdx=snopt
$call gdxmerge *.gdx
```

```
Variable AllX(*,*,*);
$gdxIn merged.gdx
$load AllX=X
$gdxIn
```

```
option AllX:5:1:2;
display AllX.L;
```

The display statement generates the following output in the listing file:

```
----      22 VARIABLE AllX.L  shipment quantities in cases
           seattle      seattle      san-diego      san-diego
           new-york      chicago      new-york      topeka

conopt                300.00000    325.00000    275.00000
cplex      50.00000    300.00000    275.00000    275.00000
minos      50.00000    300.00000    275.00000    275.00000
snopt      50.00000    300.00000    275.00000    275.00000
xpress                300.00000    325.00000    275.00000
```

Note that the different solutions are combined into a single symbol of a higher dimension. The filenames (resp. the solver used) are added as unique elements.

Instead of using the display statement, we can also use the GAMS IDE or GAMS Studio to display the merged.gdx file. The following figure shows the contents of merged.gdx after selecting the level subfield of the variable to be displayed and arranging the display:

This example is also part of the GAMS Data Utilities Library, see model `[GDXMERGEEExample17]` for reference.

6.22.3.2 Recursively Merging GDX Files

Some users generate data scenarios for a model in a hierarchical way and store the results in a directory tree: The following example demonstrates how to use three independent scenario scalars *a*, *b*, and *c* with values *low*, *medium*, and *high* to generate $3*3*3=27$ scenarios, store these in a directory tree, and merge them recursively. The resulting GDX file has for each scenario scalar a new dimension which makes this data especially suitable for viewing in a pivot table:

```

----      39 PARAMETER p  commodity price

                                new-york    chicago    topeka

a_high.b_high.c_high.report    0.25      0.17      0.14
a_high.b_high.c_low .report    0.20      0.14      0.11
a_high.b_high.c_med .report    0.23      0.15      0.13
a_high.b_low .c_high.report    0.25      0.17      0.14
a_high.b_low .c_low .report    0.20      0.14      0.11
a_high.b_low .c_med .report    0.23      0.15      0.13
a_high.b_med .c_high.report    0.25      0.17      0.14
a_high.b_med .c_low .report    0.20      0.14      0.11
a_high.b_med .c_med .report    0.23      0.15      0.13
a_low .b_high.c_high.report    0.25      0.17      0.14
a_low .b_high.c_low .report    0.20      0.14      0.11
a_low .b_high.c_med .report    0.23      0.15      0.13
...

```

The GAMS program that creates the directory structure and runs the model for all 27 scenarios looks as follows:

```

set a,b,c;
parameter
  ascen(a<) / a_low 0.9, a_med 1.0, a_high 1.1 /
  bscen(b<) / b_low 0.9, b_med 1.0, b_high 1.1 /
  cscen(c<) / c_low 0.9, c_med 1.0, c_high 1.1 /;

loop((a,b,c),
  put_utility 'shell' / 'mkdir ' a.tl:0 '\ ' b.tl:0 '\ ' c.tl:0
  put_utility 'exec' / 'gams t.gms lo=2 -idir "%gams.wdir%" -curdir ' a.tl:0 '/' b.tl:0 '/' c.tl:0
);

```

The program creates the directory tree (by creating the leaf nodes of the tree), changes into the leaf directory (`curDir`) and calls GAMS (using `iDir` to point to the starting location). The program `t.gms` is almost an identical copy of the [`transport`] model with the last few lines changed:

```

* ...
a(i) = %a%*a(i);
b(j) = %b%*b(j);
c(i,j) = %c%*c(i,j);

solve transport using lp minimizing z;

scalar tmodelstat;
tmodelstat = transport.modelstat;
parameter p(j) 'commodity price';
p(j) = demand.m(j);
execute 'test -d results || mkdir results';
execute_unload 'results/input', a, b, c;
execute_unload 'results/report', x, z, p, tmodelstat;

```

This code saves the results of a run in to GDX files `input.gdx` and `report.gdx` in a `results` subdirectory. After the program has executed the 27 runs of `t.gms` it executes some Python code that walks recursively through the directory tree and merges GDX files it finds in a `results` folder in the leaf nodes percolates the results up in the tree by calling `gdxmerge` on each high node level. The Python function `os.walk` with argument `topdown=False` ensure the walking of the tree in the correct order. The complete example can be found in the GAMS Model Library in model [`scenmerge`]:

```

embeddedCode Python:
import os
gd = -1
for root, dirs, files in os.walk(os.path.normpath(r"C:\Users\test\allscen\ ".rstrip()), topdown=False):
    if 'results' in dirs:
        if gd == -1:
            gd = root.count(os.path.sep)
            gdr = root;
        elif not gd == root.count(os.path.sep):
            raise NameError('results subdirs found at different depths in the tree: ' + root + ' and ' + gdr)
        cmd = 'cd "' + root + '" && gdxmerge results' + os.path.sep + '* output=' + root.split(os.path.sep)[-1]
        print('Merging results in ' + root)
        if not 0 == os.system(cmd + '>' + os.devnull):
            raise NameError('problems running: ' + cmd)
    elif root.count(os.path.sep) < gd:
        input = ''
        for d in dirs:
            if os.path.isfile(os.path.join(root, d, d + '.gdx')):
                input = input + ' ' + os.path.join(d, d + '.gdx')
        if len(input):
            cmd = 'cd "' + root + '" && gdxmerge' + input + ' output=' + root.split(os.path.sep)[-1]
            print('Merging' + input + ' in ' + root)
            print(cmd)
            if not 0 == os.system(cmd + '>' + os.devnull):
                raise NameError('problems running: ' + cmd)
print('All done. Final result file: ' + root.split(os.path.sep)[-1] + '.gdx')
endEmbeddedCode

```

6.23 GDXMRW

Interfacing GAMS and MATLAB. This document briefly describes GDXMRW (GDX-Matlab Read/Write), a suite of utilities to exchange data between GAMS and MATLAB. The software gives MATLAB users the ability to use all the optimization capabilities of GAMS, and allows visualization of GAMS models directly within MATLAB. The most recent version of GDXMRW is included as part of the current GAMS Distribution.

Attention

GDXMRW is deprecated (see [GAMS 38 GDXMRW release notes](#)). Please use [GAMS Transfer Matlab](#) instead.

6.23.1 Introduction

Optimization is becoming widely used in many application areas as can be evidenced by its appearance in software packages such as Excel and MATLAB. While the optimization tools in these packages are useful for small-scale nonlinear models (and to some extent for large linear models), the lack of a capability to compute automatic derivatives makes them impractical for large scale nonlinear optimization. In sharp contrast, modeling languages such as GAMS and AMPL have had such a capability for many years, and have been used in many practical large scale nonlinear applications.

On the other hand, while modeling languages have some capabilities for data manipulation and visualization (e.g., Rutherford's GNU PLOT), specialized software tools like Excel and MATLAB are much better at these tasks.

This paper describes a link between GAMS and MATLAB. The aim of this link is two-fold. Firstly, it is intended to provide MATLAB users with a sophisticated nonlinear optimization capability. Secondly, the visualization tools of MATLAB are made available to a GAMS modeler in an easy and extendable manner so that optimization results can be viewed using any of the wide variety of plots and imaging capabilities that exist in MATLAB.

In order to enable this link between GAMS and MATLAB, we have implemented MATLAB callable functions that can efficiently import and export data to and from GAMS through GDX files. The simplest read and write functions, `irgdx` and `iwgdx`, deal with indexed parameters. Without getting into their precise meaning, these parameters are essentially indexed in each dimension by the sequence of integers from 1 to the size of that dimension. As an example of the read function, the following command in MATLAB will store the matrices A and B into the caller workspace after reading from the file `foo1.gdx`:

```
>> irgdx('foo1','A','B');
```

Similarly, the call

```
>> iwgdx('foo2','C','D');
```

would write the matrices C and D (located in the MATLAB workspace) as indexed parameters into a file named `foo2.gdx`. Note that, many of the examples found in this manual are also part of the GAMS data utilities models library, referred to here as **datalib**. The statements above can be found in `datalib/example/gdxmrw_intro02_init`. For reading and writing more complex data such as sets, variables, equations, and non-indexed parameters, we can use the more sophisticated functions `rgdx` and `wgdx`. Further descriptions of these functions together with advanced use of `irgdx` and `iwgdx` are detailed in the rest of this paper.

In Section [Data Transfer](#), we discuss the data transfer utilities that allow importing and exporting data between MATLAB and GDX files: `irgdx`, `iwgdx`, `rgdx`, `wgdx`. In Section [Extended use](#), we give a few examples of the MATLAB and GAMS interface. In [APPENDIX A - Configuring GDXMRW](#), we provide information about configuring GDXMRW and testing the utilities. In [APPENDIX B - Utility functions: `gdxWhos` and `gdxInfo`](#), we describe additional utility functions, `gdxWhos` and `gdxInfo`, that allow viewing contents of GDX files in the MATLAB console. Finally, in [APPENDIX C - Calling GAMS model from MATLAB](#), we discuss the `gams` function that with a single call initializes a GAMS model with MATLAB data, executes GAMS on the model, and returns results back into MATLAB.

6.23.2 Data Transfer

This paper describes a suite of tools for exchanging data between GAMS and MATLAB. This data exchange is accomplished via the GDX (i.e. the GAMS Data eXchange) interface and API. There are many advantages to using GDX, including platform independence, space and time efficiency in storing and accessing data, and a guarantee that all GDX data contains no duplicates and is free from any logical or syntax errors that might prevent it from being read into GAMS. The GDX interface is well tested, available to the public, and is the basis for most if not all of the GAMS data utilities.

In this section we discuss four MATLAB routines. The first two, `irgdx` and `iwgdx`, are the subject of sections [irgdx](#) and [iwgdx](#) and are used to quickly and simply read indexed parameters from a GDX file into MATLAB and vice versa. For an example use of these functions, a generic quadratic program function that mimics MATLAB's `quadprog` function is provided in datalib example `gdxmrw_qp3`. The `rgdx` and `wgdx` routines (sections [rgdx](#) and [wgdx](#)) are more sophisticated versions of the first two that can read and write more general GDX data, e.g. sets, variables, equations, and non-indexed parameters. To understand the structure of this GDX data, the material in section [Indexing with labels \(UELS\)](#) is essential.

6.23.2.1 irgdx

`irgdx` is a specialized MATLAB function to do an efficient import of an indexed parameter from a GDX file. The `irgdx` call will not read non-indexed parameters; it can only read data recognized as an indexed data type. If a GDX file consists of both indexed and non-indexed data, `irgdx` can still read the indexed data. To see whether particular parameters in a GDX file are indexed, the `gdxWhos` function described in [APPENDIX B - Utility functions: gdxWhos and gdxInfo](#) can be used.

The syntax and functionality of `irgdx` closely resembles that of the MATLAB `load` function to import MATLAB formatted data, i.e data stored in MAT files. In [Basic syntax](#) and [Load symbols into output structure](#) we describe the basic modes of operation where the data read from GDX are either stored in the caller workspace or into a MATLAB structure on the left-hand side of an assignment. In [MATLAB sparse form](#), we describe an optional specification that allows read results to be stored in MATLAB sparse form. Finally, in Subsection [Renaming](#), we describe a simple syntax that allows the renaming of variables/parameters without the need to make expensive copies.

6.23.2.1.1 Basic syntax The basic syntax for `irgdx` is

```
irgdx('gdxFileName', 'sym1', 'sym2', ...);
```

The above call will read the indexed parameters named `sym1`, `sym2`, and so on from the GDX file whose name is specified in the first argument and store the results in the MATLAB caller workspace. Only the GDX name argument is mandatory. If only this argument is specified (i.e. no symbol names are provided) then *all* of the indexed parameters stored in the GDX file will be loaded into the workspace. The GDX name can be specified with or without the `'.gdx'` extension. Note that all of the input arguments must be specified in string form.

As an example of the above syntax, we can read the scalar `a0`, the vector `a1`, and the matrix `a2` from the file `idx1_.gdx` with the following command:

```
>> irgdx('idx1_', 'a0', 'a1', 'a2');
```

The three symbols are stored as MATLAB variables `a0`, `a1`, and `a2` in the caller workspace. If we want to read all the symbols from the file `idx1_.gdx`, we simply call `irgdx` with only the file name:

```
>> irgdx('idx1_');
```

6.23.2.1.2 Load symbols into output structure An alternative to storing the results in the MATLAB caller workspace is to return the results in a MATLAB structure. Here, the syntax is:

```
s = irgdx('gdxFileName','sym1','sym2',...);
```

This call will return the indexed parameters named `sym1`, `sym2`, and so on in the structure `s`, with fields `s.sym1`, `s.sym2`, and so on containing the values of the respective indexed parameters. The input arguments must all be in string form. Only the GDX name is mandatory; if only this argument is specified, all of the indexed parameters stored in the GDX file will be returned in the output structure. The GDX name can be specified with or without the `.gdx` extension.

For example, the following call returns the values of parameter `a2` in the structure `s`:

```
>> s = irgdx('idx1_', 'a2');
>> s.a2

ans =

    50    50
    50    50
```

To return all the indexed parameters in the fields of the structure `s`, we would simply call `irgdx` with only the GDX name:

```
>> s = irgdx('idx1_');
```

See datalib example `gdxmrw_irgdx01_init`.

6.23.2.1.3 MATLAB sparse form By default, `irgdx` will store results in MATLAB dense form. However, it is possible to use MATLAB sparse form for parameters with dimension less than or equal to 2; MATLAB's sparse storage scheme cannot handle matrices with more than 2 dimensions. Using sparse storage will allow for efficient import of especially large sparse indexed parameters. Note that in this context *sparse* does not refer to data represented in the form `[i,j,...,val]` but rather to MATLAB's internal sparse storage scheme. To store a particular symbol in MATLAB sparse form, one can simply append `':s'` to that symbol's name in the `irgdx` call. For example, the following call will store the parameter `a2` into the caller's workspace in sparse form:

```
>> irgdx('idx1_', 'a2:s');
```

Note that if we want to store *all* the indexed parameters from a specified file in MATLAB sparse form, we would need to specify each symbol individually in order to append the `':s'` to each symbol's name.

6.23.2.1.4 Renaming The details of this section are rather involved; it can be skipped without loss of continuity.

While an `irgdx` call will typically store results in the caller workspace or create field names in the output structure using the symbol names from the GDX file, it is possible to rename the outputs in MATLAB without making potentially expensive copies. To rename a symbol, we can take advantage of MATLAB's default copy-on-write mechanism: when an assignment occurs, the values assigned are not actually copied until one of the values (the original or the copy) is actually changed. For example, after executing the following two lines of code, the variable `a2_new` points to the same memory location as `a2` and is *not* a separate copy of `a2`:

```
>> irgdx('idx1_', 'a2');
>> a2_new = a2;
```

If however the value of `a2_new` were changed after executing the above lines, MATLAB would then need to make a separate copy, at the cost of memory and time. Now, the command

```
>> clear a2;
```

immediately following the above code would complete the rename of `a2` to `a2_new` as desired. Once `a2` is cleared, we can change `a2_new` without needing to make a copy. Similarly, we can do a rename when we have an output structure:

```
>> s = irgdx('idx1_', 'a2');
>> s.a2_new = s.a2;
>> s = rmfield(s, 'a2');
```

To convince ourselves that this code indeed does not require a copy, we can run the commands in the debug output format. That is, immediately after the assignment of `s.a2` to `s.a2_new` in the above code (before using the `rmfield` function), we can run the following commands:

```
>> format debug;
>> s.a2
```

```
ans =
```

```
Structure address = 8c1eda0
m = 2
n = 2
pr = 75fa88a0
pi = 0
    50    50
    50    50
```

```
>> s.a2_new
```

```
ans =
```

```
Structure address = 8c1eda0
m = 2
n = 2
pr = 75fa88a0
pi = 0
    50    50
    50    50
```

Note that the pointer `pr` is the same for both outputs, implying that MATLAB does not make a separate copy prior to a write. A similar test can also be done when parameters are stored in workspace variables rather than a structure.

6.23.2.2 iwgdX

`iwgdX` is a function that creates a GDX file of indexed parameters from MATLAB data. Since `iwgdX` writes only indexed parameters to GDX, the input MATLAB data is simplified: no labels are required or implied. The input matrices can be stored in the usual (dense) scheme or using the MATLAB sparse scheme: `iwgdX` detects and handles the two cases automatically. Note that matrices represented in `[i,j,...,val]` form are not acceptable as `iwgdX` input.

While the `iwgdX` function is patterned after the `save` function in MATLAB, there are important differences. Firstly, if **only** the file name is specified, the `save` function stores all variables in the caller workspace, while `iwgdX` creates an empty GDX file. The behavior of `iwgdX` in this case also differs from that of `irgdX`, which reads all parameters when only the file name is specified. Secondly, `iwgdX` has an additional pass by reference and renaming syntax, in which the parameter string name and values are passed as two consecutive arguments. In Subsection [Basic syntax](#), we describe the basic syntax for `iwgdX`. In Subsection [Pass by reference syntax](#), we introduce the pass by reference and renaming syntax. Finally, in Subsection [Dimensionality specification](#), we describe an optional dimensionality specification that allows symbols to be written with a larger dimensionality than the default.

6.23.2.2.1 Basic syntax The basic syntax for `iwgdX` is:

```
iwgdX('fileName','sym1','sym2',...);
```

The above call will write the values of the variables `sym1`, `sym2`, and so on in the MATLAB caller workspace into a GDX file with the name given by the first input argument. The file name can be specified with or without the `'.gdx'` extension. If a GDX file with the same name already exists, it will be overwritten. Note that a call with a single input argument (the GDX name) will raise a warning and will create an empty GDX file. This contrasts to the MATLAB `save` function, which writes all of the workspace variables when none are specified. In the basic form described here, all of the `iwgdX` input arguments are strings.

To illustrate, suppose the matrices `a2` and `a3` exist in the MATLAB caller workspace. We can write the results of these matrices into a file `test.gdx` with the following call:

```
>> iwgdX('test','a2','a3');
```

If the file `test.gdx` already exists, it will be overwritten. Specifying only the file name will create an empty GDX file:

```
>> iwgdX('test');
Warning: an empty gdx file was created.
```

6.23.2.2.2 Pass by reference syntax When using the basic `iwgdX` syntax, a copy of the workspace variable to be written to GDX is made as part of the call. This is unavoidable: the MATLAB executable (MEX) interface only provides functions that return *copies* of workspace variables, most likely to avoid overwriting or corrupting data. However, an alternative, more efficient approach is possible by passing the numeric data as an argument. Essentially, the pointer to the data values are passed by reference and no copy is made. This could be especially useful when writing a large amount of data. An additional benefit of this syntax is the ability to write GDX parameters with different names than used in the MATLAB caller workspace. For example:

```
>> iwgdX('test','s1',s1Mat,'s2',s2Mat);
```

In the above command, `s1` and `s2` are strings holding the GDX parameter names, while `s1Mat` and `s2Mat` are matrices containing the values to store. We can also use a mix of the basic syntax with the pass by reference syntax. For example:

```
>> iw.gdx('test','anew',a,'b','c',c);
```

This call would save matrix `a` as `anew` in GDX without making a copy, would internally make a copy of `b` while saving `b` to GDX, and would save `c` to GDX without renaming or making a copy.

We can do a timing test to see the performance difference between the basic syntax and the pass by reference syntax. The following commands create a 5000x5000 dense matrix consisting of random values in the workspace.

```
>> clear;
>> randMat = rand(5000);
```

First, we do a timing test using the basic syntax:

```
>> delete test.gdx; % delete file if it exists
>> tic;
>> iw.gdx('test','randMat');
>> t1 = toc
```

```
t1 =
    5.3346
```

Now, we do a timing test using the pass by reference syntax:

```
>> delete test.gdx; % delete file if it exists
>> tic;
>> iw.gdx('test','randMat',randMat);
>> t2 = toc
```

```
t2 =
    5.1636
```

For the above example, the improvement in time performance is about 3%. Of course, the pass by reference call will also use only the half the memory compared to the basic call. We can expect further improvement in performance time and memory use for even larger data.

6.23.2.2.3 Dimensionality specification It is possible to specify the number of dimensions (i.e. dimensionality) for the symbol written to GDX by appending `:n` to the variable/symbol name, where `n` is the desired dimensionality of the GDX symbol. This feature is motivated by two quirks of the MATLAB environment. Firstly, all scalars and vectors are stored in MATLAB as 2-dimensional matrices. For example:

```
>> s0 = 100
>> s1 = [ 100 ]
```

results in two variables with identical storage schemes: 1x1 matrices. In the MATLAB environment this isn't a problem: things behave as you would expect them to, and the `isscalar`, `isvector`, and `ismatrix` calls are available to interrogate MATLAB about how it views variables. However, in GDX there is a distinction between a scalar (something with 0 dimensions), a parameter with 1 dimension and length 1, and a 1x1 parameter. We need to be able to create GDX files containing any or all of these.

Secondly, MATLAB "flattens" all variables by removing trailing dimensions whose size is 1. For example, after executing

```
>> B = ones(2,2,2)
>> C = ones(2,2,2,1,1)
```

B and C will be identical 3-dimensional MATLAB arrays, yet we need to be able to create a 2x2x2x1x1 indexed parameter in GDX.

By default, `iwgdx` creates GDX parameters that are consistent with the MATLAB view of the data passed in. For example, executing

```
>> d0 = ones(1,1)
>> d1 = ones(3,1)
>> d2 = ones(3,3)
>> iwgdx('dd', 'd0', 'd1', 'd2')
```

results in indexed parameters with 0, 1, and 2 dimensions, respectively, being written to GDX. However, if we want to write `d0` as a vector or matrix or higher-dimensional array, we need to use the optional syntax to specify the dimensionality of the resulting symbol in GDX. For example:

```
>> d0 = pi;
>> p1 = d0;
>> d1 = pi*ones(3,1);
>> p2 = d1;
>> d2 = pi*ones(3,3,1)
>> iwgdx('pp', 'd0', 'p1:1', 'd1', 'p2:2', 'd2', 'p3:3', d2)
```

will write the following symbols to GDX:

- The 0-dimensional symbol `d0`. This is the default behavior, consistent with the MATLAB view that `d0` is a scalar.
- The 1-dimensional symbol `p1`. The scalar variable `p1` was promoted to a 1-dimensional symbol by adding an additional singleton dimension.
- The 1-dimensional symbol `d1`. This is the default behavior, consistent with the MATLAB view that `d1` is a vector.
- The 2-dimensional symbol `p2`. The vector variable `p2` was promoted to a 2-dimensional symbol by adding an additional singleton dimension.
- The 2-dimensional symbol `d2`. This is the default behavior, consistent with the MATLAB view that `d2` is a matrix, i.e. the final singleton dimension is just removed.
- The 3-dimensional symbol `p3`. The matrix variable `d2` was promoted to a 3-dimensional symbol by adding an additional singleton dimension. Independently, call-by-reference was used to rename `d2` to `p3`.

Note that the dimensionality specified must always be a promotion, i.e. the dimensionality of the resulting GDX symbol is only increased from what it would be by default.

See `datalib` example `gdxmrw_iwgdx01_init`.

6.23.2.3 Indexing with labels (UELs)

To this point we have been looking at functions to read (`irgdx`, Section [irgdx](#)) and write (`iwgdx`, Section [iwgdx](#)) *indexed* parameters from and to GDX. Indexed parameters are convenient since their structure is essentially identical to that of MATLAB matrices. This structure can be encapsulated very simply as the number of dimensions and the size or extent of each dimension. Using indexed parameters, we do not need to be very concerned with the structure of the data since little structure exists. However, there is much more to GDX data than indexed parameters. If we want to read and write GDX data in more generality we will need to understand how labels or strings are used to reference GDX data and how these labels are organized within GDX.

In general, GAMS data is referenced with labels instead of with numbers, so that one references `demand('chicago')` instead of `demand(2)` in a GAMS model. These labels are also called Unique Element Labels, or UELs. The collection of UELs used in a model or in a GDX file is ordered internally and often referred to as the *universe* of UELs. For efficiency, it is not necessary to use labels internally in GDX or when using the GDX API. Instead, a correspondence or mapping between integers and labels is established initially and/or built up as labels are introduced, so that integers can be used in place of the UELs that reference the data. It is important to keep in mind that the labels are the key thing in referencing GDX data: when integer maps are used the integers are only used to efficiently represent the labels.

A similar scheme mapping integers to labels is used in the `rgdx` and `wgdx` routines for reading and writing general GDX data. In addition to the actual data values being stored, there will be a mapping passed to allow integers to be mapped to labels and vice versa. In some cases, where no mapping is passed and data are written to GDX, a default mapping (1 to '1', 2 to '2', etc.) may be used. When reading, the default mapping to use when passing back data is the universe mapping from the GDX, but it is possible to apply a filter. A filter can reduce the amount of data returned and also change the order of that data.

6.23.2.4 rgdx

`rgdx` is a MATLAB utility to import data from a GDX file. It takes structural input and returns data back in the form of a structure. This is a very flexible routine as it gives user control over the output data structure. `rgdx` can read a set/parameter/equation/variable from a GDX file and display results in either full/dense or sparse form. A user can also perform a filtered read to read only certain specific elements of a symbol. It can also perform compression to remove extra zeros.

This routine can take up to two arguments. The first argument is a string input containing the GDX file name. It can be with or without the `.gdx` file extension. If you call this routine with only the GDX file name as an argument then the `'uels'` field of output structure will be the global UEL of the GDX file and the rest of the fields of the output structure will be NULL. The second argument is a structure input containing information regarding the desired symbol. The syntax for this call looks like this:

```
x = rgdx('fileName', structure);
```

As an example, we read a 3D parameter, `'test3'` from `'sample.gdx'`. Here we display this parameter in full format but without redundant zeros:

```
>> s.name = 'test3';
>> s.form = 'full';
>> s.compress = true;
>> x = rgdx('sample', s)
```

```
x =
```

```

name: 'test3'
type: 'parameter'
dim: 3
val: [4x2x2 double]
form: 'full'
uels: {{1x4 cell} {1x2 cell} {1x2 cell}}

>> x.val

ans(:,:,1) =

    3    4
    4    5
    5    6
    6    7

ans(:,:,2) =

    4    5
    5    6
    6    7
    7    8

>> x.uels{1}

ans =

    '1'    '2'    '3'    '4'

>> x.uels{2}

ans =

    'j1'    'j2'

>> x.uels{3}

ans =

    'k1'    'k2'

```

In the following subsections we will explain the input and output structures. Please note that except for the 'name' and 'uels' fields, all other string fields take case insensitive input. All boolean fields can also be entered as string values as well.

6.23.2.4.1 Input structure To read a symbol from a GDX file we just need to know its name in string format. Thus, the only mandatory field of the input structure is 'name'. e.g.

```
>> s.name = 'test3';
```

There are several other optional fields of the input structure that give user more control over the output structure. These optional fields are as follows:

1. form

This field represents the form of the output data. Output data can be either in 'full' or 'dense' form or it can be in [i, j, ..., val] sparse form. We will label [i, j, ..., val] as 'sparse'. A user can enter it as string input with value 'full' or 'sparse'. e.g.

```
>> s.form = 'full';
```

By default the data will be in 'sparse' format. Note that this sparse format differs from MATLAB's internal sparse storage scheme that we referred to in prior sections for the `irgdx` and `iwgdx` functions.

2. compress

By default the uels in the output structure will be a global UEL of the GDX file and the 'val' field data will be indexed to this UEL. The `rgdx` routine allows a user to remove rows and columns with all zeros from the 'val' data matrix and re-indexes the uels accordingly. This is called compression of the data. This can be achieved by setting `compress` as true in the input structure. Valid values for this field are true and false, either in logical form or in string form. e.g.

```
>> s.compress = 'true';
```

However, we note that compressing the data can be dangerous because the size of the matrix that is read can be incorrect. Essentially, all zero rows and columns are removed, including those that might actually be part of the data values in the symbol matrix.

3. uels

This input field is used to perform a filtered read, i.e. output data matrix will contain values only corresponding to the entered uels. Filtered read is very useful if user just wants certain specific set of data. Uels should be entered in cell array form. It has to be in 1xN form with each column being a cell array representing the uels for that dimension. Each column can have strings, doubles or combinations of both. It also allows a user to enter double data in shorthand notation or a 1 x N matrix. For example, in the previous example we can perform a filtered read to get data corresponding to only the '1&prime', '3' elements of the first index of the parameter 'test3'. The following function is handy when one needs to generate a UEL listing for the input structure:

```
>> guel = @(s,v) strcat(s, strsplit(num2str(v)));
```

Using the above function, we can create a listing of strings consisting of the string `s` appended to each number in the array `v`. Thus, instead of using the command

```
>> s.uels = {'1', '3'}, {'j1', 'j2'}, {'k1', 'k2'};
```

we can conveniently use the command

```
>> s.uels = {guel('', [1,3]), guel('j', 1:2), guel('k', 1:2)};
```

The benefit of using the latter command will be more apparent when creating many elements in the listing. Now, as an example, suppose we would like to do a filtered read on the parameter called `test2` in `sample.gdx`. We could use the following commands:

```
>> s.name = 'test3';
>> s.form = 'full';
>> s.compress = false;
>> s.uels = {guel('', [1,3]), guel('j', 1:2), guel('k', 1:2)};
>> x = rgdx('sample', s)
```

```
x =
```

```
name: 'test3'
type: 'parameter'
dim: 3
val: [2x2x2 double]
```

```

    form: 'full'
    uels: {{1x2 cell} {1x2 cell} {1x2 cell}}

>> x.val

ans(:,:,1) =

     3     4
     5     6

ans(:,:,2) =

     4     5
     6     7

```

Here it should be noted that we turned off compression while performing the filtered read. This is necessary because the filtered read will give data in accordance with the entered uels and the output uels will be the same as the input uels; thus compression is not possible.

4. field

This field is required when variables or equations are to be read from a GDX file. Sets and parameters in the GDX file do not have any field value but variables and equations have 5 fields namely, level, marginal, lower, upper, and scale. Thus, it may be useful to enter field as an input when reading an equation or a variable. A user can enter it as a string with valid values being 'l/m/up/lo/s'. e.g.

```
>> s.field = 'm';
```

By default, the output will be the level value of a variable or an equation.

5. ts

This represents the text string associated with the symbol in the GDX file. If a user sets this field to be 'true', then the output structure will have one more string field 'ts' that contains the text string of the symbol. e.g.

```
>> s.ts = true;
```

6. te

GAMS allows a modeler to enter text elements for a set. Similarly to the 'ts' field, if a user sets 'te' to be true in the input structure, then the output structure will contain one more field representing the text elements for that symbol. Please note that text elements only exist for 'sets'. e.g.

```
>> s.te = true;
```

6.23.2.4.2 Output Structure As mentioned earlier, output of the `rgdx` routine will be in structure form. This structure is very similar to the input structure. To get information regarding any symbol, we always need to display its basic characteristics, such as its name, type, value, uels, form, etc. An output structure will always have these fields:

1. name

It is same as that entered in the input structure name field, i.e., the symbol name in the GDX file.

2. val

It represents the the value matrix of the symbol. To save MATLAB memory by default it will be in 'sparse' format. e.g.

```

>> s = rmfield(s, 'form');
>> s

s =
      name: 'test3'
  compress: 0

>> x = rgdx('sample', s)

x =
      name: 'test3'
     type: 'parameter'
       dim: 3
       val: [16x4 double]
      form: 'sparse'
     uels: {{1x8 cell} {1x8 cell} {1x8 cell}}

```

Here `val` is a 16x4 double matrix. As it is a parameter; thus the last column of the sparse matrix will represent the value and the rest (i.e. the first three columns) will represent its index. Please note that in the case of a `'set'`, the number of columns in the sparse matrix will be equal to its dimension, i.e., it will not have a column representing its value. Here, the presence of each row in the output `'val'` field corresponds to the existence of a set element at that index. When a `'full'` matrix output is specified, a 1 represents existence of a set element and a 0 otherwise.

3. form

It represents the format in which the `'val'` field is being displayed. As mentioned earlier it can be either in `'full'` or `'sparse'` form.

4. type

While reading a symbol from a GDX file it is often very useful to know its type. The `rgdx` routine is designed to read set, parameter, variable and equation. This field will store this information as a string.

5. uels

This represents the unique element listing of the requested symbol in the form of a cell array. It is a 1 x N cell array, where N is the dimension of the symbol. Each column of this array consists of string elements. By default, the output `uels` will be the same as the global `uel` of the GDX file, but it can be reduced to element specific local `uels` if `compress` is set to be true in the input structure. If a user is using a filtered read, i.e. calling `rgdx` with input `uels`, then the output `uels` will be essentially the same as the input `uels`.

6. dim

It is a scalar value representing the dimension of the symbol.

Apart from these necessary fields there are a few additional fields as well. They are as follows:

7. field

If we are reading variables or equations, then it becomes useful to know which field we have read, i.e., `l/m/up/lo/s`. This information is displayed via this field in the form of a string.

8. ts

It display the explanatory text string associated with the symbol. This field only exists in the output structure if the `'ts'` field is set as `'true'` in the input structure.

9. te

It is an N dimensional cell array representing the text elements associated with each index of the set. This field only exists in the output structure if the `'te'` field is set as true in the input structure and the symbol is a set.

See `datalib` example `gdxmrw_rgdx01_init`.

6.23.2.5 wgdX

wgdX is a MATLAB routine to create a GDX file containing data from MATLAB. Similar to the rgdX routine, it takes a structure input and can write multiple symbols into a single GDX file with one call. The first argument is the file name of the GDX file to be created in string format; it can be with or without the '.gdX' file extension. The rest of the arguments are structures, each containing data for different symbols to be written into the GDX file. The syntax for the call is:

```
>> wgdX('fileName', s1, s2 ...);
```

If the GDX file already exists in the MATLAB current directory, wgdX will overwrite it; otherwise a new file will be created. After a successful run, it doesn't return anything back into MATLAB. Most of the fields of its input structures are the same as those of the rgdX output structure. In the example below, we use the wgdX routine to create foo.gdX containing a set 'l' and a parameter 'par'.

```
>> s.name = 'l';
>> s.uels = {'i1', 'i2', 'i3'}, {'j1', 'j2'};
>> c.name = 'par';
>> c.type = 'parameter';
>> c.val = eye(3);
>> c.form = 'full';
>> c.ts = '3 x 3 identity';
>> wgdX('foo', s, c)
```

The equivalent code in GAMS to create the above set 'l' is:

```
Set
  a / i1*i3 /
  b / j1*j2 /
  l(a,b);

l(a,b) = yes;
```

In the next subsection we will explain the input fields in detail.

6.23.2.5.1 Input Structure The necessary fields in an input structure to represent a symbol are given below:

1. name
It is a string representing the name of the symbol.
 2. val
It represents the value matrix of the parameter or set. It can be entered in either full or sparse format, whichever is convenient to the user; the corresponding format must be specified in the 'form' field. By default the value matrix is assumed to be in sparse format.
 3. type
It is a string input to specify the type of the symbol. The wgdX routine can write a set or parameter into the GDX file. In the previous example, we didn't specify the type for structure 's' because by default it is assumed to be a set.
 4. form
This is a string input representing the format in which the val matrix has been entered. By default it is assumed that the data is specified in sparse format.
-

5. uels

Similar to the `rgdx` `uels` field, this represents the local unique element listing of the symbol in an 1 x N cell array form. Each column of this cell array can contain string or double or both. Again we can make use of a handy function to create a UEL listing as mentioned previously in the section about `rgdx`:

```
>> guel = @(s,v) strcat(s, strsplit(num2str(v)));
```

As an example, we create a set using this function and the `wgdx` routine:

```
>> s.name = 'l';
>> s.uels = {guel('i',1:20),guel('j',1:40)};
>> wgdx('foo',s);
```

The above code will create `foo.gdx` that contains a 2 dimensional set 'l' with set elements for each of the specified uels. If a user would like to create a set with set elements only at specified indices, one could do so by entering the indices in the `val` field. e.g.

```
>> s.val = [1, 1; 2, 1; 3, 6; 4, 7];
>> wgdx('foo',s);
```

Now the above would result in a set with only elements existing in the indices specified in the `val` field. If a user enters a structure with only two fields, `name` and `uels`, as in the example given in the introduction of this section (structure `s`), then `wgdx` will create a full set corresponding to the global uels.

The optional fields are:

6. dim

This field is useful when a user wants to write a zero dimensional or 1 dimensional data in full format. As every data matrix in MATLAB is at least 2D, it becomes necessary to indicate its dimension for writing purposes.

7. ts

This is the text string that goes with the symbol. If nothing is entered then 'MATLAB data from GDXMRW' will be written in the GDX file.

See `datalib` example `gdxmrw_wgdx01_init`.

6.23.3 Extended use

In this section, we will discuss a few examples of the MATLAB and GAMS interface. We will give a simple example of a nonlinear optimization problem that would benefit from this capability and describe the steps that are needed in order to use our interface in this application.

- Special values

Following example shows how special values are handled by this interface. It can be seen that `rgdx` can retrieve all these values from GDX file and display them appropriately in MATLAB.

```
>> s.name = 'special';
>> s.form = 'full';
>> s.compress = true;
>> x = rgdx('sample', s)
```

x =

```
name: 'special'
```

```

    type: 'parameter'
    dim: 1
    val: [4x1 double]
    form: 'full'
    uels: {{1x4 cell}}

>> x.val

ans =

        -Inf
         NaN
    3.141592653589793
         Inf

```

- Variables and Equations

In an optimization problem, we are not only interested in level value of variables and equations but also in their marginal values, lower and upper bounds. This interface gives its user ability to read any of these values into MATLAB. By default `rgdx` and `gams` routines will read the level value of equations and variables but this can be changed very easily by using `'field'` in input structure. In `gams` call user can also specify this in `'$set matout'` statement. e.g.

```
$set matout "'matsol.gdx', x.m, dual.lo=d1 ";
```

In this case the marginal value of variable `'x'` will be read and lower bound of dual variable will be read and stored in `'d1'`.

- Text string and Text elements

GAMS allows its user to enter text string and explanatory text elements and all GDX file contain this information as well. Following example shows how to get these text elements in MATLAB.

```

>> s1.name = 'el';
>> s1.te = true;
>> s1.ts = true;
>> s1.compress = true

s1 =

    name: 'el'
     te: 1
     ts: 1
compress: 1

>> z = rgdx('sample', s1)

z =

    name: 'el'
   type: 'set'
    dim: 2
   val: [3x2 double]
   form: 'sparse'
   uels: {{1x2 cell} {1x2 cell}}
     ts: 'This is 2D set with text elements'
     te: {2x2 cell}

>> z.te

ans =

```

```

    'element1'    'element2'
    '2.j1'        []

>> z.val

ans =

     1     1
     1     2
     2     1

```

- String elements

One piece of information that may be needed within MATLAB is the modelstat and solvestat values generated by GAMS for the solves that it performed. This is easy to generate, and an example is given in `do_status.m`. This example is generated by taking the standard gamslib trnsport example, and adding the following lines to the end:

```

$set matout "'matsol.gdx', returnStat, str ";

Set
  stat / modelstat, solvestat      /
  str  / 'grunt', '%system.title%' /;

Parameter returnStat(stat);
returnStat('modelstat') = transport.modelstat;
returnStat('solvestat') = transport.solvestat;
execute_unload %matout%;

```

Note that the relevant status numbers are stored in GAMS into the parameter `returnStat` which is then written to `matsol.gdx` and read back into MATLAB using the `rgdx` call.

```

>> gamso.output = 'std';
>> gamso.form = 'full';
>> gamso.compress = true;
>> s = gams('trnsport')

s =

     1
     1

```

See datalib example `gdxmrw_ext01_init`.

- Advanced Use: Plotting

One of the key features of the GAMS/MATLAB interface is the ability to visualize optimization results obtained via GAMS within MATLAB.

Some simple examples are contained with the program distribution. For example, a simple two dimensional plot with four lines can be carried out as follows. First create the data in GAMS and export it to MATLAB using the `gams` routine (see [APPENDIX C - Calling GAMS model from MATLAB](#) for a detailed description of this routine).

We make an assumption that the user will write the plotting routines in the MATLAB environment. To create the plot in MATLAB, the following sequence of MATLAB commands should be input (saved as `do_plot.m`).

```

gamso.output = 'std';
gamso.compress = true;
gamso.form = 'full';
[a,xlabels,legendset,titlestr] = gams('simple');
figure(1)

```

```

% Plot out the four lines contained in a;
% format using the third argument
plot(a,'+-');
% only put labels on x axis at 5 year intervals
xtick = 1:5:length(xlabels{1});
xlabels{1} = xlabels{1}(xtick);
set(gca,'XTick',xtick);
set(gca,'XTickLabel',xlabels{1});
% Add title, labels to axes
title(titlestr{1});
xlabel('Year -- time step annual');
ylabel('Value');
% Add a legend, letting MATLAB choose positioning
legend(legendset{1},0);
% match axes to data, add grid lines to plot
axis tight
grid

```

The data is created using the following gams code.

```
$title Examples for plotting routines via MATLAB
```

```
$set matout "'matsol.gdx', a, t, j, sys ";
```

```
Set
```

```

sys / '%system.title%' /
t   / 1990*2030      /
j   / a, b, c, d     /;

```

```
Parameter a(t,j);
```

```
a("1990",j) = 1;
```

```
loop(t, a(t+1,j) = a(t,j)*(1 + 0.04*uniform(0.2,1.8)));;
```

```
Parameter year(*);
```

```
year(t) = 1989 + ord(t);
```

```
* Omit some data in the middle of the graph:
```

```
a(t,j)$((year(t) > 1995)*(year(t) <= 2002)) = na;
```

```
execute_unload %matout%;
```

The following figure is an example created using this utility (and the MATLAB command `print -djpeg simple`).

See datalib example `GDXMRWPlotting01`.

MATLAB supports extensive hard copy output or formats to transfer data to another application. For example, the clipboard can be used to transfer meta files in the PC environment, or encapsulated postscript files can be generated. The `help print` command in MATLAB details the possibilities on the current computing platform.

Scaling of pictures is also most effectively carried out in the MATLAB environment. The following code is an example of rescaling printed out. Note that the output of this routine is saved as a jpeg file `"rescale.jpg"`.

```

do_plot;
fpunits = get(gcf,'PaperUnits');
set(gcf,'PaperUnits','inches');
figpos = get(gcf,'Position');
pappos = get(gcf,'PaperPosition');

```

```
newpappos(1) = 0.25;
newpappos(2) = 0.25;
newpappos(3) = 4.0;
% get the aspect ratio the same on the print out
newpappos(4) = newpappos(3)*figpos(4)/figpos(3);
set(gcf,'PaperPosition',newpappos),
print -djpeg100 rescale.jpg
set(gcf,'PaperPosition',pappos);
set(gcf,'PaperUnits',fpunits);
```

Other examples of uses of the utility outlined in this paper can be found in the "m" files:

```
do_ehl
plotngon
```

that are contained in the distribution.

6.23.4 Acknowledgements

The authors would like to thank Alexander Meeraus and Michael R. Bussieck of GAMS corporation for constructive comments on the design and improvement of this tool. Thanks to Rishabh Jain for work on an earlier version.

6.23.5 APPENDIX A - Configuring GDXMRW

6.23.5.1 Installation

This section describes the installation procedure for all types of machines. The following section describes the testing procedure for verifying a correct installation.

First of all, you need to install both MATLAB and GAMS on your machine. For brevity, we will assume that the GAMS system (installation) directory is (for Windows)

```
C:\GAMS
```

and for non-Windows systems:

```
/usr/local/gams
```

All of the utilities come as a part of the GAMS distribution, so to use them you have only to add the GAMS directory to the MATLAB path. One way to do this is from the MATLAB command prompt, as follows:

```
>> addpath 'C:\GAMS'; savepath;
```

OR this can be done by following these steps:

1. Start MATLAB
 2. Click on 'File' tab.
 3. Now click on 'Set Path'
 4. Click on 'Add Folder'
 5. Select GAMS directory and click 'OK'.
 6. Save it and then close it.
-

6.23.5.2 Testing

The GAMS system comes with some tests that you should run to verify the correct configuration and operation of the GDXMRW utilities. In addition, these tests create a log file that can be useful when things don't work as expected. To run the tests, carry out the following steps.

1. Create a directory to run the tests in, e.g.

```
% mkdir \tmp
```

2. Extract the test models and supporting files from the GAMS test library into the test directory.

```
% cd \tmp
% testlib.gdxmrw03
% testlib.gdxmrw04
% testlib.gdxmrw05
% testlib.gdxmrw06
```

3. Execute the GAMS files `gdxmrw03`, `gdxmrw04`, and `gdxmrw06`. The files `gdxmrw03` and `gdxmrw04` test that the `rgdx` and `wgdx` routines are working properly, and `gdxmrw06` test `irgdx` and `iwgdx`. In addition to calling MATLAB in batch mode, they verify that the data are read and written as expected and give a clear indication of success or failure.
4. The GAMS file `gdxmrw05` tests the `gams` MATLAB routine. Like the other tests, it can be run in batch mode. You can also run it interactively by starting MATLAB, making `tmp` the current directory, and running the script `'testinst.m'`.

```
>> testinst
```

In addition to messages indicating success or failure, this test produces a log file `testinstlog.txt` that will be useful in troubleshooting a failed test.

6.23.6 APPENDIX B - Utility functions: `gdxWhos` and `gdxInfo`

In this section, we'll describe two utilities, `gdxWhos` and `gdxInfo`, provided with GDXMRW that can be called from the MATLAB command prompt. The `gdxWhos` function is patterned loosely after the MATLAB function `whos` used to query `.mat` files. It provides information about symbols in a specified GDX file. The only input argument is the name of a GDX file, which can be with or without the `'.gdx'` extension. With no output argument, `gdxWhos` lists the symbols in the specified GDX file in the MATLAB command prompt. When used with an output argument, information about the symbols in the GDX file is returned as an array of structures. This meta-data can be used in a variety of ways and is especially useful when programming.

An example `GDXWhos` call without an output argument is shown below:

```
>> gdxWhos('idx1_.gdx');
Symbol info of GDX idx1_.gdx
  Index Type      Dim      NRecs  Name
    1 Parameter    0         1    a0
    2 Parameter    1         3    a1(5)
    3 Parameter    2         4    a2(2,2)
    4 Parameter    3         6    a3(3,5,2)
    5 Parameter   10        256   a10(3,5,2,2,2,2,2,2,2,2)
```

The above output indicates that there are five indexed parameters in the file 'idx1_.gdx'. The way we can recognize an indexed parameter is by noticing numbered arguments of the parameters under the 'Name' column. For non-indexed data, the arguments will appear either as the name of a set or by a '*'. For example, the first three symbols are non-indexed and the last symbol is indexed in the output from this call:

```
>>.gdxWhos('fake.gdx');
Symbol info of GDX fake.gdx
  Index Type      Dim      NRecs  Name
    1 Set         1         3    i(*)
    2 Parameter   1         3    a(i)
    3 Set         1         3    d_i_m__3(*)
    4 Parameter   1         3    aa(3)
```

The GDXInfo function is patterned after the `gdxdump` utility in GAMS. It lists and dumps all of the data values for each symbol in the specified GDX file to the MATLAB console. The only input argument is the name of a GDX file, which can be with or without the '.gdx' extension. It accepts no output arguments. It is especially useful to see the entire contents of smaller GDX files. To use the function, we could simply enter a command such as `gdxInfo('idx1_')` in the MATLAB command prompt, and the entire data contents would be displayed in the console. Further information about what is displayed can be found in the GAMS documentation of the `gdxdump` utility.

6.23.7 APPENDIX C - Calling GAMS model from MATLAB

Until now we have discussed the data Import/Export utility between MATLAB and GAMS. In this section, we will discuss a new MATLAB utility 'gams' that initializes a GAMS model with MATLAB data then executes GAMS on that model and bring the results back into MATLAB. This 'gams' routine is based on the same design as `rgdx` and `wgdx` but instead it does everything in one call. This routine can take multiple input arguments and can return multiple output arguments. Its standard syntax is as follows:

```
>> [x1, x2, x3] = gams('model', s1, s2.., c1, c2..);
```

Here note that the first argument of `gams` is the GAMS model name plus any user specific command line settings. If a user wants to solve the given model (in this case found in `qp.gms`) using a different solver then it can be done by adding that solver to the GAMS model name as "`qp nlp=baron`". This feature allows a user to change the execution time behavior of the model.

The rest of the input arguments of GAMS are structures. Their positioning is not important. These structures are of two kinds; one is similar to the input structure of `wgdx` and the other structure has just two string fields, name and val. This latter structure is used to set or overwrite values in the model using the "\$set" variables syntax of GAMS. We will explain it in detail a later section.

The first step is to generate a working GAMS model. For example, we can set up a simple model file to solve a quadratic program that minimizes $\frac{1}{2} x^T Q x + c^T x$ subject to $Ax \geq b$ and $x \geq 0$.

The GAMS model for this quadratic problem is as given in the following code.

```
$set matout "'matsol.gdx', x, dual, obj, returnStat ";

Set
  i / 1*2 /
  j / 1*3 /;
```

```

Alias (j1,j);

Parameter
  Q(j,j1) / 1 .1 1.0
           2 .2 1.0
           3 .3 1.0 /
  A(i,j) / 1 .1 1.0
           1 .2 1.0
           1 .3 1.0
           2 .1 -1.0
           2 .3 1.0 /
  b(i) / 1 1.0
         2 1.0 /
  c(j) / 1 2.0 /;

Variable obj;

Positive Variable x(j);

Equation cost, dual(i);

cost..    obj =e= 0.5*sum(j, x(j)*sum(j1, Q(j,j1)*x(j1))) + sum(j, c(j)*x(j));

dual(i).. sum(j, A(i,j)*x(j)) =g= b(i);

Model qp / cost, dual /;

$if exist matdata.gms $include matdata.gms

solve qp using nlp minimizing obj;

Set stat / modelStat, solveStat /;

Parameter returnStat(stat);
returnStat('modelStat') = qp.modelstat;
returnStat('solveStat') = qp.solvestat;

execute_unload %matout%;

```

This GAMS qp model can be executed directly at the command prompt using the following command

```
gams qp (for Unix/Linux)
```

or

```
gams.exe qp (for Windows)
```

or the user can simply hit the run button in the GAMSIDE. The optimal value is 0.5. In order to run the same model within MATLAB and return the solution vector x back into the MATLAB workspace, no change is required to the GAMS file. In MATLAB, all you have to do is to execute the following command:

```
>> x = gams('qp');
```

This command will first collect the input structure data and create 'matdata.gdx' and 'matdata.gms' that contains include statements for the symbols written in a file matdata.gdx. In the previous example there is no structural input, so an empty 'matdata.gdx' file will be created and 'matdata.gms' will have just have a load statement for the GDX file but no load statements for any symbol. This is done to prevent any undesirable loading of data in the main model if there had already existed a 'matdata.gdx' or 'matdata.gms file'. After creating these two files then the 'gams' routine will execute "gams qp" using a system call. When this model is executed, another file 'matsol.gdx' will be created because of the `execute_unload` statement in the last line of the model. Here it should be noted that any model that you want to execute using the MATLAB `gams` routine should contain something like

```
$set matout "'matsol.gdx', x, dual, obj, returnStat ";
```

either as the first line, or somewhere near the start of the model file. This is a standard `gams $set` statement, setting the value of the local variable 'matout'. The reason to have this statement near the start of the gms file is that the `gams` routine searches the file from the beginning for "\$set matout" in the gms file. As these files can be very large, it is wise to have this statement near the start of the file. In this statement 'fileName' is the gdx file name that will be created containing symbols 'x1', 'x2', etc. These symbols can then be exported to MATLAB. The last line of the model should always be

```
execute_unload %matout%;
```

The purpose of setting the first and last line of the model in this manner is to specify what data the user wants to export to MATLAB in a "header" of the model. As MATLAB does not give any information about the output arguments except the number of expected arguments, we have to specify what data to export to MATLAB in the GAMS model with minimum modification to the existing model. In the previous example, there is only one output argument, thus the `gams` routine will get data for its first element from the output gdx file and store it in the MATLAB output argument.

If there is more than one output argument, e.g.,

```
>> [x, u] = gams('qp');
```

then the `gams` routine will read the output gdx file and store its first element information of the GDX file as the first output argument of MATLAB, i.e. 'x,' and the second element information of the GDX file in the second output argument of MATLAB, i.e. 'u' and so on. If the number of MATLAB output arguments is greater than the number of elements in the GDX file then `gams` will throw an error.

See datalib example `gdxmrw_qp4`.

6.23.7.1 Input Structure

As mentioned earlier, the `gams` routine takes input arguments in structured form. It allows two different types of structure input. One contains the symbol data similar to the `wgdx` input structure, to be exported to the GDX file. The other structure will just have two string fields 'name' and 'value'. Example use:

```
>> s.name = 'Q';
>> s.val = eye(3);
>> s.form = 'full';
>> m = struct('name','m','val','2');
>> [x] = gams('qpmcp',s, m);
```

In this example both 's' and 'm' are structures but 'm' has only two fields and both are strings. The `gams` routine will use the 's' structure to create a 'matdata.gdx' file and 'm' to modify the execution command line to include "--m=2" at the end i.e. a command that will be executed will be "gams qpmcp --m=2"

The structure 's' is the same as the input structure for `wgdx` but with two important differences. Firstly, it can be seen in the above example that 's' doesn't have a 'type' field. In `wgdx` we assume the type to be 'set' by default, but in the `gams` routine the type is assumed to be 'parameter' by default. The second change is an optional additional input field (in addition to those given in Section [Input Structure](#)) called "load".

- load

It is a string input representing how the corresponding data will be loaded into the GAMS program. Depending on the value of the global option "gamso.input" (see next section) the input data will be read into GAMS in different ways. Suppose the input structure 's' has a 'name' field called 'foo'. By default (where `gamso.input = 'compile'`), the file `matdata.gms` will

```
$loadR foo
```

The GAMS parameter (or set) foo will be replaced by the data that is in the 'matdata.gdx' container called 'foo'. If the data has been initialized before in the model, this will replace that initial data with the new data from 'matdata.gdx'. The option can also be explicitly set using

```
s.load = 'replace'
```

There are two other compile time load options, namely 'initialize' and 'merge'. The first is only valid if the parameter values have not been initialized in the GAMS file, otherwise an error is thrown. It uses the GAMS syntax

```
$load foo
```

The merge option is valid when the GAMS file being run has already initialized the parameter values. The new values in the MATLAB structure 's' are merged into the parameter simply overwriting existing values with the new values given. Explicitly, the 'matdata.gms' file contains the statement

```
$loadM foo
```

to direct GAMS accordingly.

Finally, if `gamso.input = 'exec'`, the loading will occur at execution time. In this case, `s.load = 'initialize'` is not a valid input, the default setting is `s.load = 'replace'` which carries out

```
execute_load "matdata.gdx" foo
```

and the alternative setting `s.load = 'merge'` carries out

```
execute_loadpoint "matdata.gdx" foo
```

In this way, the data is loaded at execution time and performs an appropriate replace or merge.

6.23.7.2 Global input to change default behavior

Until now we have seen how to specify different input to the `gams` routine and in this section we will see how to change the default behavior of a `gams` call. This can be done by creating a structure 'gamso' in the current workspace and adding different fields to that structure. There are currently nine fields that can be set in that structure that affect the behavior of the program. Except the `uels` field, all other string fields take case insensitive data. These are as follows:

- `gamso.output`

By default, output of the `gams` routine will be in structure form but it might be the case that a user is only interested in the data matrix, i.e., the `val` field of that structure. This can be done by setting `gamso.output` as `'std'`. This will give only the value matrix as output. If this is not set to `'std'` then output will be in the structure form described in the `wgdx` section.

```
>> gamso.output = 'Std';
>> x = gams('qp nlp=baron')
```

```
x =
    0.5000
```

- `gamso.input`

By default, the interface updates data at compile time. Thus, if execution time updates are made to the parameters before the line `'$include matdata.gms'` these may override the data that is provided in `'matdata.gms'` (i.e. from the command line). This may not be desirable. If you wish to perform execution time updates to the data, you should set `gamso.input` to `'exec'`.

- `gamso.write_data`

If this is set to `'no'`, then all parameters on the call to `gams` are ignored, except the program name. This is useful for dealing with large datasets. Consider the following invocation:

```
x = gams('largedata','A');
y = gams('resolve','A');
```

The first call generates a file `'matdata.gms'` containing the elements of the matrix `A` for use in the `largedata.gms` program. The second call rewrites a new `'matdata.gms'` file that again contains `A`. If we wish to save writing out `A` the second time we can use the following invocation:

```
x = gams('largedata','A');
gamso.write_data = 'no';
y = gams('resolve','A');
clear gamso;
```

or the equivalent invocation:

```
x = gams('largedata','A');
gamso.write_data = 'no';
y = gams('resolve');
clear gamso;
```

- `gamso.show`

This is only relevant on a Windows platform. This controls how the `'command box'` that runs GAMS appears on the desktop. The three possible values are:

- `'minimized'` (default): The command prompt appears iconified on the taskbar.
- `'invisible'` : No command prompt is seen.
- `'normal'` : The command prompt appears on the desktop and focus is shifted to this box.

- `gamso.path`

This option is used to specify fully qualified path for the `gams` executable. This is very useful if you have multiple versions of GAMS installed on your system and want to make sure which version you are running for the `gams` call. e.g.

```
>> gamso.path = 'C:\Program Files\GAMS23.4\GAMS.exe';
```

The output of `gams` is similar to `rgdx` but unlike the `rgdx gams` routine it doesn't take input specific to a particular symbol. Thus it becomes important to implement a way to change the default behavior of the output. This can be achieved by adding following field to the global structure `'gamso'`. All these fields behave similar to that described in `rgdx` and take the same input as of `rgdx`.

- `gamso.compress`
- `gamso.form`
- `gamso.uels`
- `gamso.field`

This is a global option however.

6.24 GDXRANK

A GAMS Utility for Ranking One-Dimensional Numeric Data.

Author

Thomas F. Rutherford, Department of Economics, University of Colorado
Paul van der Eijk, GAMS Development Corporation

Date

July, 2003

Source of this document: <http://www.mpsge.org/gdxrank/index.html>

This utility consists of an executable file, `gdxrank.exe`, and a GAMS libinclude file, `rank.gms`. The former resides in the GAMS system directory, and the latter resides in the `inclib/` subdirectory of GAMS system.

6.24.1 Usage

6.24.1.1 Usage for GDXRANK

GDXRANK reads one or more one dimensional parameters from a GDX file, sorts each parameter and writes the sorted indices as a one dimensional parameters to the output GDX file.

Usage:

```
gdxrank inputfile outputfile
```

Each one dimensional parameter is read from the input file, sorted and the corresponding integer permutation index written to the output file using the same name for the symbol. GAMS special values such as `Eps`, `+Inf` and `-Inf` are recognized.

6.24.1.2 Usage for RANK

```
$libInclude rank v s r [p]
```

The first three arguments are required. The last is optional. These are defined as following:

Type	Argument	Description
Input:	$v(s)$	Array of values to be ranked.
	s	A one-dimensional set, the domain of array v .
Output:	$r(s)$	Rank order of element $v(s)$, an integer between 1 and $\text{card}(s)$, ranking from smallest to largest.
Optional: (input and output)	$p(*)$	On input this vector specifies percentile levels to be computed. On output, it returns the linearly interpolated percentiles.

6.24.2 General Comments

- RANK only works for numeric data. You cannot sort sets.
- The first invocation must be outside of a loop or if block. This routine may be used within a `loop` or `if` block only if it is first initialized with blank invocations ("`$libInclude rank`" in a context where set and parameter declarations are permitted (See Example 3).
- The following names are used within these routines and may not be used in the calling program:

`rank_tmp` `rank_u` `rank_p`

- This routine returns rank values and does not return `sorted vectors`, however rank values are easily used to produce a sorted array. This can be done using computed "leads" and "lags" in GAMS' ordered set syntax, as illustrated in examples 1 and 3 below.

6.24.3 GDXRANK Example

In this example we sort a parameter, create a sorted version and verify that the sort worked correctly:

```
Set I / i1*i6 /;

Parameter A(I) / i1 +Inf, i2 -Inf, i3 Eps, i4 10, i5 30, i6 20 /;

display A;

* write symbol A to.gdx file
execute_unload "rank_in.gdx", A;

* sort symbol; permutation index will be named A also
execute 'gdxrank rank_in.gdx rank_out.gdx';

* load the permutation index
Parameter AIndex(i);

execute_load "rank_out.gdx", AIndex=A;

display AIndex;

* create a sorted version
Parameter ASorted(i);
ASorted(i + (AIndex(i) - ord(i))) = A(i);
display ASorted;
```

```

* check that the result is sorted
Set C(i);
C(i)=yes$(ord(i) < card(i)) and (ASorted(i) > ASorted(i+1));

display C;

abort$(card(C) <> 0) 'sort failed';

```

6.24.4 RANK Example

6.24.4.1 Example 1: Rank a vector, and display the data in sorted order

```

Set
  i 'Set on which random data are defined' / a, b, d, c, e, f /
  k 'Ordered set for displaying sorted data' / 1*6 /;

Parameter
  x(i) 'Random data to be sorted'
  r(i) 'Rank values'
  s(k,i) 'Sorted data';

x(i) = uniform(0,1);

$libInclude rank x i r
display x;

* Generate a sorted list using the ordered set k.

* This assignment statement illustrates how the rank orders
* can be used to sort output for display in proper order. This
* statement uses GAMS support for computed "leads" and "lags"
* on the ordered set k. The loop is used to improve execution
* speed for larger dimensional sets:

loop(k$sameas(k,"1"),
  s(k+(r(i)-1),i) = x(i);
);

option s:3:0:1;
display s;

```

This example is also part of the GAMS Data Utilities Library, see model [\[rank01\]](#) for reference. It writes the following lines to ex1.lst:

```

-----      11 PARAMETER x  Random data to be sorted

a 0.172,    b 0.843,    d 0.550,    c 0.301,    e 0.292,    f 0.224

-----      75 PARAMETER s  Sorted data

1.a 0.172
2.f 0.224
3.e 0.292
4.c 0.301
5.d 0.550
6.b 0.843

```

The RANK libinclude can be used to also sort variable levels as the following example shows:

```

Set
  i 'Set on which random data are defined' / a, b, d, c, e, f /
  k 'Ordered set for displaying sorted data' / 1*6 /;

Variable
  x(i) 'Random data to be sorted'
Parameter
  r(i) 'Rank values'
  s(k,i) 'Sorted data';

x.l(i) = uniform(0,1);

$onDotL
$libInclude rank x i r
display x.l;

loop(k$sameas(k,"1"),
  s(k+(r(i)-1),i) = x(i);
);

option s:3:0:1;
display s;

```

Before the "\$libInclude rank" the dollar control option [\\$onDotL](#) needs to be activated.

6.24.4.2 Example 2: Generate percentiles for a random vector

```

Set
  i 'Set on which random data are defined' / a, b, d, c, e /
  p 'Percentiles (all of them)' / 0*100 /;

Parameter x(i) 'Random data to be sorted';

* Generate the random data on set i:
x(i) = uniform(0,1);
display x;

Parameter
  r(i) 'Rank values'
  pct(*) 'Percentiles to be computed' / 20 20.0, median 50.0, 75 75.0 /;

* Generate ranks and compute the specified percentiles (Note that
* the rank array, r, is required, even if the values are not used.)

$libInclude rank x i r pct

* Display three percentiles:
display pct;

```

This example is also part of the GAMS Data Utilities Library, see model [\[rank02\]](#) for reference. The random data are displayed as follows in the listing file:

```

----      11 PARAMETER x  Random data to be sorted
a 0.172,   b 0.843,   d 0.550,   c 0.301,   e 0.292

```

The interpolated percentiles are computed as follows:

```

----      103 PARAMETER pct  Percentiles
20      0.268,   75      0.550,   median 0.301

```

The following code evaluates a full set of percentiles, from 1 to 100. The GAMS special value of EPS is used to represent zero in the percentile calculation. (Percentiles between zero and one are not permitted to avoid misunderstandings about how percentiles are scaled.) The code makes use of Tom Rutherfords plot libInclude available at <http://www.mpsge.org/gnuplot/index.html>

```

pct(p) =(ord(p) - 1) + eps;
pct("median") = 0;
display pct;

$libInclude rank x i r pct
display pct;

* Plot the results using GNUPLOT:

Set pl(p) / 20, 40, 60, 80, 100 /;
$setGlobal domain p
$setGlobal labels pl
$libInclude plot pct

```

This is the generated plot:

6.24.4.3 Example 3: Use GDXRANK to report multisectoral Monte Carlo results

One of the most perplexing challenges in economic modeling with GAMS is to present multisectoral results in an easily interpreted format. One simple idea is to present sectoral results in a sorted sequence to make it easier to identify the most seriously affected sectors. The presentation of results in a multisectoral model is made even more challenging when model results are generated for a randomized set of scenarios. A summary of Monte Carlo results involves reporting both mean results and their sensitivity. One means of characterizing the sensitivity of model results is to report functions of the sample distribution such as the upper and lower quartiles.

In this example, I illustrate how gdxrank can be used to help report results from the Monte Carlo analysis of a multisectoral model.

The complete model used as example here is part of the GAMS Data Utilities Library, see model `[rank03]` for reference. The following extract of that model generates the result we want to look at.

```

* Determine ranking of sectors by mean impact:
mean(i) = qvalue(i,"mean");
$libInclude rank mean i meanrank

* The following statement creates a tuple matching the ordered
* set, ki, to the set of sectors, i. In this tuple, the sequence of
* assignments corresponds to increasing mean impacts:
imap(ki+(meanrank(i)-ord(ki)),i) = yes;

* Evaluate quartiles of sectoral impacts for each sector:
loop(i,
  x(s) = v(s,i);

* Load quartile with the perctiles to be
* evaluated (25th, 50th and 75th):
quartile(qtl) = qv(qtl);

$ libInclude rank x s r quartile

* Save the quartile values:
  qvalue(i,qt1) = quartile(qtl);
);
display qvalue;

Parameter results(ki,i,*) 'Summary of impacts (sorted)';
results(ki,i,"mean")$imap(ki,i) = mean(i);
results(ki,i,qt1)$imap(ki,i) = qvalue(i,qt1);
display results;

```

The program produces the following display output:

	q25	q50	q75	mean
1 .FOO	-13.767	-12.110	-10.671	-12.259
2 .MWO	-13.496	-11.982	-10.512	-12.035
3 .SCS	-12.244	-10.418	-8.738	-10.588
4 .CLO	-8.763	-7.407	-6.158	-7.480
5 .ADM	-7.865	-5.601	-3.470	-5.812
6 .CNM	-6.437	-5.320	-4.404	-5.461
7 .OTH	-5.732	-4.781	-4.012	-4.892
8 .PIP	-3.142	-1.930	-0.836	-2.145
9 .OIN	-2.124	-1.339	-0.563	-1.358
10 .TPP	-2.527	-0.988	0.521	-1.041
11 .GEO	-1.542	-0.826	-0.196	-0.883
12 .AGF	-1.178	-0.624	-0.072	-0.625
13 .ECM	0.137	0.466	0.796	0.441
14 .SSM	0.303	0.711	1.079	0.684
15 .CON	0.604	1.071	1.479	1.041
16 .PST	0.814	1.924	2.966	1.858
17 .RLW	1.885	2.787	3.632	2.738
18 .OFU	2.789	3.300	3.829	3.330
19 .OLE	3.155	3.553	3.964	3.554
20 .ELE	3.480	3.896	4.318	3.892
21 .PSM	3.733	4.134	4.591	4.168
22 .CAT	3.216	4.417	5.461	4.369
23 .TRO	3.953	5.123	6.549	5.282
24 .OLP	4.614	5.262	5.909	5.295

25. TRD	5.694	6.454	7.250	6.476
26. AIR	5.227	7.182	9.276	7.320
27. FIN	4.919	7.301	10.175	7.640
28. COA	6.581	7.818	9.125	7.878
29. TMS	5.668	8.530	11.086	8.591
30. CHM	8.071	9.299	10.534	9.319
31. TRK	7.031	9.367	11.851	9.577
32. MAR	9.485	13.072	16.424	13.049
33. GAS	4.437	13.183	22.311	13.462
34. FME	14.794	16.617	18.382	16.642
35. NFM	23.299	26.398	29.281	26.263

The tabular report is helpful, but it does not convey the results as immediately as a picture. GNUPLOT's errorbar plot format is a convenient graphical format for portraying this information. The libinclude interface to GNUPLOT does not support this type of plot, so the continuation of the program produces the GNUPLOT command and data files before invoking the GNUPLOT program:

* Write out a GNUPLOT file to generate a chart of the results:

```
File kplt / ex3.gnu /;
put kplt;
kplt.lw = 0;

put "reset"/;
put 'set title "Sectoral Impacts with Quartiles"'/;
put "set linestyle 1 lt 8 lw 1 pt 8 ps 0.5"/;
put "set grid"/;
put 'set ylabel "% change"'/;
put "set xzeroaxis"/;
put "set bmargin 4"/;
put "set xlabel 'sector'"/;
put 'set xrange [1:',card(i),']'/;
put 'set xtics rotate (';
loop(ki, loop(i$imap(ki,i), put '\'/ ' ',i.tl,'" ', ord(ki):0,','););
put @(file.cc-1) )'/;
put "plot 'ex3.dat' notitle with errorbars ls 1"/;
putClose;

File kpltdata / ex3.dat /;
put kpltdata;
kpltdata.nr = 2;
kpltdata.nw = 14;
kpltdata.nd = 6;
loop(ki, loop(i$imap(ki,i), put ord(ki):0,qvalue(i,"mean"), qvalue(i,"q25"), qvalue(i,"q75")/;));
putClose;
execute 'wgnupl32 ex3.gnu -';
```

This is the generated plot:

6.24.4.4 Example 4: Repeated computation of percentiles within a loop

The following code extract shows how to do repeated computation of percentiles within a loop while the data is changing. This is an extract of the model [rank04] from the GAMS Data Utilities Library.

* Do several iterations, computing percentiles in each step:

```

loop(iter,
* Substitute a call to the NLP solver by a call to the random
* number generator. In many applications, this substitution
* produces profoundly more sensible results.
*
* solve catchment using nlp maximizing max;

    z(week) = uniform(0,1);

* If you want to retrieve percentile values, you need to reassign
* the percentiles that you wish to retrieve at this point in the
* program. If pct() were not reassigned at this point, the INPUT
* values would correspond to the OUTPUTs from the previous call.

    pct(pctl) = pct0(pctl);

$ libInclude rank z week rnk pct

    pctval(iter,pctl) = pct(pctl);
);

display pctval;

```

Output:

```

----      58 Here are the INPUT values of PCT0 and PCT prior to the call to rank:

----      58 PARAMETER pct0  Percentiles to be computed

50 50.000,    75 75.000,    80 80.000,    95 95.000

----      58 PARAMETER pct  Percentiles to be computed (input) and those values (output)

50 50.000,    75 75.000,    80 80.000,    95 95.000

----      153 Here are the values of PCT0 and PCT after the call to rank:

----      153 PARAMETER pct0  Percentiles to be computed

50 50.000,    75 75.000,    80 80.000,    95 95.000

----      153 Note that rank has changed the OUTPUT value of pct

----      153 PARAMETER pct  Percentiles to be computed (input) and those values (output)

50 0.424,    75 0.662,    80 0.712,    95 0.864

----      273 PARAMETER pctval  Percentile values in successive iterations

                50                75                80                95

```

iter1	0.345	0.594	0.638	0.922
iter2	0.385	0.633	0.672	0.941
iter3	0.474	0.705	0.766	0.962
iter4	0.627	0.796	0.823	0.978
iter5	0.428	0.682	0.793	0.904
iter6	0.422	0.690	0.729	0.958
iter7	0.558	0.716	0.756	0.902
iter8	0.451	0.638	0.726	0.942
iter9	0.464	0.704	0.755	0.916
iter10	0.564	0.805	0.831	0.974

6.24.4.5 Example 5: Use GDXRANK generating percentiles for heterogenous households.

```
$title Percentile ranking of household expenditure data with heterogenous household size
```

```
Set h / 0*100 /;
```

```
Parameter
```

```
  y(h)    'Aggregate expenditure associated with household type h'
  n(h)    'Number of persons associated with household type h'
  ypc(h)  'Per-capita expenditure of household type h'
  rank(h) 'Rank of household in per-capita expenditure';
```

```
* Assign some random values:
```

```
y(h)    = uniform(0.2,1.2);
n(h)    = uniform(1,6);
ypc(h)  = y(h)/n(h);
```

```
* Assign ranks to household based on per-capita expenditures:
```

```
$libInclude rank ypc h rank
```

```
* Now determine percentile ranking of the households taking into account
```

```
* differences in numbers of members and household representation:
```

```
Set r 'Temporary set used for ranking' / r0*r100 /;
```

```
Parameter
```

```
  pcttmp(r) 'Temporary array for computing percentiles'
  pct(h)    'Percentile rankings for households';
```

```
Set r0(r) / r0 /;
```

```
* First, create an array with households assigned
```

```
loop((r0(r),h), pcttmp(r+(rank(h)-1)) = n(h));
loop(r,      pcttmp(r) = pcttmp(r) + pcttmp(r-1));
pcttmp(r) = pcttmp(r)/sum(h, n(h));
```

```
loop((r0(r),h), pct(h) = pcttmp(r+(rank(h)-1)));
```

```
Parameter ranking 'Ranking of households and expenditures';
```

```
loop((r0(r),h),
  ranking(r+(rank(h)-1),h,"n")    = n(h);
  ranking(r+(rank(h)-1),h,"ypc") = ypc(h);
  ranking(r+(rank(h)-1),h,"pct") = pct(h);
);
```

```
display ranking;
```

This example is also part of the GAMS Data Utilities Library, see model [rank05] for reference. It produces the following output:

		n	ypc	pct
r0	.43	5.662	0.044	0.018
r1	.8	5.682	0.047	0.036
r2	.58	4.477	0.052	0.050
r3	.14	5.742	0.058	0.068
r4	.55	4.815	0.063	0.083
r5	.65	3.702	0.063	0.094
r6	.61	5.880	0.064	0.113
r7	.54	4.463	0.064	0.127
....				
r98	.62	1.134	0.640	0.991
r99	.10	1.673	0.716	0.997
r100	.73	1.053	1.076	1.000

6.25 GDXRENAME

The GDXRENAME program renames the unique elements in a GDX file using the unique elements from a second GDX file.

6.25.1 Usage

```
gdxrename data-file map-file {options}
```

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

The GDXRENAME utility renames the unique elements in the **data-file** using a two dimensional set called **map** in the **map-file**. The renaming of the unique elements only affects the string stored for each element, and does not change the data order for the symbols in the data-file. Because no data is changing in the data-file, only the strings for the unique elements, these changes are applied to the data-file directly and no new data-file is created.

data-file = *fileName* (default = none)

Name of the file where the renaming is to be applied.

map-file = *fileName* (default = none)

Name of the file where the map set appears containing the renaming tuples.

6.25.2 Options

`-reverse` (disabled by default)

Synonym: `-r`

Reverse the direction of the rename operation; see below

6.25.3 Example

A simple example, where the labels of the parameter A are renamed according to the map specified.

```
Set c / r, g, b, y /;

Parameter A(c);
A(c) = ord(c);

execute_unload 'data.gdx', A;
execute 'gdxdump data.gdx';

Set map(*,*) / r.red, g.green, b.blue, y.yellow /;
execute_unload 'map.gdx' map;

execute 'gdxrename data map';

Scalar rc;
rc = errorLevel;
abort$(rc <> 0) 'GDXRENAME execution error';

execute 'gdxdump data.gdx';
```

Symbol A before the rename:

```
Parameter A(*) /
'r' 1,
'g' 2,
'b' 3,
'y' 4 /;
```

Symbol A after the rename:

```
Parameter A(*) /
'red' 1,
'green' 2,
'blue' 3,
'yellow' 4 /;
```

6.26 GDXRRW

Interfacing GAMS and R

Author

Michael C. Ferris (ferris@cs.wisc.edu), Computer Sciences Department, University of Wisconsin - Madison, 1210 West Dayton Street, Madison, Wisconsin 53706

Steven Dirkse (sdirkse@gams.com) GAMS Development Corp.

GDXRRW is a suite of utilities to import/export data between GAMS and R (both of which the user is assumed to have already) and to call GAMS conveniently from R. The software gives R users the ability to use all the optimization capabilities of GAMS, and allows visualization and other operations on GAMS data directly within R.

The GDXRRW tool is unique among the GDX interface utilities in that it is an R extension made available as an R package. As such, it is run as part of an R session or script, not as part of a GAMS run, and it follows the usual R package conventions.

1. **Installation:** The R software is designed to be easily extended. Thousands of extension packages are freely and conveniently available online and can be installed easily using a simple, standard procedure. The GDXRRW package is one of these. The latest version is available on [GitHub](#) in both source and binary form, along with a FAQ list, some hints and tips on common problems and solutions, and other helpful content. For convenience, the source and binary packages are also available in the `gdxrrw` directory of the GAMS distribution.
2. **Documentation:** The GDXRRW documentation is installed as part of the GDXRRW package and is available from within R in the usual way. See the GDXRRW [GitHub](#) page for details and hints.
3. **Examples, tests, and data:** Like many R packages, GDXRRW comes with examples and data that help a user get started using the package. The R help system and the GDXRRW [GitHub](#) provide pointers to these. GDXRRW [GitHub](#) page also provides hints on finding and running the thousands of lines of tests that come with the GDXRRW package.

6.27 GDXTROLL

`gdx troll` reads `TROLL` data files into a GDX container.

6.27.1 Usage

```
gdx troll in [out]
```

where

in

TROLL data text file (default extension is `.txt`)

out

GDX container file name (default `in.gdx`)

Accepts `SPECS:NUmeric` and the following periodicities `scalar NA`, `annual yyyyA`, `quartely yyyyQq`, `monthly yyyyMm` `weekly yyyyWwww` (ISO 8601)

6.28 GDXVIEWER

6.28.1 Overview

GDXVIEWER is a tool to view and convert data contained in [GDX](#) files.

Besides inspecting a GDX file, gdxviewer allows you to export to a large number of data formats, including ASCII text, CSV, HTML, XML, database, and spreadsheet formats.

This tool is designed as an interactive Windows program, but it can also be operated through command line parameters.

6.28.2 Requirements

GDXVIEWER runs only on PC's running Windows (95/98/NT/XP). The DLL **GDXDCLIB.DLL** needs to be in the same location as **GDXVIEWER.EXE**. If XLS files are saved, MS Excel needs to be present. If MDB database files are saved, MS Access needs to be present.

If GDXDCLIB.DLL is not found in the same directory as the executable gdxviewer.exe, the following window will be shown:

A simple way to make sure that GDXVIEWER has access to the GDXDCLIB.DLL dynamic load library is to place **gdxviewer.exe** in the GAMS system directory, e.g. `c:\program files\GAMS21.3`.

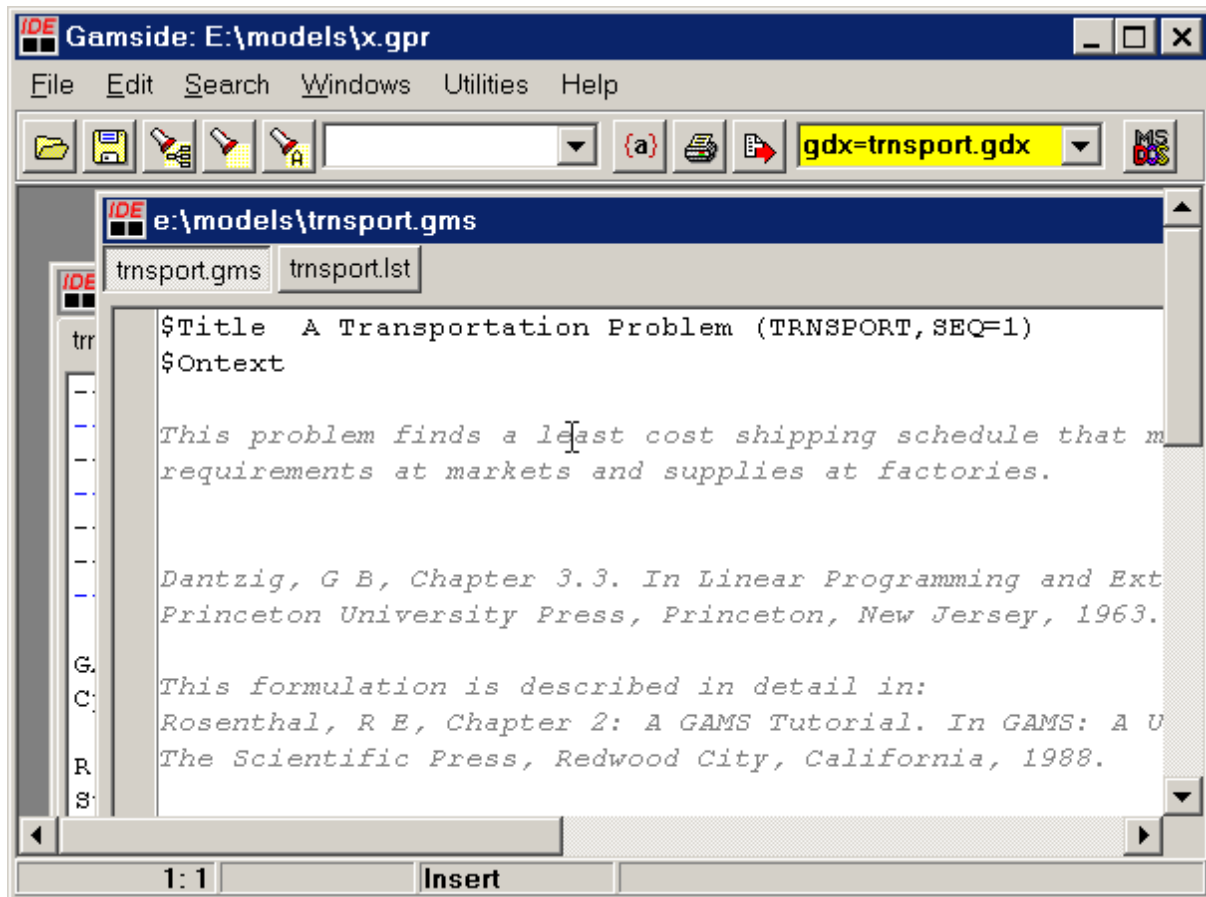

6.28.3 Creating GDX files

GDX files are binary data files. They can contain sets, parameters (including scalars), equations and variables. These files can be generated by a number of tools: by GAMS itself, by utilities such as [MDB2GMS](#), [SQL2GMS](#), [GDXXRW](#).

To save all data from a GAMS model into a GDX file you can use the **GDX=fn** command line parameter:

```
C:\> gams trnsport.gms GDX=trnsport.gdx
```

From the IDE you can specify the command line parameter **GDX=trnsport.gdx** in the parameter edit box:

To selectively place identifiers in a GDX file you can use the `execute_unload` statement:

```
Model transport / all /;
solve transport using lp minimizing z;

display x.l, x.m;

execute_unload 'results.gdx', i, j, x;
```

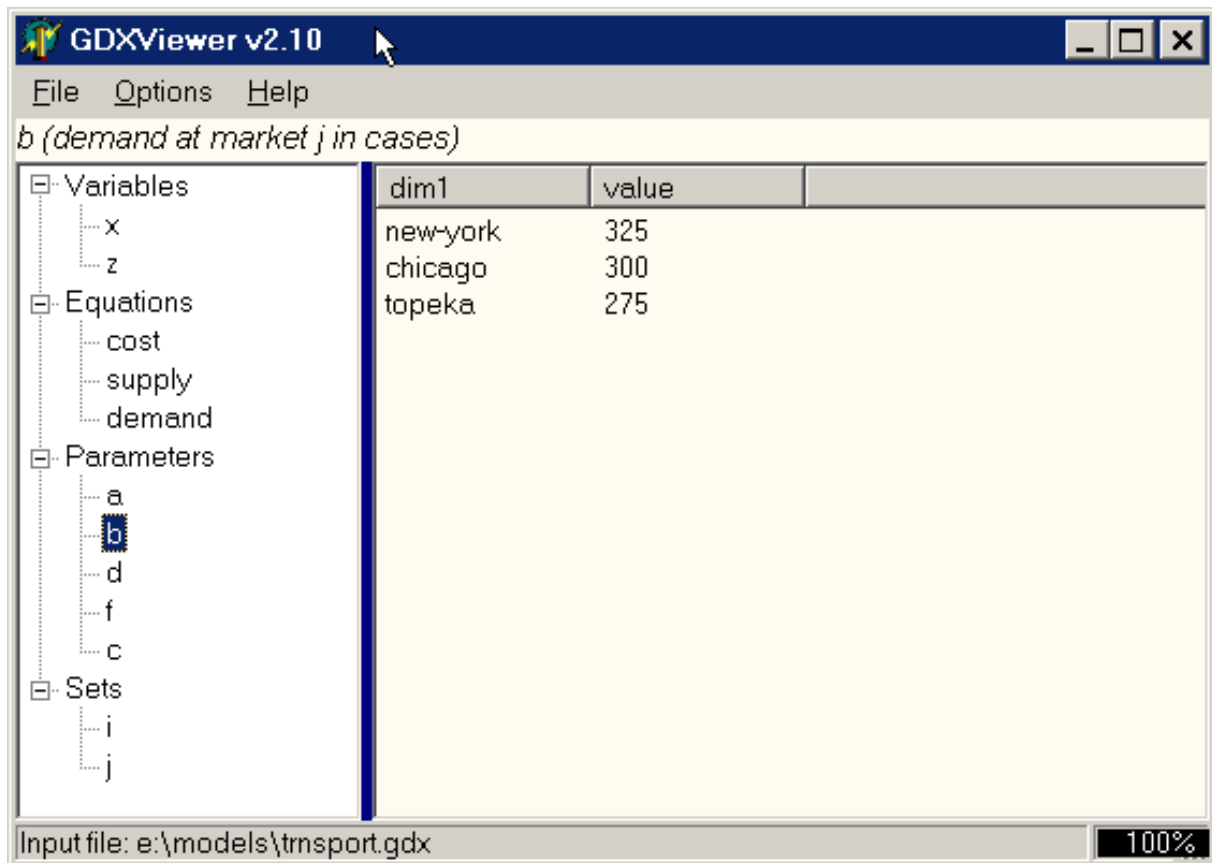

In this example the sets `i` and `j` and the variable `x` are saved to the GDX file `results.gdx`.

Other ways to create GDX files include:

- The [MDB2GMS](#) tool can be used to convert data stored in MS Access tables to GDX files
- The [SQL2GMS](#) tool can read data from virtually any SQL database (including any ODBC accessible database) and can create GDX files.
- The tool [GDXRW](#) allows data from an Excel spreadsheet to be stored in a GDX file.
- [\\$GDXOUT](#) allows you to write data to a GDX file during GAMS compile time. This is not as useful as `execute_unload` but may have its use in special cases.
- You can write your own program to write a GDX file. There is an API and bindings for different languages such as Delphi, Kylix, VB6, VBA, VB.NET, C/C++, C#, Java, Fortran.

6.28.4 Viewing GDX files

After loading a GDX file in **gdxviewer** the content of the file is displayed in list view. The left-hand side of the window shows the index of the GDX file organized in a tree structure. When clicking on an identifier, the right-hand-side will display the actual data for the identifier.

When variables are shown, more information is available, such as bounds (lower and upper bounds) and marginals.

The GDX file can be loaded interactively using the **File|Open** menu, or it can be launched from the command line:

```
C:\> gdxviewer e:\models\trnsport.gdx
```

The command line specification can also be used to launch **gdxviewer** from within a GAMS model as in:

```
Model transport / all /;
solve transport using lp minimizing z;

display x.l, x.m;

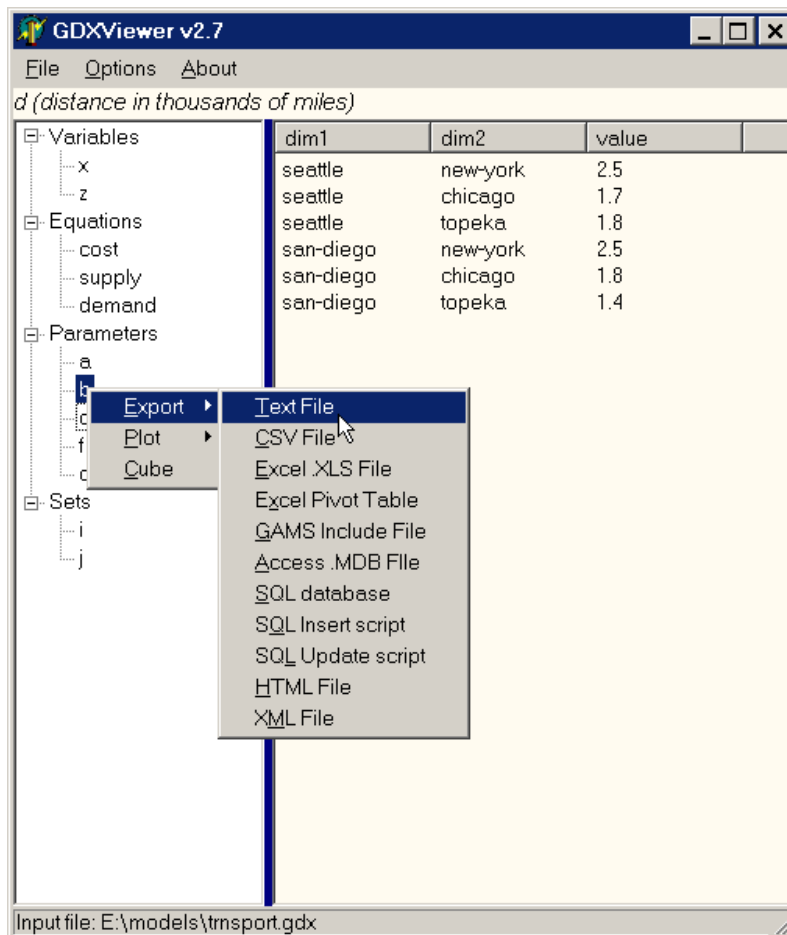

execute_unload 'results.gdx', i, j, x;
execute '=gdxviewer results.gdx';
```

In this case **gdxviewer.exe** was located in the GAMS system directory, such that **execute** had no problems in finding it.

Note: there are alternative tools to view GDX files. The GAMS IDE has a built-in GDX file viewer (use **File|Open**) and there is a command line utility called **GDXDUMP**.

6.28.5 Exporting an identifier

When the right mouse button is clicked on an identifier a pop-up menu is presented that allows you to export an identifier to a number of target formats.

The same operation can be invoked from the File|Export menu:

6.28.6 Exporting to a Text File

The text file export facility (**File|Export|Text File**) will write a GAMS identifier to a standard ASCII text file. Such a text file can look like:

```
seattle new-york 2.5
seattle chicago 1.7
seattle topeka 1.8
san-diego new-york 2.5
san-diego chicago 1.8
san-diego topeka 1.4
```

The separator symbol can be set using the menu **Options|Configuration|Text File**:

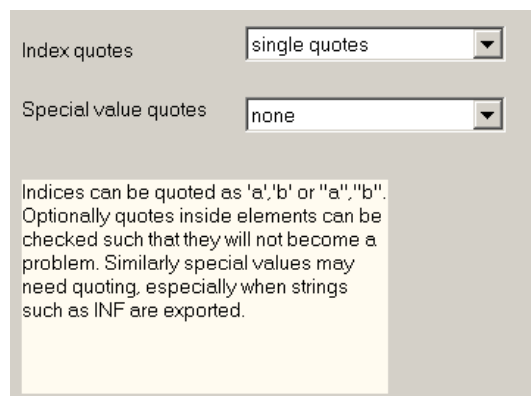

Other options that involve the format of the text file being written are: **Options|Configuration|Export** and **Options|Configuration|Special Values**. Currently there are no facilities to write fixed format text files. If you need to write fixed format text files you can use the GAMS PUT statement.

6.28.7 Exporting to a CSV files

Comma-separated Values ([File|Export|CSV File](#)) is a popular format to exchange data between applications. An example of such a file is:

```
'new-york',325  
'chicago',300  
'topeka',275
```

Strings are surrounded by quotes and each field is separated by a comma. The precise format can be specified using the menu [Options|Configuration|CSV File](#):

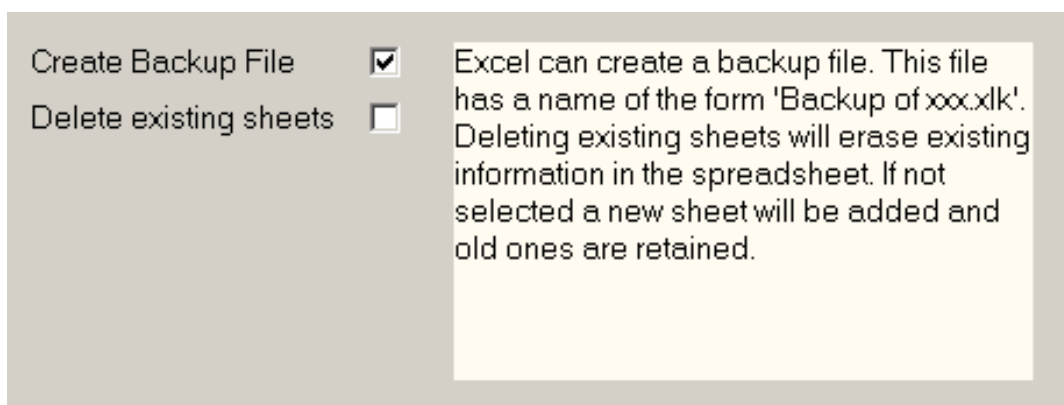

Other options that involve the format of the CSV file being written are: [Options|Configuration|Export](#) and [Options|Configuration|Special Values](#).

6.28.8 Exporting to an XLS file

A GAMS identifier can be exported directly to an MS Excel spreadsheet using [File|Export|Excel XLS File](#):

There are a few options available for this operation. Under [Options|Configuration|Excel](#) the following settings can be changed:

Other options that involve the format of the CSV file being written are: [Options|Configuration|Export](#) and [Options|Configuration|Special Values](#). Exporting to Excel is only available if you have Microsoft Excel installed on your machine.

Note: We can write all symbols in the gdx file to Excel by specifying `ID=*` on the command line.

6.28.9 Exporting to an XLS Pivot Table

We can export to an XLS file and create a Pivot Table automatically (File|Export|Excel Pivot Table):

Pivot tables are a very convenient way to analyze multi-dimensional data.

The following options are available: [Options|Configuration|Excel](#), [Options|Configuration|Export](#) and [Options|Configuration|Special Values](#).

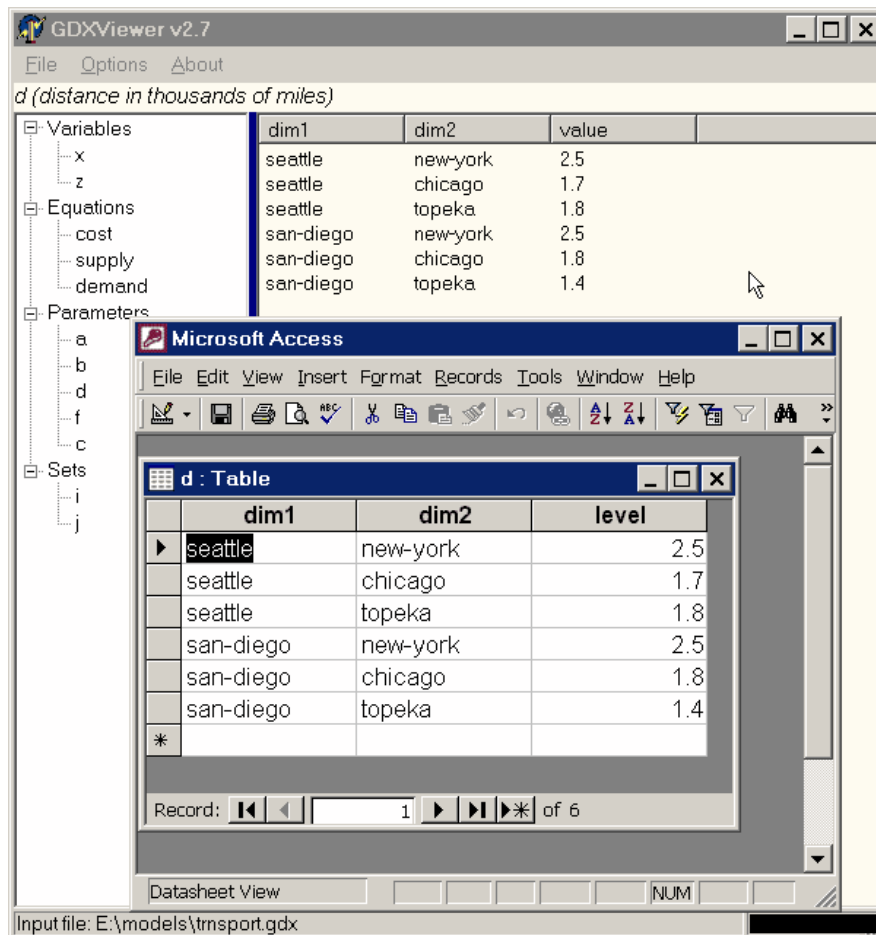

6.28.10 Exporting to a GAMS Include Files

The option File|Export|GAMS Include file will export an identifier to a GAMS include file format. An example of such an exported include file can look like:

```
Parameter d 'distance in thousands of miles'
/ seattle.new-york 2.5, san-diego.new-york 2.5
  seattle.chicago 1.7, san-diego.chicago 1.8
  seattle.topeka 1.8, san-diego.topeka 1.4 /;
```

6.28.11 Exporting to an Access Tables

GDXVIEWER can export data directly to a table in an Access database using **File|Export|Access** (MDB or ACCDB) File. The name of the table will be the name of the parameter. If the table already exists, GDXVIEWER will try to create a new table with a slightly different name (e.g. d2, d3,...).

An option **Options|Configuration|Access** allows you to set the length of the text fields where the GAMS indices are stored. This length is used when creating the table.

Max length of indices

Access import method

- Indirect (CSV files)
- Direct (INSERT statements)
- Indirect (CSV files)

The indices are stored in text fields. The length of the text fields needs to be large enough so that all indices can be stored. The program will throw an exception if an index is found that does not fit in the text field. The export can be done directly using INSERT statements or via intermediate CSV files. It may come as a surprise that the direct approach is slower.

A feature added in version 2.9 is the possibility to use intermediate CSV (comma separated value) files instead of using direct SQL INSERT statements. The CSV files can be read into Access using a bulk operation and is therefore faster for large datasets. When using CSV files make sure double quotes are used (if single quotes are used they will become part of the data). The temporary CSV files will be written to the Windows TEMP directory (e.g. C:\WINDOWS\TEMP). When the import is done, these scratch files will be removed automatically. If you want to look at the CSV files that are being fed into Access, export the data to a CSV file.

6.28.12 Exporting to an SQL Table

It is possible to export data to SQL databases through ADO which includes all databases accessible through ODBC. The configuration information can be specified in Options|Configuration|SQL Database.

Connection string

User ID: Password:

SQL double type: Max. length of indices:

To specify an ODBC data source use 'DSN=mydsn'. For connecting to other databases directly use a connection string as explained in <http://www.gams.com/~erwin/interface/interface.html>, section SQL2GMS. The test connection button allows for testing the connection before actually writing to the database. The double type is used when creating a table. It is the SQL type used to store numeric data. The max. index length indicates the size of the VARCHAR index fields.

6.28.15 Exporting to SQL Update script

An SQL script with UPDATE statements like:

can be generated with File|Export|SQL Update script. The following settings in Options|Configuration|SQL Update were used:

DB Columns	GDX column:	Quote:	
city1	dim1	<input checked="" type="checkbox"/>	
city2	dim2	<input checked="" type="checkbox"/>	
distance	level	<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	
		<input type="checkbox"/>	

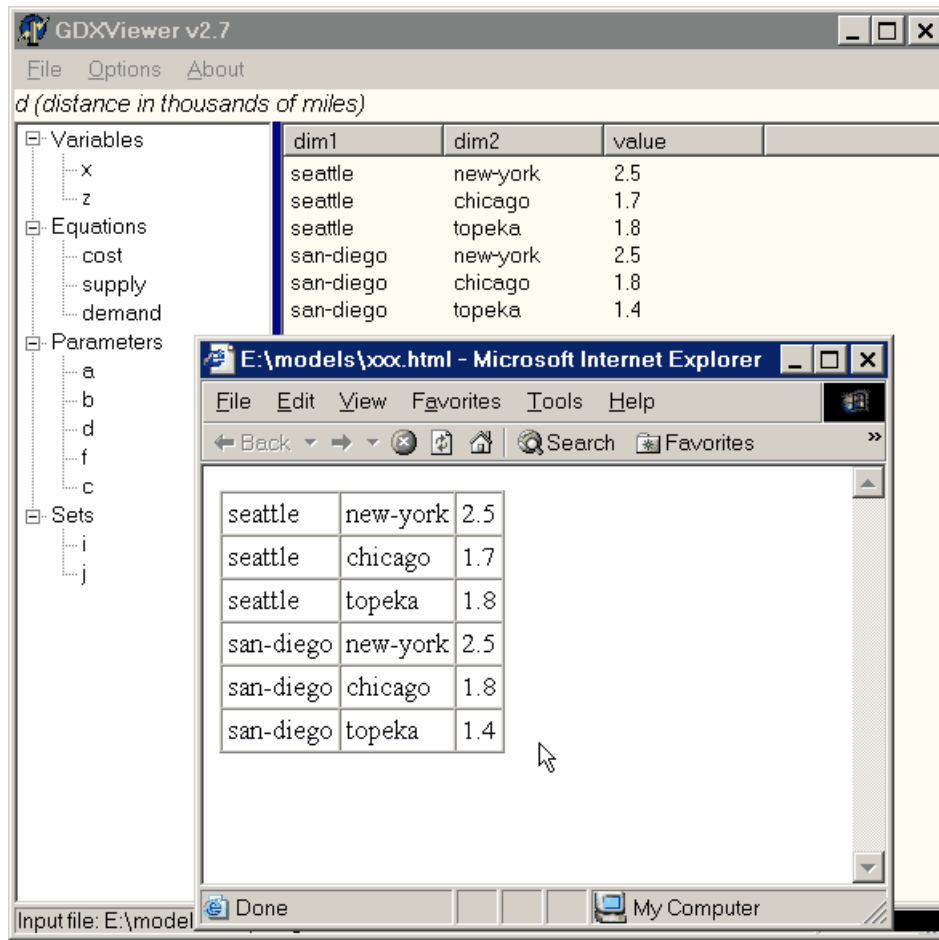

Table name:

Semicolon separator

SQL UPDATE statements will be generated of the form: UPDATE tablename SET dbcol1=gdxval1,dbcol2=gdxval2 WHERE dbcol3=gdxdim1 and dbcol4=gdxdim2. Column values can be quotes and UPDATE statements are often terminated with a semicolon.

6.28.16 Exporting HTML

GDXVIEWER can write an identifier to an HTML file using File|Export|HTML File.

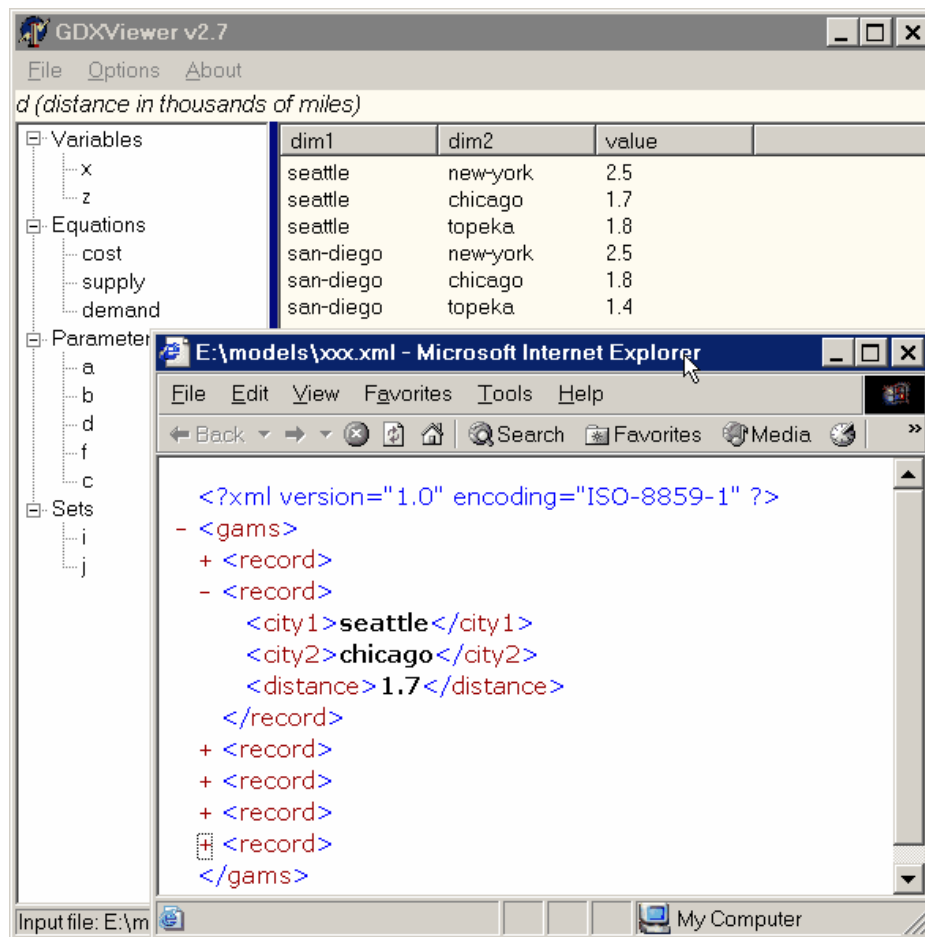

The options relevant to this format are specified in `Options|Configuration|HTML`.

6.28.17 Exporting XML

GDXVIEWER can write an identifier to an XML file using `File|Export|XML File`.

The XML tags can be specified in Options|Configuration|XML.

root	<input type="text" value="gams"/>	index tags	
record	<input type="text" value="record"/>	dim1	<input type="text" value="city1"/>
Parameter		dim2	<input type="text" value="city2"/>
value	<input type="text" value="distance"/>	dim3	<input type="text" value="dim3"/>
Equation/Variable		dim4	<input type="text" value="dim4"/>
lo	<input type="text" value="lo"/>	dim5	<input type="text" value="dim5"/>
level	<input type="text" value="level"/>	dim6	<input type="text" value="dim6"/>
up	<input type="text" value="up"/>	dim7	<input type="text" value="dim7"/>
marginal	<input type="text" value="marginal"/>	dim8	<input type="text" value="dim8"/>
		dim9	<input type="text" value="dim9"/>
		dim10	<input type="text" value="dim10"/>

Specification of the XML tag names.

6.28.18 Exporting fields

The menu `Options|Configuration|Export` allows you to set which fields are exported.

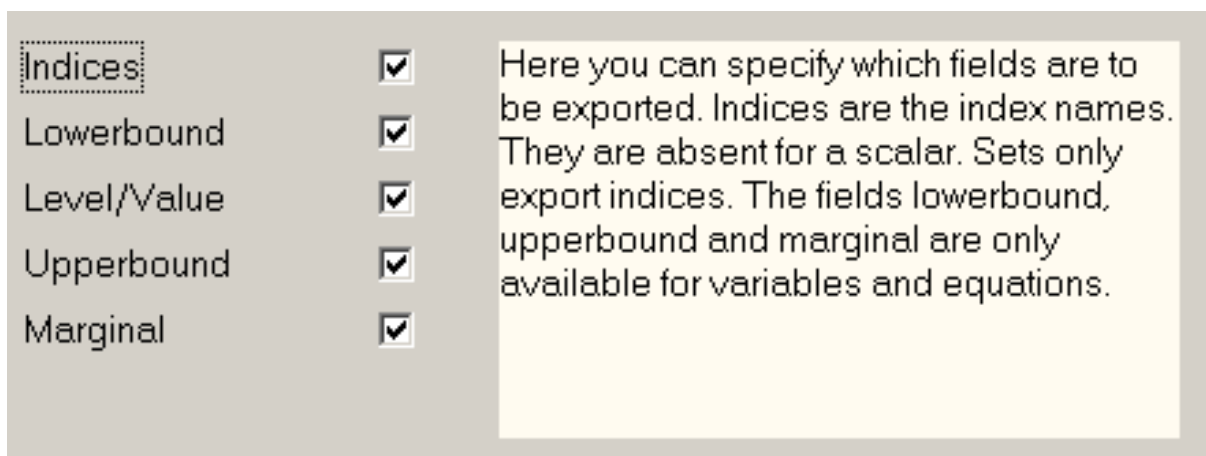

Figure 6.43 400px

The following table gives the possibilities for exports:

	set	scalar	parameter	variable	equation
Indices	+		+	+	+
Lower bound				+	+
Level/Value		+	+	+	+
Upper bound				+	+
Marginal				+	+

6.28.19 Special Values

GAMS data can assume so called special values: `-INF`, `+INF`, `EPS`, `NA`, and `UNDF`. The meaning of these special values is as follows:

Value	Description
<code>-INF</code>	Minus infinity. Mostly used for non-binding lowerbounds.
<code>+INF</code>	Plus infinity. Mostly used for non-binding upperbounds.
<code>EPS</code>	Mostly used for marginals where it can indicate non-basic but numerically zero.
<code>NA</code>	Not available. Not often used.
<code>UNDF</code>	Undefined. Not often used.

When exporting GAMS identifiers we need to map such values to strings that the receiving program can understand. E.g. we could map `{INF}` to `{1.0e10}` and `+INF` to `+1.0e10`. A good choice for `EPS` would be `0.0`.

The mapping can be specified in `Options|Configuration|Special Values`:

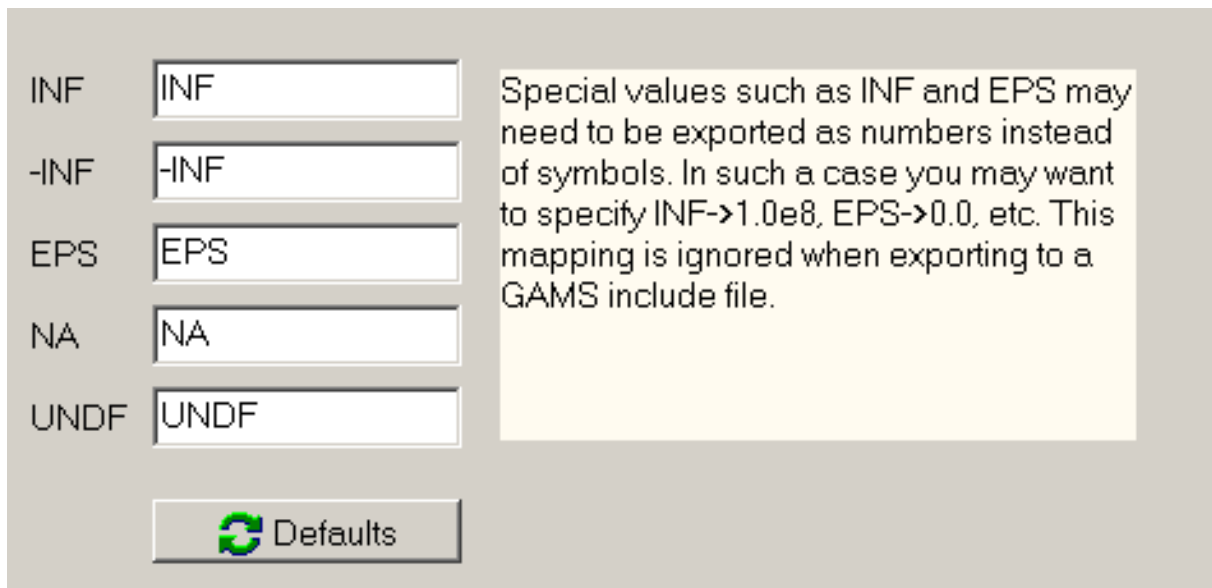

Figure 6.44 400px

When we export to a GAMS include file all special values are understood, so the mapping is not used. The defaults button will reset the mapping to their default values.

6.28.20 Plotting Data

GDXVIEWER has a built-in facility to quickly plot data. It includes LINE, BAR and PIE charts, examples are shown below. The plots can be made through the menu File|Plot.

For multi-dimensional data it may be needed to take a “slice” of the data to make meaningful graphs. In the example above we plotted a two dimensional quantity \mathbf{vf} which looks like:

GDViewer v2.7

File Options About

vf (import of final products) (1000 tpy)

Variables	dim1	dim2	lo	level	up	marginal
zm	plate	mexico-df	0	7.199999999...	INF	0

	lightshape	l-cardenas	0	0	INF	0.501759999...
	lightshape	coatzacoal	0	0	INF	0.191049999...
	rebars-ld	mexico-df	0	0	INF	0.002469999...
	rebars-ld	puebla	0	0	INF	0.076149999...
	rebars-ld	queretaro	0	0	INF	0.068969999...
	rebars-ld	san-luis	0	0	INF	0.01159
	rebars-ld	monterrey	0	0	INF	0.097279999...
	rebars-ld	guadalajara	0	0.324345491...	INF	0
	rebars-ld	l-cardenas	0	0	INF	0.076759999...

Input file: E:\models\mexls.gdx 100%

In this case we want to plot a pie graph of **vf(*,'mexico-df')** which can be specified in the index-selection tab:

dim1 *****PLOTTED*****

dim2 **mexico-df**

dim3

dim4

dim5

dim6

dim7

dim8

dim9

dim10

Plot Type

Line

Bar

Pie

Here you can set which dimensions are held constant and which ones are varied. To fix a dimension choose a set element. Choose *****PLOTTED***** if it can be varied. Usually only one dimension varies.

6.28.21 Cube View

GDXVIEWER has a Cube View which allows to select rows and columns in a flexible way. In the example below we show a six dimensional variable where three dimensions are fixed, one dimension is chosen for the rows and two dimensions are chosen for the columns.

Below are some of the possibilities using parameter $d(i,j)$ from the `transport.gms` model:

6.28.22 Exporting cubes

After creating a [cube view](#), we can export that configuration by a right mouse click:

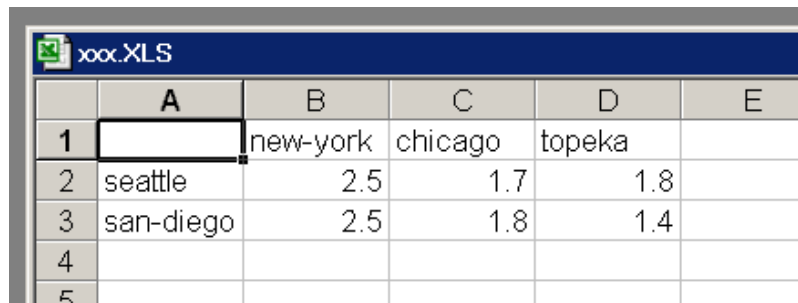

Exporting a cube will only export the selected slice (if certain dimensions are held fixed) and depending on the target format it will preserve the layout, e.g. an exported aligned text file can look like:

```

           new-york  chicago  topeka
seattle    2.5      1.7      1.8
san-diego  2.5      1.8      1.4

```

Similarly, the XLS file can look like:

	A	B	C	D	E
1		new-york	chicago	topeka	
2	seattle	2.5	1.7	1.8	
3	san-diego	2.5	1.8	1.4	
4					
5					

6.28.23 Commandline operation

The GDXViewer utility from version 2.3 accepts several command line parameters, so it can be used in a batch environment. When running in batch mode, the same configuration and option settings are used as for the interactive system and they can be changed by running GDXviewer interactively using the Options menu (the settings are saved in an INI file). It is advised to first run the program interactively until the results are as intended.

- **Single parameter** A single parameter is the filename of the GDX file. GDXViewer will load this file, and will continue to run interactively. Example: .

```
Gdxviewer.exe test.gdx
```

- **XLS writing** To write an XLS file, one can use the syntax `i=inputfile.gdx xls=outputfile.xls id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx xls=d:\tmp\result.xls id=x';
```

- **Text file writing** To write a text file, one can use the syntax `i=inputfile.gdx txt=outputfile.txt id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx txt=d:\tmp\result.txt id=x';
```

- **CSV file writing** To write a CSV file, one can use the syntax `i=inputfile.gdx csv=outputfile.csv id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx csv=d:\tmp\result.csv id=x';
```

- **HTML file writing** To write an HTML file, one can use the syntax `i=inputfile.gdx html=outputfile.html id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx html=d:\tmp\result.html id=x';
```

- **XML file writing** To write an XML file, one can use the syntax `i=inputfile.gdx xml=outputfile.xml id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx xml=d:\tmp\result.xml id=x';
```

- **GAMS include file writing** To write a GAMS include file, one can use the syntax `i=inputfile.gdx inc=outputfile.inc id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx inc=d:\tmp\result.inc id=x';
```

- **Access MDB file writing** To write a Access MDB file, one can use the syntax `i=inputfile.gdx mdb=outputfile.mdb id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx mdb=d:\tmp\result.mdb id=x';
```

- **Excel Pivot Table writing** To write a file containing a pivot table, one can use the syntax `i=inputfile.gdx pivot=outputfile.xls id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (""). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';
```

- **SQL Database Table writing** To write a table to an SQL database, first interactively configure the connection to the database. The Export SQL Database option allows you to see if a connection succeeded and if the correct database was accessed. The configuration information is written to the SQLVIEWER.INI configuration file. The information in this file is used also when performing a batch command-line operation. The syntax is: `i=inputfile.gdx sql id=x`. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx sql id=x';
```

If you need to access several different databases, you can copy the file SQLVIEWER.INI (located in the directory where SQLVIEWER.EXE is placed). To tell GDXVIEWER to read a different INI file, you can say:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx ini=copy.ini sql id=x';
```

GDXVIEWER uses the MS Access and MS Excel applications as COM Object to write files in XLS (both XLS and PIVOT commands) or MDB format. Those applications may write to C:\My Documents in case no full path is specified. Other formats use the default GAMS working directory. In case when running under the IDE this is the location of the project file (*.GPR).

If a path or file name contains a blank, then it is possible to surround the name by double quotes as in:

```
execute_unload 'result.gdx',x;
execute 'gdxviewer.exe i=result.gdx csv="c:\my documents\result.csv" id=x';
```

Under windows 98 ME the call

```
execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';
```

will cause GAMS to continue while GDXVIEWER is executing. If we use:

```
execute '=gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';
```

GAMS will wait until **gdxviewer.exe** is terminated before executing more statements. This situation is different under other operating systems such as XP and NT.

6.28.24 Notes

GDX

GDX stands for **Gams Data Exchange**. It is a binary file format to get data in and out of GAMS.

6.29 GDXXRW

GDXXRW is a utility to read and write Excel spreadsheet data. **GDXXRW** can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet.

Note

GDXXRW is available on Windows only. This is an important factor to consider when moving an existing code to GAMS Engine.

6.29.1 Usage

```
gdxxrw inputFile {outputFile} {options} [symbols]
```

Options and symbol specifications can also be read from a text file; the use of an option file is indicated by preceding the file name with a @ (At sign.). When reading from a text file, lines starting with an asterisk (*) will be ignored and act as a comment.

Options and symbol specifications can also be read from an area in a spreadsheet; see [index](#) below.

Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. The use of file names with embedded blanks is allowed as long as the file name is enclosed in double-quotes ("").

Note

A small utility program is available to see if Excel is installed, to close an Excel file etc. See [XLSTALK](#) for more details. To read data from an Excel file without Excel installed see [XLSDUMP](#).

6.29.2 Options

Describing the actions to be taken by GDXXRW requires passing a number of options and symbol specifications to the program. The ability of GDXXRW to process multiple actions in a single call makes the option passing and interpretation more complex.

There are four kinds of options:

1. **Immediate** [Immediate options](#) are recognized and processed before any other actions are taken and can only be specified once. Examples are:

```
input= output= trace=
```

2. **Global** [Global options](#) are interpreted from left to right and affect every action that follows. The same option can be used multiple times to affect the actions that follow. Examples are:

```
skipEmpty= epsOut=
```

3. **Symbol** A [symbol](#) definition introduces a new action for reading or writing a symbol. Examples are:

```
par= set= dSet=
```

4. **Symbol attributes** [Attributes](#) specify additional information for the last symbol defined. Examples are:

```
dim= cDim= merge clear
```

6.29.2.1 Immediate Options

Immediate options are recognized independent of their position on the command line. They are global and they can only be specified once.

Option	Default	Description
input	none	Specify the input filename (required).
output	inputFileName	Specify the output filename.
log	none	Specify the log filename.
logAppend	none	Appending the log information to the file specified.
index	none	Indicates reading the options and symbols directly from the spreadsheet.
password	none	Password for an encrypted input file.
rWait	0	Delay after opening a spreadsheet.
checkDate	disabled	Write GDX file only if the input file is more recent than the GDX file.
useRC	disabled	Use Row-Column notation to specify cells and ranges.
reCalc	N	Controls if recalculations of cells inside Excel are executed after writing to the spreadsheet.
trace	1	Controls the amount of information written to the log.
maxDupeErrors	0	Maximum number of duplicate records allowed for a symbol.
updLinks	0	Updating of cells that refer to other spreadsheets.
runMarcos	0	Execution of Excel Auto macros.

Some more detailed remarks on the immediate options:

input = *fileName* (required, default = none)

Synonym: i

Either use the keywords **input** or **i** to specify the input file name anywhere on the command line or just specify the input file name without keyword at the first position behind **GDXXRW**. The file extension of the input file is required and determines the action taken by the program.

The extension **.gdx** for the input file will read data from a GDX file and write data to a spreadsheet. The extension **.xls**, **.xlsx**, **.xslm**, or **.xlsb** for the input file will read a spreadsheet and write the data to a **.gdx** file. In addition to the **.xls**, **.xlsx**, **.xslm**, or **.xlsb** input file extension, the following file extensions are also valid for spreadsheet input files: **.wk1**, **.wk2**, **.wk3** and **.dbf**.

A file sharing conflict will arise when writing to a spreadsheet with the target file open in Excel. Either close the file in Excel before executing **GDXXRW**, or mark the spreadsheet as a shared workbook in Excel. To change the shared status of a workbook, use the Excel commands available under: **Tools|Share Workbook**.

Writing to a shared workbook can be painfully slow; simply closing the file and reopen the file after **GDXXRW** has finished is often a better option.

output = *fileName* (default = inputFileName)

Synonym: o

When an output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. The file type, i.e. the file extension, depends on the installed version of Excel. Versions prior to Excel 2007 use the **.xls** file extension, later version use **.xlsx**, **.xslm**, and **.xlsb**. Excel 2007 can write **.xls** files, but in that case the output file has to be specified with an **.xls** file extension.

log = *fileName* (default = none)

Specifies the filename of the log file. When omitted, log information will be written to standard output. When using **GDXXRW** in a GAMS model that is started from the GAMS IDE, the output will be written to the IDE process window.

logAppend = *fileName* (default = none)

Using **logAppend** will add the log information to the end of the file specified. If the file does not exist yet, a new one will be created.

index = *Excel Range*

The **index** option is used to obtain the global options, symbols and symbol attributes specified by reading them from the spreadsheet directly. The parameters are read using the specified range, and treated as if they were specified directly on the command line. The first three columns of the range have a fixed interpretation: **dataType**, **Symbol identifier** and **dataRange**. The fourth and following columns can be used for additional parameters. The column header contains the keyword when necessary, and the cell content is used as the parameter value. See [Reading Spreadsheet using the Index Option](#) for instance.

password = *string* (default = none)

Specifies a password for a protected spreadsheet file.

rWait = *integer* (default = 0)

Introduce a delay (in milliseconds) after opening a spreadsheet before accessing the data. This parameter can be used to work around an issue we encountered that Excel indicated it was not ready. The issue can arise during the data exchange with Excel Sheets that contain macros, plots or pivot tables where GDXXRW attempts to access a sheet while Excel is busy updating macros, graphs, and pivot tables.

checkDate (disabled by default)

When specified, no data will be written if the output file already exists and the file date for the output file is more recent than the file date for the input file. Provides a simple check to update the output file only if the input file has changed to save resources.

useRC (disabled by default)

Specify that all cell and range references use RC notation. So, instead of specifying the range Sheet1!A1:D6, one specifies Sheet1!R1C1:R6C4. When tracing is enabled, ranges will be reported in RC notation. This is a global option and applies to all cell references.

reCalc = *flag* (default = N)

Enable or disable the recalculations of cells inside Excel after writing to the spreadsheet. If there are many formulas in the spreadsheet the recalculation of cells can become very expensive and slowing down the writing process. By default, the recalculation is disabled and can be enabled via this option.

trace = *integer* (default = 1)

Sets the amount of information written to the log (for a better debugging). Higher values will generate more output. Valid range is 0..4.

0 Minimal information is included in the output

1 Message appears telling about each GDXXRW call indicating input file, output file and execution time

2 Message appears giving the level 1 output plus a listing for each symbol specified, indicating the type, sheet name, dimension, data range and the range of the row and column headers

3 Message appears giving the level 2 output plus cell ranges affected by reading, writing and clearing

4 Message appears giving the level 3 output plus cell addresses, and numerical or string values for every cell worked with

maxDupeErrors = *integer* (default = 0)

Sets the maximum number of duplicate records that is allowed when reading a spreadsheet and writing to a GDX file. The duplicate records for each symbol will be reported in the logfile, and if their accumulated number does not exceed the maximum specified using this option, the GDX file will not be deleted. This is a global option and applies to each symbol read from the spreadsheet.

The option is demonstrated in [Reading Set from Lists with Duplication](#).

updLinks = *integer* (default = 0)

Specifies how links in a spreadsheet should be updated. The valid range is 0..3.

- 0 Doesn't update any references
- 1 Updates external references but not remote references
- 2 Updates remote references but not external references
- 3 Updates both remote and external references

runMacros = *integer* (default = 0)

This option controls the execution of the 'Auto_open' and the 'Auto_close' macros when opening or closing a spreadsheet. Valid range is 0..3.

- 0 Doesn't execute any macros
- 1 Executes Auto_open macro
- 2 Executes Auto_close macro
- 3 Executes Auto_open and Auto_close macro

6.29.2.2 Global Options

The following options affect the symbols that follow the option. They remain in effect unless they are redefined and used again for another symbol.

Option	Default	Description
acronyms	0	Controls the handling of acronyms.
cMerge	0	Controls the handling of merged Excel ranges.
dSetText	N	Read explanatory text for set elements of domain sets .
epsOut	Eps	String to be used when writing the value for 'Epsilon'.
filter	0	Set the Excel filter for symbols written to Excel.
incRC	N	Include Excel row and column indices when a symbol is written to the GDX file.
mInfOut	-Inf	String to be used when writing the value for 'Negative infinity'.
NaIn	none	String to be used when reading a value for 'Not available'.
nameConv	N	Controls the interpretation of an Excel range.
NaOut	NA	String to be used when writing the value for 'Not available'.
pInfOut	+Inf	String to be used when writing the value for 'Positive infinity'.
resetOut	disabled	Reset the output strings for special values to their defaults.
squeeze	Y	Controls writing of default values of sub-fields of variables and equations resp. the handling of zero values within parameters when reading from spreadsheet.
skipEmpty	1	Number of empty rows or columns indicating the end of a block when reading from spreadsheet using the top left cell specification.
UndfOut	Undf	String to be used when writing the value for 'Undefined'.
allUELS	Y	Controls the handling of UELs without associated values in the data range.
zeroOut	0	String to be used when writing the value for 'Zero'.

Some more detailed remarks on the global options:

acronyms = *integer* (default = 0)

A non-zero value indicates that acronyms can be expected and should be processed.

If no acronym processing takes place, reading an identifier in the data section of a sheet will generate an error. Writing an acronym to a sheet will write the internal numerical representation of the acronym.

Processing acronyms:

When reading a spreadsheet, an identifier in the data section of the sheet will be interpreted as an acronym and will be written to the GDX file.

When writing to a spreadsheet, a data tuple containing an acronym will be stored using the corresponding identifier of the acronym.

cMerge = *integer* (default = 0)

Option indicating how to read an empty cell that is part of a merged Excel range. See [Reading merged Excel Ranges with cMerge](#). Possible values and their interpretation are:

- 0 Leave the cell empty
- 1 Use merged value in row and column headers only
- 2 Use merged value in all cells

dSetText = *flag* (default = N)

Valid only when reading a spreadsheet.

This controls the reading of explanatory text for set elements of [domain sets](#). By default, no text is read for domain sets. If this option is activated this is changed. If an element appears more than once, the first one defines the explanatory text read.

epsOut = *string* (default = Eps)

String to be used when writing the value for 'Epsilon'. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#) and [Writing Parameter to Spreadsheet including Zero Values](#).

filter = *integer* (default = 0)

Adds basic Excel filter to the columns of the spreadsheet to display only those values matching some conditions. Using this option when reading an Excel file will result in an error. Specifying **filter=1** will set an Excel filter for the row of labels that are closest to the data values. When there are multiple rows in a column header (**cDim** > 1) we can specify **filter=x** where **x** is a number of the range 2..**cDim**, indicating to use a row farther away from the data values. See also [Writing to Spreadsheet using a Filter](#).

incRC = *flag* (default = N)

Valid only when reading a spreadsheet.

Include Excel row and column indices when a symbol is written to the GDX file. For example, when we write a parameter P with indices I and J, without this option it will be written as P(I, J). When **incRC** is enabled, the parameter will be written as P(Excel.Rows, I, Excel.Columns, J). Note that the sets **Excel.Rows** and **Excel.Columns** will be added to the GDX file automatically.

mInfOut = *string* (default = -Inf)

String to be used when writing the value for 'Negative infinity'. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

NaIn = *string* (default = none)

String to be used when reading a value for 'Not available'; this string is recognized in addition to the string 'NA' and is not case-sensitive. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

nameConv = *flag* (default = N)

Synonym: nC

The naming convention parameter is used to change the interpretation of an Excel range that does not contain an '!' (exclamation mark). For details see [Excel Ranges](#) below.

NaOut = *string* (default = NA)

String to be used when writing the value for 'Not available'. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

pInfOut = *string* (default = +Inf)

String to be used when writing the value for 'Positive infinity'. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

resetOut (disabled by default)

Reset the output strings for special values to their defaults. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

squeeze = *flag* (default = Y)

Synonym: sq

Writing to a spreadsheet:

The **squeeze** option affects the writing of sub-fields of variables and equations. A value for the field that is the default value for that type of variable or equation will not be written to the spreadsheet. For example, the default for .1 (level value) is 0.0, and therefore zero will not be written to the spreadsheet. When we set **squeeze=n**, all values will be written to the spreadsheet.

The **squeeze** option for writing data is demonstrated in [Reading Data from Spreadsheet and writing Data to Spreadsheet](#) and [Writing Parameter to Spreadsheet including Zero Values](#).

Reading a spreadsheet:

When the **squeeze** option is enabled, zero values for parameters will not be written to the GDX file. When the **squeeze** option is disabled, zero values will be written to the GDX file. In either case, empty cells, or cells containing blanks only, will never be written to the GDX file.

The **squeeze** option for reading data is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

skipEmpty = *integer* (default = 1)

Synonym: sE

The **skipEmpty** option can be used when reading a spreadsheet and the range is specified using the top left corner instead of a block range. The value defines the number of empty row or column cells signal the end of a block. Valid values are 0..n. If the range is specified using a block range, **skipEmpty** will be ignored. Blank rows or columns will be skipped automatically.

Note that **skipEmpty** is also valid when using the **merge** resp. **clear** options in order to write data to spreadsheet (in a specific order determined by matching row and column labels already stored in the spreadsheet).

See [Skipping Empty Rows and Columns](#) or [Reading Multi-dimensional Parameter from Spreadsheet](#) for instance.

UndfOut = *string* (default = Undf)

String to be used when writing the value for 'Undefined'. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

allUEls = *flag* (default = Y)

Valid only when reading a spreadsheet.

When enabled, all unique elements found in a range will be entered in the GDX file. When disabled, only those unique elements that are used in conjunction with a value will be entered in the GDX file.

zeroOut = *string* (default = 0)

String to be used when writing the value for 'Zero'; by default this is '0'. This option is demonstrated in [Reading Special Values from Spreadsheet and writing to Spreadsheet](#).

6.29.2.3 Symbols

To write data to a spreadsheet or to a GDX file, one or more symbols and their associated Excel range need to be specified. See also [Excel Ranges](#).

The general syntax for a symbol specification is:

dataType=*symbolName* {**symbolAttributes**}

Among the **symbolAttributes**, one specifies the **dataRange**, the **dimensions** of the symbol and some additional **symbolOptions** in general.

dataType

dataType	Description
par	Declare the symbol as parameter and define a individual name when reading from spreadsheet, or specify a parameter from a GDX file when writing to spreadsheet.
equ	Specify a sub-field of a equation from a GDX file when writing to spreadsheet.
var	Specify a sub-field of a variable from a GDX file when writing to spreadsheet.
set	Declare the symbol as set and define a individual name when reading from spreadsheet, or specify a set from a GDX file when writing to spreadsheet.
dSet	Declare the symbol as domain set and define a individual name when reading from

par = *GAMS_Parameter*

Specify a GAMS parameter to be read from a GDX file and written to spreadsheet, or to be read from a spreadsheet and written to a GDX file.

When writing to a spreadsheet, special values such as **Eps**, **NA** and **Inf** will be written in ASCII. When reading data from a spreadsheet, the ASCII strings will be used to write the corresponding special values to the GDX file.

This datatype is used in the most examples. Reading parameters is demonstrated in [Reading Parameter from Spreadsheet](#) or [Reading Multi-dimensional Parameter from Spreadsheet](#). Writing parameters from GDX to spreadsheet is demonstrated in [Writing Parameter to Spreadsheet](#).

equ = *GAMS_Equation*

var = *GAMS_Variable*

A sub-field of a variable or equation can be written to a spreadsheet and should be specified as part of the symbolName. The fields recognized are **.l** (level), **.m** (marginal), **.lo** (lower bound), **.up** (upper bound), **.prior** (priority), and **.scale** (scale). The sub-field names are not case-sensitive. See also [Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve](#).

A sub-field of a variable or equation cannot be read from a spreadsheet and written to a GDX file.

set = *GAMS_Set* [values = *valueType*]

In GAMS we can define a set by specifying all its elements. In addition, each tuple can have an associated text. To read a set from a spreadsheet, the values option is used to indicate if there is any data, and if there is, if the data should be interpreted as associated text or as an indicator whether the tuple should be included in the set or not.

Reading sets is demonstrated in [Reading Set from Spreadsheet](#) or [Reading Set Elements associated with Data o](#) (focusing on the **values** option) for instance. Writing sets from GDX to spreadsheet is demonstrated in [Writing Set to Spreadsheet](#).

valueType	Interpretation
auto	Based on the range, row and column dimensions for the set, the program decides on the valueType to be used. This is the default for values .
noData	There is no data range for the set; all tuples will be included.
YN	Only those tuples will be included that have a data cell that is not empty and does not contain '0', 'N' or 'No'.
sparse	Only those tuples will be included that have a data cell that is not empty. The string in the data cell will be used as the associated text for the tuple.
dense	All tuples will be included. A string in the data cell will be used as the associated text for the tuple.

Due to backward compatibility, **valueType=string** or **all** are also recognized and are synonyms for **valueType=dense**. The following table summarizes which valueType will be used when reading a set, if a valueType was not specified:

Range specification	rDim = 0 Or cDim = 0	rDim > 0 And cDim > 0
Top left corner only	dense	YN
A block, but the data range is empty	dense	YN
A block, and there is a data range	dense	YN

When writing to a spreadsheet, the entire set is written to the spreadsheet and the writing of the associated text is governed by the values option:

valueType	Interpretation
auto	If rDim=0 or cDim=0, auto means string, otherwise auto means YN.
noData	Neither associated text nor 'Y' is written for a set element.
YN	A 'Y' is written for a set element.
string	The associated text is written for a set element. If no text is stored with set element the cell will be empty.

Due to backward compatibility, `valueType=dense`, `sparse` or `all` are also recognized and are synonyms for `valueType=string`.

dSet = *GAMS_Set*

A domain set is used to read the domain of a set from a spreadsheet row or column. Either the row or the column dimension (`rDim` or `cDim`) should be set to '1' to specify a row or column for the set, resulting in a one-dimensional set. Duplicate labels in the range specified do not generate an error message. For instance, see also [Reading Set from Lists with Duplication](#).

Note that reading explanatory text of set elements is not supported by `dSet`. In order to read explanatory text, use `set` instead. If there are duplicate set element labels in your data, use the `set` symbol specification while increasing the value of the immediate option `maxDupeErrors` to oppress an error message when reading duplicates.

text = "String of characters" {dataRange}
textID = Identifier {dataRange}

Write the text to the cell specified in the DataRange. In addition, `textID` will write the explanatory text of the Identifier in the cell to the right of the dataRange.

A Text directive can be followed by a `link=Address` or `linkID=identifier` directive. Using `link` will create a hyperlink to an external page or to a cell in the spreadsheet, while `linkID` will create a hyperlink to the top left corner of the symbol specified. See [Writing to Spreadsheet adding Text and Hyperlinks](#) for instance.

hText = "String of characters" {dataRange}
vText = "String of characters" {dataRange}

Write a string of characters in the horizontal direction for `hText` or vertical direction for `vText`. Text for the next cell is indicated by a comma. In order to write a comma as part of the text, the comma needs to be preceded by a backslash. See [Writing Set to Spreadsheet](#) for instance.

6.29.2.3.1 Symbol Attributes The following options apply to the symbol preceding the option, and only affect that symbol:

Parameter	Default	Description
dataRange	Cell A1 of the first sheet	Specify the Excel range of the symbol for reading from spreadsheet or for writing to spreadsheet.
dim	2 when reading from spreadsheet Defined by the symbol dimension stored in the GDX file when writing to spreadsheet	Total dimension of the symbol.
cDim	1	Column dimension of the symbol.
rDim	<code>dim-1</code>	Row dimension of the symbol.
merge	disabled	When enabled, the data will be written in a specific order determined by matching row and column labels already stored in the spreadsheet.
clear	disabled	In addition to the effect of <code>merge</code> , already existing values in the data range of the spreadsheet are removed before writing.
colMerge	0	Determines the columns for which non-empty content of the previous cell will be used as content for the empty cell of a column.
intAsText	Y	Determines the cell format when writing unique elements that are a proper integers to spreadsheet.
ignoreRows/Cols	none	Specify rows and columns to be ignored when reading from spreadsheet.

Some more detailed remarks on the symbol attributes:

dataRange

rng = *Excel Range*

The [Excel Range](#) for the data for the symbol. Note that an empty range is equivalent to the first cell of the first sheet.

dimensions

dim = *integer*

The total dimension for the symbol.

cDim = *integer*

Column dimension: the number of rows in the data range that will be used to define the labels for the columns. The first `cDim` rows of the data range will be used for labels.

rDim = *integer*

Row dimension: the number of columns in the data range that will be used to define the labels for the rows. The first `rDim` columns of the data range will be used for the labels.

More about dimensions:

When reading data from a GDX file and writing to a spreadsheet, the dimension of the symbol is known. When reading a spreadsheet and writing to a GDX file, the dimension is not known.

The sum of `cDim` and `rDim` determine the dimension of the symbol. This dimension is used when writing data to a GDX file, and is used to verify the dimension of a symbol when reading from a GDX file.

When reading a GDX file, the dimension of a symbol is known, and therefore the `cDim` or `rDim` parameter can be omitted. If both `cDim` and `rDim` are omitted, the program assumes that `cDim=1` and `rDim=dim-1`.

symbolOptions

The options below are only valid when reading a GDX file and writing to a spreadsheet.

By default, writing data to a spreadsheet will include the row and column labels in addition to the data. The row and column labels will appear in the same order as they appear in the GDX file.

merge (disabled by default)

Using the **merge** option assumes that the row and column labels are in the spreadsheet already. For each value read from the GDX file, the location of the row and column labels is used to update the spreadsheet. Using the **merge** option will force the data to be presented in a given order using the row and column labels. Spreadsheet cells for which there is no matching row/column pair will not be changed. The matching of labels is not case-sensitive. See also [Writing to Spreadsheet with merge Option Example](#).

Note that the **skipEmpty** option value affects the reading of the row and column labels from spreadsheet in case of top left range specification (while **skipEmpty** is ignored in case of block range specification).

Warning: The **merge** or **clear** option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.

clear (disabled by default)

The **clear** option is similar as the **merge** option, except that the data range will be cleared before any data is written. See also [Writing to Spreadsheet with clear Option Example](#).

colMerge = *integer* (default = 0)

The number of columns that will use a previous value in that column if the cell is empty. Can only be used when reading from a spreadsheet. See [Reading empty Cells with colMerge](#).

intAsText = *flag* (default = Y)

Unique elements that are a proper integer can be written as text or as an integer value. The default is Y, which will write the unique element as a string. Note that this impacts the sorting order and can be used when using an Excel filter on a data range.

Ignoring Rows and Columns when reading from a spreadsheet

ignoreRows = *rownr*, *rownr*, *rownr:rownr*

ignoreColumns = *colnr*, *colnr*, *colnr:colnr*

Row numbers are represented by integers. Column numbers are represented by Excel column numbers, like A, CD, IV etc, or by integers.

Note

- Ignoring rows or columns is only allowed when reading a spreadsheet.
- The specification of ignored rows or columns follows the symbol specification and only applies to that symbol.
- When ignoring a column that would be part of an index if the column was not ignored, the range for the index will be extended for each column that is ignored. The same holds for ignored rows that are part of an index.

See also [Ignoring Rows and Columns](#).

6.29.2.4 Syntax Elements

The most options are specified by using an integer, a string or a flag. Note that the options `useRC`, `resetOut`, `checkDate`, `merge` and `clear` are enabled or disabled by simply adding the keyword to your `GDXXRW` statement.

Element	Description
integer	An unsigned integer
string	A string of characters; a string can be quoted with single or double quotation marks.
flag	True values: 1, Y or Yes False values: 0, N or No (not case-sensitive)

6.29.2.5 Excel Ranges

An Excel Range is specified using the standard Excel notation: `SheetName!CellRange`.

When the `SheetName!` is omitted, the first sheet will be used. A `CellRange` is specified by using the `TopLeft:BottomRight` cell notation like `A1:C12`. When `:BottomRight` is omitted, the program will extend the range as far down and to the right as possible. (Using `!..!` in stead of `!:` is supported.)

Excel also allows for named ranges; a named range includes a sheet name and a cell range. Before interpreting a range parameter, the string will be used to search for a pre-defined Excel range with that name. See [Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges](#) for instance.

When writing to a spreadsheet and a sheet name has been specified that does not exist, a new sheet will be added to the workbook with that name. Reading a spreadsheet and using an unknown range or sheet name will result in an error.

The following table summarizes all possible input combinations and their interpretation:

Input	Sheet used	Cell(s) used	Condition
	First sheet	A1	
!	First sheet	A1	
Name	First sheet	Name	When nc=0
Name	Name	A1	When nc=1
Name!	Name	A1	
!Name	First sheet	Name	
Name1!Name2	Name1	Name2	

The term nc= refers to the [nameConv](#) option.

6.29.3 Return Codes

On success, GDXXRW will return 0 as error code. However, there might be an error which will be signaled with a specific return code in addition to an error message.

Return Code	Interpretation
0	No error
1	Cannot write log
2	GDX error
3	No input file
4	Input file not found
5	Bad parameter
6	Read error
7	Problem loading GDX DLL
8	Symbol not found
9	Dimension different
10	Types different
11	Bad UELs
12	Bad output file
13	Problem opening Excel
14	Problem writing to Excel
15	Problem reading from Excel
16	Duplicate entry
17	Cannot add sheet
18	Bad cell value
19	Dimension conflict
20	Data exceeds range
21	Exceeds range or memory problem
22	Deprecated

Return Code	Interpretation
23	Program aborted
24	Merge range empty
25	Too many columns skipped
26	Too many rows skipped

6.29.4 Warning

When executing GDXRW twice and redirecting output to the same log file may result in a fatal error.

For example:

```
gdxxrw step1 parameters > logfile
gdxxrw step2 parameters > logfile
```

The execution of step2 may fail, because Excel will close the logfile in step1 in a delayed fashion, but return control to GDXRW immediately. Using the [log](#) or [logAppend](#) parameter will avoid this problem.

6.29.5 Reading from Spreadsheet - Examples:

6.29.5.1 Reading Set from Spreadsheet

Assuming we want to read set elements from the first sheet of the spreadsheet file exampleData.xlsx and write the data to exampleData.gdx.

Either of the following two statements below reads the second row of set elements from the spreadsheet above:

```
gdxxrw exampleData.xlsx set=i1 rng=readingSets!A2:C2 cDim=1
gdxxrw exampleData.xlsx dSet=i1a rng=readingSets!A2:C2 cDim=1
```

When the output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. Since all elements in the second row are unique, there is no need of increasing the [maxDupeErrors](#) parameter to avoid an error message when defining the symbol as [set](#). By specifying the symbol directly as a [dSet](#) (domain set) in the second statement, duplicate labels would be removed without throwing an error. We set [cDim](#) to one so that the first row of the range is used for the labels of the set.

On the other hand if we want to read set elements listed in a column:

Either of the following two statements reads column A of set elements from the spreadsheet above:

```
gdxxrw exampleData.xlsx set=j1 rng=readingSets!A35:A37 rDim=1
gdxxrw exampleData.xlsx dSet=j1a rng=readingSets!A35:A37 rDim=1
```

Besides the range we also had to change the parameter [rDim](#) to indicate that the first column of the range is to be used for the labels.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample18\]](#) for reference.

6.29.5.2 Reading Set and Explanatory Text

Suppose we want to read the set elements in the ninth row and their associated text in the tenth row of the following spreadsheet:

We can read the set elements and their explanatory text by executing the command:

```
gdxxrw exampleData.xlsx set=i3 rng=readingSets!A9:E10 cDim=1
```

To read the explanatory text, we simply include the tenth row within the range of the symbol `i3` and specify `cDim=1`. By doing this, the first row of the range, i.e. the elements of the ninth row, will be used as the set elements, while the tenth row will be interpreted as their associated text (depending on the `values` option specified. By default, the `values` option is set to `dense` in this example, i.e. all elements will be included and the string in the associated data cell will be used as explanatory text. See also [Reading set elements associated with Data or Text](#) for instance.).

Note here the explanatory text of the set element `skipme2` is just a `Y` as it has a blank entry for the explanatory text.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWEExample18\]](#) for reference.

6.29.5.3 Reading Set Elements associated with Data or Text using the values Option

When reading set elements from spreadsheet, the `values` option can be used to control whether elements and associated text are included in the set or not. We use the data displayed in the spreadsheet below to demonstrate the `yn`, `dense`, `sparse` and `noData` specifications:

The set element names are stored in the first row, the associated data cells in the second row.

1. values=yn

Run the following command to load those element names associated with nonzero data or yes without storing the data as explanatory text:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=yn
```

The set `A` will contain the elements `a`, `b`, `e`, `f`, `h`, `i`, `k` and `m`, since the elements `c`, `d`, `g`, `j` and `l` are associated with a zero, a blank or a no resp. `N` (case insensitive).

2. values=dense

This option must be specified, if we want to read all elements while using the strings in the data cells as explanatory text.

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=dense
```

3. values=sparse

To read in all elements having a non-empty data cell while interpreting the string in the data cell as explanatory text, run the following command:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=sparse
```

The set A will contain all elements except for j, since the associated data cell is empty.

4. values=noData

This option must be used, if we want to read all set elements while ignoring the data range. Especially, the data cells will not be interpreted as explanatory text. To read the elements from the range A1:M1, one could run the following command:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1
```

While all elements a - m will be included this way, the second row will be automatically interpreted as explanatory text (even though we specified only the first row within the `rng` statement). This might be not desirable at all in some situations, e.g. when reading the city names in the next example [Reading Set from Data Tables](#), we do not want to have the numbers 5000, 6000 and 0 to be explanatory text for the city names. Run the following command to include all elements in your set without interpreting the cells in the second row as explanatory text:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1 values=noData
```

5. values=auto (default)

The second table within the description of the [values](#) options indicates which value type will be used by default based on the `rng`, `cDim` and `rDim` specifications for the set. For instance, when running the following command:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1
```

the value type used is `dense`, since we specified a block range with a data row and `rDim` equals zero.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample9\]](#) for reference.

6.29.5.4 Reading Set from Data Tables

One may wish to load set elements from a data table. Given a spreadsheet segment like the following:

We can take the set across the top containing the elements cleveland, chicago and dallas with any of the following commands:

```
gdxxrw exampleData.xlsx set=i6 rng=readingSets!B20:D20 cDim=1 values=noData
gdxxrw exampleData.xlsx dSet=i6a rng=readingSets!B20:D20 cDim=1
gdxxrw exampleData.xlsx set=i6c rng=readingSets!B20:D21 cDim=1 values=noData
```

Note the usage of the `values` option in order to avoid reading the numbers as explanatory text. See also [Reading set elements associated with Data or Text](#). However, this can also be avoided by declaring the symbol as a domain set using the symbol declaration `dSet`.

We can also take a set vertically from column A as follows:

```
gdxxrw exampleData.xlsx dSet=j4 rng=readingSets!A21:A23 rDim=1
```

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample18\]](#) for reference.

6.29.5.5 Reading Set from Lists with Duplication

One may wish to extract set elements from a spreadsheet where there is no unique list of elements that can be read but rather a list where some names are repeated. In the example below note that in rows 26 and 27 there are set element names but they are duplicated:

One can read this using `dSet` as follows:

```
gdxxrw exampleData.xlsx dSet=i7 rng=readingSets!B26:E26 cDim=1 dSet=i8 rng=readingSets!B27:E27 cDim=1
```

Both domain sets will be read within a single GDXXRW call. The `rng` and `cDim` specifications affect only the symbol that they are following directly.

It may be favored in some situation to use the `set` symbol instead (e.g. for reading explanatory text). To suppress an error message when reading sets with duplication, one must specify a sufficient large number within the `maxDupeErrors` option.

```
gdxxrw exampleData.xlsx maxDupeErrors=4 set=i7 rng=readingSets!B26:E26 cDim=1 values=noData set=i8 r
```

For the data in this example, four is a sufficient large number since there are two duplicates for the first and two duplicates for the second set within each range. Note the usage of the `values` option in order to avoid reading 'cleveland' as explanatory text for the elements of set `i7` and to avoid reading the numbers as explanatory text for the elements of `i8`. See also [Reading set elements associated with Data or Text](#) for more informations about the `values` option.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample18]` for reference.

6.29.5.6 Reading Parameter from Spreadsheet

Assuming we want to read parameter `data1` from the file `Test1.xlsx` and write the data to `Test1.gdx`.

The following statement reads parameter `data1` from the spreadsheet above (using the `par` data type):

```
gdxxrw Test1.xlsx par=data1 rng=A1:D3 cDim=1 rDim=1
```

The sheet name in a range can be omitted when it refers to the first sheet. The elements in the first row and first column of the data range will be used as labels for the two dimensional parameter `data1` by defining `cDim=1` and `rDim=1` (see also `cDim` resp. `rDim`).

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample5]` for reference.

6.29.5.7 Reading Parameter from Spreadsheet with Duplication

The same data as in the previous example, but organized differently. We use the `dSet` symbol specification instead of `set` to read set I (in column A) and set A (in column B), since there are duplicate entries in column A resp. column B.

The following statement reads parameter `data2` from the spreadsheet above:

```
gdxxrw Test1.xlsx par=data2 rng=EX2!A1 rDim=2 dSet=I rng=EX2!A1 rDim=1 dSet=A rng=EX2!B1 rDim=1
```

By setting `rDim=2` for the parameter `data2` we indicate to use the first two columns of the data range as the labels for the parameter values. Since the sheet does not contain further data, one can specify the ranges using the top left cell notation without hesitation.

When using a few symbols, the command line can become too long to be practical. In such case, use a text file to hold the parameters. A parameter file can contain multiple lines to increase readability and a line starting with a `'*'` will be ignored.

```
* file example6.txt
par =data2 rng=EX2!A1 rDim=2
dSet=I     rng=EX2!A1 rDim=1
dSet=A     rng=EX2!B1 rDim=1
```

An option file is indicated by preceding the file name with a `@` (At sign.).

```
gdxxrw Test1.xlsx @example6.txt
```

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample6\]](#) for reference.

Note

- An option file can contain multiple lines to increase readability.
- When reading parameters from a text file, lines starting with an asterisk (`*`) will be ignored and act as a comment.
- An option file can also be written during the execution of a GAMS model using the [GAMS Put Facility](#) and the subsequent `GDXXRW` commands must use `execute` command so the put file is written before it is to be read (this would happen when using the compile time command `$call` to run `GDXXRW`).
- Using an option file can be useful in reducing execution time by combining the options and symbols from multiple `GDXXRW` calls in a single option file used in a single `GDXXRW` call.

6.29.5.8 Reading Multi-dimensional Parameter from Spreadsheet

This example illustrates how to read a four dimensional parameter from spreadsheet:

The strings in the first two columns and the first two rows of the data range A1:F6 shall be used as labels for the parameter values. Therefore, we define `rDim=2` and `cDim=2` (see also `rDim` and `cDim`). The parameter will be named `data3` (within the `par` declaration). Run the following command to read the data with `GDXXRW`:

```
gdxxrw Test1.xlsx par=data3 rng=EX3!A1:F6 rDim=2 cDim=2
```

Note that the data range was specified using the block range notation. However, it might be more comfortable to specify only the top left corner sometimes, but empty rows or columns may affect the reading process, i.e. `GDXXRW` might stop to early when encountering empty rows or columns or it will try to read data separated by empty rows or columns not being part of the data you wish to read. When we specify the range as a block, an empty row or column will always be ignored. When we specify the top left cell only, the `skipEmpty` option can be used to ignore one or more empty rows or columns. However, for the data in this example, we do not need to ignore empty rows or columns within the data range, but suppose there is non-relevant data starting in column H. By default (`skipEmpty=1`), `GDXXRW` would try to read the data starting in H. When we specify `skipEmpty=0` and cells A7, B7, G1 and G2 are empty, the range can be specified with the top left cell only in this example:

```
gdxxrw Test1.xlsx skipEmpty=0 par=data3 rng=EX3!A1 rDim=2 cDim=2
```

Since `skipEmpty` is a global option, affecting every symbol that follows, we define it before declaring the parameter `data3`.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample7]` for reference.

6.29.5.9 Reading Spreadsheet using the Index Option

The `index` option is used to read a number of parameters and sets based on information stored in the spreadsheet itself. By doing this, the `GDXXRW` command becomes quit short and the informations on how to read the data can be written directly within the spreadsheet to increase readability. The first row of the range is used for column headings indicating additional parameters. We will discuss the results only briefly, because all other options used in this example were demonstrated before.

Suppose we want to read the parameters and sets from the following spreadsheet:

The informations about all parameters and sets are stored within the sheet index in the same spreadsheet file `exampleData.xlsx` as `testIndex` above:

The following statement reads parameters and sets from the spreadsheets using the `index` option:

```
gdxxrw exampleData.xlsx output=gdxAll.gdx index=index!A1
```

We use the `output` option to write the data to `gdxAll.gdx` for demonstration here. By default, `GDXXRW` would write to `testIndex.gdx`. Some brief remarks on the results:

- Elements of set `i1` and `i1a`: `trains`, `cars` and `planes`. There is no explanatory text, since the data range (third row) is empty. We can use `dim=1` equivalently to `cDim=1` in this example, because by default, `cDim=1` and `rDim=dim-1`. See also [dimensions](#).
- When reading the sets `i2` and `i3`, we are defining which elements and explanatory text will be stored by specifying the `values` option.
- The set `i4` will contain all elements of the thirteenth row. Afterwards, `skipEmpty` is set to zero, affecting the reading of `i4a` and `i5`. Unlike `i4`, the sets `i4a` and `i5` will not contain the element `houston`, since `skipEmpty=0` and the empty column signals `GDXXRW` to stop reading (note that the range is not defined using the block range specification). Since there is a data range for `i5`, the strings `city1 - city5` will be used as explanatory text by default. After reading `i4a` and `i5`, `skipEmpty` is reset to zero (default).
- Each of the sets `i6`, `i6a` and `i6b` will contain the elements `cleveland`, `chicago` and `dallas`. There is no explanatory text for any of the sets in the GDX file, however, one must enforce this for the set `i6` with `values=noData`.

There are no interesting details for the remaining sets and parameters to discuss here. The complete example and the results displayed within GAMS can be found in the GAMS Data Utilities Library, see model [\[GDXXRWExample10\]](#) for reference.

Note

- The parameters and sets are read using the specifications within the `myIndex` sheet. They are treated as if they appeared directly on the command line.
- In the spreadsheet, the first three columns of the range have a fixed interpretation: `DataType` (`par`, `set`, `dSet`, `equ`, or `var`), Item name identifier and spreadsheet data range. The fourth and following columns can be used for additional parameters like `dim`, `rDim`, `cDim`, `merge`, `clear` and `skipEmpty`. The column header contains the keyword when necessary, and the cell content is used as the option value.
- When an entry appears in a column without a heading then it is directly copied into the `GDXXRW` option file. Thus in the example above the items in column G are directly copied into the file.
- Rows do not need to have entries in the first three columns if one just wants to enter persistent options such as `skipEmpty` or some of the special character string re-definitions (as in row seven and ten from the spreadsheet above).

6.29.5.10 Reading Data from Spreadsheet and Loading into GAMS

One can use `$call` to execute the `GDXXRW` command in the GAMS code to read from spreadsheet at compilation time (the data is taken from the previous example):

```
$call gdxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData
```

Getting a set from the spreadsheet into a GDX file is only half the battle. One must also use commands in GAMS to load the data as discussed in the chapter [Using GAMS Data Exchange or GDX Files](#). At compile time this is done using:

```

Set i9;
* read/load set from data at compile time
$call gdxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData
$gdxIn testIndex.gdx
$load i9

```

where the set must be declared in a set statement then one can if needed create the GDX file using GDXXRW, then one uses a \$gdxIn to identify the source file and a \$load to bring in the data.

Some users may wish to load sets at execution time. However, this is limited to subsets that are dynamic sets and cannot be used in domains. To do this one simply uses the statements as above, but substitutes execute in place of \$call as follows:

```

Set i9(i6a);
* read/load set from data at execution time
execute 'gdxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData'
execute_load 'testIndex' i9;

```

where the set i9 must be declared as a subset in a set statement (of i6a in this case), then one can if needed create the GDX file using execution time GDXXRW, and an execute_load to bring in the data with an identification of the GDX source file name. Note that we used the set i6a as superset, fitting best to the data from the previous example. However, one could also use the statement Set i9(*);.

One can load the universe of labels from a GDX file into a set at run-time using the syntax:

```
execute_load 'someFile', someSet=*
```

Note

In doing this, only labels known to the GAMS program will be loaded.

6.29.5.11 Reading empty Cells with colMerge

Suppose we want to read the four dimensional parameter from the following spreadsheet:

The cells B4, B5, C4 and D5 might be empty to avoid duplication, i.e., the non-empty content of the previous cell in the same column shall be used as content for the empty cell. In particular: the content of B3 shall be used for the content of B4 and B5, the content of C3 for C4 and the content of D4 for cell D5. Reading the above spreadsheet using the following GAMS statement:

```
gdxrw exampleData.xlsx par=A_d rng=colMerge!B2 rDim=3 cDim=1
```

results in empty cells B4, B5, C4 and D5, causing troubles if you want to declare the parameter as A(number,number,number,color) certainly:

Adding the symbol attribute colMerge, we use the non-empty content of the previous cell in the same column as the content for the empty cell. Specifying colMerge=2 will do this for the first two columns for instance.

```
gdxrw exampleData.xlsx par=A_2 rng=colMerge!B2 rDim=3 cDim=1 colMerge=2
```

Only the two entries corresponding to the cell D5 are still empty, since we do not specify all three columns within colMerge:

Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an `<empty>` entry instead.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample20]` for reference.

6.29.5.12 Reading merged Excel Ranges with `cMerge`

Suppose we want to read the three dimensional parameter from the following spreadsheet:

Note that the label 'red' is centered over the merged cells B1, C1 and D1 and label 'green' over the merged cells E1 and F1. Additionally, in the data range, the cells B3:C3 and B4:C4 are merged, too. The option `cMerge` can be used to control the way merged cells are handled. We will discuss the effect of the possible values for `cMerge` on the data presented above by running the following commands (an option file is used to increase readability):

```
$onEcho > howToRead.txt
cMerge=0 par=B_d rng=cMerge!A1 rDim=1 cDim=2
cMerge=1 par=B_1 rng=cMerge!A1 rDim=1 cDim=2
cMerge=2 par=B_2 rng=cMerge!A1 rDim=1 cDim=2
$offEcho

$call gdxrw exampleData.xlsx output=cMerge.gdx @howToRead.txt
```

We specify `cMerge` in advance, since it is a global option affecting every symbol that follows. Executing the three statements will create three different output files, all displayed in GAMS Studio:

Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an `<empty>` entry instead.

Some remarks on the results:

cMerge=0 (default)

Empty cells being part of a merged Excel range will remain empty. Thus, the cells C1, D1, F1, C3 and C4 from the spreadsheet above will remain empty when reading with `GDXXRW`. Since C3 and C4 are empty while being part of the data range, they won't show up in the GDX file. The values in the last column of the GDX file are useful to compare the results with the spreadsheet. For instance, the UELs of the value 5 are `a`, `<empty>` and `two`, since the cell F1 is empty, while A3 contains the string `a` and F2 the string `two`.

cMerge=1

The value of a merged range within a row or column header will be used for all cells being part of the merged range. Thus, the string 'red' will be used for the cells in the column header C1 and D1 and the string 'green' for the cell F1. Since C3 and C4 are part of the data range, they will remain empty and are not displayed in the GDX file. As you can see, there is no longer an empty UEL.

cMerge=2

The value of a merged range will be used for all cells being part of the merged range, i.e. `cMerge=1` is extended to the data range. Therefore, the value 1 resp. 11 will be also used for the cell C3 resp. C4, appearing in the GDX file for the first time. Since there is no change in handling merged cells within the row or column header, all values have non-empty labels.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample20]` for reference.

6.29.5.13 Skipping Empty Rows and Columns

By using the `skipEmpty` option, we can control the way blank rows or columns are handled and causes GDXXRW to either stop or skip over if a blank row or column is encountered when using the top left corner range specification instead of a block range. If the range is specified using the `TopLeft:BottomRight` cell notation (often referred as block range notation), empty rows or columns will be skipped automatically. Suppose the data is stored in the following spreadsheet:

We can read this spreadsheet and skip blank rows and columns with the following command:

```
gdxxrw exampleData.xlsx      par=A_d rng=skippingRC!A2 rDim=2 cDim=1
```

or

```
gdxxrw exampleData.xlsx se=1 par=A_1 rng=skippingRC!A2 rDim=2 cDim=1
```

Note that there will be no difference concerning the generated GDX files, since `skipEmpty` is set to one by default. On the other hand, if `skipEmpty` is set to zero

```
gdxxrw exampleData.xlsx se=0 par=A_0 rng=skippingRC!A2 rDim=2 cDim=1
```

the blanks terminate the read not reading the `rail` column and the `san francisco.chicago` row. After loading into GAMS the data become:

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample21]` for reference.

Note

The `skipEmpty` option must appear before any `par`, `set`, `dSet` etc statements that use it and will persist for the rest of the statements in a command unless it is set to another value.

6.29.5.14 Ignoring Rows and Columns

We can use the options [ignoreColumns](#) and [ignoreRows](#) to ignore columns and rows when reading data for a symbol. Suppose we want to ignore the red colored rows and columns of the following spreadsheet, when reading the four dimensional parameter:

We can read this spreadsheet and ignore the red colored columns and rows with `GDXXRW` by running the following command:

```
gdxxrw exampleData.xlsx par=A rng=ignoringRCC1 cDim=2 rDim=2 ignoreRows=2,6 ignoreColumns=D,G
```

The options `ignoreRows` and `ignoreColumns` are symbol options and therefore must appear after the symbol specification, affecting only this particular symbol.

In the example above we ignored column D which would have been part of the index for the rows. So the range for the row index was extended with column E. The E column is no longer part of the data range. The treatment of the column index is similar. The second row would have been part of the column index, and now that the row is ignored, the next row becomes part of the column index and the third row is no longer part of the data range.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample21\]](#) for reference.

Note

The `ignoreColumns` and `ignoreRows` options appear after any `par`, `set`, `dSet` etc `GDXXRW` command instruction and only affect reading of that item.

6.29.5.15 Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges

As mentioned in section [Excel Ranges](#), the range of a symbol to be read can be defined by using named ranges. To name a cell range within Excel, simply select the cell range and type in the name you want to assign to this particular range by using the name-box next to the top left corner of your spreadsheet. Suppose we want to read the data in the range A1:D3 taken from the example [Reading Parameter from Spreadsheet](#):

Instead of specifying the range explicitly by `rng=A1:D3`, we use the pre-defined named range 'parRange', i.e. `rng=parRange`. `GDXXRW` uses the string specified to search for a matching pre-defined named range first. In summary, run the following command to read the parameter `data4` from the file `Test1.xlsx`:

```
gdxxrw Test1.xlsx par=data4 rng=parRange rDim=1 cDim=1
```

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample5\]](#) for reference.

Note

In Excel, one can assign a single name to several separated block ranges, e.g. assign the name 'disconnected' to the block ranges A1:D3 and F4:H5 (by holding 'Strg' while selecting the second block range and using the name-box to assign the name). However, such disconnected data cannot be read using the named-range specification.

6.29.6 Writing to Spreadsheet - Examples:

6.29.6.1 Unloading Data from GAMS before Writing to Spreadsheet

When writing to spreadsheet with GDXXRW, one must use commands in GAMS to place the data into the GDX file at first (see also [Using GAMS Data Exchange or GDX files](#)). When reading data, it is often desirable to use a \$call command to run GDXXRW and the statements \$gdxIn and \$load afterwards to load the data, allowing also domain definitions (at compile time) for instance. This is hardly ever desirable or realizable when unloading and writing to a spreadsheet, for example, if one wish to write the solution after solving a model to spreadsheet. This should generally not be done at compile time so one should only use the `execute` and `execute_unload` commands at execution time as follows:

```
execute_unload 'test.gdx' someParameter;
execute 'gdxrw test.gdx par=someParameter rng=A1'
```

where the `execute_unload` tells what data to place in the GDX file and determines the GDX source file name. The matching GDXXRW execution tells the name of the GDX file, the name of the spreadsheet (optional) and identifies the data to write.

See also [Writing Set to Spreadsheet](#) and [Writing Parameter to Spreadsheet](#) for demonstration.

Note

- One must be careful when using GDXXRW as each time the command is executed the GDX file is erased and only has the current contents and thus should be written just before if reusing the name.
- One also obtains output of sets using the command `execute_unloaddi` where the GDX file automatically includes all sets associated with unloaded parameters, variables and equations without need to list the set element names.

6.29.6.2 Writing Set to Spreadsheet

At fist, we will create a GDX file containing a simple set using the `execute` and `execute_unloading` directives. Most of the elements have an explanatory text:

```
Set x / element1 'explanatory text'
      element2
      element3 'previous element does not have explanatory text' /;

execute_unload 'writingSet.gdx' x;
```

Of course, in this particular code section above, one could also use \$gdxOut and \$unload. The [values](#) option can be used to control whether explanatory text is written to the spreadsheet. We'll demonstrate all three possible values explicitly within a single GDXXRW execution:

```

$onEcho > howToWrite.txt
hText="values: noData,,values: yn,,values: string" rng=Sheet1!A1
set=x rng=Sheet1!A2 rDim=1 values=noData
set=x rng=Sheet1!D2 rDim=1 values=yn
set=x rng=Sheet1!G2 rDim=1 values=string
$offEcho

execute 'gdxxrw writingSet.gdx output=writingSet.xlsx @howToWrite.txt'

```

Before executing this example, check if the Excel file (writingSet.xlsx) is open. If you run GDXXRW for writing a file sharing conflict will arise. To avoid this problem, either close the Excel file or use the Excel Tools menu to make this a shared notebook. After writing to the spreadsheet (still opened), use the Excel "File Save" command to verify the changes made.

By adding two additional commas within the `hText` statement, the cells B1, C1 and E1, F1 will be skipped when writing the text to the first row of the spreadsheet. If `values=noData`, neither explanatory text nor a Y are written to spreadsheet for the set elements. If `values=yn`, GDXXRW writes a Y for each set element to spreadsheet. To write the explanatory text, specify `values=string`.

Since `cDim=0`, the default option is `string` (see `values`). Imagine a two dimensional set, one could write the set in a table format, i.e. `cDim=1` and `rDim=1`. By default, GDXXRW would write this set using the `values=yn` format.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample11b]` for reference.

Note

- A workbook cannot in general be open unless you have made special provisions with an error signaled indicating a file sharing conflict will arise when the target file is open in Excel.
- To avoid the sharing conflict error the user must either close the file or indicate that the spreadsheet is a shared Excel workbook by using the Excel Tools Share Workbook dialogue.
- In an open shared workbook the contents are not updated until you have done a file save in Excel.
- Writing to a shared workbook can be painfully slow.
- In general, it is best to close the workbook.

6.29.6.3 Writing Parameter to Spreadsheet

At first, we create a GDX file, containing some random data:

```

* file makeData.gms
Set
  i / i1*i4 /
  j / j1*j4 /
  k / k1*k4 /;

Parameter V(i,j,k);
V(i,j,k)$ (uniform(0,1) < 0.30) = uniform(0,1);

```

When we run this GAMS model from the command prompt using the following statement, the file `writingPar.gdx` will be created at the end of the run.

```
GAMS makeData.gdx=writingPar
```

Using the file `writingPar.gdx`, we can write to a spreadsheet:

Write parameter `V` to the first cell in the first sheet; because we only specify the top left corner of the sheet, the complete sheet can be used to store the data. We do not specify the row and column dimension, so they will be set to `rDim=2` and `cDim=1` by default. (See also [dimensions](#))

By using the following command (remember to close an already existing file `writingPar.xlsx` in advance or make it a shared notebook as discussed in the previous example):

```
gdxxrw writingPar.gdx output=writingPar.xlsx par=V rng=A1
```

The steps above can be combined in a single GAMS model using the `execute_unload` and `execute` statements as follows:

```
Set
  i / i1*i4 /
  j / j1*j4 /
  k / k1*k4 /;

Parameter V(i,j,k);
V(i,j,k)$ (uniform(0,1) < 0.30) = uniform(0,1);

execute_unload 'writingPar.gdx', i, j, k, V;
execute 'gdxxrw writingPar.gdx par=V rng=A1';
```

The resultant spreadsheet looks like:

Note that if we only want to write the parameter `V`, there is no need to unload the sets `i`, `j` and `k` explicitly. The labels written to the columns A and B and to the first row are stored directly together with `V` in the GDX file.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample11b\]](#) for reference.

6.29.6.4 Writing to Spreadsheet with merge Option

When writing to a spreadsheet one can control data handling and matching using the `merge` command line option. When `merge` is active, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already. Also under `merge`, spreadsheet cells for which there is no matching row/column pair will not be changed. This option might be very useful, e.g., if there is a fixed report layout/framework already in your spreadsheet file which should not be changed when writing the data from GAMS.

Suppose we want to write the parameter `A`, already stored in `data.gdx`, to an existing spreadsheet:

In the following spreadsheet, there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non existing row labels 'san francisco.chicago':

Use the following commands to write the data from GDX to spreadsheet twice to different ranges for comparison:

```
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B1:G4 rDim=2 cDim=1 merge
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B8      rDim=2 cDim=1
```

Note that `merge` is a symbol option affecting only the symbol `A`. The resultant spreadsheet looks like:

The parameter is written to the range B8-F12 without `merge` enabled, while the option is enabled when writing to the range B1:G4, respecting the data arrangement already existing. Note that the column and row orders vary and the san francisco - chicago row is missing since it is not mentioned in the labels within the spreadsheet before the merge operation, while the horse column is still present with it's data left alone, not being overwritten by the parameter.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample12]` for reference.

Note

- Using the `merge` option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a `merge` option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements at all.
- The matching of labels is not case-sensitive.
- Warning: Enabling the `merge` option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.

6.29.6.5 Writing to Spreadsheet with clear Option

When writing to a spreadsheet one can also use the [clear](#) option to control data handling and matching. When `clear` is enabled, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already but all data and formulas in the target range will be removed.

Suppose the parameter `A` from [the previous example](#) is stored in `data.gdx` and there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non existing row labels 'san francisco.chicago':

Use the following command to write to `exampleData.xlsx` with `clear` enabled:

```
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!I1 rDim=2 cDim=1 clear
```

then the result is

The results are similar to those under `merge` but the old data in the column labeled 'horse' has been removed.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample12\]](#) for reference.

Note

- Using the `clear` option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a `clear` option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements.
- The matching of labels is not case-sensitive.
- Warning: The `clear` option will clear all Excel formulas and values in the rectangle used, even if the cells do not have matching row/column labels in the GDX file.

6.29.6.6 Writing to Spreadsheet using a Filter

In Excel, you can filter the data by some specified conditions so that only the data matching the conditions is displayed. This might be useful in some cases, e.g. it helps you to focus on the most relevant data within a large table of data. With `GDXXRW` you can add some basic filter to your spreadsheet when writing data from a GDX file.

The following example creates a small GDX file with some random data, which is used to write the symbol `A` to a spreadsheet later on with the [filter](#) option enabled.

Set

```
i / i1*i2 /
j / j1*j2 /
k / k1*k2 /;
```

Parameter `A(i,j,k)`;

```
A(i,j,k) = uniform(0,1);
```

```
execute_unload 'test.gdx', A;
```

```
execute 'gdxxrw test.gdx filter=1 par=A rDim=1 cDim=2 rng=Sheet1!A1';
```

Since `filter` is a global option, it must be specified in advance of the symbols for which you want to add a filter. The default value is zero, i.e. no filter will be added. If there are multiple rows in the column header, i.e. `cDim` is greater than zero, the valid range for the filter option is `1..cDim`.

The screenshot above shows the filter in Excel. When we specify `filter=2` in this example with two dimensions for the column header, the row with the filter moves away from the data range as illustrated below:

One could now filter the data, e.g. displaying only the values where the label of the first dimension is `i1` by selecting this value exclusively within the drop down menu of column A.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample15]` for reference.

6.29.6.7 Writing to Spreadsheet adding Text and Hyperlinks

The following example illustrates the use of the `text` directive. Adding text and hyperlinks to your spreadsheet is useful to customize the output and to navigate more quickly through the data.

First, we write some data to a GDX file and we use the text directive to write text to various cells in the spreadsheet; some of the cells are hyperlinks to other locations. To increase readability, we'll use a parameter file `howToWrite.txt` to shorten the `GDXXRW` statement.

```
Set
  i / i1*i9 /
  j / j1*j9 /;

Parameter A(i,j);
A(i,j) = 10*ord(i) + ord(j);

execute_unload 'pv.gdx' A;

$onEcho > howToWrite.txt
text="Link to data" rng=Index!A2 linkID=A
text="Below the data for symbol A" rng=data!C2
par=A rng=data!C4
text="Back to index" rng=data!A1 link=Index!A1
text="For more information visit GAMS" rng=data!C1 link=http://www.gams.com
$offEcho

execute 'gdxxrw pv.gdx output=pv.xlsx @howToWrite.txt'
```

We will write the text "Link to data" to the cell A2 of sheet Index. The option `linkID` is used to add a hyperlink to the range of the symbol `A`. In addition, we create a hyperlink "Back to index" in the cell A1 of sheet data using the `link` option pointing to the cell A1 of sheet Index. One can also specify links to external sources. For demonstration, we add a link to the GAMS homepage.

Below a screen shot showing both sheets data and Index created by the commands above:

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample16]` for reference.

6.29.7 Reading and Writing, Extended Use - Examples:

6.29.7.1 Reads a Table from Spreadsheet, manipulates the Data and writes back to Spreadsheet

In the following example, we read data from a spreadsheet and save the data in a GDX file. Using the `$gdxIn` and `$load` GAMS directives, we load the data from the GDX file into GAMS afterwards. The GAMS program modifies the data and at the end of the run the data is saved in a new GDX file (`tmp.gdx`). The last step updates the spreadsheet with the modified parameter.

We read the spreadsheet and load the data from the resultant GDX file at compile time. The data modification and the unloading and writing process are done at execution time, using the `execute_unload` and `execute` directives:

```
$call gdxrw test1.xlsx dSet=I rng=A2:A3 rDim=1 dSet=A rng=B1:D1 cDim=1 par=X rng=A1:D3 rDim=1 cDim=
$gdxIn test1.gdx

Set I(*), A(*);
$load I A

Parameter X(I,A);
$load X

display I, A, X;
$gdxIn
X(I,A) = - X(I,A);

execute_unload 'tmp.gdx', I, A, X;
execute 'gdxrw tmp.gdx output=test1.xlsx par=X rng=EX6!A1:D3 rDim=1 cDim=1';
```

The parameter is written to the sheet EX6. However, since we only write the parameter X, we do not necessarily have to unload the set I and A.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample13\]](#) for reference.

6.29.7.2 Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve

In this example, we use a modified version of the `[transport]` model from the GAMS model library to demonstrate the process of reading data, defining and solving the model and writing a solution report to spreadsheet altogether. This example illustrates in particular:

- Compilation phase
 - Read data from a spreadsheet and create a GDX file
 - Loading sets from the GDX file
 - Using the sets as a domain for additional declarations
 - Reading additional data elements
-

- Execution phase
- Solve the model
- Write solution to a GDX file
- Use GDX file to update spreadsheet

A parameter file `howToRead.txt` is used to increase the readability of the `GDXXRW` call. Note that the dimension of the scalar we want to read is set to zero. The range of each parameter can be specified by using the top left corner only, since there are two empty rows separating the data blocks from each other and the default value of `skipEmpty` signals to stop reading if two empty rows occur.

```

$onEcho > howToRead.txt
dSet=i rng=A3:A4 rDim=1
dSet=j rng=B2:D2      cDim=1
par =d rng=A2      rDim=1 cDim=1
par =a rng=A8      rDim=1
par =b rng=A13     rDim=1
par =f rng=A19     dim=0
$offEcho
$call gdxxrw TrnsportData.xlsx @howToRead.txt
$gdxIn TrnsportData.gdx

Set
  i(*) 'canning plants'
  j(*) 'markets';

$load i j

display i, j;

Parameter
  a(i)  'capacity of plant i in cases'
  b(j)  'demand at market j in cases'
  d(i,j) 'distance in thousands of miles';

Scalar f 'freight in dollars per case per thousand miles';
$load d a b f
$gdxIn

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

Variable
  x(i,j) 'shipment quantities in cases'
  z      'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
  cost      'define objective function'
  supply(i) 'observe supply limit at plant i'
  demand(j) 'satisfy demand at market j';

cost..      z =e= sum((i,j), c(i,j)*x(i,j));
supply(i).. sum(j, x(i,j)) =l= a(i);
demand(j).. sum(i, x(i,j)) =g= b(j);

```

```

Model transport / all /;

solve transport using lp minimizing z;

display x.l, x.m;

execute_unload 'TrnsportData.gdx', x;
execute 'gdxxrw TrnsportData.gdx output=TrnsportData.xlsx squeeze=n var=x.l rng=Sheet2!A1';

```

The solution is written to Sheet2 of the input file TrnsportData.xlsx by executing GDXXRW at execution time. The `var` statement is used in the symbol specification to write out the level of variable `x`. In order to write zero values, the `squeeze` option is disabled. Otherwise, the cells C4 and D3 remain blank.

This example is also part of the GAMS Data Utilities Library, see model `[GDXXRWExample14]` for reference.

6.29.7.3 Reading Special Values from Spreadsheet and writing to Spreadsheet

This example demonstrates the reading and writing of special values with GDXXRW.

Reading Special Values

Assuming we want to read the special values stored in the spreadsheet below:

The following statement reads parameter `vIN` from the spreadsheet above:

```
gdxxrw exampleData.xlsx output=specialValues.gdx NaIn=N/A squeeze=n par=vIN cDim=1 rng=specialValues
```

To affect the parameter `vIN`, the `global` options `NaIn` and `squeeze` (to display zero values in the GDX file) must be specified in advance.

The cells containing the strings `Eps`, `+Inf`, `-Inf`, `Inf`, `NA` and `Undf` are read in correctly. The division by zero error in the spreadsheet will be written as `Undf`. We defined a new string - 'N/A' - within the option `NaIn` to be recognized as `NA` additionally. Within GAMS, there is no directly comparable data type for 'None' and 'Null', so these strings will be interpreted as `Undf`. Note the importance of the cell format specified within Excel. For instance, the values for `v13` and `v14` are different, although both fields contain a Dollar sign, since the cell format of M2 is 'General', while the cell format of N2 is 'Currency'. The boolean 'False' turns into zero after reading, while 'True' turns into -1. Note here, that this is independent whether the booleans are written as plain text within Excel or by using the formulas '=True()' resp. '=False()'. We disabled `squeeze` in order to display the zero values for the elements `v16`, `v18` and `v19` in the GDX file.

Writing Special Values

Initially, we declare a parameter with special values and generate a GDX file from it:

```

$onUndf
Set v / v1*v7 /;
Parameter vOUT(v) / v1 Eps, v2 +Inf, v3 -Inf, v4 Inf, v5 Undf, v6 0.0, v7 NA /;
Scalar S / 0 /;

execute_unload 'specialValues.gdx', v, vOUT, S;

```

We will write the parameter `vOUT` to spreadsheet twice. At first to demonstrate the usage of `EpsOut`, `pInfOut`, `mInfOut`, `UndfOut`, `zeroOut` and `NaOut`, the second time to show the default settings when writing. Those output string options may be useful, if the GAMS default settings are not appropriate for your Excel calculations later on or to customize the representation of the values in Excel in general. Note that there is also a scalar declaration in order to demonstrate the different behavior when writing scalars and parameter with zero values to Excel while using the `zeroOut` option.

```
$onEcho > howToWrite.txt
* defining new strings to be used when writing special values:
EpsOut=0 pInfOut=+1E+100 mInfOut=-1E+100 UndfOut=undefined zeroOut=zero NaOut=notAvailable

* now write parameter vOUT with merge to force the column F containing set element "v6" and vOUT("v6")
set=v    rng=specialValues!A6:G6 cDim=1
par=vOUT rng=specialValues!A6:G7 cDim=1 merge
text="Special values of Parameter vOUT written with user defined output strings:" rng=specialValues!A6:G7
text="Scalar S / 0 /:" rng=specialValues!I6
par=S rng=specialValues!I7

* reset the strings for special values back to default und write vOUT again
resetOut
set=v    rng=specialValues!A10:G10 cDim=1
par=vOUT rng=specialValues!A10:G11 cDim=1 merge
text="Special values of Parameter vOUT written with default output strings:" rng=specialValues!A10:G11
text="Scalar S / 0 /:" rng=specialValues!I10
par=S rng=specialValues!I11
$offEcho

execute 'gdxrw specialValues.gdx output=exampleData.xlsx @howToWrite.txt';
```

In order to increase readability when executing `GDXRW`, we use a parameter file named `howToWrite.txt` and additionally, we write some text out to structure the Excel file. The range for the non-default values is `A6:G7`. We define the new strings to be used for the special values first, affecting the following symbols. To write the default values to the range `A10:G11`, we use the `resetOut` option to reset the output strings to default, otherwise, the new strings remain in effect, since they are global options.

As mentioned briefly above, the `zeroOut` option affects the scalar `S` and the parameter `vOUT` differently. While we get the expected result - 'zero' - for the scalar `S`, the cell `F7` for the zero value of `vOUT` remains empty, since zero values of parameters are not even part of the GDX file in general (and cannot be added from your GAMS model; Note here, that the `squeeze` options only affects the writing of sub-fields of variables and equations). Therefore, cell `F11` has no value, too. Though scalars with zero values are stored in the GDX file. We'll present a workaround for writing zero values of a parameter to spreadsheet in the next example [Writing Parameter to Spreadsheet including Zero Values](#).

The complete example is also part of the GAMS Data Utilities Library, see model [\[GDXRWExample8\]](#) for reference.

Note

- When writing to a spreadsheet, special values such as `Eps`, `NA`, `Undf` and `Inf` will be written but this can be changed. When reading data from a spreadsheet, the ASCII strings for these special character strings will be used to write corresponding special values to the GDX file.
- Cells that are empty or zero will not be written to the GDX file.

6.29.7.4 Writing Parameter to Spreadsheet including Zero Values

There is no straight way to write zero values of a GAMS parameter to spreadsheet from your model using GDXXRW, since zero values of a parameter are not stored in the GDX file (see also the previous example [Reading Special Values from Spreadsheet and writing to Spreadsheet](#)). However, instead of the zero values one can store an EPS in the GDX file and instruct GDXXRW to use a zero when writing the value for EPS using the `epsOut` option afterwards as demonstrated below:

```
Set i / i1*i9 /;
Parameter A(i), Amod(i);
A(i) = uniformInt(0,1);

* Amod(i) = A(i) if A(i) <> 0 and Amod(i) = EPS if A(i) = 0
Amod(i) = EPS$(not A(i)) + A(i);

* Unload the unmodified and modified parameter and write to spreadsheet using an option file
execute_unload 'zeroPar1.gdx' A Amod;

$onEcho > howToWrite1.txt
text="Parameter A" rng=A1
par=A rng=A2
text="Modified Parameter Amod written with epsOut: 0" rng=A5
epsOut=0 par=Amod rng=A6
$offEcho
execute 'gdxxrw zeroPar1.gdx output=writingZeros.xlsx @howToWrite1.txt';
```

This approach is impracticable in the unlikely event that there are already EPS values in your parameter and you want to write these as EPS to your spreadsheet.

An alternate approach regarding variables while exploiting the `squeeze` option is demonstrated below (parameter A and set i refer to the data above):

```
Variable dummyPar(i);
dummyPar.l(i) = A(i);

* In order to write every entry of dummyPar in the spreadsheet, one must allocate
* a non-zero value to one of the variable attributes .m, .lo or .up
dummyPar.up(i) = 1;

* Unload the dummy variable and write the .l subfield to spreadsheet while disabling squeeze
execute_unload 'zeroPar2.gdx' dummyPar;

$onEcho > howToWrite2.txt
text="Variable dummyPar written with squeeze: n" rng=A9
squeeze=n var=dummyPar.l rng=A10
$offEcho
execute 'gdxxrw zeroPar2.gdx output=writingZeros.xlsx @howToWrite2.txt';
```

Creating the additional variable and the allocation of a non-zero value to one of the other variable attributes are the drawbacks of this approach. Note that we only declared the parameter Amod to keep the original data of A untouched in order to run the code in a single model and to write A to spreadsheet, too.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample19\]](#) for reference.

6.29.7.5 Reading several Scalars from Spreadsheet

Suppose you want to read a large number of scalars (i.e. scalar names and their associated values) for your model from a spreadsheet file as shown below. Originally, the data was taken from the model [\[indus89\]](#) of the GAMS Model Library.

Natively, one could declare all scalars directly inside the model and read every single one of them with `GDXXRW` afterwards (the following code is shortened for representation):

```
Scalar baseyear, repco;
```

```
$call gdxrw exampleData.xlsx output=indus89Scalars.gdx par=baseyear rng=indus89Scalars!B2 dim=0 par
$gdxIn indus89Scalars.gdx
$load baseyear repco
```

However, the code would become quit long and circumstantially for this example, especially the `GDXXRW` statement, because every scalar must be specified individually. Therefore, we present a more sneaky way to tackle the problem. At first, the file `mkScalar.gms` is written. We declare a set and a parameter to hold the scalar names and their values. A simple `GDXXRW` call is used to read the names and values from the file `exampleData.xlsx`. Afterwards, we load the data using `$gdxIn` and `$load`. The result of this is a single parameter containing the scalar values defined over a set containing the scalar names. However, this is not exactly what we are looking for. To transform this representation into several single scalar definitions, we use a simple loop over the set `scalarNames` and the [Put Writing Facility](#) to generate a file `scalars.gms`, containing those single scalar statements.

```
$onEchoV > mkScalar.gms
Set scalarNames;
Parameter scalarValues(scalarNames);

$call gdxrw exampleData.xlsx output=indus89Scalars.gdx set=scalarNames rng=indus89Scalars!A2:A22 rD
$ifE errorLevel<>0 $abort Problems reading sheet indus89Scalars with GDXXRW
$gdxIn indus89Scalars.gdx
$load scalarNames scalarValues

File fs / 'scalars.gms' /;
put fs;
loop(scalarNames, put / 'Scalar ' scalarNames.tl ' / ' scalarValues(scalarNames):>20:10 ' /;');
$offEcho

$call gams mkScalar
$include scalars.gms
```

Calling the file `mkScalar.gms` will create the file `scalars.gms`, containing all those scalar statements (shortened for representation):

```
Scalar baseyear      /      1988.0000000000 /;
Scalar repco         /           2.5000000000 /;
```

Finally, the file `scalars.gms` is included to your model.

This example is also part of the GAMS Data Utilities Library, see model [\[GDXXRWExample17\]](#) for reference.

6.29.8 Changes in the Set Values Parameter

The following documents some changes that were made when reading a set using the `values=string` option. Reading a domain or a parameter was not affected by these changes.

To illustrate the various behaviors in different versions of GDXXRW, we are using the spreadsheet data as shown below, using the following call:

```
$call gdxxrw test.xlsx set=one rng=B2 rDim=1 values=string set=two rng=B1 rDim=1 cDim=1 values=string
```

We read the one dimensional set in column B by specifying the top-left corner of the data (cell B2) or the full range (B2..B5). A two dimensional set is read using the top-left corner of the data (cell B1) or the full range (B1..E5). Variations are introduced by specifying options for `values` to be `string` or `yn` or `noData`. The option value `all` is only available in later versions of GDXXRW and was used to introduce the same behavior as `strings` in earlier versions.

6.29.8.1 Chronological description of the changes made to the Values option:

- **GAMS versions prior to version 24.3:**

`values=string` results in reading the data dense. The contents of a cell is used for the set associated text and an element is included even if the data cell is empty.

- **GAMS version 24.3.1**

We changed the interpretation of `string` to mean that the set element was only to be included when the string data was not empty. Note below that element a4 is missing from the one-dimensional set and so are a1.b1, a2.b2 etc from the two-dimensional set. For the two-dimensional case this looked more or less how the GAMS compiler interprets a table statement. Unfortunately, the interpretation of empty data cells was also applied to one-dimensional sets leading to undesired results.

- **GAMS version 24.4.1**

Recognizing that reading a set dense was no longer available, we introduced a new option `values=all`. This allowed us to read Excel data the same way as was possible before version 24.3.1 using the `values=string` i.e. reading the data dense and including all cells whether the data cell is empty or not and use the content of the data cell for the set associated texts.

- **GAMS version 24.4.6 (Current status)**

We decided to remove some confusion with the interpretation of the `values` option by introducing the options `dense` and `sparse` and flagging the options `strings` and `all` as deprecated. Both `strings` and `all` are replaced with `dense`.

Backward compatibility issues.

With these changes we broke our in house rule not to introduce changes that break backward compatibility. Because of this, the user needs to change the parameters for the GDXXRW call or change the workbook data. The parameters for the call should be changed from `values=string` to `values=dense` for one-dimensional sets where we specify the top-left corner only. In case the data in the workbook needs to be changed, inserting a string to in the data cell will address the issue. In the example on the top of the page, inserting a 'Y' in cell C5.

6.30 INVERT

INVERT inverts a matrix.

6.30.1 Usage

```
invert gdxin i a gdxout inva
```

where

gdxin

name of gdxfile with matrix

i

name of set used in matrix

a

name of 2 dimensional parameter inside gdxin

gdxout

name of gdxfile for results (inverse matrix)

inva

name of 2 dimensional parameter inside gdxout

Calculates the inverse of a matrix $a(i,j)$, where i and j are aliased sets. The matrix `inva` in `gdxout` will contain the inverse.

6.30.2 Example

```
$onText
```

```
Finds the inverse of a matrix through an external program.
```

```
Erwin Kalvelagen, march 2005
```

```
Reference: model gauss.gms from the model library
```

```
http://www.gams.com/modlib/libhtml/ gauss.htm
```

```
$offText
```

```
Set i /i1*i3 /;
```

```
Alias (i,j);
```

```
Table a(i,j) 'original matrix'
```

	i1	i2	i3
i1	1	2	3
i2	1	3	4
i3	1	4	3;

```
Parameter inva(i,j) 'inverse of a';
```

```
execute_unload 'a.gdx', i, a;
```

```
execute '=invert.exe a.gdx i a b.gdx inva';
```

```
execute_load 'b.gdx', inva;
```

```
display a, inva;
```

6.31 MCFILTER

MCFilter filters duplicate and dominated points from a solution set.

6.31.1 Usage

`mcfilter` InputFile

The *input* is a gdx file with the following data:

```
parameter X(point, i)
    Points containing binary values; use EPS when all zero for a point
parameter F(point, obj)
    Objectives for the points X; use EPS when all zero for a point
parameter S(obj)
    Direction of each objective: 1=max,-1=min
```

The *output* will be a gdx file called `InputFile_res.gdx` with the same parameters but without duplicates and dominated points.

6.31.2 Example

```
* Generate random data to test MCFilter
Set
  Ri / R1*R65535 /
  Xi / X1*X16 /
  Fi / F1*F5 /;

Parameter
  X(Ri,Xi) 'the binary variables'
  F(Ri,Fi) 'calculated F variables'
  S(Fi) 'sign on the F variables';

* The following points will be unique
X(Ri,Xi) = mod(floor(Ri.ord/power(2, Xi.off)), 2);

F(Ri,Fi) = uniform(1,2);

S(Fi) = -1 + 2$(uniform(0,1) <= 0.5);

execute_unload 'testdata.gdx', X F S;
execute 'mcfilter testdata.gdx';

* The file testdata_res.gdx will contain the results
```

Below is the partial log after running the above model:

```
mcfilter v3.
Number of records      =    65535
Number of X variables =     16
Number of F variables =     5
Loading GDX data      =    156 ms
After X Filter, count =    65535
X Duplicate filter    =     16 ms
After F Filter, count =    1070
F Dominance filter    =    249 ms
Writing GDX data      =     16 ms
```

6.32 MDB2GMS

Author

Erwin Kalvelagen

6.32.1 Overview

MDB2GMS is a tool to convert data from an Microsoft Access database into GAMS readable format. The source is an MS Access database file (.mdb or .accdb) and the target is a [GAMS Include File](#) (.inc) or a [GAMS GDX File](#) (.gdx).

When running the executable mdb2gms.exe without command-line arguments, the tool will run [interactively](#) with a built-in GUI interface. Alternatively MDB2GMS can be run in [batch mode](#), which is useful when running it directly from a GAMS model without user intervention using the `$call` command at compile time or the `execute` command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL's should not be allowed to get into a GAMS data structure. The handling of NULL's can be specified in an option.

Besides parameters it is also possible to generate set data.

6.32.2 Requirements

MDB2GMS runs only on Windows PC's and with MS Access installed. MS Access comes with certain versions of MS Office, but some MS Office versions will not include Access. The actual retrieval of the database records is performed by [DAO](#) or Data Access Objects, an object layer for accessing the database. The actual database is the Jet engine, which performs the queries and retrieves the data. Also consider to use [SQL2GMS](#) instead of MDB2GMS, if MS Access is not installed on your system.

To use this tool effectively you will need to have a working knowledge of [SQL](#) in order to formulate proper database queries.

6.32.3 Batch Usage

MDB2GMS can be run in batch mode without user intervention from within the GAMS model by using the `$call` resp. `execute` statements or directly from command prompt while specifying all arguments in the command-line. A MDB2GMS batch call is of the following form:

```
mdb2gms inputFile outputFile queryString
```

A proper batch call will at least contain the following three command-line arguments:

1. The name of the MS Access database inputFile must be specified (.mdb or .accdb format). Use the **I** argument to enter the file name, i.e. **I=inputFile**.
2. The name of outputFile, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option **O**, i.e. **O=outputFile.inc**, while the use of a GDX file is indicated by the option **X**, i.e. **X=outputFile.gdx**.
3. The SQL queryString, containing the SQL statement to be executed on the database, must be specified within the option **Q**, i.e. **Q=queryString**.

See also [Command-line Arguments](#) below for a complete list of all possible command-line arguments. Consider that the `$call` or `execute` usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the [interactive](#) built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a `@` (At sign).

Also consider to take a look at the section [Strategies](#), mentioning some of the drawbacks of the batch usage and how to overcome them.

If you only specify **I=inputFile** then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command-line argument. Only if an input file, an output file and a query string is provided, the call will be considered as batch invocation.

6.32.3.1 Command-line Arguments

The following table summarizes the command-line arguments that can be specified when using MDB2GMS directly from the GAMS model or command prompt.

Argument	Interpretation	Default	Description
I	inputFile	none	Specify the name of the input file (required).
O	outputIncludeFile	none	Specify the name of the output file (.inc). Either O= or X= must be specified (or both).
On	n-th outputIncludeFile	none	Match the nth query with the nth output file (.inc format) if multiple queries are used.
X	outputGDXFile	none	Specify the name of the output file (.gdx). Either O= or X= must be specified (or both).
Q	Query	none	This option can be used to specify a SQL query (required).
Qn	n-th Query	none	Match the nth query with the nth output file (.inc) format or with the nth set- or parameter name when writing to GDX if multiple queries are used.
S	setName	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file.
Sn	n-th setName	none	Match the nth query with the nth set in the GDX file if multiple queries are used.

Argument	Interpretation	Default	Description
Y	setName (with expl. text)	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. Use this argument to store a set with explanatory text.
Yn	n-th setName (with expl. text)	none	Match the nth query with the nth set (with explanatory text) in the GDX file if multiple queries are used.
P	parameterName	none	If we write to a GDX file, use this option to specify the name of a parameter to be used inside the GDX file.
Pn	n-th parameterName	none	Match the nth query with the nth parameter in the GDX file if multiple queries are used.
D	Debug	disabled	Generate debug information.
B	Quote Blanks	disabled	Quote strings if they contain blanks or embedded quotes.
M	Mute	disabled	Controls if additional information is written to the log and include file.
L	Listing	disabled	Controls if the data is embedded in the listing file.
@fileName	ext. options file	none	Causes the program to read options from an external text file.
N	iniFileName	mdb2gms.ini	Indicates the usage of a different INI file.
F	formatString	none	Specify a format string.
W	Wiring	none	Maps database columns to GAMS index positions.
R	rowBatchSize	100	Row batch size; the default is 100 records.

Some more detailed remarks on the command-line arguments:

I = *string* (inputFile, default = none)

This option is required and specifies the name of the .mdb or .accdb file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. On a network [UNC Names](#) can be used, and files from another computer can be accessed, e.g.

```
"\\hostname\c\my documents\a.mdb."
```

This option is required for batch processing. To specify a path equal to the location where the .gms file is located, you can use:

```
I=system.fpsydb.mdb
```

This option is demonstrated in most examples, see [Example 1 - Reading a single valued Table](#) for instance.

O = *string* (outputIncludeFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is writable. [UNC Names](#) can be used. An output file must be specified for batch operation: i.e. either **O=** or **X=** needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the [\\$include](#) command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in most examples, see [Example 1 - Reading a single valued Table](#) for instance.

On = *string* (outputIncludeFile, default = none)

When using multiple queries in a single MDB2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

See also section [Multi-Query Batch Usage](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

X = *string* (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS [GDX file](#). Make sure the directory is writable. [UNC names](#) can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either **O=** or **X=** needs to be specified (or both). This option is demonstrated in [Example 5 - Reading Set with Explanatory Text](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

Q = *string* (Query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by Access we refer to the documentation that comes with MS Access. The query is passed on directly to the Jet database engine, so the complete power and expressiveness of Access SQL is available. For an exact description of allowed expressions consult a text on MS Access.

One notable syntax feature is that when field names or table names contain blanks, they can be specified in square brackets. Examples:

```
Q="SELECT * FROM mytable"
Q="SELECT year, production FROM [production table]"
Q="SELECT [GAMS City], value FROM [example table], CityMapper
WHERE [Access City]=city"
```

This option is demonstrated in [Example 1 - Reading a single valued Table](#) for instance

Qn = *string* (Query, default = none)

When using multiple queries in a single MDB2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

or (GDX output file format - where several sets and parameters can be stored in a single file):

```
Q1="SELECT a, b FROM table"
P1=abParameter
Q2="SELECT c FROM table"
S2=cSet
```

Note the usage of the arguments **P_n** resp. **S_n** in order to store the results as parameter resp. set and to specify the name of the symbols. See also section [Multi-Query Batch Usage](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

S = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in [Example 4 - Reading a multi dimensional Set](#).

S_n = *string* (setName, default = none)

If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet
```

See also section [Multi-Query Batch Usage](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

Y = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in [Example 5 - Reading Sets with Explanatory Text](#) for instance.

Y_n = *string* (setName, default = none)

If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.

```

Q1="SELECT i, explTextForSeti FROM table"
Y1=iSet
Q2="SELECT j, explTextForSetj FROM table"
Y2=jSet

```

The last column specified within the select clause in the SQL statements will be used as explanatory text.

P = *string* (parameterName, default = none)

If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query).

Pn = *string* (parameterName, default = none)

If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth parameter to be stored in the GDX file (containing the results of the nth query), e.g.

```

Q1="SELECT i, j, value FROM table"
A1=ijValue
Q2="SELECT n, m, value FROM table"
A2=nmValue

```

See also section [Multi-Query Batch Usage](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

D (Debug, default = disabled)

This option can be used for debugging purposes. If specified the import filter will not run minimized but "restored", i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of MDB2GMS.

B (Quote Blanks, default = disabled)

If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off. For more information see subsection [Quotes](#). This option only applies to an output include file.

M (Mute, default = disabled)

Run in modest or mute mode: no additional information, such as version number, number of rows in the data, elapsed time, used query etc. is written to the log and include file.

L (Listing, default = disabled)

Embed the data between the `$offListing` and `$onListing` dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

@fileName = *string* (fileName, default = none)

Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also [Command Files](#) for some further details.

N = *string* (fileName, default = mdb2gms.ini)

Use a different INI file than the standard mdb2gms.ini located in the same directory as the executable mdb2gms.exe.

F = *string* (formatString, default = none)

In special cases we can apply a format string on the include file output (not for GDX output). Each column in the result set is a string and can be represented by a s in the format string.

W = *string* (wiring, default = none)

By using the W option, one can map database columns to GAMS index positions. See model [\[Wiring\]](#) for reference.

R = *integer* (rowBatchSize, default = 100)

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of MDB2GMS.

6.32.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the [\[transport\]](#) model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.mdb).

Distances		
City1	City2	Distance
SEATTLE	CHICAGO	1,7
SAN-DIEGO	CHICAGO	1,8
SEATTLE	NEW-YORK	2,5
SAN-DIEGO	NEW-YORK	2,5
SEATTLE	TOPEKA	1,8
SAN-DIEGO	TOPEKA	1,4

Figure 6.45 Table: distances

The data can be queried with a simple SQL statement:

```
SELECT city1, city2, distance
FROM distances
```

By running the following MDB2GMS statement, the connection to the database Sample.mdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).

```
mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
```

The MS Access database file name is specified using the argument **I**. Note that the string is enclosed by quotes, as the string contains blanks. The arguments **Q** and **O** are used to specify the query and the output file name (and format).

The generated include file `distances.inc` looks like:

```
* -----
* MDB2GMS          24.8.5 r61358 Released May 10, 2017 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----
* DAO version: 14.0
* Jet version: 4.0
* Database:       F:\datalib\Sample.mdb
* Query:          SELECT city1, city2, distance FROM distances
* -----
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----
```

The commented header section summarizes some information about the `MDB2GMS` resp. `GAMS` version and about the executed database query. The standard export format is to consider the last column as the value column (containing the distances) and the previous columns as the indices (containing the city names). The indices are separated by a dot, allowing the generated include file to be used as part of a parameter declaration statement in your `GAMS` model.

Retrieving the data using `MDB2GMS` from the database and including the queried data in your `GAMS` model within the parameter declaration statement (at compile time) can be combined in the following way:

```
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets'        / new-york, chicago, topeka /;

$call mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
Parameter d(i,j) 'distance in thousands of miles' /
$include distances.inc
/;

display d;
```

Finally, the values of the parameter `d` are displayed:

	new-york	chicago	topeka
seattle	2.500	1.700	1.800
san-diego	2.500	1.800	1.400

This example is also part of the `GAMS` Data Utilities Library, see model `[Distances1]` for reference. Note that the query results are written to a `GDX` file in addition.

6.32.3.3 Example 2 - Reading a multi valued Table

In this scenario, we want to read the three index columns `year`, `loc`, `prod` and the value columns `sales` and `profit` from the database file `Sample.mdb`. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for `sales` resp. `profit`) and a `UNION select`.

Consider the table with two value columns `sales` and `profit`:

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.46 Table: data (shortened for presentation)

Two separate Parameters

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```
SELECT year, loc, prod, sales
FROM data
SELECT year, loc, prod, profit
FROM data
```

We can generate a include file `sales.inc` by running the following command:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
```

Note that we specify the first query in order to select the sales and the relevant index columns within the `Q` argument. The query results are written to `sales.inc` using the `O` argument. Analogously we generate a include file `profit.inc` by running the following command while specifying the second query in order to obtain the profits and the relevant index columns:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
```

Retrieving the data using `MDB2GMS` from the database `Sample.mdb` and including the queried data in your GAMS model within the parameter declaration statements of `sales` and `profit` (at compile time) can be combined in the following way:

```
Set
  year 'years'      / 1997*1998 /
  loc  'locations' / nyc, was, la, sfo /
  prd  'products'  / hardware, software /;

$call mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
Parameter sales(year,loc,prd) /
```

```

$include sales.inc
/;

$call mdb2gms I=Sample.mdb" Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
Parameter profit(year,loc,prd) /
$include profit.inc
/;

```

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB1] for reference.

Single Parameter with extra Index Position

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index `type` to indicate the data type (sales or profit). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.

```

SELECT year, loc, prod, 'sales', sales
FROM data
UNION
SELECT year, loc, prod, 'profit', profit
FROM data

```

The data is accessed, queried and written to data.inc by running the following command:

```

mdb2gms @howToRead.txt

```

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

```

I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc

```

The generated include file data.inc looks like (shortened for presentation):

```

* -----
* MDB2GMS          24.8.5 r61358 Released May 10, 2017 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----
* DAO version: 14.0
* Jet version: 4.0
* Database:      F:\datalib\Sample.mdb
* Query:        SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
* -----
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
1997.nyc.software.sales 100
1997.sfo.hardware.profit 9
1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50

```

```

1997.was.hardware.profit 7
1997.was.hardware.sales 120
1997.was.software.profit 20
1997.was.software.sales 70
1998.la.hardware.profit 6
1998.la.hardware.sales 70

```

```
* -----
```

Retrieving the data using MDB2GMS from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index `type` in order to access the data type `sales` resp. `profit`):

```

$onEcho > howToRead.txt
I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
$offEcho

Set
  year 'years'      / 1997*1998 /
  loc  'locations' / nyc, was, la, sfo /
  prd  'products'  / hardware, software /
  type 'data type' / sales, profit      /;

$call mdb2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
$include data.inc
/;

```

This example is also part of the GAMS Data Utilities Library, see model `[SalesProfitDB2c]` for reference.

6.32.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a MS Access database file. Suppose we want to read the column `City1` (see table `distances`) in order to define the set `i` in the GAMS model. Make sure elements are unique by using the `distinct` operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```

SELECT distinct(City1)
FROM distances

```

The include file `city1.inc` looks like (header informations are removed in order to shorten the representation):

```

* -----
SAN-DIEGO
SEATTLE
* -----

```

All steps (data access via MDB2GMS, set definition) can be combined:

```

$call mdb2gms I=Sample.mdb Q="SELECT distinct(city1) FROM distances" O=city_i.inc
Set i 'canning plants' /
$include city_i.inc
/;

display i;

```

The display statement generates the following output in the listing file:

```

----      56 SET i

seattle  ,      san-diego

```

6.32.3.5 Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using the `O` argument, one has to observe that the elements in the include file must have the correct format in order to be interpreted as element of a multi dimensional set. For instance, a line containing `a b c` is not recognized as a proper set element of a three dimensional set. In particular, one has to add periods between the single elements, i.e. `a.b.c` will be interpreted correctly.

There are different ways to add these periods explicitly within the SQL statement. E.g. add a dummy value field by adding a quoted blank to the select clause (`index1`, `index2`, `index3` and `dataTable` are some placeholders):

```
SELECT index1, index2, index3, " " FROM dataTable
```

or by adding the periods explicitly within the select clause (`||` or `&` depending on DBMS):

```
SELECT index1&'.'&index2&'.'&index3 FROM dataTable
SELECT index1||'.'||index2||'.'||index3 FROM dataTable
```

For instance, suppose we want to define a two dimensional set

```
Set ij(i,j) 'canning plants - markets';
```

based on the data of the table `distances` stored in `Sample.mdb`. The following `MDB2GMS` statement connects you to the database, queries the columns with the city names and adds an empty value field in order to create periods between the set elements:

```
mdb2gms I=Sample.mdb Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc
```

The include file `city_ij.inc` looks like (header informations are removed in order to shorten the representation):

```
* -----
SEATTLE.NEW-YORK ' '
SAN-DIEGO.NEW-YORK ' '
SEATTLE.CHICAGO ' '
SAN-DIEGO.CHICAGO ' '
SEATTLE.TOPEKA ' '
SAN-DIEGO.TOPEKA ' '
* -----
```

Without adding the empty value field, the resulting include file would look like (shortened):

```
* -----
SEATTLE NEW-YORK
SAN-DIEGO NEW-YORK
* -----
```

Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

```
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /;

$call mdb2gms I=Sample.mdb Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc

Set ij(i,j) 'two dimensional set' /
$include city_ij.inc
/;

display ij;
```

The display statement generates the following output in the listing file:

```
----      75 SET ij  two dimensional set

                new-york      chicago      topeka
SAN-DIEGO      YES           YES           YES
SEATTLE        YES           YES           YES
```

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the **X** and **S** resp. **Y** arguments, i.e. there is no need to modify the query:

```
SELECT index1, index2, index3 FROM datatable
```

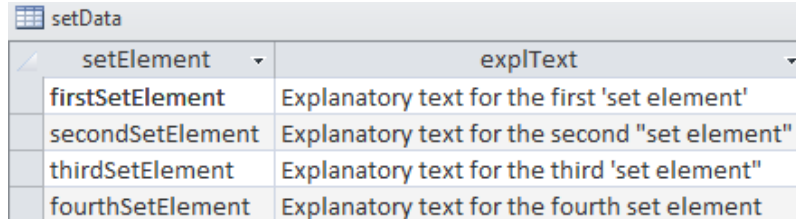

when using MDB2GMS in the following way:

```
mdb2gms I=Sample.mdb Q="SELECT index1, index2, index3 FROM datatable" X=setData.gdx S=setName
```

which will generate the file setData.gdx with a three dimensional set named `setName` containing the results of the query.

6.32.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a MS Access database file using MDB2GMS. In the first place, we are going to write the query results to an include file, afterwards we use the **Y** argument in order to store the query results as a set with explanatory text in a GDX file.

setElement	explText
firstSetElement	Explanatory text for the first 'set element'
secondSetElement	Explanatory text for the second "set element"
thirdSetElement	Explanatory text for the third 'set element'
fourthSetElement	Explanatory text for the fourth set element

Figure 6.47 Table: setData

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```
SELECT setElement, explText
FROM setData
```

Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument **B** in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file setData.inc:

```
$call mdb2gms I=Sample.mdb B Q="SELECT setElement, explText FROM setData" O=setData.inc

Set a /
$include setData.inc
/;
```

The resulting include file will look like (header informations are removed in order to shorten the representation):

```
* -----
firstSetElement "Explanatory text for the first 'set element'"
secondSetElement 'Explanatory text for the second "set element"'
thirdSetElement "Explanatory text for the third 'set element'"
fourthSetElement 'Explanatory text for the fourth set element'
* -----
```

Note the handling of the quotes according to the description in **B**.

Writing the Query Results in a GDX File

When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the **Y** argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file setData.inc:

```
$call mdb2gms I=Sample.mdb Q="SELECT setElement, explText FROM setData" X=setData.gdx Y=set_b

Set b;
$gdxIn setData.gdx
$load b = set_b
$gdxIn
```

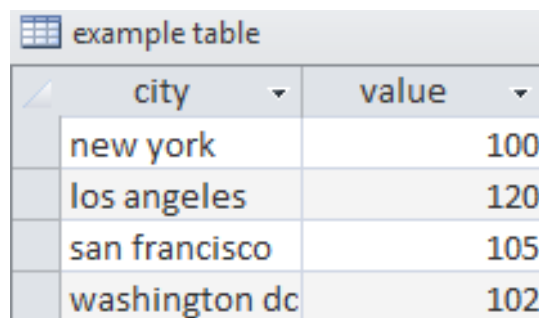

Note that the name of the set in the GDX file is `set_b` (specified within the `Y` argument), while the name of the GDX file was specified within the `X` argument.

6.32.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g. consider the case where the GAMS model has defined a set as:

```
Set i / NY, DC, LA, SF /;
```

Now assume a data table looks like:

city	value
new york	100
los angeles	120
san francisco	105
washington dc	102

Figure 6.48 Table: example table

This means we have to map 'new york' to 'NY' etc. This mapping can be done in two places: either in GAMS or in the database.

6.32.3.7.1 Index Mapping done in GAMS When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

```
* -----
'new york' 100
'los angeles' 120
'san francisco' 105
'washington dc' 102
* -----
```

Note that the single quotes are added by activating the option `B` (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:

```

Set i / NY, DC, LA, SF /;

Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;

$call mdb2gms I=Sample.mdb B 0="city1.inc" Q="SELECT city, value FROM [example table]"
Parameter dbdata(idb) /
$include city1.inc
/;

Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /;

Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;

```

The display statement generates the following output in the listing file:

```

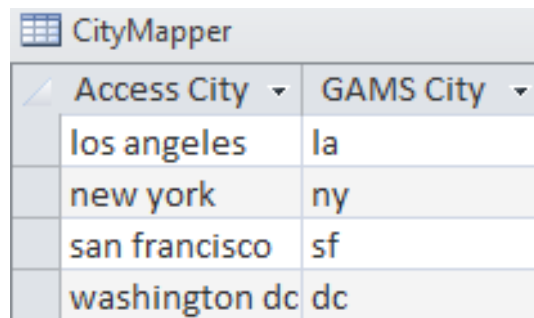

----      47 PARAMETER data

NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000

```

This example is also part of the GAMS Data Utilities Library, see model [\[IndexMapping1\]](#) for reference.

6.32.3.7.2 Index mapping done in Database The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:

Access City	GAMS City
los angeles	la
new york	ny
san francisco	sf
washington dc	dc

Figure 6.49 Table: CityMapper

This table can be used in a join to export the data in a format we can use by executing the query:

```

SELECT [GAMS City], value
FROM   example_table, CityMapper
WHERE  CityMapper.[Access City]=example_table.city

```

The resulting include file looks like (header informations are removed in order to shorten the representation):

```

* -----
la 120
ny 100
sf 105
dc 102
* -----

```

All steps can be combined in the GAMS model:

```
Set i / NY, DC, LA, SF /;
```

```
$onEcho > howToRead.txt
```

```
I=Sample.mdb
```

```
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_
```

```
O=city2.inc
```

```
$offEcho
```

```
$call mdb2gms @howToRead.txt
```

```
Parameter data(i) /
```

```
$include city2.inc
```

```
/;
```

```
display data;
```

The display statement generates the following output in the listing file:

```
----      38 PARAMETER data
```

```
NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000
```

Note: MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [\[IndexMapping2\]](#) for reference.

6.32.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual `MDB2GMS` execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single `MDB2GMS` call and write several GAMS include files containing the results of the queries, we can use the command-line arguments `Qn` and `On`. The structure of a multi-query call looks like:

```
I=sample.mdb
```

```
Q1=firstQuery
```

```
O1=outputFileName.inc
```

```
Q2=secondQuery
```

```
O2=outputFileName.inc
```

```
Q3=thirdQuery
```

```
O3=outputFileName.inc
```

The terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. We see that the argument `Qn` is matched by an argument `On`. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments `Qn`, `Sn`, `Pn` and `Yn`. The structure of a multi-query call when writing to a GDX file looks like:

```

I=sample.mdb
X=sample.gdx

Q1=firstQuery
S1=setName

Q2=secondQuery
S2=setName

Q3=thirdQuery
A3=parameterName

Q4=fourthQuery
A4=setName

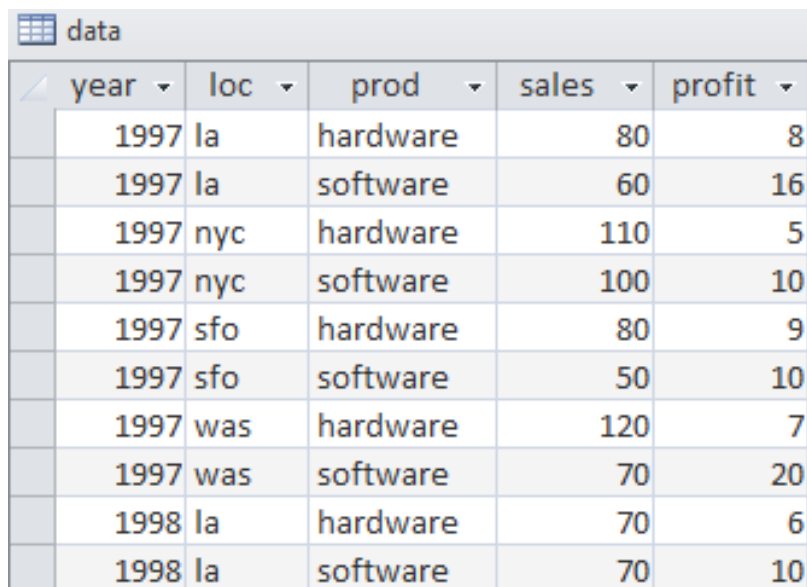

```

Again, the terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. Here we see that a query `Qn` is matched by either a set name `Sn` or a parameter name `Pn`, i.e. the results of the first query will be stored as a set whose name is specified within the `S1` argument, the results of the third query will be stored as a parameter whose name is specified within the `P3` argument etc. The `X` argument is used to specify the name of the GDX file.

For a complete example see section [Example 7 - Multi-Query Batch Example](#).

6.32.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file `Sample.mdb`):

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.50 Table: data (shortened for presentation)

We want to extract the following information:

- The set `year`
- The set `loc`

- The set **prd**
- The parameter **sales**
- The parameter **profit**

Output: Several include Files

This can be accomplished using the following GAMS code with multiple queries in a single **MDB2GMS** call (note the usage of the distinct operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):

```
$onEcho > howToRead.txt
I=Sample.mdb

Q1=SELECT distinct(year) FROM data
O1=year.inc

Q2=SELECT distinct(loc) FROM data
O2=loc.inc

Q3=SELECT distinct(prod) FROM data
O3=prod.inc

Q4=SELECT prod, loc, year, sales FROM data
O4=sales.inc

Q5=SELECT prod, loc, year, profit FROM data
O5=profit.inc
$offEcho

$call =mdb2gms @howToRead.txt

Set y 'years' /
$include year.inc
/;
Set loc 'locations' /
$include loc.inc
/;
Set prd 'products' /
$include prod.inc
/;

Parameter sales(prd,loc,y) /
$include sales.inc
/;
display sales;

Parameter profit(prd,loc,y) /
$include profit.inc
/;
display profit;
```

This example is also part of the GAMS Data Utilities Library, see model **[SalesProfitDB3]** for reference.

Output: A single GDX File

The same example imported through a GDX file can look like:

```
$onEcho > howToRead.txt
I=Sample.mdb
X=Sample.gdx

Q1=SELECT distinct(year) FROM data
S1=year

Q2=SELECT distinct(loc) FROM data
S2=loc

Q3=SELECT distinct(prod) FROM data
S3=prd

Q4=SELECT prod, loc, year, sales FROM data
P4=sales

Q5=SELECT prod, loc, year, profit FROM data
P5=profit
$offEcho

$call =mdb2gms @howToRead.txt

Set
  y 'years'
  loc 'locations'
  prd 'products';

Parameter
  sales(prd,loc,y)
  profit(prd,loc,y);

$gdxIn Sample.gdx
$load y=year prd loc sales profit
$gdxIn

display sales, profit;
```

The call of the [GDXViewer](#) will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model [\[SalesProfitDB4\]](#) for reference.

6.32.5 Interactive Usage

When the tool is called without command-line parameters, it will startup interactively. Using it this way, one can specify the database file (.mdb or .accbd file), the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.

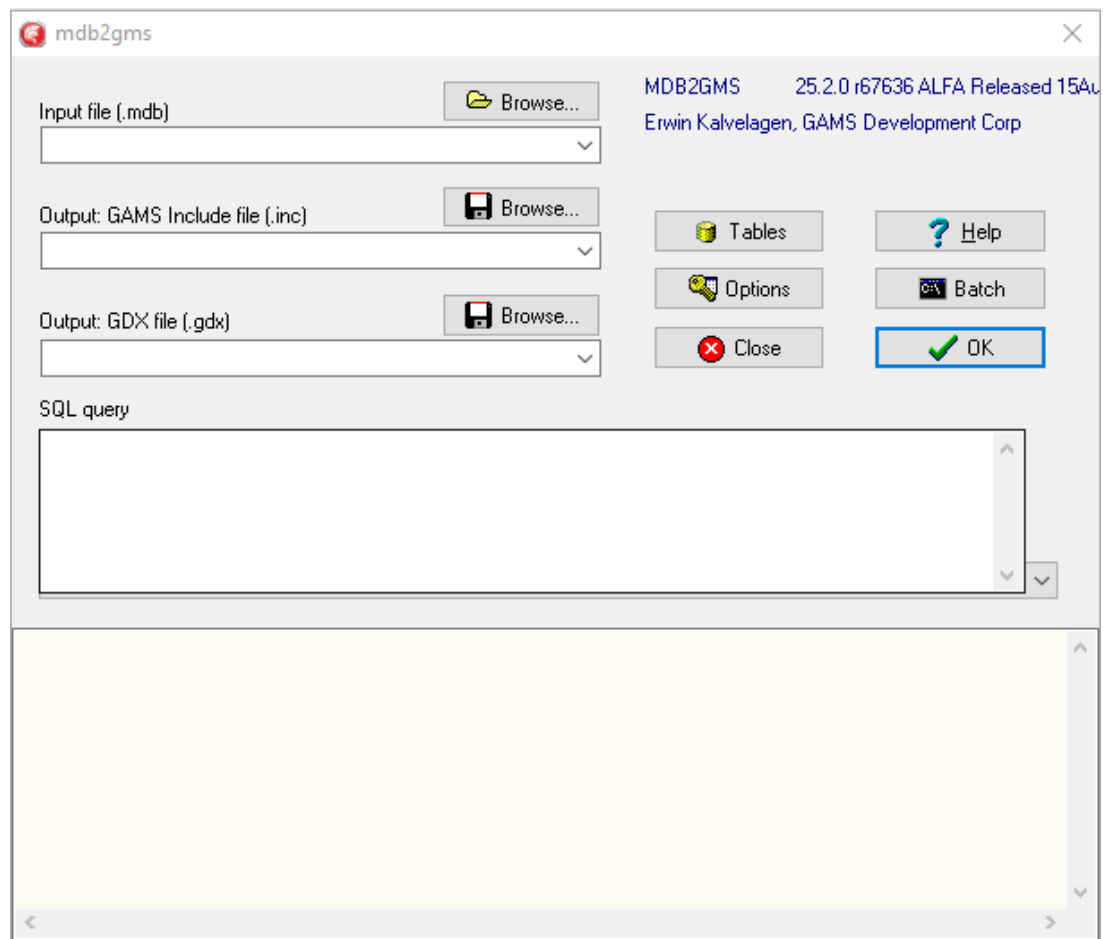

Figure 6.51 MDB2GMS - Graphical User Interface

- **Input file (.mdb or .accdb).** This is the combo box to specify the input file. See also [inputFile](#) for some more detailed remarks. The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation `\\machine\directory\file.mdb`.

- **Output GAMS Include file (*.inc).** If you want to create a GAMS include file, then specify here the destination file. See also [outputIncludeFile](#) for some more detailed remarks.

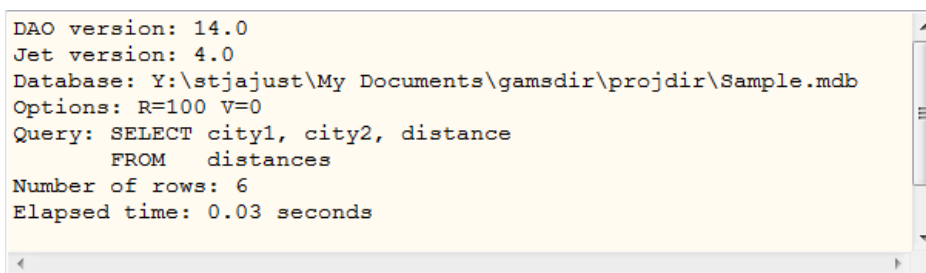

- **Output GDX file (*.gdx).** As an alternative to a GAMS include file, the tool can also generate a [GDX file](#). One or both of the output files need to be specified. See also [outputGDXFile](#) for some more detailed notes.

- **SQL Query.** The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also [Q](#) for some more detailed remarks. For an exact description of allowed expressions consult a text on MS Access.

- **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

- The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.

- The **Options button** will pop up a window where you can specify a number of options.

- Pressing the **Help button** will show this documentation.

- Pressing the **OK button** will execute the query and an include file or GDX file will be generated.

- Pressing the **Batch button** will give information on how the current query can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied to the clipboard. In the IDE press **Ctrl-C** or choose **Edit|Paste** to copy the contents of the clipboard to a GAMS text file.

- Pressing **Close button** will exit the application. The current settings will be saved in an INI file so when you run **MDB2GMS** again all current settings will be restored.

6.32.5.1 Options

The **Options** window can be created by pressing the options button:

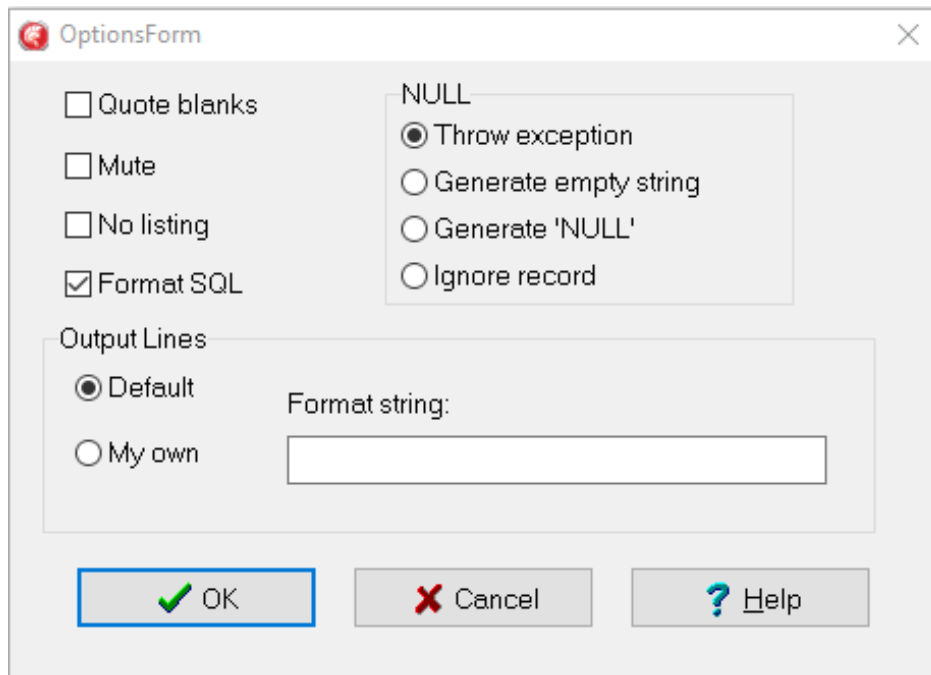

Figure 6.52 Options Menu of the Graphical User Interface

The following options are available in the options window:

- **Quote blanks:** Quote strings if they contain blanks or embedded quotes. See also [B](#) for some more detailed notes.

Quote blanks

- **Mute:** Don't include the extra informational text (such as used query etc.) in the include file.

Mute

- **No listing:** Surround the include file by `$offListing` and `$onListing` so that the data will not be echoed to the listing file. The equivalent command-line argument is [L](#).

No listing

- **Format SQL:** If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.

Format SQL

The following options are only needed in special cases:

- **NULL:** This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.

NULL

Throw exception

Generate empty string

Generate 'NULL'

Ignore record

- **Output Lines:** By default output lines are created as follows: all first n-1 fields are considered indices and the last n-th column is the value. The format corresponding to this situation is '%s.%s.%s %s' (for a three dimensional parameter). In special cases you may want to tinker with the format string being used. The fields are all considered strings, so only use s as format placeholder. Make sure you specify exactly the same number of s's as there are columns in the result set.

Output Lines

Default

My own

Format string:

The buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made, and all option settings will revert to their previous values.

- **Help button** will show this help text.

6.32.6 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.
- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.
- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:

Data Extraction --> Data Manipulation --> Model Definition --> Model Solution --> Report Writing

we can conveniently use the save/restart facility. The individual submodel are coded as:

- **Step 0: sr0.gms**

```
$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
$offText
```

```
Set
  i 'suppliers'
  j 'demand centers';
```

```
Parameter
  demand(j)
  supply(i)
  dist(i,j) 'distances';
```

```

$onEcho > howtoRead.txt
I=transportation.mdb

Q1=select name from suppliers
O1=i.inc

Q2=select name from demandcenters
O2=j.inc

Q3=select name,demand from demandcenters
O3=demand.inc

Q4=select name,supply from suppliers
O4=supply.inc

Q5=select supplier,demandcenter,distance from distances
O5=dist.inc
$offEcho

$call =mdb2gms.exe @howtoRead.txt

Set i /
$include i.inc
/;

Set j /
$include j.inc
/;

Parameter demand /
$include demand.inc
/;

Parameter supply /
$include supply.inc
/;

Parameter dist /
$include dist.inc
/;

display i, j, demand, supply, dist;

```

- **Step 1: sr1.gms**

```

$onText
step 1: data manipulation step
execute as: > gams sr1 restart=s0 save=s1
$offText

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;

```

- **Step 2: sr2.gms**

```

$onText
step 2: model definition

```

```

execute as: > gams sr2 restart=s1 save=s2
$offText

Variable
  x(i,j) 'shipment quantities in cases'
  z      'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
  ecost      'define objective function'
  esupply(i) 'observe supply limit at plant i'
  edemand(j) 'satisfy demand at market j';

ecost..      z =e= sum((i,j), c(i,j)*x(i,j));

esupply(i).. sum(j, x(i,j)) =l= supply(i);

edemand(j).. sum(i, x(i,j)) =g= demand(j);

```

- **Step 3: sr3.gms**

```

$onText
step 3: model solution
execute as: > gams sr3 restart=s2 save=s3
$offText

option lp = cplex;

Model transport / all /;
solve transport using lp minimizing z;

```

- **Step 4: sr4.gms**

```

$onText
step 4: report writing
execute as: > gams sr4 restart=s3
$offText

abort$(transport.modelStat <> 1) "model not solved to optimality";

display x.l, z.l;

```

A model that executes all steps can be written as:

```

execute '=gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute '=gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute '=gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute '=gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute '=gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";

```

If you only change the reporting step, i.e. generating some output using PUT statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [MDBSr5] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

MDB2GDX1.gms

```
execute '=gams.exe sr0 lo=3.gdx=transport.gdx';
abort$errorLevel "step 0 failed";

execute '=gdxviewer.exe transport.gdx';
```

The model [MDB2GDX1] is also part of the GAMS Data Utilities Library.

We can also let MDB2GMS create the GDX file:

MDB2GDX2.gms

This model demonstrates how to store data from Access database (file Transportation.mdb) into a GDX file.

```
$onEcho > howToRead.txt
I=Transportation.mdb
X=Transportation.gdx

Q1=SELECT name FROM suppliers
S1=i

Q2=SELECT name FROM demandcenters
S2=j

Q3=SELECT name, demand FROM demandcenters
P3=demand

Q4=SELECT name, supply FROM suppliers
P4=supply

Q5=SELECT supplier, demandcenter, distance FROM distances
P5=dist
$offEcho

$call =mdb2gms.exe @howToRead.txt
```

The first approach has the advantage that a complete audit record is available from the data moved from the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the database and how this was stored in the GDX file, that file gives the answer.

The model [MDB2GDX2] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

GDXTRANSPORT.gms

This model demonstrates how to load the transportation data from GDX file at compile time.

```

Set
  i 'suppliers'
  j 'demand centers';

Parameter
  demand(j)
  supply(i)
  dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist

display i, j, demand, supply, dist;

```

DBTimestamp1.gms

In one application I had to retrieve data from the database each morning, at the first run of the model. The rest of the day, the data extracted that morning could be used. The following logic can implement this:

```

$onText
Retrieve data from data base first run each morning.
$offText

$onEcho > getdate.txt
I=%system.fp%transportation.mdb
Q=select day(now())
O=dbtimestamp.inc
$offEcho

$if not exist dbtimestamp.inc $call "echo 0 > dbtimestamp.inc"

Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc
/;

Scalar currentday 'day of this run';
currentday = gday(jnow);

display "compare", dbtimestamp, currentday;

if(dbtimestamp <> currentday,
  execute '=gams.exe sr0 lo=3 gdx=transportation.gdx';
  abort$errorLevel "step 0 (database access) failed";
  execute '=mdb2gms.exe @getdate.txt'
);

```

The include file dbtimestamp.inc contains the day of the month (1,...,31) on which the data was extracted from the database. If this file does not exist, we initialize it with 0. We then compare this number with the current day of the month. If the numbers do not agree, we execute the database extraction step and rewrite the dbtimestamp.inc file. This last operation could be done using a PUT statement, but in this case we used an SQL statement.

The model [DBTimestamp1] is also part of the GAMS Data Utilities Library.

6.32.7 Command Files

Parameters can be specified in a command file. This is important if the length of the command-line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines. Instead of specifying a long command-line as in:

```
$call =mdb2gms I="c:\My Documents\test.mdb" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"
```

we can use a command-line like:

```
$call =mdb2gms @"c:\My Documents\options.txt"
```

The command file

```
c:\My Documents\options.txt
```

can look like:

```
I=c:\My Documents\test.mdb
O=c:\My Documents\data.inc
Q=SELECT * FROM mytable
```

It is possible to write the command file from inside a GAMS model using the `$echo` command. The following example will illustrate this:

```
$set cmdfile "c:\windows\temp\commands.txt"
$echo "I=E:\models\labordata.mdb" > "%cmdfile%"
$echo "O=E:\models\labor.INC" >> "%cmdfile%"
$echo "Q=SELECT * FROM labor" >> "%cmdfile%"
$call =mdb2gms @"%cmdfile%"
```

```
Parameter p /
$include "E:\models\labor.INC"
/;
```

```
display p;
```

Newer versions of GAMS allow the usage of the `$onEcho` and `$offEcho` commands:

```
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho > "%cmdfile%"
I=E:\models\labordata.mdb
O=E:\models\labor.INC
Q=SELECT * FROM labor
$offEcho
$call =mdb2gms @"%cmdfile%"
```

```
Parameter p /
$include "E:\models\labor.INC"
/;
```

```
display p;
```

Note that the quotes enclosing strings with blanks like `Q=SELECT * FROM labor` can be omitted when using an external parameter file.

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character `\` as the last character. E.g.:

```
Q=SELECT prod, loc, year, 'sales', sales FROM data \  
UNION \  
SELECT prod, loc, year, 'profit', profit FROM data
```

6.32.8 Notes

6.32.8.1 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: `$gdxIn`, `$load`, `execute_load`, `execute_unload`. The `GDX=filename` command-line argument will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using `File|Open`.

6.32.8.2 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```
\\<server>\<share>\<path>\<file>
```

Examples:

```
\\athlon\c\My Documents\MDB2GMS.rtf
```

6.32.8.3 Quotes

Examples of handling of indices when the option `B` for quoting strings containing blanks is used:

6.32.8.4 \$CALL Command

The `$call` command in GAMS will execute an external program at [compile time](#). There are two forms:

The `$call` command in GAMS will execute an external program at compile time. There are two forms:

```
$call externalProgram
```

```
$call =externalProgram
```

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form `$call externalProgram` which uses the command processor.
2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form `$call externalProgram`.
3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form `$call =externalProgram`. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: `$call =externalProgram`.
4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: `$call start /w externalWindowsProgram`. Otherwise, it is preferred to use: `$call =externalWindowsProgram`.

Attention

In general it is recommended to use the `$call =externalProgram` version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

```
$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2
```

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

```
$call '"external program" "parameter 1" "parameter 2"'
$call ="external program" "parameter 1" "parameter 2"
```

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the `$call` in GAMS. The second form work without additional quotes *only if* the = appears outside the double quotes.

6.32.8.5 Compile Time Commands

All \$ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed **before** an execution time command, even if it is below. As an example consider:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
$call x.bat
```

This fragment does not work correctly as already during compilation, the \$call is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

```
$echo "dir" > x.bat
$call x.bat
```

or by moving the external program invocation to execution time:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
execute x.bat;
```

Notice that all \$ commands do not include a semi-colon but are terminated by the end-of-line.

6.33 MessageReceiverWindow

6.33.1 Introduction

MessageReceiverWindow is a graphical tool that receives and displays Windows messages. The tool can either be used with the [put.utility](#) feature or with an arbitrary client (e.g. a Python program) that sends messages to a previously spawned instance of `MessageReceiverWindow.exe`.

6.33.2 Usage

An instance of `MessageReceiverWindow.exe` can be started as follows:

```
MessageReceiverWindow <title>
```

The optional argument `title` specifies the title of the `MessageReceiverWindow` instance. If the argument is omitted, the instance gets the default title `Form1`. Windows messages of type `WM_COPYDATA` that are sent to the spawned instance, appear in its message log. The `Copy To Clipboard` button allows to copy the content of the message log to the clipboard. The `Save As ...` button can be used to save the content to a file.

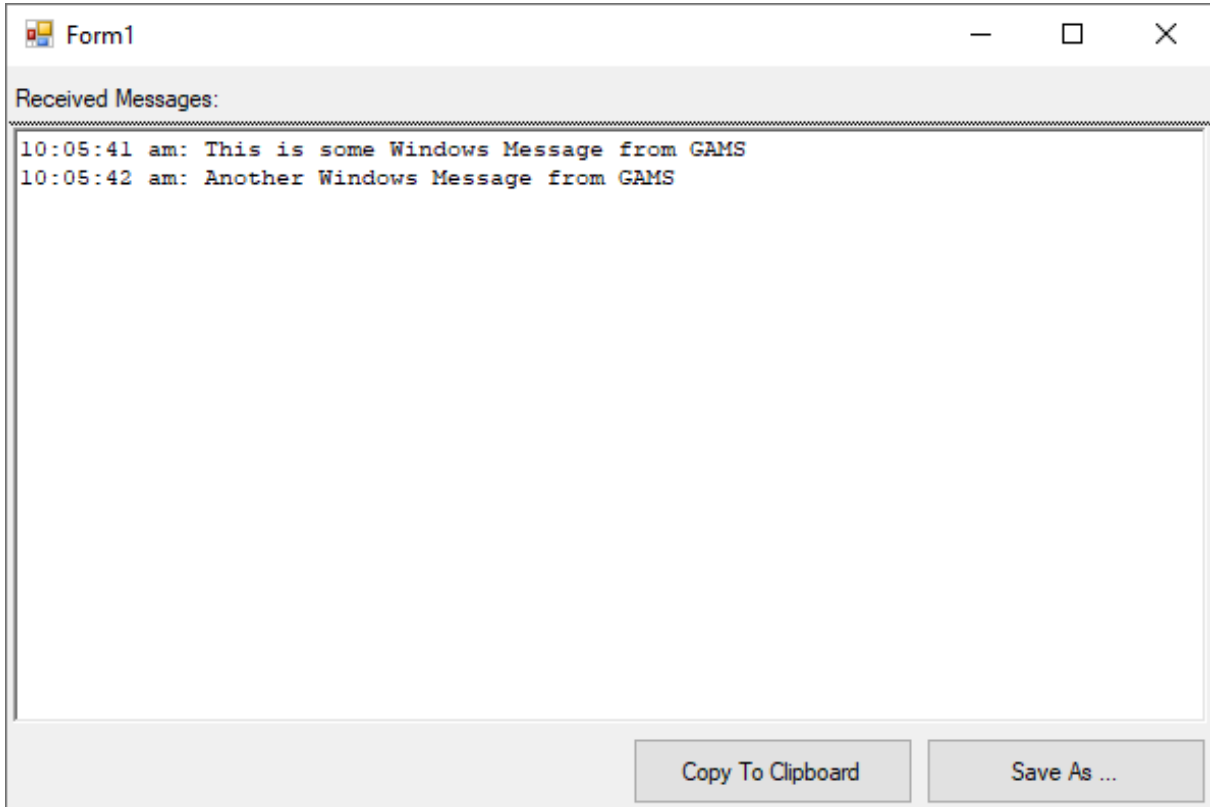

Figure 6.53 `MessageReceiverWindow` during the execution of Test Library model `MRW01`.

6.33.3 Special Commands

While arbitrary text messages are displayed in the message log, there are special commands for controlling special behavior of an instance of `MessageReceiverWindow`:

Message	Action
@CopyToClipboard	Copies the content of the message log to the clipboard
@SaveAs [file]	Writes the content of the message log to [file]
@Terminate	Terminates the <code>MessageReceiverWindow</code> executable

6.33.4 Usage With `put_utility`

The `put_utility` feature offers a convenient integration of `MessageReceiverWindow`. The example `MRW01` shows how this works. First of all, an instance of `MessageReceiverWindow` needs to be spawned from within GAMS:

```
$set title Form1
Execute.Async "MessageReceiverWindow.exe %title%";
```

As soon as the window is ready, text messages or [special commands](#) can be sent by using `put_utility` with the command `winMsg`:

```
file f;
put_utility f 'WinMsg' / '%title%' / 'This is some Windows Message from GAMS';
```

By sending `@Terminate`, the instance can be terminated:

```
put_utility f 'WinMsg' / '%title%' / '@Terminate';
```

6.33.5 Usage With Python

The example `MRW02` from the GAMS Test Library demonstrates the use of `MessageReceiverWindow` from within Python. While it uses the Python programming language from within an [Embedded Code](#) section, other programming languages can be used as long as they provide access to Windows messages.

First of all, a `ctypes.Structure` derived class is defined which is used for sending Windows message to a `MessageReceiverWindow` instance:

```
class _CopyDataStruct(ctypes.Structure):
    _fields_ = [('dwData', ctypes.c_char_p),
               ('cbData', ctypes.c_ulong),
               ('lpData', ctypes.c_char_p)]
```

The function `sendMessage()` sends a message to the window with the title `windowName`. It makes use of functions `FindWindowA` and `SendMessageA` from `ctypes.windll.user32`:

```
def sendMessage(windowName, message):
    cs = _CopyDataStruct()
    receiver = ctypes.windll.user32.FindWindowA(None, bytes(windowName, 'utf-8'))
    cmd = bytes(message, 'utf-8')
    cs.dwData = 1
    cs.cbData = len(cmd)+1
    cs.lpData = cmd
    WM_COPYDATA = 0x4A
    ctypes.windll.user32.SendMessageA(receiver, WM_COPYDATA, 0, ctypes.byref(cs))
```

`Popen` from the `subprocess` module is used in order to start an instance of `MessageReceiverWindow`. The `system_directory` property of a `GamsWorkspace` instance from the [GAMS Python API](#) is used for finding a GAMS system directory:

```
windowName = 'MRW Python'
p = Popen([os.path.join(GamsWorkspace().system_directory, 'MessageReceiverWindow.exe'), windowName])
```

As soon as the window is ready, text messages or [special commands](#) can be sent by using the previously defined `sendMessage` function:

```
sendMessage(windowName, "This is some Windows Message from Python")
```

Sending `@Terminate` will terminate the running `MessageReceiverWindow` instance:

```
sendMessage(windowName, "@Terminate")
```

6.34 MODEL2TEX

A Tool to generate a documentation from GAMS source code in LaTeX format.

Author

Clemens Westphal

Special thanks to Ingmar Schlecht for supporting us and sharing his [gamsToLatex implementation](#).

6.34.1 Introduction

MODEL2TEX is a tool to generate a documentation from GAMS source code in LaTeX format. This LaTeX output can then be further processed in order to generate pretty output files like PDF. The tool can be found in the root directory of GAMS. The tool allows to document one specific model symbol inside of a GAMS program. The resulting documentation contains two parts. The first part shows a list of symbols that are used by the model. The second part shows the actual algebra of the used equations and information about the types of used variables. An optional third part can contain additional notes.

6.34.2 Usage

MODEL2TEX is a command line tool. The general command line usage is as follows:

```
model2tex baseName [-h] [-m MODEL] [-f] [-o OUTPUT]
```

Since it operates on output files generated by GAMS, the first step is to generate the required files using the docfile option. In order to to that, execute the following command line:

```
gams myModel.gms docfile=myModel
```

The second step is to call MODEL2TEX: `model2tex` is distributed as Python source code (`model2tex.py`) and is executed via `model2tex.cmd` on Windows and `model2tex.sh` on all other platforms. For platforms other than Windows, Linux, or macOS, it is required to provide a Python 3 installation with access to the [GAMS Python API](#).

Windows:

```
model2tex myModel [-m MODEL] [-f] [-o OUTPUT]
```

Linux/Mac OS X:

```
model2tex.sh myModel [-m MODEL] [-f] [-o OUTPUT]
```

The output file `myModel.tex` can be further processed for example by calling `pdflatex` in order to generate a PDF file.

```
pdflatex myModel.tex
```

6.34.3 Options

The following parameters can be used when calling MODEL2TEX:

Parameter	Description
<code>-m model</code>	Since MODEL2TEX generates documentation for one model symbol, the model name needs to be specified explicitly, if the GAMS file contains more than one model symbol
<code>-f</code>	MODEL2TEX does not allow the occurrence of suffixes in equations. This option can be used in order to force the creation of the tex file by skipping the checks for suffixes.
<code>-o output</code>	Use this name for the generated TeX file instead of the base name.

6.34.4 Using a JSON style file

MODEL2TEX automatically creates a JSON file that can be modified in order to customize the output. If you want to get the default settings back, just delete the generated JSON file and let MODEL2TEX create it again. The following list shows the available options in the JSON file:

Parameter	Default	Description
fontSize	11	The size of the used font
hrules	true	Horizontal rules are added between equations.
colors	black	Specifies the used colors in equations for variables, parameters, and sets.
landscape	false	Allows to change the page format to landscape.
noPowerFunc	false	Beside a power operator, GAMS offers several power functions. Setting this option to true will replace all power functions with the power operator.
reduceFrac	false	Try to resolve unbalanced fractions. This means that fractions with an unbalanced length of denominator and numerator will be changed in order to shrink the fraction.
reduceFracRatio	5.0	This number has only effect when <code>reduceFrac</code> is set to true. It specifies the ratio between denominator and numerator that is used as a threshold for <code>reduceFrac</code> .
latexDescription	false	Explanatory text for symbols is expected to be arbitrary text. In order to display the text correctly in LaTeX, some automatic adjustments are applied. If all explanatory text already contains valid LaTeX strings, this option can be enabled.
nameMap	the original names	This map allows to specify alternative names for symbols.
extraSymbols	empty list	On default, only the required symbols in a GAMS model symbol are contained in the generated LaTeX file. This list can be used in order to specify further symbols that should be included as well.
notes	empty list	Allows to specify additional notes for the documentation. Each list element will result in a new line.

6.34.5 Example

This example creates a PDF file for the pump model from the GAMS Model Library.

1. Retrieve model pump from GAMS Model Library

```
gamslib pump
```

2. Generate required doc files

```
gams pump.gms docfile=pump
```

3. Generate the LaTeX files

```
model2tex pump -m=pump
```

4. Generate PDF documentation

```
pdflatex pump.tex
```

The following pictures show snippets from the resulting PDF file:

Equation Definitions

f

$$\text{objval} = \sum_i ((C_i + Cd_i \cdot P_i) \cdot np_i \cdot ns_i \cdot z_i)$$

g_i

$$P_i = \text{ldata}_{i,m1} \cdot \text{power}\left(\frac{w_i}{w_{\text{max}}}, 3\right) + \text{ldata}_{i,m2} \cdot \text{power}\left(\frac{w_i}{w_{\text{max}}}, 2\right) \cdot \text{vdot}_i - \frac{\text{ldata}_{i,m3} \cdot w_i}{w_{\text{max}}} \cdot \text{power}(\text{vdot}_i, 2) \quad \forall i$$

gd_i

$$\text{dp}_i = \frac{\text{ldata}_{i,m4} \cdot w_i}{w_{\text{max}}} \cdot \text{vdot}_i + \text{ldata}_{i,m5} \cdot \text{power}\left(\frac{w_i}{w_{\text{max}}}, 2\right) - \text{ldata}_{i,m6} \cdot \text{power}(\text{vdot}_i, 2) \quad \forall i$$

5. Customizing the JSON style file In order to change the appearance of the PDF file, the generated JSON file `pump.json` can be modified. Changing the options in `pump.json` according to the picture and executing the commands from step 3 and 4 again will result in a customized PDF output.

```

"fontSize": 10,
"hrules": false,
"colors": {
  "variables": "red",
  "parameters": "blue",
  "sets": "black"
},
"landscape": false,
"noPowerFunc": true,
"reduceFrac": false,
"reduceFracRatio": 5.0,
"latexDescription": false,
"nameMap": {
  ..
  "vdot": "$\dot{v}$",
  "sumx": "sumx",
  ..
},
"extraSymbols": [],
"notes": []

```

Variables

Name	Domains	Description
P	i	power output of pumps on level i
w	i	rotation speed for pumps on level i
dp	i	pressure rise on level i
\dot{v}	i	flow through pumps on level i

Equation Definitions

f

$$\text{objval} = \sum_i ((C_i + Cd_i \cdot P_i) \cdot np_i \cdot ns_i \cdot z_i)$$

 g_i

$$P_i = ldata_{i,m1} \cdot \frac{w_i}{w_{max}}^3 + ldata_{i,m2} \cdot \frac{w_i}{w_{max}}^2 \cdot \dot{v}_i - \frac{ldata_{i,m3} \cdot w_i}{w_{max}} \cdot \dot{v}_i^2 \quad \forall i$$

 gd_i

$$dp_i = \frac{ldata_{i,m4} \cdot w_i}{w_{max}} \cdot \dot{v}_i + ldata_{i,m5} \cdot \frac{w_i}{w_{max}}^2 - ldata_{i,m6} \cdot \dot{v}_i^2 \quad \forall i$$

6.35 MPS2GMS

Translates an MPS file into an equivalent short generic GAMS program using a GDX file to store data. A number of solver specific extensions often used by CPLEX, MOSEK, OSL and XPRESS are recognized. Recently introduced QP extensions QMATRIX, QUADOBJ, QSECTION and NAME/QSECTION/ENDATA are recognized as well. Currently all Qsections are assumed to belong to the objective function only (quadratic constraints are added to the objective function). The Mosek CSECTION extensions for QUAD and RQUAD cones are recognized as well.

6.35.1 Usage

```
mps2gms mpsfile [ gdxfile gmsfile [key=value] ]
```

The MPS file is read in free format (no blanks in names). Row and column names can have up to 63 characters and are tested for case sensitivity because row and column names become GAMS set members.

GAMS Data Exchange (GDX) files, MPS files and matching GAMS source code can be written. Minimizing is the default.

If no optimization direction is given, minimization will be assumed.

MPS files may contain multiple section and objective functions. If none are specified the first one encountered will be used. Those keys are the same as the MPS type or section names: NAME, N, RHS, RANGES and BOUNDS.

Quick guide to parameters:

Key	Description
MPS	MPS file
GDX	GDX file
GMS	Name of GAMS program output file
NAME	name of MPS name section
N	name of objective function row
RHS	name of MPS Rhs section
RANGES	name of MPS Range section
BOUNDS	name of MPS Bounds section
MPSout	rewritten MPS file file
Trace	debugging options

6.35.2 Examples

```
mps2gms old.mps MpsOut=new.mps
```

```
mps2gms old.mps old.gdx old.gms RHS=somerhs N=MYOBJ
```

```
mps2gms old.mps old.gdx old.gms Name=MYModel
```

6.36 MSAPPAVAIL

Checks if a MS Office Application is available.

6.36.1 Usage

```
msappavail [option]
```

Option:

?

List all known applications and their status. Check for specific application (ExitCode = 0 when available)

Access

Excel

Explorer

FrontPage

Outlook

PowerPoint

Project

Word

See how [cta] example from the GAMS model library uses this feature.

6.37 GAMS Posix Utilities

Starting with distribution 20.6 the GAMS system for Windows includes a collection of Posix utilities which are usually available for the different Unix systems and therefore help to write platform independent scripts. The following utilities are available:

- awk - [Pattern scanning and processing language \(1\)](#)
- cat - [Concatenate and print files](#)
- cksum - [Write file checksums and sizes](#)
- cmp - [Compare two files](#)
- comm - [Select or reject lines common to two files](#)
- cp - [Copy files](#)
- cut - [Cut out selected fields of each line of a file](#)
- diff - [Compare two files](#)
- expr - [Evaluate arguments as an expression](#)
- fold - [Fold lines](#)
- gsort - [Sort, merge, or sequence check text files \(1\)](#)
- grep - [File pattern searcher](#)
- gdate - [Write the date and time \(1\)](#)
- head - [Copy the first part of files](#)
- join - [Relational database operator](#)
- mv - [Move files](#)
- od - [Dump files in various formats](#)
- paste - [Merge corresponding or subsequent lines of files](#)
- printf - [Write formatted output](#)
- rm - [Remove directory entries](#)
- sed - [Stream editor](#)
- sleep - [Suspend execution for an interval](#)
- tail - [Copy the last part of a file](#)
- tee - [Duplicate standard input](#)
- test - [Evaluate expression](#)
- tr - [Translate characters](#)
- uniq - [Report or filter out repeated lines in a file](#)
- wc - [Word, line, and byte count](#)
- xargs - [Construct argument list\(s\) and invoke utility](#)

(1) Please note that the utilities "date" and "sort" have been renamed to "gdate" and "gsort" to avoid conflicts with the Windows commands "date" and "sort". For compatibility reasons the GNU implementation of awk called "gawk" has been renamed to "awk".

The collection consists of native Windows ports of GNU implementation of these utilities taken from the [Sourceforge](#). Detailed descriptions of the utilities can be found at the [GNU website](#).

The Posix tools and in particular the awk utility can be used to transform a variety of different text inputs into GAMS readable input files. Examples can be found in the [GAMS Model Library](#) (Subject "GAMS Tools").

6.38 SCENRED

6.38.1 Release Notes

- May, 2002: Level 001 (GAMS Distribution 20.6)
 - GAMS/SCENRED introduced.

6.38.2 Introduction

Stochastic programs with recourse employing a discrete distribution of the random parameters become a deterministic programming problem. They can be solved by an appropriate optimization algorithm, ignoring the stochastic nature of (some or all) parameters.

SCENRED is a tool for the reduction of scenarios modeling the random data processes. The scenario reduction algorithms provided by SCENRED determine a scenario subset (of prescribed cardinality or accuracy) and assign optimal probabilities to the preserved scenarios. The reduced problem is then solved by a deterministic optimization algorithm provided by GAMS.

6.38.3 Scenario Reduction Algorithms

Many solution methods for stochastic programs employ discrete approximations of the uncertain data processes by a set of scenarios (i.e., possible outcomes of the uncertain parameters) with corresponding probabilities.

For most practical problems the optimization problem that contains all possible scenarios (the so-called deterministic equivalent program) is too large. Due to computational complexity and to time limitations this program is often approximated by a model involving a (much) smaller number of scenarios.

The reduction algorithms developed in [1,2] determine a subset of the initial scenario set and assign new probabilities to the preserved scenarios. All deleted scenarios have probability zero.

SCENRED contains three reduction algorithms: The Fast Backward method, a mix of Fast Backward/Forward methods and a mix of Fast Backward/Backward methods. In general, the computational performance (accuracy, running time) of the methods differ. For huge scenario trees the Fast Backward method has the best expected performance with respect to running time. The results of the Forward and Backward methods are more accurate, but at the expense of higher computing time. The Forward method is the best algorithm when comparing accuracy, but it can only be recommended if the number of preserved scenarios is small (strong reduction). The combined methods improve the result of the Fast Backward method if the Forward or Backward method, respectively, can be completed within the running time limit. If no reduction method is selected, the method with the best expected performance with respect to running time is chosen.

The reduction algorithms exploit a certain probability distance of the original and the reduced probability measure. The probability distance trades off scenario probabilities and distances of scenario values. Therefore, deletion will occur if scenarios are close or have small probabilities.

The reduction concept is general and universal. No requirements on the stochastic data processes (e.g. the dependency or correlation structure of the scenarios, the scenario probabilities or the dimension of the process) or on the structure of the scenarios (e.g. tree-structured or not) are imposed. The reduction algorithms can be tailored to the stochastic model if the user provides additional information (How many decision stages are involved? Where do the random parameters enter the model – in objective and/or right hand sides and/or technology matrices?) The information is used to choose the probability distances (cf. Remark 1 in [1]).

6.38.4 Using GAMS/SCENRED

The reduction algorithms require additional data preparation and reformulation of the GAMS program for the stochastic programming model.

GAMS offers great flexibility with respect to the organization of data specification, model definition and solve statements. The most common way to organize GAMS/SCENRED programs is shown below. Since the initial scenarios and a number of input parameters have to be passed to SCENRED, the corresponding components of the GAMS program have to be defined before the SCENRED call. The reduced scenarios have to be defined before the equations of the (reduced) stochastic programming model are used in a solve statement. Therefore the SCENRED call can be placed anywhere between the definitions of the GAMS parameters and the solve statement of the reduced stochastic programming model.

When building or modifying a model for use with GAMS/SCENRED the following steps should be taken:

- Analyse the GAMS program of the stochastic programming model.
Since the initial scenarios and a number of input parameters have to be passed to SCENRED (see Section [The SCENRED Input File](#)), one must identify the corresponding components of the GAMS model and create or calculate them if they do not already exist.
- Reformulate the GAMS program.
Check if the model can handle varying scenario or node probabilities, and whether the equations are defined in terms of a (possibly reduced) tree. If the model doesn't already contain a scenario tree, one should be added. If it does, it is a simple task to rewrite the equation definitions (and possibly other statements too) in terms of a subset of the original nodes or tree.
- Add the statements for passing the initial set of scenarios to SCENRED, for the execution of SCENRED and for the import of the reduced scenarios from SCENRED.

A reduction of the initial scenarios makes sense only if we are able to generate that part of the model that corresponds to the preserved scenarios (i.e. the reduced subtree). This is done by declaring a subset of the nodes in the original tree. The parameters and equations are declared over the original node set, but are defined over only the subtree. This will be illustrated by an example later in the section.

Further, one should verify that the model can handle changing probabilities. Many practical models involve scenarios with equal probabilities. This property will not be maintained by the probabilities in the reduced subtree.

ORGANIZATION OF GAMS/SCENRED PROGRAMS

Component	Contents
1. DATA	* set & parameter declarations and definitions * \$libinclude scenred.gms * assignments displays
2. SCENRED CALL	* export the initial scenarios from GAMS to SCENRED * execute SCENRED * import the reduced scenarios from SCENRED to GAMS
3. MODEL	* variable declaration * equation declarations * equation definitions (using sets from reduced tree) * model definition & solution

Prior to calling SCENRED, you should include the declaration of the SCENRED input and output parameters and the definition of the sets they are indexed by from the GAMS include library:

```
$libinclude scenred.gms
```

Once you have created all the inputs to SCENRED and assigned values to them, you are ready to write the SCENRED GDX data input file, write the SCENRED options file, call SCENRED, and read the reduced tree data from the SCENRED GDX data output file (see Section [The SCENRED Input File](#), Section [SCENRED Options and the Option File](#), and Section [The SCENRED Output File](#)). Assuming your model is formulated to use a subtree of the original, you can now continue with the solve and any subsequent reporting.

SCENRED is executed by issuing the statement

```
execute 'scenred optfilename';
```

where `optfilename` is the name of the SCENRED option file.

As an example, consider the `srkandw` model in the GAMS model library, and the `kand` model upon which it is based (get these from the `modlib` now!). To produce `srkandw` from `kand`, we first reformulate the original to allow for solution over a reduced tree. To do this, we introduce a subset of the node set: `set sn(n) 'nodes in reduced tree'`; For convenience and clarity, we introduce a second subset at the same time, the set of leaf nodes: `set leaf(n) 'leaf nodes in original tree'`; as well as some code to compute this set based on the existing time-node mapping. We also declare a new parameter, the probabilities for the reduced tree: `parameter sprob(n) 'node probability in reduced tree'`; Once these are declared, we can quickly edit the equation *definitions* so that they run only over the reduced subtree: we simply substitute the reduced probabilities `sprob` for the original `prob`, and the reduced node set `sn` for the original node set `n`. Note that the *declaration* of the equations does not change.

This example illustrates one other change that may be required: the stochastic data must be in parameters having the node set as their last index. This is not the case in the `kand` model, so we simply reversed the indices in the `dem` parameter to meet the requirement in `srkandw`. It is also possible to create a transposed copy of the original data and pass that to SCENRED if the original data cannot be changed conveniently.

6.38.5 The SCENRED Input File

The SCENRED input file contains the initial scenarios and their stochastic parameter data, as well as statistics describing this input and (possibly) options to control the SCENRED run. This input file has a special binary format; it is a GDX (GAMS Data Exchange) file. The name of the SCENRED input file is assigned in the option file (see Section [SCENRED Options and the Option File](#)).

The scalar inputs to SCENRED are collected in the one-dimensional parameter `ScenRedParms`, the first parameter stored in the SCENRED input file. Some of the elements of `ScenRedParms` are required (e.g. statistics for the input tree) while others are optional (e.g. the run time limit). SCENRED will stop if a required element is missing or out of range.

Table 1 Required `ScenRedParms` elements

Element	Description
<code>num_leaves</code>	the number of initial scenarios or leaves of the scenario tree (i.e., before the reduction)
<code>num_nodes</code>	number of nodes in the initial tree (the number of scenarios if not tree-structured)
<code>num_random</code>	Number of random variables assigned to a scenario or node, i.e., the dimension of the random data process
<code>num_time_steps</code>	Length of a path from the root node to a leaf of the scenario tree, i.e., the number of time steps involved

Table 2 Optional ScenRedParms elements

Element	Description	Default
<code>red_num_leaves</code>	specifies the desired number of preserved scenarios or leaves	none
<code>red_percentage</code>	specifies the desired reduction in terms of the relative distance between the initial and reduced scenario trees (a real between 0.0 and 1.0)	none
<code>num_stages</code>	Set the number of branching levels of the scenario tree, i.e., the number of stages of the model -1. Hence <code>num_stages=1</code> if no branching occurs, i.e., the values of the scenarios differ for all time steps	1
<code>where_random</code>	An integer indicating where the randomness enters the model. The value is interpreted as a digit map computed using the formula $100 \cdot \text{inObj} + 10 \cdot \text{inRHS} + \text{inMatrix}$, where <code>inObj</code> is 1 if the objective contains random parameters and 0 otherwise, <code>inRHS</code> is 1 if the right-hand side contains random parameters and 0 otherwise, and <code>inMatrix</code> is 1 if the constraint matrix contains random coefficients and 0 otherwise.	10 (random right-hand side)
<code>reduction_method</code>	Select a reduction method: 0: automatic (best expected performance with respect to running time) 1: Fast Backward method 2: Mix of Fast Backward/Forward methods 3: Mix of Fast Backward/Backward methods	0
<code>run_time_limit</code>	Defines a limit on the running time in seconds	none
<code>report_level</code>	Control the content of the SCENRED log file: 0: Standard SCENRED log file 1: Additional information about the tree	0

A few comments on the parameters `red_percentage` and `red_num_leaves` are in order. At least one of these values must be set. The value of `red_percentage` will be ignored if the parameter `red_num_leaves` is non-zero. Otherwise, the tree will not be reduced if `red_percentage=0`, while the reduction of the tree will be maximal (i.e. only one scenario will be kept) if `red_percentage=1`. A numeric value of 0.5 means that the reduced tree maintains 50% of the information contained in the original tree. The reduction algorithms are skipped if `red_num_leaves=num_leaves` or if `red_num_leaves=0` and `red_percentage=0`. These values can be assigned if the user wishes to run the scenario tree diagnostic.

The second data element in the input file is the set of nodes making up the scenario tree. Note that the cardinality of this set is part of `ScenRedParms`.

The third data element is the ancestor mapping between the nodes. This mapping determines the scenario tree. Note that the mapping can be either an ancestor mapping (i.e. child-parent) or a successor mapping (parent-child). By default, SCENRED expects an ancestor mapping. If the check for this fails, it looks for a successor mapping.

The fourth data element is the parameter of probabilities for the nodes in the original tree. It is only required that probabilities for the scenarios (i.e. the leaf nodes) be provided, but the parameter can contain probabilities for the non-leaf nodes as well.

The remaining elements in the input data file specify the parameter(s) that comprise the random values assigned to the initial scenarios, or to the nodes of the scenario tree. There can be more than one such

parameter, included in any order. The only requirement is that the node set be the final index in each of these parameters.

Table 3 summarizes the content of the SCENRED input file. Please keep in mind that the order of the entries must not be altered!

Table 3 Content of the SCENRED Input File

No.	Symbol	Type	Dimension	Content
1	ScenRedParms	Parameter	1	scalar SCENRED input
2	(any name)	Set	1	nodes in the scenario tree
3	(any name)	Set	2	the ancestor set
4	(any name)	Parameter	1	node probabilities; at least for the leaves
≥ 5	(any name)	Parameter	≥ 1	random values assigned to the nodes

To create the SCENRED data input file, the GAMS `execute_unload` statement is used. This statement is used to transfer GAMS data to a GDX file at execution time. As an example, to create a GDX file with the 4 required input parameters and one parameter `demand` containing the stochastic data, you might have the following statement:

```
execute_unload 'sr_input.gdx', ScenRedParms, node, ancestor, prob, demand;
```

6.38.6 SCENRED Options and the Option File

When the SCENRED executable is run, it takes only one argument on the command line: the name of the SCENRED option file. The option file is a plain text file. Typically, it is used to specify at least the names of the SCENRED data input and output files. The option file must be created by the SCENRED user (typically via the GAMS put facility during the GAMS run). The syntax for the SCENRED option file is

```
optname value or optname = value
```

with one option on each line. Comment lines start with an asterisk and are ignored.

Some of the SCENRED options may be specified in two places: as elements of the `ScenRedParms` parameter of the SCENRED input file, or as entries in the options file. These parameters have been summarized in Table 2. If an option is set in both these places, the value in the option file takes precedence over the value from `ScenRedParms`. In addition, the parameters in Table 4 can only be specified in the option file.

Table 4 Options - optfile only

Option	Description	Default
input_gdx	Name of the SCENRED data input file	xllink.gdx
output_gdx	Name of the SCENRED data output file	scenred.gdx
log_file	Name of the SCENRED log file	scenred.log

6.38.7 The SCENRED Output File

The SCENRED output file contains the reduced scenario tree and the `ScenRedReport` parameter. Like the input file, the output file has a special binary format; it is a GDX (GAMS Data Exchange) file.

The first data element in the output file is the **ScenRedReport** parameter containing the scalar outputs and statistics from the SCENRED run. The elements of this parameter are summarized in Table 5. The second data element is the parameter containing the probabilities of the nodes in the reduced scenario tree. These node probabilities are required to construct the reduced tree. The third and final data element is the ancestor map for the reduced scenario tree. This map can be read from the GDX file, or the reduced tree can be built from the original one by using the reduced probabilities. The content of the data output file is summarized in Table 6.

Table 5 ScenRedReport elements

Element	Description
ScenRedWarnings	number of SCENRED warnings
ScenRedErrors	number of SCENRED errors
run_time	running time of SCENRED in sec.
orig_nodes	number of nodes in the initial scenario tree
orig_leaves	number of leaves (scenarios) in the initial scenario tree
red_nodes	number of nodes in the reduced scenario tree
red_leaves	number of leaves(scenarios) in the reduced tree
red_percentage	relative distance of initial and reduced scenario tree
red_absolute	absolute distance between initial and reduced scenario tree
reduction_method	reduction method used: 0: the program stopped before it could select a method 1: Fast Backward method 2: Mix of Fast Backward/Forward methods 3: Mix of Fast Backward/Backward methods

Table 6 Content of the SCENRED Output File

No.	Symbol	Type	Dimension	Content
1	ScenRedReport	Parameter	1	report of the SCENRED run
2	red_prob	Parameter	1	node probabilities for the reduced scenarios
3	red_ancestor	Set	2	the ancestor map for the reduced scenarios

To read the SCENRED data output file, the GAMS `execute_load` statement is used. This statement is used to transfer GDX data to GAMS at execution time. As an example, to read a GDX file named `sr_output.gdx` created by SCENRED, you might have the following statement:

```
execute_load 'sr_output.gdx', ScenRedReport, sprob=red_prob, sanc=red_ancestor;
```

In the statement above, the equal sign = is used to indicate that the data in the GDX parameter `red_prob` should be read into the GAMS parameter `sprob`, and the data in the GDX set `red_ancestor` should be read into the GAMS set `sanc`.

6.38.8 Diagnostic Check of Scenario Trees

When SCENRED reads its input data, it performs a number of checks to verify that the data is correct. The diagnostic checks of the input parameters include:

- consistency of the desired input parameters with the contents of the SCENRED input file (number of nodes, number of leaves, number of time steps, number of random values assigned to a node)

- range check of desired input parameters and options
- check of scenario and node probabilities
- check of the ancestor matrix (check the orientation of the graph, check if the graph contains a cycle, check if the graph contains incomplete forests or scenarios, check the consistency of the parameter `num_time_steps` with the ancestor matrix)

The following errors in the specification of the scenario tree cause SCENRED to skip the reduction algorithms:

- The input files cannot be opened.
- Not all required input parameters are given.
- The required input parameters are not consistent with the contents of the SCENRED input file.
- The required input parameters are out of range.
- Missing or negative scenario probabilities (probabilities of leaves).
- The ancestor set contains too many entries (more than $2 * \text{num_nodes}$).
- SCENRED detects a cycle in the ancestor set.
- SCENRED detects incomplete scenarios in the ancestor set.
- Run time limit reached

6.38.9 SCENRED Errors and Error Numbers

When SCENRED encounters a serious error in the input files or in the scenario tree, it sends an error message to the screen and to the log file. These messages always start with

```
**** SCENRED run-time error ...
```

The number of SCENRED errors are contained in the parameter `ScenRedReport` of the SCENRED output file (if it could be created). The occurrence of an error can also be detected from the last line that SCENRED sends to the screen:

```
**** SCENRED ErrCode=...
```

The numerical values of `ErrCode` and their meaning are given below.

ErrCode	Meaning
1	(for internal use)
2	fatal error while reading from SCENRED input file
3	fatal error while writing to SCENRED output file
4	fatal error while reading from SCENRED option file
5	log file cannot be opened
6	a memory allocation error occurred
7	there are missing input parameters
8	could not access the GAMS names for the nodes
9	(for internal use)
10	ancestor set not given or contains too many entries
11	node probabilities cannot be not read or are wrong
12	random values for the nodes cannot be read
13	input parameters are out of range
14	ancestor set contains a cycle
15	incomplete scenarios or forests detected

6.38.10 SCENRED Warnings

SCENRED warnings are caused by misspecification of the initial scenarios that can be possibly fixed. When SCENRED encounters such an error in the input files or in the scenario tree, it sends a message to the screen and to the log file. These messages always start with

```
**** SCENRED Warning ...
```

The following list gives an overview of the cases that produce warnings, and the action taken by SCENRED in these cases.

- The user assigned an option value that is out of range.
Action: Assign the default value.
- Both parameters `red_num_leaves` and `red_percentage` are assigned nontrivial values.
Action: The value of `red_percentage` will be ignored.
- The scenario probabilities (probabilities of leaves) do not sum up to 1.
Action: The scenario probabilities are rescaled. Assign new probabilities to the remaining (inner) nodes that are consistent with the scenario probabilities.
- Missing probabilities of inner nodes.
Action: Assign node probabilities that are consistent with the scenario probabilities.
- The ancestor set contains more than one ancestor for a node.
Action: SCENRED assumes to be given a successor set instead of an ancestor set (i.e., the transpose of an ancestor matrix. This means that the graph corresponding to the ancestor set has the wrong orientation). SCENRED starts the tree diagnostic for the successor set. The reduced tree will be defined in terms of a successor set as well (if the successor set passes the tree diagnostic and if SCENRED locates no fatal error during the run).
- The fast backward method delivered a result, but the result cannot be improved by the forward or backward method (running time limit reached).
Action: Use the result of the fast backward method.

6.39 SCENRED2

6.39.1 Introduction

Scenred2 is a fundamental update of the well-known scenario reduction software Scenred. A lot of new features come along with the latest release version. Beside updates and extensions concerning the control of the scenario reduction action an all new device for scenario tree construction has been implemented in Scenred2. Moreover, a lot of visualization functions to plot scenario trees and scenario processes linked to the free Gnuplot plotting software are available with Scenred2 now.

Table: Summary of basic new functions in Scenred2

Description	Section
Additional options for controlling the scenario reduction	Scenario Reduction
New device of scenario tree construction	Scenario Tree Construction
Visualization of scenario trees and processes	Visualization
Command line interface and data export	Command Line Interface

6.39.2 Using Gams/Scenred2

Successful applying Scenred or Scenred2 requires a special formulation of the stochastic programming model within the Gams program. Probabilistic information must be given by a set of nodes implying a certain ancestor structure including a well-defined root node. Note that the usage of Gams/Scenred2 is basically the same as the usage of Gams/Scenred. Hence, it is recommended for new users to look at the Scenred documentation first. All details about how to organize your Gams program, how to run Scenred from the Gams program by using the.gdx interface, and, of course, examples can be found in that documentation.

The Gams/Scenred2 link provides the same.gdx interface. But, due to new features some small changes in controlling the options are needed. Scenred2 supports now two types of option files. The first one is the SR-Command-File which must be passed to Scenred2 together with the Scenred2 call. The second one, the SR-Option-File includes more specific options to control the selected scenario reduction or scenario construction methods and can be declared in the SR-Command-File.

6.39.2.1 SR-Command-File

The command file includes the basic specifications. These are input/output.gdx file names, the log file name, all other file names which are needed for diverse visualization and output options. It also includes the name of the SR-Option-File.

Option	Description	Required
log_file	specify a log file name	yes
input_gdx	specify the.gdx input file for Scenred	yes
output_gdx	specify the.gdx output file of Scenred	yes
sr_option	specify a SR-Option-File	no
visual_init	specify a name for visualization of input tree	no
visual_red	specify a name for visualization of reduced/constructed tree	no
plot_scen	specify a name for visualization of scenario processes	no
out_scen	specify a file for scenario data output in fan format	no
out_tree	specify a file for scenario data output in tree format	no

Example:

Scenred2 must be called together with a command file, which contains at least all required options. The data exchange via the.gdx interface and the Scenred2 call from the Gams program is of the form (be careful with the meanings and right order of.gdx symbols):

```
execute_unload 'srin.gdx', ScenRedParms, n, ancestor, prob, random;
execute 'scenred2 scenred.cmd';
execute_load 'srou.gdx', ScenRedReport, ancestor=red_ancestor, prob=red_prob;
```

For example, the command file could be the following (note the compatible.gdx file names):

```
* scenred command file 'scenred.cmd'

log_file      sr.log
input_gdx     srin.gdx
output_gdx    srou.gdx
sr_option     scenred.opt
visual_red    tree
out_scen      raw.dat
```

6.39.2.2 ScenRedParms

With the symbol list of the parameter ScenRedParms and the SR-Option-File all necessary information regarding the Scenred2 run can be assigned. The Gams parameter ScenRedParms can easily included to the Gams program by the statement:

```
$libInclude scenred2
```

Of course, the include must be stated before calling Scenred2. After that statement all supported parameters can be assigned, but at least all required parameters regarding the input scenarios. By the symbols of the parameter ScenRedParms you make also the decision of what features you exactly want to use with Scenred2. Moreover, some other usefull parameters for the Scenred2 run are included in the symbol list of the parameter ScenRedParms.

Table: Supported Scenred2 parameters in ScenRedParms

Symbol	Description	Required
num_time_steps	path length from root to leaf	yes
num_leaves	leaves/scenarios in the initial tree	yes
num_nodes	nodes in the initial tree	yes
num_random	random variables assigned to a scenario or node	yes
red_num_leaves	desired number of preserved scenarios or leaves	no
red_percentage	desired relative distance (accuracy)	no
reduction_method	desired reduction method	no
construction_method	desired tree construction method	no
num_stages	number stages	no
run_time_limit	time limit in seconds	no
report_level	report level: more messages by higher values	no
scen_red	scenario reduction command	no
tree_con	tree construction command	no
visual_init	visualization initial tree	no
visual_red	visualization reduced (constructed) tree	no
plot_scen	visualization scenario processes	no
out_scen	output of scenario raw data	no
out_tree	output of scenario tree data	no

To enable some options assign a value to the parameter. A parameter value of zero (default) disables an option. Note that when running Scenred2 either scenario reduction or scenario tree construction can be performed. Hence, only `scen_red` or `tree_con` should be used at once.

Example:

The following statements describe a possible example setup for proceeding the scenario tree construction with visualization of the scenario tree and output of the scenarios to a raw data file afterwards. Note that for the visualization and the scenario output the name of output files must be specified in the SR-Command-File. Otherwise a warning will inform you about not selected file names.

```
* general parameters
ScenRedParms('num_leaves') = 100;
ScenRedParms('num_nodes') = 200;
```

```

ScenRedParms('num_time_steps') = 5;
ScenRedParms('num_random') = 2;
ScenRedParms('report_level') = 2;
ScenRedParms('run_time_limit') = 30;

* execution commands
ScenRedParms('tree_con') = 1;
ScenRedParms('visual_red') = 1;
ScenRedParms('out_scen') = 1;

```

Scenred2 can also be used for plotting tasks only. Disable both the `scen_red` and `tree_con` option and use one or more visualization options only (see also Section [Visualization](#) for more details regarding visualizations).

6.39.2.3 SR-Option-File

The SR-Option-File is the more specific option file and will be passed to Scenred2 by the `sr_option` statement specified in the SR-Command-File. It serves as control unit for available methods provided by Scenred2. The supported options depend on what kind of method is called with Scenred2. A detailed list of all options together with examples are given below for both the scenario reduction and the scenario construction devices (see Sections [Scenario Reduction](#) and [Scenario Tree Construction](#), respectively). Note that certain parameters can be assigned by using both ScenRedParms and the SR-Option-File. In case of having parameters defined twice a warning by Scenred2 will be generated to inform you.

6.39.3 Scenario Reduction

The scenario reduction device consists of approved methods for reducing the model size by reducing the number of scenarios in an optimal way. Here it doesn't make any difference whether the input data is structured as scenario tree or not. But note, the classical scenario reduction approach is actually developed for two-stage models. Extensions for the multistage case are planned in the near future. To learn more about the mathematical theory see, for example,

- H. Heitsch, W. Römisch, and C. Strugarek. Stability of multistage stochastic programs. *SIAM Journal on Optimization*, 17, 2006.
- H. Heitsch and W. Römisch. A note on scenario reduction for two-stage stochastic programs. *Operations Research Letters*, 35:731-738, 2007.
- H. Heitsch and W. Römisch. Scenario tree reduction for multistage stochastic programs. *Computational Management Science*, 6:117-133, 2009.

With Scenred2 the most popular and accurate reduction algorithms of forward and backward type are maintained further on. New options make it possible to proceed with the scenario reduction more individual. The most important new parameter is given by the option `metric_type` which allows to control the reduction process by different type of probability distances. Altogether three distances can be selected (see Table below). All probability distances are associated with a special order specification which can be set by the new option `order`. Both options replace the old option `where_random` which is not used any longer.

Table: SR Options - Scenario Reduction

Option	Description
<code>red_num_leaves</code>	desired number of scenarios (integer)

Option	Description
red_percentage	relative accuracy (number from 0.0 to 1.0)
reduction_method	1 - Forward, 2 - Backward, 0 - Default
metric_type	1 - Transport (default), 2 - Fortet-Mourier, 3 - Wasserstein
p_norm	choice of norm (example: 0 - max, 1 - sum, 2 - Euclidian)
scaling	0 - scaling off, 1 - scaling on (default)
order	metric order (integer, default is 1)

Example:

For example, a valid SR-Option-File is the following:

```
* scenred option file

reduction_method 1
red_percentage 0.3
metric_type 2
order 2
p_norm 1
scaling 0
```

Lines starting with the star symbol (route symbol can be used too) provide comment lines. The star symbol can also be used to out comment and disable certain options.

6.39.4 Scenario Tree Construction

Scenario tree construction is the outstanding all new device of Scenred2. It allows to construct scenario trees as accurate input for multistage stochastic programs (cf. H. Heitsch and W. Römis, Scenario tree modeling for multistage stochastic programs, *Mathematical Programming*, 118:371–406, 2009). The input are individual scenarios in form of a fan which must be allocated before calling Scenred2. A lot of options are offered to control the tree construction process. Note that in some cases due to sensibility of certain parameters some tuning is indispensable for producing good results.

Table: SR Options (basic) - Scenario Tree Construction

Option	Description
construction_method	1 - forward, 2 - backward
reduction_method	1 - forward, 2 - backward, used within the iteration
first_branch	time period of first branch (integer)
red_percentage	relative accuracy (level from 0.0 to 1.0)
eps_growth	1 - linear, 2 - exponential
eps_evolution	tree structure parameter (from 0.0 to 1.0)
scaling	0 - scaling off, 1 - scaling on (default)
order	order of metric

The Table above displays the main options to control the tree construction process. They are very similar to the reduction options. The role of the option `red_percentage` is here to prescribe a total epsilon accuracy (level) for the approximation scheme. But the approximation scheme is based on stagewise

approximations which requires a splitting of the total level to the stages. Two strategies are offered by Scenred2 a linear and an exponential mapping of the total level to the intermediate levels. Use option `eps_growth` to select one of them. Both strategies allow a second tuning parameter `eps_evolution` which effects the slope of the epsilon splitting.

Even though this kind of control may generate good results for many applications, sometimes a more individual control can be needed. For example, some applications require a localization of branching stages. Moreover, to setup approximation bounds directly to stages can be very useful. To this end the standard options are extended by a new section environment.

6.39.4.1 Additional options - The section environment

An alternative control for the accurate constructions is provided by using the section environment. The section environment aims to establish a better monitoring of the construction process. There are overall three section types supported by Scenred2 with the same syntax.

Branching control:

This section environment allows to specify branching points, i.e., an explicit selection of stages serving for branching. For example, use

```
section branching
  2
  4
  6
end
```

to allow branching only at time period 2, 4, and 6. Note that each stage statement must be placed in one line. But stages can be merged. A shorter formulation of the same contents can be written in closed form

```
section branching
  2*6 2
end
```

This statement reads branching within time periods from period 2 to period 6 with increment 2 steps. Both assignments can be combined and should be used together with the `red_percentage` option.

Epsilon control:

In the similar way by the epsilon section it is possible to assign epsilon tolerances for the stage approximations explicitly. This environment overcomes difficulties at times coming across with the automatic epsilon control. Note that this environment disables the option `red_percentage`. For example, use

```
section epsilon
  2 0.04
  3*4 0.03
  5 0.02
  6 0.01
end
```

to control the approximation scheme by assigning different epsilon values per stage. Note that the value 0.03 is assigned to time period 3 and 4 in the example.

Node control:

The node control is the most specific control you have over the tree construction. With this environment the number of nodes of the tree which will be generated can be assigned for each time stage explicitly. For example, use

```
section num_nodes
  1      1
  2*3   5
  4*5   10
  6     15
end
```

The syntax is the same as before. Note that only one section environment can be used at once. In particular, only the first section environment detected in the option file is used. The section environment can be commented like a standard option too.

Experimental option:

There is one other useful option to speed up computations when building different scenario trees from exactly the same input data. In this case the scenario distances needed to compute the trees could be saved to an external file at the first run and reloaded at later runs. Hence, the distances must be calculated only once. For example, use the option

```
write_distance dist.sr2
```

to save the computed distances to the file 'dist.sr2'. To reload them at the next run use the option

```
read_distance dist.sr2
```

The option is classified as experimental since no validation of the input file takes place. Before using this option, please ensure that the distances loaded with the `read_distance` option are the right ones.

Example:

Finally, look at the following example to see a valid SR-Option-File which can be passed to the scenario tree construction:

```
* tree construction option file
```

```
construction_method 2
reduction_method    1
order                1
scaling              0
```

```
section epsilon
  2*4   0.1
  5     0.2
  6     0.1
end
```

6.39.4.2 Example problems 'srtree.gms' and 'srpchase.gms'

Small example problems has been included to the GAMS Model Library.

The implementation can be found in the Gams programs 'srtree.gms' and 'srpchase.gms'. It might help you to practice in building scenario trees using Gams/Scenred2. The problem 'srtree.gms' converts a fan format scenario representation into a tree format representation and then reduces the tree size. The problem 'srpchase.gms' is to solve a simple stochastic purchase problem involving three stages. Sample scenarios which are generated from a fixed distribution using a random value generator serve as input for the tree construction.

6.39.5 Visualization

Visualization is another all new feature of Scenred2. In this section an easy way for making plots of scenario processes and tree structures is described. To this end you need the free Gnuplot software or any other plotting software which allows plotting directly from simple data files.

The concept of plotting tasks is the following. For each plot two files are generated, a Gnuplot access file (name.plt) and a raw data file (name.dat). The access file contains basic Gnuplot options and it can be adjusted for individual liking afterwards. The default output is the display. The supported plotting commands are

```
visual_init, visual_red, plot_scen
```

for plotting the initial tree structure, the reduced/constructed tree structure, and the scenario process(es), respectively.

Example:

For example, to visualize the constructed tree use the option

```
visual_red tree
```

within the SR-Command-File to specify the name for the output and activate the ScenRedParms parameter

```
ScenRedParms('visual_red') = 1;
```

in the Gams program. The result are the output files 'tree.plt' and 'tree.dat'. To compute the picture now you simply open the file 'tree.plt' with Gnuplot from the directory, where both output files are located (that should be the working directory). Alternatively, from the command line prompt call

```
>gnuplot tree.plt
```

Gnuplot will automatically generate the picture. Feel free to change any option in the Gnuplot access file for individual requirements. See also the Gnuplot manual for more details. In particular, to compute a well-scaled encapsulated postscript picture (eps), you simply have to uncomment a few lines in the Gnuplot option file above and to open it with Gnuplot once again.

With the command `plot_scen` the scenario process(es) can be visualized. Note that Scenred2 generates Gnuplot access and data files according to the number of random values.

6.39.6 Command Line Interface

The command line interface allows to run Scenred2 stand alone without using Gams. In this case the input for scenario reduction and scenario tree construction is handled by special input data files. The command file will be extended by the parameters having with the ScenRedParms otherwise.

To execute Scenred2 from the command line prompt together with a specified command file (which is required again), for example, call

```
>scenred2 command.file -nogams
```

To avoid diverse error messages do not forget the '-nogams' option to switch off the Gams interface. The command file can include some of the following options.

```
report_level <integer>
runtime_limit <integer>
read_scen <input file>
scen_red <option file>
tree_con <option file>
visual_init <name>
visual_red <name>
plot_scen <name>
out_scen <file name>
out_tree <file name>
```

The denotation is not accidental the same as in case of using the Gams interface. The meaning of a certain option is maintained for the command line interface. To compute any scenario reduction or scenario tree construction the same SR-Option-Files are supported. It remains to clarify the data input format which comes across with the new `read_scen` command.

6.39.6.1 Data input format

To feed Scenred2 with data the scenario parameters must be passed by the `read_scen` command. Two types of input file formats are accepted.

a) The tree format:

This file is a formatted data file including all information of the input scenarios tree. It must have a header with dimension information and the scenario data separated for each node. The header includes the type declaration, the number of nodes, and the number of random values.

The data part starts with the key word `DATA` (do not forget). The tree data has to be ordered node by node. For every node the following information is expected separated by white spaces: The unique predecessor node (root node points to itself) followed by the node probability and followed by the assigned number of random data values. All information to one node should be written to one line (only for clearness reasons). Comment lines are allowed.

Match the following conventions:

- Nodes are identified by a sequence of integer numbers.
 - The root node is expected to be the node '1'.
 - The predecessor of root is '1' too, i.e., the root points to itself.
-

- All nodes numbers require a canonical order by stages and scenarios (see example).

Example:

```
# input tree example for scenred

TYPE TREE

NODES 9
RANDOM 4

DATA
* PRED PROB RAND-1 RAND-2 RAND-3 RAND-4
  1 1.0 42.5 9.1 7.5 120.0
  1 1.0 39.8 11.2 8.4 90.0
  2 1.0 37.6 14.0 6.3 110.0
  3 0.5 38.9 12.4 8.1 130.0
  3 0.5 35.7 13.8 7.5 120.0
  4 0.25 40.3 14.9 7.2 120.0
  4 0.25 38.4 15.2 8.9 100.0
  5 0.3 37.6 14.9 9.3 80.0
  5 0.2 36.3 12.8 10.3 90.0

END
```

b) The fan format:

A scenario fan serves as input for the scenario tree construction but it can be used also for the scenario reduction. The scenario fan represents a special form of a scenario tree, where we consider individual scenarios merged to a collective root node (the root node can also be viewed here as some kind of artificial node).

Accordingly, the fan input file is a formatted data file including all information of the scenarios in individual form now. It must have a similar header with dimension information and the scenario data separated now for each scenario. The header gets the type declaration **FAN** instead of **TREE** and includes the number of scenarios, the number of time periods, and the number of random values. The data part is opened again with the **DATA** key word.

Every scenario is specified by a dataset including the scenario probability first followed by the different random values in ascending order w.r.t. time periods. All entries must be separated by a white space. Comment lines can be placed by the star and route symbols again. Note that in case of having an undetermined root node the mean of random values will taken for the first time period to appoint a unique root node. The example tree represented as input in scenario fan format is displayed in the next example.

Example:

```

# input fan example for scenred

TYPE  FAN

TIME  5
SCEN  4
RANDOM 4

DATA
0.2500
42.5   9.1   7.5   120.0
39.8   11.2  8.4   90.0
37.6   14.0  6.3   110.0
38.9   12.4  8.1   130.0
40.3   14.9  7.2   120.0

0.2500
42.5   9.1   7.5   120.0
39.8   11.2  8.4   90.0
37.6   14.0  6.3   110.0
38.9   12.4  8.1   130.0
38.4   15.2  8.9   100.0

0.3000
42.5   9.1   7.5   120.0
39.8   11.2  8.4   90.0
37.6   14.0  6.3   110.0
35.7   13.8  7.5   120.0
37.6   14.9  9.3   80.0

0.2000
42.5   9.1   7.5   120.0
39.8   11.2  8.4   90.0
37.6   14.0  6.3   110.0
35.7   13.8  7.5   120.0
36.3   12.8  10.3  90.0

END

```

Note that even though all scenarios coincide at the first three time periods, in this example, the scenarios will be represented by one node each for every time period by the fan input format. The exception is the first time period, where a unique root node is expected in general and, therefore, only one node is assigned. The following picture shows the structure of the scenario fan which is generated by the example input.

6.39.6.2 Data Export

Scenred2 allows to export scenario data after computing the scenario reduction or scenario tree construction to external data files. Data export is available for both the Gams and the command line interface. To export data from Scenred2 two output options `out_tree` and `out_scen` can be use. These options generate data files according to the tree and fan format, respectively. The name of the data files will be specified in the SR-Command-File. When using the Gams interface the options must be connected by activating the corresponding `ScenRedParms` parameter, additionally.

6.39.7 A Simplified Interface to Scenred2: `$libinclude runscenred2`

While the previously described interface between GAMS and Scenred2 provides a maximum of flexibility, it also is rather complex and error-prone. The GAMS utility `runscenred2` tries to hide most of the mechanics of the GAMS/Scenred2 interface. The call to `runscenred2` looks as follows:

```
$libInclude runscenred2 myprefix tree_con n tree p rtree rp rv1 rv2
```

Table: runscenred2 Arguments:

	Argument	Description
1	<code>myprefix</code>	base name for files used with Scenred2
2	<code>tree_con</code> or <code>scen_red</code>	select Scenred2 action: tree construction or scenario reduction
3	<code>n</code>	the set of nodes in the tree
4	<code>tree</code>	the set of ancestor relations describing the tree
5	<code>p</code>	the parameter containing the node probabilities
6	<code>rtree</code>	the set of ancestor relations of the reduced tree (output)
7	<code>rp</code>	the parameter containing the node probabilities for the reduced tree (output)
8	<code>rv1, rv2, ...</code>	parameters containing random values of the nodes

The table above describes the arguments of the `runscenred2` call. Arguments 3, 4, 5, 8 and following correspond to the symbols that need to be exported to the Scenred2 data input file (done with the `execute_unload` call in the complex interface). The output arguments 6 and 7 correspond to the symbols imported from the Scenred2 data output file (done with the `execute_load` call in the complex interface). The parameters `ScenRedParms` and `ScenRedReport` are invisibly communicated with Scenred2.

The second argument instructs Scenred2 either to construct a tree (`tree_con`) or to reduce a tree (`scen_red`).

Instead of providing an explicit name for all the different files in the Scenred2 command file, the first argument determines the name of all files using a simple naming scheme. The following name scheme is observed:

Filename	Command option	Description
<code>sr2myprefix.log</code>	<code>log_file</code>	log file name
<code>sr2myprefix.in.gdx</code>	<code>input_gdx</code>	gdx input file name
<code>sr2myprefix.out.gdx</code>	<code>output_gdx</code>	gdx output file name
<code>sr2myprefix.opt</code>	<code>sr_option</code>	option file name
<code>sr2myprefix.vi.plt</code>	<code>visual_init</code>	file name for visualization of input tree

Filename	Command option	Description
sr2myprefix_vr.plt	visual_red	file name for visualization of reduced/constructed tree
sr2myprefix_plot.plt	plot_scen	file name for visualization of scenario process
sr2myprefix_raw.dat	out_scen	file name for scenario data output in fan format
sr2myprefix_tree.dat	out_tree	file name for scenario data output in tree format

The first three files (`log_file`, `input_gdx` and `output_gdx`) are always used. The only optional input file `sr_option` is read by Scenred2 if `ScenRedParms('sroption')=1`. When you create this file, make sure to use the proper file name. The output files are created by Scenred2 if the corresponding option is set to 1 in `ScenRedParms`, e.g. `ScenRedParms('out_tree')=1`.

In addition to a simpler communication of data between GAMS and Scenred2, the newer versions of GAMS/Scenred2 (starting with GAMS distribution 23.1) release the user of setting required fields in the `ScenRedParms` parameter: `num_time_steps`, `num_leaves`, `num_nodes`, and `num_random`. GAMS/Scenred2 calculates these numbers from its input data. In case the user still sets these fields, Scenred2 will ensure that the internally calculated numbers and the user provided numbers match.

March 25, 2004

6.40.1 Overview

`shellexecute` is a small wrapper program for the `ShellExecute` Windows API call. It allows you to spawn an external program based on the file type of the document to open.

GAMS provides the `execute` statement to execute external programs. In some cases we want to let the system figure out what application to start for a given document. This can be accomplished with `shellexecute`. For instance, when we call:

```
> shellexecute demo.html
```

Windows will launch the web browser and show `demo.html`. This works correctly, irrelevant whether the user installed Microsoft Internet Explorer or Netscape's web browser.

6.40.2 Usage

The command line for `shellexecute` looks like:

```
shellexecute [/verb=vvv] [/showcmd=flag] [/dir=ddd] filename args
```

The filename is either a document (e.g. `demo.html` or `book1.xls`) or an application (e.g. `winword.exe` or `notepad`). If a document is provided, the associated application will be launched. If a directory name is provided the windows explorer will be launched.

If additional parameters are specified they are considered as command line parameters for the process to be spawned.

The following options are recognized:

- `/verb=vvv` Specifies the action to be performed. The allowed actions are application dependent. Some commonly available verbs include:

verb	Description
edit	Launches an editor and opens the document for editing.
find	Initiates a search starting from the specified directory.
open	Launches an application. If this file is not an executable file, its associated application is launched.
print	Prints the document file.
properties	Displays the object's properties.

If no verb is specified the default command for the file class will be used (in many cases this is `open`).

- `/showcmd=flag` Flag that specifies how an application is to be displayed when it is opened. The actual behavior is up to the launched program. The possible values are:

showcmd	Description
SW_HIDE	Hides the window and activates another window.
SW_MAXIMIZE	Maximizes the specified window.
SW_MINIMIZE	Minimizes the specified window and activates the next top-level window in the <code>z</code> -order.
SW_RESTORE	Activates and displays the window. If the window is minimized or maximized, Windows restores it to its original size and position. An application should specify this flag when restoring a minimized window.
SW_SHOW	Activates the window and displays it in its current size and position.
SW_SHOWMAXIMIZED	Activates the window and displays it as a maximized window.
SW_SHOWMINIMIZED	Activates the window and displays it as a minimized window.
SW_SHOWMINNOACTIVE	Displays the window as a minimized window. The active window remains active.
SW_SHOWNA	Displays the window in its current state. The active window remains active.
SW_SHOWNOACTIVATE	Displays a window in its most recent size and position. The active window remains active.

showcmd	Description
SW_SHOWNORMAL	Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position. An application should specify this flag when displaying the window for the first time.

The default is `SW_SHOWNORMAL`.

- `/dir=ddd` the default directory for the sub-process.

In many cases you will not need to use any options.

6.40.3 Examples

Below are some examples of `ShellExecute`. It is noted that much of the behavior is depending on the file associations that are installed on your machine. These file associations can be inspected and changed with the Windows Explorer, see [Figure 1](#).

6.40.3.1 Spawning a web browser

```
> shellexecute turkey.html
```

6.40.3.2 Spawning notepad

```
> shellexecute trnsport.txt
```

If a different program is associated with a `.TXT` file, a different program will be launched. In my case notepad will be launched due to the file association shown in [Figure 1](#).

6.40.3.3 Spawning the GAMS IDE to view a GDX file

```
> shellexecute trnsport.gdx
```

6.40.3.4 Spawning Excel

```
> shellexecute test.xls
```

6.40.3.5 Calling shellexecute from GAMS

```
execute '=shellexecute trnsport.html';
```

6.40.3.6 A complete GAMS example

The following model is the `transport` model from the model library. We write the solution both to an HTML file and a CSV file. HTML is standard ASCII and is easily written using the PUT facility. CSV is even easier, as setting the FILE suffix `csv.pc=5;` will automatically generate comma separated values. The web browser is launched to view the HTML file, while Excel will be spawned to view the CSV file.

```

$title A Transportation Problem (TRANSPORT,SEQ=1)

$onText
Write a solution report in HTML and CSV and spawn
a browser and Excel to view the results.

Erwin Kalvelagen, May 2004
$offText

Set
  i 'canning plants' / seattle, san-diego /
  j 'markets'         / new-york, chicago, topeka /;

```

6.40.3.7 Exporting to MS Access

This example will launch MS Access after exporting a parameter to a MDB file.

```
$onText
Test of GDx2ACCESS. Dumps a symbol to an Access Database,
and launches MS ACCESS.
$offText

Set i / i1*i100 /;
Alias (i,j);

Parameter p(i,j);
p(i,j) = uniform(-100,100);
execute_unload 'test.gdx',p;

execute '=gdx2access test.gdx';
execute '=ShellExecute test.mdb';
```

6.40.4 Common error messages

6.40.4.1 File does not exist

```
E:\wtools\ver000\examples>shellexecute xxxx.html
ShellExecute Version 1.0
The system cannot find the file specified
```

6.40.4.2 No file association

```
E:\wtools\ver000\examples>shellexecute table02.dbf
ShellExecute Version 1.0
No application is associated with the specified file for this operation
```

6.41 SQL2GMS

Author

Erwin Kalvelagen

6.41.1 Overview

SQL2GMS is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft's Data Access components including [ADO](#), [ODBC](#) and [OLEDB](#). The target is a [GAMS Include File](#) (.inc) or a [GAMS GDX File](#) (.gdx).

When running the executable sql2gms.exe without command line arguments, the tool will run [interactively](#) with a built-in GUI interface. Alternatively [SQL2GMS](#) can be run in [batch mode](#), which is useful when running it directly from a GAMS model without user intervention using the `$call` command at compile time or the `execute` command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL's should not be allowed to get into a GAMS data structure. The handling of NULL's can be specified in an option.

Besides parameters it is also possible to generate set data.

If you need to read data from an MS Access database or MS Excel spreadsheet, the accompanying tools [MDB2GMS](#) or [XLS2GMS](#) resp. [GDXXRW](#) may be more appropriate. In some cases it may be more useful to use [SQL2GMS](#) to read from Access and Excel data sources.

6.41.2 Requirements

SQL2GMS runs only on Windows PC's with [MDAC](#) (Microsoft Data Objects) installed. In many cases this will be installed on your computer. Otherwise it can be downloaded from the [Microsoft Download Center](#) (direct link to MDAC).

In order to use [SQL2GMS](#) effectively, you will need to have a working knowledge of [SQL](#) in order to formulate proper database queries. In addition you will need some knowledge on how to connect to your database using ODBC or ADO.

6.41.3 Batch Usage

SQL2GMS can be run in batch mode without user intervention from within the GAMS model by using the `$call` resp. `execute` statements or directly from command prompt while specifying all arguments in the command-line. A SQL2GMS batch call is of the following form:

```
sql2gms connectionString outputFile queryString
```

A proper call will at least contain the following three command-line arguments:

1. The name of the database and the instruction for connecting to the database must be specified within the `connectionString`, which is indicated by the option **C**. i.e. `C=connectionString`.
2. The name of `outputFile`, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option **O**, i.e. `O=outputFile.inc`, while the use of a GDX file is indicated by the option **X**, i.e. `X=outputFile.gdx`.
3. The SQL `queryString`, containing the SQL statement to be executed on the database, must be specified within the option **Q**, i.e. `Q=queryString`.

See also [Command-line Arguments](#) below for a complete list of all possible command-line arguments. Consider that the `$call` or `execute` usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the [interactive](#) built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a `@` (At sign).

Also consider to take a look at the section [Strategies](#), mentioning some of the drawbacks of the batch usage and how to overcome them.

6.41.3.1 Command-line Arguments

The following table summarizes the command-line arguments that can be specified when using `SQL2GMS` directly from the GAMS model or command prompt.

Argument	Interpretation	Default	Description
C	<code>connectionString</code>	none	Specify the <code>connectionString</code> (required).
O	<code>outputIncludeFile</code>	none	Specify the name of the output file (.inc). Either <code>O=</code> or <code>X=</code> must be specified (or both).
On	<code>nth outputIncludeFile</code>	none	Match the <code>nth</code> query with the <code>nth</code> output file (.inc format) if multiple queries are used.
X	<code>outputGDXFile</code>	none	Specify the name of the output file (.gdx). Either <code>O=</code> or <code>X=</code> must be specified (or both).
Q	Query	none	This option can be used to specify a SQL query (required).
Qn	<code>nth query</code>	none	Match the <code>nth</code> query with the <code>nth</code> output file (.inc) format or with the <code>nth</code> set- or parameter name when writing to GDX if multiple queries are used.
S	<code>setName</code>	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file.
Sn	<code>nth setName</code>	none	Match the <code>nth</code> query with the <code>nth</code> set in the GDX file if multiple queries are used.
Y	<code>setName (with expl. text)</code>	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. Use this argument to store a set with explanatory text.

Argument	Interpretation	Default	Description
Yn	nth setName (with expl. text)	none	Match the nth query with the nth set (with explanatory text) in the GDX file if multiple queries are used.
A	parameterName	none	If we write to a GDX file, use this option to specify the name of a parameter to be used inside the GDX file.
An	nth parameterName	none	Match the nth query with the nth parameter in the GDX file if multiple queries are used.
L	Listing	disabled	Controls if the data is embedded in the listing file.
M	Mute	disabled	Controls if additional information is written to the log and include file.
B	Quote Blanks	disabled	Quote strings if they contain blanks or embedded quotes.
@fileName	ext. options file	none	Causes the program to read options from an external text file.
N	iniFileName	sql2gms.ini	Indicates the usage of a different INI file.
T1	connectionTimeOut	15	Indicates how long to wait while establishing a connection before terminating the attempt and generating an error.
T2	commandTimeOut	30	Indicates how long to wait while executing a command before terminating the attempt and generating an error.
T	timeOut	none	Sets both T1 and T2.
D	Debug	disabled	Generate debug information.
E	Empty sets	disabled	Allow an empty result set; without this option an empty result set will generate an error.
R	rowBatchSize	100	Row batch size; the default is 100 records.
P	Password	none	Specify a password for the database.
W	Wiring	none	Maps database columns to GAMS index positions.

Some more detailed remarks on the command-line arguments:

C = *string* (connectionString, default = none)

This option is required and specifies which database is to be used and how SQL2GMS talks to the database. A collection of valid connection strings can be found in section [Connection Strings](#). Often the connection string will need to be surrounded by quotes, as in: `C="DSN=sample"`. This option is demonstrated in all examples, see [Example 1 - Reading a single valued Table](#) for instance.

O = *string* (outputIncludeFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is

writable. [UNC names](#) can be used. An output file must be specified for batch operation: i.e. either `O=` or `X=` needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the `$include` command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in [Example 1 - Reading a single valued Table](#) for instance.

On = *string* (outputIncludeFile, default = none)

When using multiple queries in a single SQL2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

See also section [Multi-Query Batch Usage](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

X = *string* (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS [GDX file](#). Make sure the directory is writable. [UNC names](#) can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either `O=` or `X=` needs to be specified (or both). This option is demonstrated in [Example 5 - Reading Set with Explanatory Text](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

Q = *string* (query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by the database we refer to the documentation that comes with your RDBMS (Relational DataBase Management System). The query is passed on directly to the RDBMS so the complete power and expressiveness of SQL is available including stored procedures etc. For an exact description of allowed expressions consult a text on your database system. This option is demonstrated in [Example 1 - Reading a single valued Table](#) for instance.

Qn = *string* (query, default = none)

When using multiple queries in a single SQL2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

or (GDX output file format - where several sets and parameters can be stored in a single file):

```

Q1="SELECT a, b FROM table"
A1=abParameter
Q2="SELECT c FROM table"
S2=cSet

```

Note the usage of the arguments **An** resp. **Sn** in order to store the results as parameter resp. set and to specify the name of the symbols. See also section [Multi-Query Batch Usage](#) or [Example 7 - Multi-Query Batch Example](#) for instance.

S = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in [Example 4 - Reading a multi dimensional Set](#).

Sn = *string* (setName, default = none)

If multiple queries are used in a single SQL2GMS call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

```

Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet

```

See section [Multi-Query Batch Usage](#) and [Example 7 - Multi-Query Batch Example](#) for instance.

Y = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in [Example 5 - Reading Sets with Explanatory Text](#) for instance.

Yn = *string* (setName, default = none)

If multiple queries are used in a single SQL2GMS call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.

```

Q1="SELECT i, explTextForSeti FROM table"
Y1=iSet
Q2="SELECT j, explTextForSetj FROM table"
Y2=jSet

```

The last column specified within the select clause in the SQL statements will be used as explanatory text.

A = *string* (parameterName, default = none)

If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query).

Note: MDB2GMS uses P, but P was already taken in SQL2GMS for specifying the password.

An = *string* (parameterName, default = none)

If multiple queries are used in a single `SQL2GMS` call while writing to a GDX file, use this option to specify the name of the `nth` parameter to be stored in the GDX file (containing the results of the `nth` query), e.g.

```
Q1="SELECT i, j, value FROM table"
A1=ijValue
Q2="SELECT n, m, value FROM table"
A2=nmValue
```

See section [Multi-Query Batch Usage](#) and [Example 7 - Multi-Query Batch Example](#) for instance.

L (Listing, disabled by default)

Embed the data between the `$offListing` and `$onListing` dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

M (Mute, disabled by default)

Controls if additional information (GAMS and `SQL2GMS` version numbers, number of rows in the data, elapsed time, used query etc.) is written to the log and include file.

B (Quote Blanks, disabled by default)

Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. In the special case that the string contains both, the double quotes are replaced by single quotes. For more information see subsection [Quotes](#). This option only applies to an output include file.

@fileName = *string* (fileName, default = none)

Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also [Parameter Files](#) for some further details.

N = *string* (fileName, default = none)

Use a different INI file than the standard `sql2gms.ini` located in the same directory as the executable `sql2gms.exe`.

T1 = *integer* (connectionTimeout, default = 15)

Indicates how long to wait while establishing a connection before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for the connection to open. Default is 15. If you set the property to zero, ADO will wait indefinitely until the connection is opened. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.

T2 = *integer* (commandTimeout, default = 30)

Indicates how long to wait while executing a command before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for a command to execute. Default is 30. If you set the property to zero, ADO will wait indefinitely until the execution is complete. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.

T = *integer* (timeOut, default = none)

Sets both **T1** and **T2**.

D (Debug, disabled by default)

Generate debug information. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

E (Empty sets, disabled by default)

Allow an empty result set; without this option an empty result set will generate an error. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

R = *integer* (rowBatchSize, default = 100)

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

P = *string* (password, default = none)

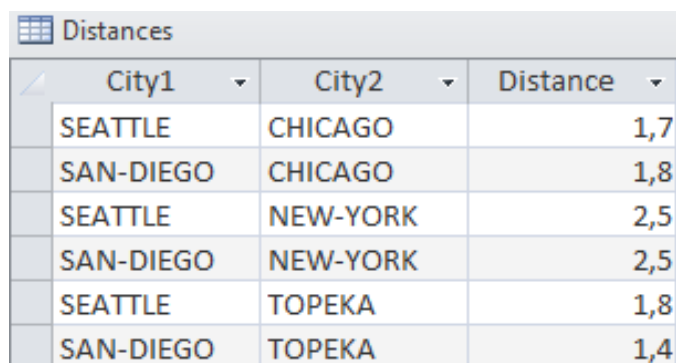

Specify a password for the database.

W = *string* (wiring, default = none)

By using the **W** option, one can map database columns to GAMS index positions. See model **[Wiring]** for reference (note that **MDB2GMS** is used to access the MS Access database instead of **SQL2GMS**, however this does not affect the **wiring** specification).

6.41.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the **[transport]** model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.accdb).

City1	City2	Distance
SEATTLE	CHICAGO	1,7
SAN-DIEGO	CHICAGO	1,8
SEATTLE	NEW-YORK	2,5
SAN-DIEGO	NEW-YORK	2,5
SEATTLE	TOPEKA	1,8
SAN-DIEGO	TOPEKA	1,4

Figure 6.54 Table: distances

The data can be queried with a simple SQL statement:

```
SELECT city1, city2, distance
FROM distances
```

By running the following SQL2GMS statement, the connection to the database Sample.accdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).

```
sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2, distan
```

The connection string is specified using the argument **C**. Note that the string is enclosed by quotes, as the string contains blanks. The database file name `Sample.accdb` is also specified within the connection string. For more information on how to connect to your database, see section [Connection Strings](#). The arguments **Q** and **O** are used to specify the query and the output file name (and format).

The generated include file `distances.inc` looks like:

```
* -----
* SQL2GMS 3.0      25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----
* ADO version: 10.0
* Connection string: Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb
* Provider: MSDASQL
* Query: SELECT city1, city2, distance FROM distances
* -----
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----
```

The commented header section summarizes some information about the `SQL2GMS` resp. `GAMS` version and about the executed database query. The standard export format is to consider the last column as the value column (containing the distances) and the previous columns as the indices (containing the city names). The indices are separated by a dot, allowing the generated include file to be used as part of a parameter declaration statement in your `GAMS` model.

Retrieving the data using `SQL2GMS` from the database and including the queried data in your `GAMS` model within the parameter declaration statement (at compile time) can be combined in the following way:

Set

```
  i 'canning plants' / seattle, san-diego /
  j 'markets'        / new-york, chicago, topeka /;
```

```
$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2,
Parameter d(i,j) 'distance in thousands of miles' /
$include distances.inc
/;
```

display d;

Finally, the values of the parameter `d` are displayed:

	new-york	chicago	topeka
seattle	2.500	1.700	1.800
san-diego	2.500	1.800	1.400

This example is also part of the `GAMS Data Utilities Library`, see model [\[Distances2\]](#) for reference. Note that the query results are written to a `GDX` file in addition.

6.41.3.3 Example 2 - Reading a multi valued Table

In this scenario, we want to read the three index columns `year`, `loc`, `prod` and the value columns `sales` and `profit` from the database file `Sample.accdb`. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for `sales` resp. `profit`) and a `UNION select`.

Consider the table with two value columns `sales` and `profit`:

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.55 Table: data (shortened for presentation)

Two separate Parameters

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```
SELECT year, loc, prod, sales
FROM data
SELECT year, loc, prod, profit
FROM data
```

We can generate a include file `sales.inc` by running the following command:

```
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year, loc, prod, sales
```

Note that we specify the first query in order to select the sales and the relevant index columns within the `Q` argument. The query results are written to `sales.inc` using the `O` argument. Analogously we generate a include file `profit.inc` by running the following command while specifying the second query in order to obtain the profits and the relevant index columns:

```
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year, loc, prod, profit
```

Retrieving the data using `SQL2GMS` from the database `Sample.accdb` and including the queried data in your GAMS model within the parameter declaration statements of `sales` and `profit` (at compile time) can be combined in the following way:

Set

```
year 'years'      / 1997*1998 /
loc  'locations' / nyc, was, la, sfo /
prd  'products'  / hardware, software /;
```

```
$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year,
Parameter sales(year,loc,prd) /
$include sales.inc
/;
```

```
$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year,
Parameter profit(year,loc,prd) /
$include profit.inc
/;
```

Single Parameter with extra Index Position

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index type to indicate the data type (sales or profit). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.

```
SELECT year, loc, prod, 'sales', sales
FROM data
UNION
SELECT year, loc, prod, 'profit', profit
FROM data
```

The data is accessed, queried and written to data.inc by running the following command:

```
sql2gms @howToRead.txt
```

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

```
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
```

The generated include file data.inc looks like (shortened for presentation):

```
* -----
* SQL2GMS 3.0      25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----
* ADO version: 10.0
* Connection string: DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb
* Provider: MSDASQL
* Query: SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
* -----
1997.la.hardware.profit 8

1998.la.hardware.sales 70

```

```
* -----
```

Retrieving the data using SQL2GMS from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index type in order to access the data type sales resp. profit):

```

$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM
O=data.inc
$offEcho

```

```

Set
  year 'years'      / 1997*1998 /
  loc  'locations' / nyc, was, la, sfo /
  prd  'products'  / hardware, software /
  type 'data type' / sales, profit      /;

```

```

$call sql2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
$include data.inc
/;

```

This example is also part of the GAMS Data Utilities Library, see model [\[SalesProfitDB5\]](#) for reference.

6.41.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a database file. Suppose we want to read the column City1 (see table [distances](#)) in order to define the set *i* in the GAMS model. Make sure elements are unique by using the distinct operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```

SELECT distinct(City1)
FROM distances

```

The include file city1.inc looks like (header informations are removed in order to shorten the representation):

```

* -----
SAN-DIEGO
SEATTLE
* -----

```

All steps (data access via SQL2GMS, set definition) can be combined:

```
$call sql2gms C="Provider=MMicrosoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT distinct(city)
Set i 'canning plants' /
$include city_i.inc
/;

display i;
```

The display statement generates the following output in the listing file:

```
----      56 SET i

seattle  ,    san-diego
```

6.41.3.5 Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using the `O` argument, one has to observe that the elements in the include file must have the correct format in order to be interpreted as element of a multi dimensional set. For instance, a line containing `a b c` is not recognized as a proper set element of a three dimensional set. In particular, one has to add periods between the single elements, i.e. `a.b.c` will be interpreted correctly.

Depending on your DBMS (DataBase Management System), these periods must be added explicitly in a different way within the SQL statement. E.g. add a dummy value field by adding a quoted blank to the select clause (index1, index2, index3 and dataTable are some placeholders):

```
SELECT index1, index2, index3, " " FROM dataTable
```

or by adding the periods explicitly within the select clause (`||` or `&` depending on DBMS):

```
SELECT index1&'.'&index2&'.'&index3 FROM dataTable
SELECT index1||'|'&index2||'|'&index3 FROM dataTable
```

For instance, suppose we want to define a two dimensional set

```
Set ij(i,j) 'canning plants - markets';
```

based on the data of the table `distances` stored in `Sample.accdb`. The following SQL2GMS statement connects you to the database, queries the columns with the city names and adds an empty value field in order to create periods between the set elements:

```
sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2, ' ' F
```

The include file `city_ij.inc` looks like (header informations are removed in order to shorten the representation):

```
* -----
SEATTLE.NEW-YORK ' '
SAN-DIEGO.NEW-YORK ' '
SEATTLE.CHICAGO ' '
SAN-DIEGO.CHICAGO ' '
SEATTLE.TOPEKA ' '
SAN-DIEGO.TOPEKA ' '
* -----
```

Without adding the empty value field, the resulting include file would look like (shortened):

```
* -----
SEATTLE NEW-YORK
SAN-DIEGO NEW-YORK
* -----
```

Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

```
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /;
```

```
$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2,
```

```
Set ij(i,j) 'two dimensional set' /
$include city_ij.inc
/;
```

```
display ij;
```

The display statement generates the following output in the listing file:

```
----      75 SET ij  two dimensional set

           new-york      chicago      topeka
SAN-DIEGO      YES          YES          YES
SEATTLE        YES          YES          YES
```

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the **X** and **S** resp. **Y** arguments, i.e. there is no need to modify the query:

```
SELECT index1, index2, index3 FROM datatable
```

when using SQL2GMS in the following way:

```
sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT index1, index2, ind
```

which will generate the file setData.gdx with a three dimensional set named setName containing the results of the query.

6.41.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a database file using SQL2GMS. In the first place, we are going to write the query results to an include file, afterwards we use the **Y** argument in order to store the query results as a set with explanatory text in a GDX file.

setElement	explText
firstSetElement	Explanatory text for the first 'set element'
secondSetElement	Explanatory text for the second "set element"
thirdSetElement	Explanatory text for the third 'set element'
fourthSetElement	Explanatory text for the fourth set element

Figure 6.56 Table: setData

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```
SELECT setElement, explText
FROM setData
```

Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument **B** in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file setData.inc:

```
$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" B Q="SELECT setElement,
Set a /
$include setData.inc
/;
```

The resulting include file will look like (header informations are removed in order to shorten the representation):

```
* -----
firstSetElement "Explanatory text for the first 'set element'"
secondSetElement 'Explanatory text for the second "set element"'
thirdSetElement "Explanatory text for the third 'set element'"
fourthSetElement 'Explanatory text for the fourth set element'
* -----
```

Note the handling of the quotes according to the description in **B**.

Writing the Query Results in a GDX File

When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the **Y** argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file setData.inc:

```
$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT setElement, e
Set b;
$gdxIn setData.gdx
$load b = set_b
$gdxIn
```

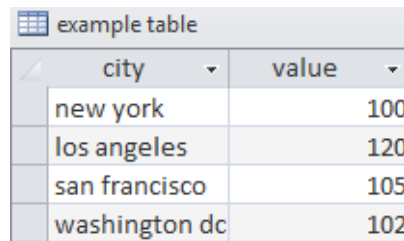

Note that the name of the set in the GDX file is **set.b** (specified within the **Y** argument), while the name of the GDX file was specified within the **X** argument.

6.41.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g. consider the case where the GAMS model has defined a set as:

```
Set i / NY, DC, LA, SF /;
```

Now assume a data table looks like:

city	value
new york	100
los angeles	120
san francisco	105
washington dc	102

Figure 6.57 Table: example table

This means we have to map 'new york' to 'NY' etc. This mapping can be done in two places: either in GAMS or in the database.

6.41.3.7.1 Index Mapping done in GAMS When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

```
* -----
'new york' 100
'los angeles' 120
'san francisco' 105
'washington dc' 102
* -----
```

Note that the single quotes are added by activating the option **B** (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:

```
Set i / NY, DC, LA, SF /;
```

```
Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;
```

```
$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" B 0="city1.inc"
Parameter dbdata(idb) /
$include city1.inc
/;
```

```
Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /;
```

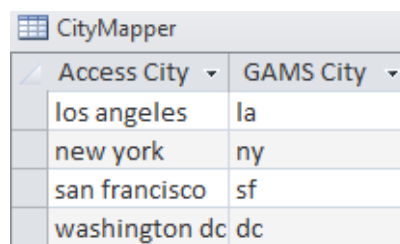

```
Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;
```

The display statement generates the following output in the listing file:

```
----      47 PARAMETER data
NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000
```

This example is also part of the GAMS Data Utilities Library, see model [\[IndexMapping3\]](#) for reference.

6.41.3.7.2 Index mapping done in Database The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:

Access City	GAMS City
los angeles	la
new york	ny
san francisco	sf
washington dc	dc

Figure 6.58 Table: CityMapper

This table can be used in a join to export the data in a format we can use by executing the query:

```
SELECT [GAMS City], value
FROM   example_table, CityMapper
WHERE  CityMapper.[Access City]=example_table.city
```

The resulting include file looks like (header informations are removed in order to shorten the representation):

```
* -----
la 120
ny 100
sf 105
dc 102
* -----
```

All steps can be combined in the GAMS model:

```
Set i / NY, DC, LA, SF /;

$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_
O=city2.inc
$offEcho

$call sql2gms @howToRead.txt
Parameter data(i) /
$include city2.inc
/;
display data;
```

The display statement generates the following output in the listing file:

```
-----      38 PARAMETER data
NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000
```

Note: MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [\[IndexMapping4\]](#) for reference.

6.41.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual SQL2GMS execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single SQL2GMS call and write several GAMS include files containing the results of the queries, we can use the command-line arguments [Qn](#) and [On](#). The structure of a multi-query call looks like:

```
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=sample.accdb

Q1=firstQuery
O1=outputFileName.inc

Q2=secondQuery
O2=outputFileName.inc

Q3=thirdQuery
O3=outputFileName.inc
```

The terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. We see that the argument `Qn` is matched by an argument `On`. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments [Qn](#), [Sn](#), [An](#) and [Yn](#). The structure of a multi-query call when writing to a GDX file looks like:

```
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=sample.accdb
X=sample.gdx

Q1=firstQuery
S1=setName

Q2=secondQuery
S2=setName

Q3=thirdQuery
A3=parameterName

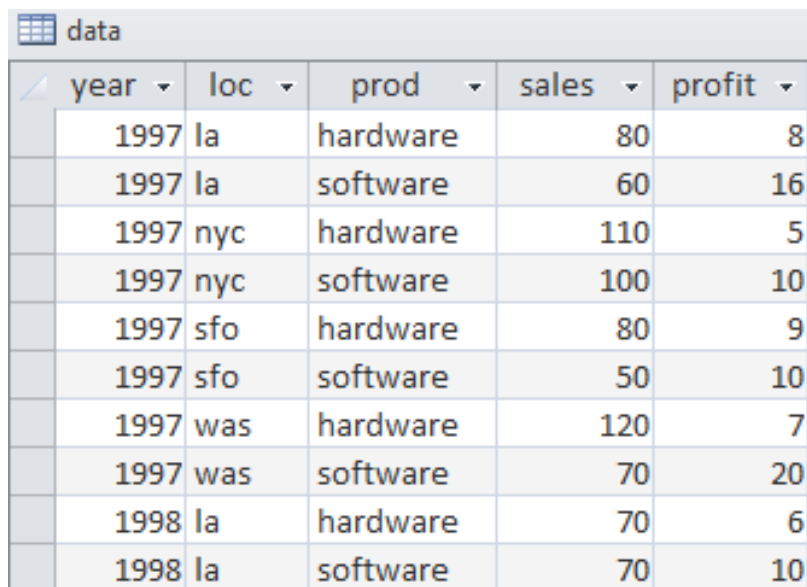

Q4=fourthQuery
A4=setName
```

Again, the terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. Here we see that a query `Qn` is matched by either a set name `Sn` or a parameter name `An` (the letter `P` was taken already: it is used to specify a password), i.e. the results of the first query will be stored as a set whose name is specified within the `S1` argument, the results of the third query will be stored as a parameter whose name is specified within the `A3` argument etc. The `X` argument is used to specify the name of the GDX file.

For a complete example see section [Example 7 - Multi-Query Batch Example](#).

6.41.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file `Sample.mdb`):

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.59 Table: data (shortened for presentation)

We want to extract the following information:

- The set **year**
- The set **loc**
- The set **prd**
- The parameter **sales**
- The parameter **profit**

Output: Several include Files

This can be accomplished using the following GAMS code with multiple queries in a single `SQL2GMS` call (note the usage of the `distinct` operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):

```

$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb

Q1=SELECT distinct(year) FROM data
O1=year.inc

Q2=SELECT distinct(loc) FROM data
O2=loc.inc

Q3=SELECT distinct(prod) FROM data
O3=prod.inc

Q4=SELECT prod, loc, year, sales FROM data
O4=sales.inc

Q5=SELECT prod, loc, year, profit FROM data
O5=profit.inc
$offEcho

$call =sql2gms @howToRead.txt

Set y 'years' /
$include year.inc
/;
Set loc 'locations' /
$include loc.inc
/;
Set prd 'products' /
$include prod.inc
/;

Parameter sales(prd,loc,y) /
$include sales.inc
/;
display sales;

Parameter profit(prd,loc,y) /
$include profit.inc
/;
display profit;

```

This example is also part of the GAMS Data Utilities Library, see model [\[SalesProfitDB6\]](#) for reference.

Output: A single GDX File

The same example imported through a GDX file can look like:

```

$onEcho > howToRead.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb
X=Sample.gdx

Q1=SELECT distinct(year) FROM data
S1=year

Q2=SELECT distinct(loc) FROM data
S2=loc

```

```
Q3=SELECT distinct(prod) FROM data
S3=prd

Q4=SELECT prod, loc, year, sales FROM data
A4=sales

Q5=SELECT prod, loc, year, profit FROM data
A5=profit
$offEcho

$call =sql2gms @howToRead.txt
$call ="%gams.sysdir%studio/studio" Sample.gdx

Set
  y  'years'
  loc 'locations'
  prd 'products';

Parameter
  sales(prd,loc,y)
  profit(prd,loc,y);

$gdxIn sample.gdx
$load y=year prd loc sales profit
$gdxIn

display sales, profit;
```

The call of the [GDXViewer](#) will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model [\[SalesProfitDB7\]](#) for reference.

6.41.5 Interactive Usage

When the tool is called without command-line arguments, it will startup interactively. Using it this way, one can specify options such as the connection string, the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.

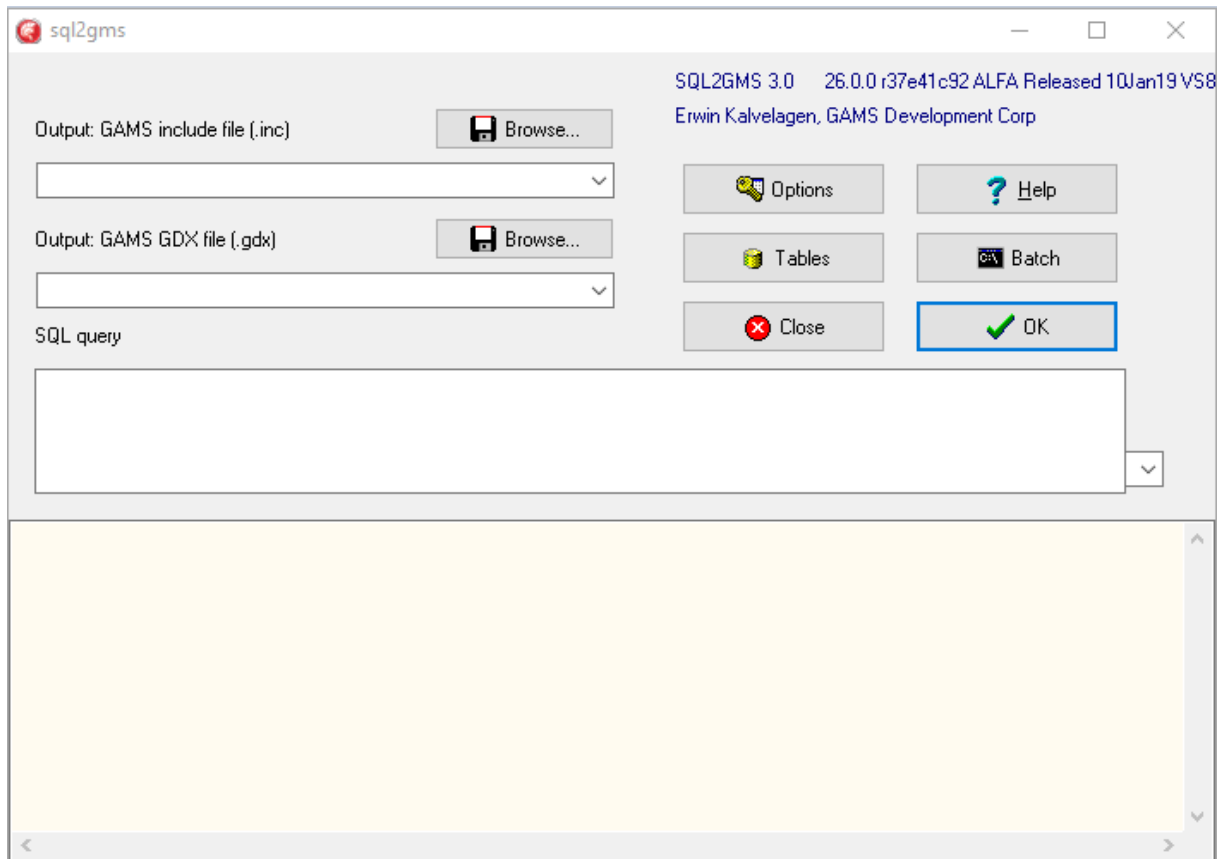

Figure 6.60 SQL2GMS - Graphical User Interface

- **Output GAMS Include file (*.inc).** If you want to create a GAMS include file, then specify here the destination file. See also [outputIncludeFile](#) for some more detailed remarks.

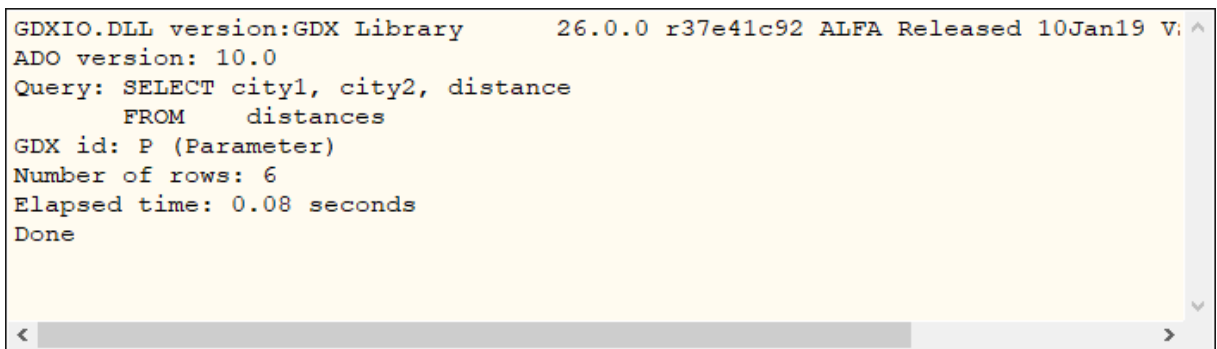

- **Output GDX file (*.gdx).** As an alternative to a GAMS include file, the tool can also generate a [GDX file](#). One or both of the output files need to be specified. See also [outputGDXFile](#) for some more detailed notes.

- **SQL Query.** The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also [Q](#) for some more detailed notes.

- **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).
- The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.

- The **Options button** will pop up a window where you can specify a number of options. The connection string is an important [option](#), which needs to be set correctly before a query can be submitted successfully.

- Pressing the **Help button** will show this documentation.

- Pressing the **OK button** will execute the query and an output file will be generated.

- The **Batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press **Ctrl-C** or choose **Edit|Paste** to copy the contents of the clipboard to a GAMS text file.

- Pressing the **Close button** will exit the application. The current settings will be saved in an INI file so when you run SQL2GMS again all current settings will be restored.

6.41.5.1 Options

The **Options** window can be created by pressing the options button:

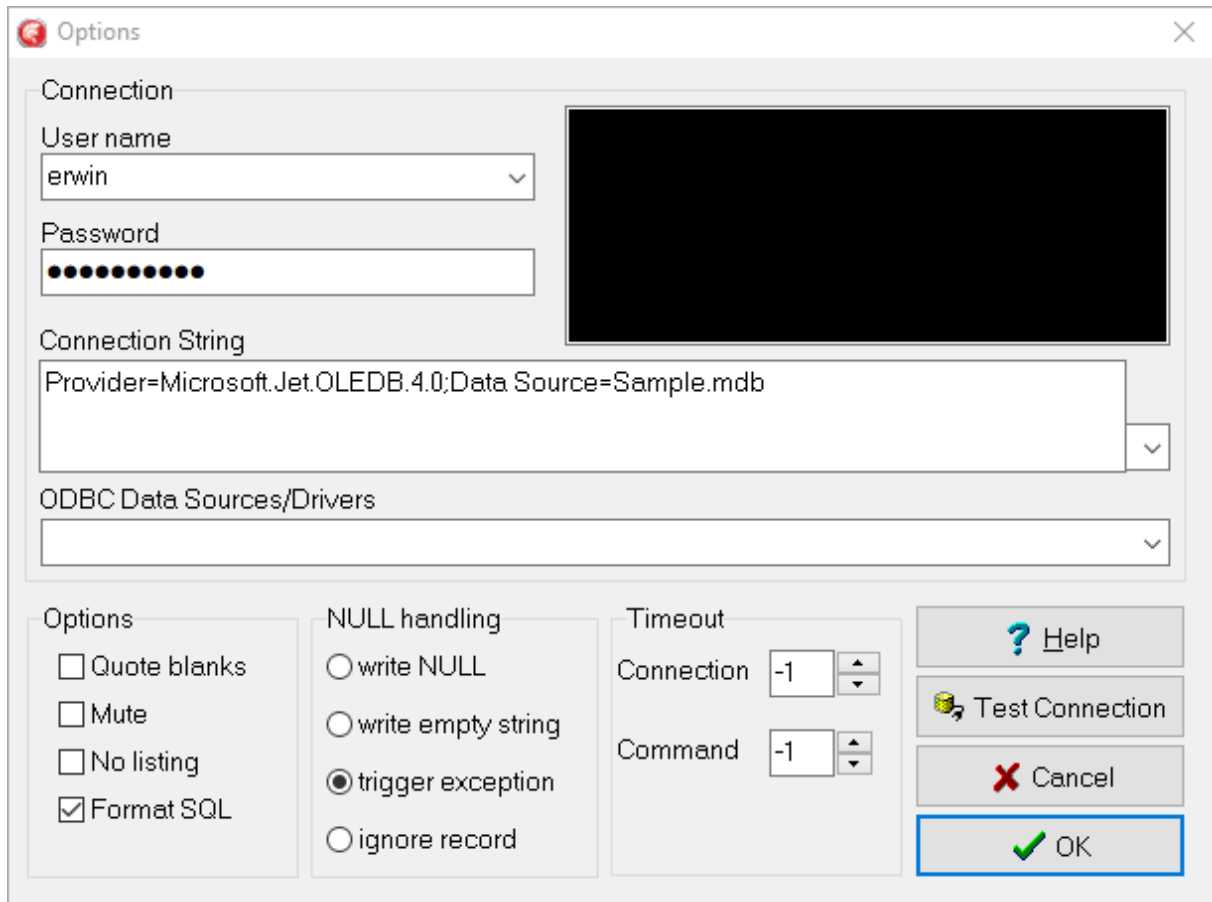

Figure 6.61 Options Menu of the Graphical User Interface

The following options are available in the options window:

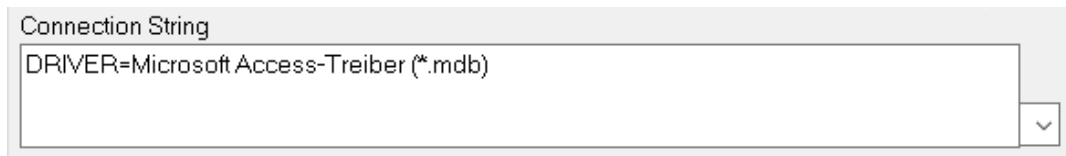

- **User name:** Here you can specify the user name for logging in to the RDBMS. For databases without user authentication, this can be left empty.

User name

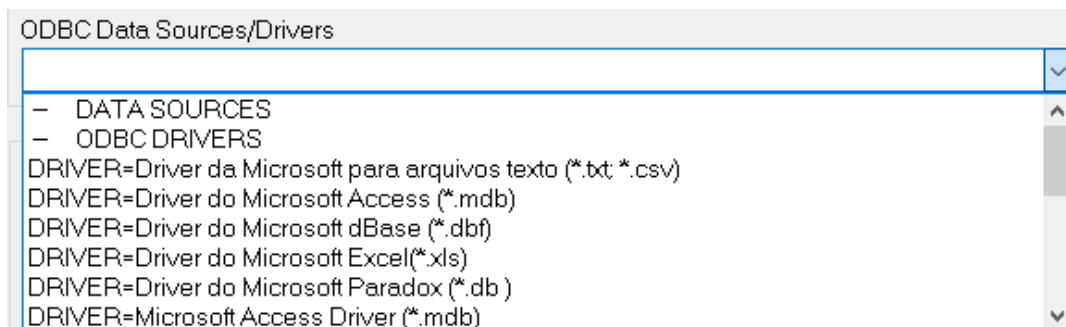

- **Password:** This edit box allows you to specify the password for the database system. The characters are echoed as a '!*!'.

Password

- **Connection String:** The connection string determines how SQL2GMS talks to the database. For more informations see [Connection Strings](#).

- **ODBC Data Sources/Drivers:** This drop down list can be used to compose a connection string when an ODBC data source or driver is involved. The list will show all configured data sources and all available ODBC drivers.

- **Quote blanks:** Quote strings if they contain blanks or embedded quotes. See also [B](#) for some more detailed notes.

Quote blanks

- **Mute:** Don't include the extra informational text (such as used query etc.) in the include file. The equivalent command-line argument is [M](#).

Mute

- **No listing:** Surround the include file by `$offListing` and `$onListing` so that the data will not be echoed to the listing file. The equivalent command-line argument is [L](#).

No listing

- **Format SQL:** If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.

Format SQL

The following options are only needed in special cases:

- **NULL:** This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.

NULL handling

write NULL

write empty string

trigger exception

ignore record

- **Time-out** values for connection time and command execution time expressed in seconds. If -1 is specified then it will use the default value which is 15 seconds for the connection and 30 for the commands. See also [T1](#), [T2](#) resp. [T](#) for some more detailed notes.

Timeout

Connection -1

Command -1

The following buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made and all option settings will revert to their previous values.

- **Help button** will show this documentation.

- **Test Connection** will try to make a connection to the database using the given connection string.

If the settings are correct you will see something like:

```
ADO version: 10.0
Connect OK
Disconnect OK
```

The following options can only be specified in an INI file; there is no interactive equivalent:

Key	Type	Meaning
D		Generate debug output
E		Allow an empty result set; without this option an empty result set will generate an error
R	integer	Row batch size; the default is 100 records

6.41.6 Connection Strings

The connection string determines to which database the tool will try to connect. You can give simply the name of an ODBC Data Source or provide much more elaborate connection strings. Here is an example list:

- [ODBC Examples](#)
- **OLE DB Examples**
- **MS Remote Examples**

For more information consult the documentation with your database driver. ODBC drivers can be had from several sources: Microsoft delivers ODBC with a number of drivers; database providers may have likely an ODBC driver for their RDBMS available and finally there are a number of third party ODBC drivers available (e.g. from <http://www.easysoft.com>).

6.41.7 ODBC Examples

In this section we show a few examples using SQL2GMS with ODBC data sources.

6.41.7.1 ODBC Driver Manager

To configure ODBC data sources use the ODBC Data Source Administrator. This tool can be invoked from the Start button menu: **Settings|Control Panel**, and click on the ODBC Data Sources icon:

Under Windows XP the sequence is: **Control Panel|Performance and Maintenance|Administrative Tools** and click on the **Data Sources (ODBC)** icon. Under Windows 10, access the **Control Panel** at first, type 'odbc' in the top right box and select either 'Set up ODBC data sources (32-bit)' or 'Set up ODBC data sources (64-bit)'. The ODBC Data Source Administrator tool looks like:

To create a new data source, click the **Add** button, select a driver, give it a name (this is the DSN name) and configure the data source.

6.41.7.2 Example 8 - Reading from an MS Access Database

There are several ways to export data from an SQL database into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Access Export. See also [CSV Files](#).
2. Use the [MDB2GMS](#) tool.
3. Use SQL2GMS with a configured ODBC data source. The connection string will look like:

```
"DSN=mydsn".
```

4. Use SQL2GMS with a DSN-less ODBC connection. In this case we need to specify both the driver and the location of the database file explicitly in the connection string. The connection string will look like:

```
"Driver=Microsoft Access Driver (*.mdb, *.accdb);dbq=D:\data\mydata.accdb".
```

5. Use SQL2GMS with an OLE DB driver. The connection string can look like:

```
"Microsoft.ACE.OLEDB.12.0;Data Source=D:\data\mydata.accdb"
```

6.41.7.3 Example 9 - Reading from an MS Excel Spreadsheet

There are numerous ways to export data from an Excel spreadsheet into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Excel Export.
2. Use the [XLS2GMS](#) tool.
3. Use the [GDXXRW](#) tool.
4. Use SQL2GMS with an Excel ODBC connection. An example is shown below.

Consider the spreadsheet ExcelDist.xls:

	A	B	C	D	E
1					
2		city1	city2	Distance	
3		SEATTLE	NEW-YORK	2.5	
4		SAN-DIEGO	NEW-YORK	2.5	
5		SEATTLE	CHICAGO	1.7	
6		SAN-DIEGO	CHICAGO	1.8	
7		SEATTLE	TOPEKA	1.8	
8		SAN-DIEGO	TOPEKA	1.4	
9					

After configuring a data source ExcelDist that uses the Excel ODBC driver and points to the .xls file containing the above sheet, we can use the connection string: "DSN=ExcelDist". With the database browser we see:

I.e. the table name is Sheet1\$. We now can formulate the query: `SELECT city1, city2, distance FROM [Sheet1$]`. We need the brackets to protect the funny table name. The result is (header removed in order to shorten the presentation=:

```
* -----
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----
```

Although other tools are often more convenient to use, this approach is useful if you need to select a subsection of the spreadsheet table. It is easy to select just a few columns or rows from a table using a properly formulated SQL query. The skeleton would be: `SELECT columns_to_extract FROM [sheet1$] WHERE rows_to_extract`.

An example of a more complex spreadsheet is (profit.xls):

	A	B	C	D	E	F
1	<i>year</i>	<i>loc</i>	<i>prod</i>	<i>sales</i>	<i>profit</i>	
2	1997	la	hardwar	80	8	
3	1997	la	software	60	16	
4	1997	nyc	hardwar	110	5	
5	1997	nyc	software	100	10	
6	1997	sfo	hardwar	80	9	
7	1997	sfo	software	50	10	
8	1997	was	hardwar	120	7	
9	1997	was	software	70	20	
10	1998	la	hardwar	70	6	
11	1998	la	software	70	10	
12	1998	nyc	hardwar	120	7	
13	1998	nyc	software	120	14	
14	1998	sfo	hardwar	90	12	
15	1998	sfo	software	70	15	
16	1998	was	hardwar	130	12	
17	1998	was	software	80	15	
18						

A DSN-less connection string would be: "DRIVER=Microsoft Excel Driver (*.xls); DBQ=d:\gams projects\sql2gms\ver2.0\profit.xls". The browser will show:

A possible query that maps the two value columns into a GAMS parameter is:

```
SELECT year, loc, prod, 'sales', sales
FROM [profitdata$]
UNION
SELECT year, loc, prod, 'profit', profit
FROM [profitdata$]
```

The result is (shortened for presentation):

```
* -----
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
1997.nyc.software.sales 100
1997.sfo.hardware.profit 9
1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50
1997.was.hardware.profit 7
1997.was.hardware.sales 120
1997.was.software.profit 20
1997.was.software.sales 70
1998.la.hardware.profit 6
1998.la.hardware.sales 70
* -----
```

This example is also part of the GAMS Data Utilities Library, see model [Excel] for reference.

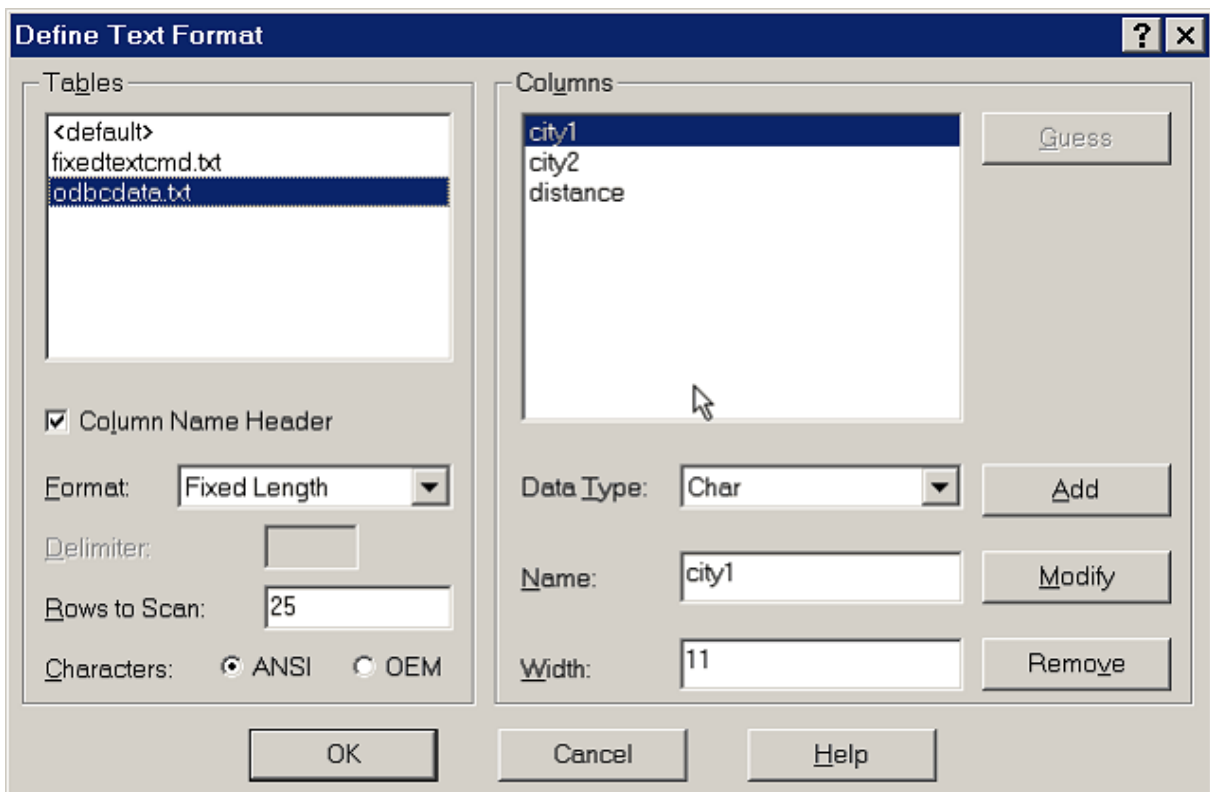

6.41.7.4 Example 10 - Reading from a Text File

Microsoft delivers ODBC with a text file driver which allows you to read a text file as if it is a database table.

A fixed format file such as:

```
City1      City2      Distance
SEATTLE   NEW-YORK   2.5
SAN-DIEGO NEW-YORK   2.5
SEATTLE   CHICAGO    1.7
SAN-DIEGO CHICAGO    1.8
SEATTLE   TOPEKA     1.8
SAN-DIEGO TOPEKA     1.4
```

can be read using Fixed Length setting of the text driver:

The resulting include file will look like:

```
* -----
* SQL2GMS Version 2.0, January 2004
* Erwin Kalvelagen, GAMS Development Corp
* -----
* ADO version:      2.7
* Connection string: DSN=text
* Query:            SELECT city1, city2, distance FROM odbcdata.txt
* Provider:         MSDASQL
* -----
```

```
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
```

* -----

Note that the text file is specified directly within the FROM clause.

A CSV file can be interpreted as a table as well, or any other separated format. We will try to read:

```
City1;City2;Distance
SEATTLE;NEW-YORK;2.5
SAN-DIEGO;NEW-YORK;2.5
SEATTLE;CHICAGO;1.7
SAN-DIEGO;CHICAGO;1.8
SEATTLE;TOPEKA;1.8
SAN-DIEGO;TOPEKA;1.4
```

This can be read using:

The actual formats used are stored by ODBC in an INI file schema.ini (located in the directory of the data files) which can be inspected directly:

```
[odbcdata.txt]
ColNameHeader=True
Format=FixedLength
MaxScanRows=25
CharacterSet=ANSI
Col1=city1 Char Width 11
Col2=city2 Char Width 11
Col3=distance Float Width 10
```

```
[odbcdata2.txt]
ColNameHeader=True
Format=Delimited(;)
MaxScanRows=25
CharacterSet=OEM
Col1=City1 Char Width 255
Col2=City2 Char Width 255
Col3=Distance Float
```

This example is also part of the GAMS Data Utilities Library, see model [Text] for reference.

6.41.8 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.
- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.
- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:

```
Data Extraction --> Data Manipulation --> Model Definition --> Model Solution --> Report Writing
```

we can conveniently use the save/restart facility. The individual submodel are coded as:

- **Step 0 - Data Extraction: sr0.gms**
-

```

$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
$offText

Set
  i 'suppliers'
  j 'demand centers';

Parameter
  demand(j)
  supply(i)
  dist(i,j) 'distances';

$onEcho > howtoRead.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=%system.fp%transportation.accdb

Q1=SELECT name FROM suppliers
O1=i.inc

Q2=SELECT name FROM demandcenters
O2=j.inc

Q3=SELECT name,demand FROM demandcenters
O3=demand.inc

Q4=SELECT name, supply FROM suppliers
O4=supply.inc

Q5=SELECT supplier, demandcenter, distance FROM distances
O5=dist.inc
$offEcho

$call =sql2gms.exe @howtoRead.txt

Set i /
$include i.inc
/;

Set j /
$include j.inc
/;

Parameter demand /
$include demand.inc
/;

Parameter supply /
$include supply.inc
/;

Parameter dist /
$include dist.inc
/;

display i, j, demand, supply, dist;

```

- Step 1 - Data Manipulation: sr1.gms
-

```

$onText
step 1: data manipulation step
execute as: > gams sr1 restart=s0 save=s1
$offText

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;

```

- **Step 2 - Model Definition: sr2.gms**

```

$onText
step 2: model definition
execute as: > gams sr2 restart=s1 save=s2
$offText

Variable
  x(i,j) 'shipment quantities in cases'
  z      'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
  ecost      'define objective function'
  esupply(i) 'observe supply limit at plant i'
  edemand(j) 'satisfy demand at market j';

ecost..      z =e= sum((i,j), c(i,j)*x(i,j));

esupply(i).. sum(j, x(i,j)) =l= supply(i);

edemand(j).. sum(i, x(i,j)) =g= demand(j);

```

- **Step 3 - Model Solution: sr3.gms**

```

$onText
step 3: model solution
execute as: > gams sr3 restart=s2 save=s3
$offText

option lp = cplex;

Model transport / all /;
solve transport using lp minimizing z;

```

- **Step 4 - Report Writing: sr4.gms**

```

$onText
step 4: report writing
execute as: > gams sr4 restart=s3
$offtext

abort$(transport.modelStat <> 1) "model not solved to optimality";

display x.l, z.l;

```

A model that executes all steps can be written as:

```

execute '=gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute '=gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute '=gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute '=gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute '=gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";

```

If you only change the reporting step, i.e. generating some output using PUT statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [SQLSr5] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

SQL2GDX1.gms

```

$onText
Store data from Access database into a GDX file.
$offText

execute '=gams.exe sr0 lo=3 gdx=transport.gdx';
abort$errorLevel "step 0 failed";

execute '=gdxviewer.exe transport.gdx';

```

The model [SQL2GDX1] is also part of the GAMS Data Utilities Library.

We can also let SQL2GMS create the GDX file:

SQL2GDX2.gms

```

$onText
Store data from Access database into a GDX file.
$offText

$onEcho > howToRead.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=%system.fp%transportation.accdb
X=%system.fp%transportation.gdx

Q1=SELECT name FROM suppliers
S1=i

Q2=SELECT name FROM demandcenters

```

```

S2=j

Q3=SELECT name, demand FROM demandcenters
A3=demand

Q4=SELECT name, supply FROM suppliers
A4=supply

Q5=SELECT supplier, demandcenter, distance FROM distances
A5=dist
$offEcho

$call =sql2gms.exe @howToRead.txt

```

The first approach has the advantage that a complete audit record is available from the data moved from the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the database and how this was stored in the GDX file, that file gives the answer.

The model [SQL2GDX2] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

GDXTTRANSPORT.gms

This model demonstrates how to load the transportation data from GDX file at compile time.

```

Set
  i 'suppliers'
  j 'demand centers';

Parameter
  demand(j)
  supply(i)
  dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist
$gdxIn

display i, j, demand, supply, dist;

```

DBTimestamp2.gms

In one application I had to retrieve data from the database each morning, at the first run of the model. The rest of the day, the data extracted that morning could be used. The following logic can implement this:

```

$onText
Retrieve data from data base first run each morning.
$offText

$onEcho > getdate.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=%system.fp%transportation.accdb
Q=select day(now())
O=dbtimestamp.inc
$offEcho

```

```

$if not exist dbtimestamp.inc $call "echo 0 > dbtimestamp.inc"

Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc
/;

Scalar currentday 'day of this run';
currentday = gday(jnow);

display "compare", dbtimestamp, currentday;

if(dbtimestamp<>currentday,
  execute '=gams.exe sr0 lo=3 gdx=transportation.gdx';
  abort$errorLevel "step 0 (database access) failed";

  execute '=sql2gms.exe @getdate.txt'
);

```

The include file `dbtimestamp.inc` contains the day of the month (1,...,31) on which the data was extracted from the database. If this file does not exist, we initialize it with 0. We then compare this number with the current day of the month. If the numbers do not agree, we execute the database extraction step and rewrite the `dbtimestamp.inc` file. This last operation could be done using a PUT statement, but in this case we used an SQL statement.

The model `[DBTimestamp2]` is also part of the GAMS Data Utilities Library.

6.41.9 Parameter Files

Parameters can be specified in an external parameter file. This is important if the length of the command-line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines. Instead of specifying a long command line as in:

```
$call =sql2gms C="DSN=sample" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"
```

we can use a command line like:

```
$call =sql2gms @"c:\My Documents\options.txt"
```

The parameter file

```
c:\My Documents\options.txt
```

can look like:

```
C=DSN=sample
O=c:\My Documents\data.inc
Q=SELECT * FROM mytable
```

It is possible to write the parameter file from inside a GAMS model using the `$echo` command. The following example will illustrate this:

```
$set cmdfile "c:\windows\temp\commands.txt"
$echo "C=DSN=sample" > "%cmdfile%"
$echo "O=E:\models\labor.INC" >> "%cmdfile%"
$echo "Q=SELECT * FROM labor" >> "%cmdfile%"
$call =sql2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

Newer versions of GAMS allow the usage of the `$onEcho` and `$offEcho` commands:

```
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho > "%cmdfile%"
C=DSN=sample
O=E:\models\labor.INC
Q=SELECT * FROM labor
$offEcho

$call =sql2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character `\` as the last character. E.g.:

```
Q=SELECT prod, loc, year, 'sales', sales FROM data \
UNION \
SELECT prod, loc, year, 'profit', profit FROM data
```

6.41.10 Notes

6.41.10.1 ADO

ActiveX Data Objects. Microsoft's data-access object model. An object-oriented architecture for accessing data stored in SQL databases and related data sources. Accessible from a large number of host languages such as VB, C++, Delphi. Supersedes ODBC. Many SQL databases provide ADO access through either OLEDB or ODBC.

6.41.10.2 ODBC

An API and driver manager system for accessing data stored in an RDBMS. The API provides applications a way to talk to databases while the driver manager application allows users to install, configure and manage ODBC drivers for different databases.

6.41.10.3 OLEDB

Driver architecture for SQL databases. A driver is called a OLE DB provider. This is used from [ADO](#).

6.41.10.4 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```
\\<server>\<share>\<path>\<file>
```

Examples:

```
\\athlon\c\My Documents\sql2gms.rtf
```

6.41.10.5 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: [\\$gdxIn](#), [\\$load](#), [execute_load](#), [execute_unload](#). The GDX=filename command-line option will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using [File|Open](#).

6.41.10.6 MDB2GMS

MDB2GMS is a tool to import tables from MS Access databases. This utility directly uses MS Access and DAO (Data Access Objects) resulting in a somewhat simpler interface. It is not needed to specify a connection string, but just a .accdb or .mdb file. The query mechanism is similar: a query is sent as it is to the database server and the result set is translated into a GAMS representation. For more information see [MDB2GMS](#).

6.41.10.7 XLS2GMS

XLS2GMS is a tool to import data from an Excel spreadsheet. It considers the content of a selected range as GAMS source code. For more information [XLS2GMS](#).

6.41.10.8 GDXXRW

GDXXRW is a utility to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet. For more information [GDXXRW](#).

6.41.10.9 Quotes

Examples of handling of indices when the option **B** for quoting strings containing blanks is used:

6.41.10.10 \$CALL Command

The `$call` command in GAMS will execute an external program at compile time. There are two forms:

```
$call externalProgram
```

```
$call =externalProgram
```

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form `$call externalProgram` which uses the command processor.
2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form `$call externalProgram`.
3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form `$call =externalProgram`. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: `$call =externalProgram`.
4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: `$call start /w externalWindowsProgram`. Otherwise, it is preferred to use: `$call =externalWindowsProgram`.

Attention

In general it is recommended to use the `$call =externalProgram` version for its better error-handling.

When command-line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

```
$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2
```

The total length of the command-line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

```
$call '"external program" "parameter 1" "parameter 2"'
$call ="external program" "parameter 1" "parameter 2"
```

It is noted that the first form needs additional quotes around the whole command-line due to bugs in the parsing of the `$call` in GAMS. The second form work without additional quotes *only if* the = appears outside the double quotes.

6.41.10.11 Compile Time Commands

All \$ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed **before** an execution time command, even if it is below. As an example consider:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
$call x.bat
```

This fragment does not work correctly as already during compilation, the \$call is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

```
$echo "dir" > x.bat
$call x.bat
```

or by moving the external program invocation to execution time:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
execute x.bat;
```

Notice that all \$ commands do not include a semi-colon but are terminated by the end-of-line.

6.42 XLS2GMS

Author

Erwin Kalvelagen, GAMS Development Corp

Version

2.4

Date

May 2004

6.42.1 Overview

Note

The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only [GDXXRW](#) is under active development. Therefore, we strongly recommend using [GDXXRW](#) for data exchange with Excel.

XLS2GMS is a tool to convert spreadsheet data from a Microsoft Excel spreadsheet into GAMS readable format. The source is a MS Excel spreadsheet file (*.XLS) and the target is a GAMS Include File.

When running the executable **XLS2GMS.EXE** without command line parameters the tool will run [interactively](#) with a built-in GUI interface. Alternatively XLS2GMS can be run in [batch mode](#) which is useful when calling it directly from a GAMS model using the `$call` command.

The philosophy of the tool is to consider the content of a spreadsheet as **Text**. This text can contain GAMS statements, or parts of GAMS statements (e.g. the data part of a table statement). The text is exported to a GAMS include file where some spacing is introduced to maintain cell boundaries. This allows tables to be exported directly to GAMS include files.

6.42.2 Requirements

XLS2GMS runs only on PC's running Windows (95/98/NT/XP) and with MS Excel installed. Microsoft Excel is included in the MS Office suite.

6.42.3 Converting spreadsheet data to GAMS data

Spreadsheet data are often differently organized than is suitable for import into a GAMS model. In some cases the data is scattered around different sheets, and in a format that is not compatible with a more structured multi-dimensional parameter as are used in a GAMS model. To export spreadsheet data to GAMS parameters, tools will either require a strict format to be used inside the spreadsheet or they will need to offer a complex specification step where the data representation in the spreadsheet is described so that it can be understood by the tool. This tool will use the first approach: the modeler is required to lay-out the data in the spreadsheet in a well defined format. Instead of defining a new format, we use the GAMS language syntax as the required representation. In effect the spreadsheet is considered as an alternative editor for GAMS source code.

As an example consider the GAMS table in the model `[TRANSPORT]` which is part of the `GAMS model library`:

```
Table d(i,j) 'distance in thousands of miles'
      new-york  chicago  topeka
seattle      2.5      1.7      1.8
san-diego    2.5      1.8      1.4;
```

This table can be expressed comfortably in a spreadsheet as follows:

	A	B	C	D	E
1		new-york	chicago	topeka	
2	seattle	2.5	1.7	1.8	
3	san-diego	2.5	1.8	1.4	
4					
5					

XLS2GMS can convert this table into a GAMS include file, which results in:

```
* -----
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----
* Application: Microsoft Excel
* Version:      9.0
* Workbook:    D:\gams projects\xls2gms\ver2.0\Book2.xls
* Sheet:       Sheet1
* Range:       $A$1:$D$3
* -----
      new-york  chicago  topeka
seattle 2.5      1.7      1.8
san-diego 2.5    1.8      1.4
* -----
```

The tool will try to keep cells in a column aligned so that table statements can be used in the GAMS model. The above file **book2.inc** can be imported directly into a GAMS model by:

```
Table d(i,j) 'distance in thousands of miles'
$include book2.inc
;
```

As the tool does not expect any special formatting, we could have include the table statement in the spreadsheet, as in:

	A	B	C	D	E	F
1	table d(i,j) 'distance in thousands of miles'					
2		new-york	chicago	topeka		
3	seattle	2.5	1.7	1.8		
4	san-diego	2.5	1.8	1.4		
5	:					
6						
7						

This would result in:

```
* -----
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----
* Application: Microsoft Excel
* Version:      9.0
* Workbook:     D:\gams projects\xls2gms\ver2.0\Book3.xls
* Sheet:        Sheet1
* Range:        $A$1:$D$5
* -----
table d(i,j) 'distands in thousands of miles'
      new-york  chicago  topeka
seattle  2.5      1.7      1.8
san-diego 2.5      1.8      1.4
;
* -----
```

In some cases the data will need to be copied and massaged to fit into the above format. It is convenient to add a sheet dedicated for this purpose to your workbook. This interface sheet can be filled either manually, with formulas that automatically update values, or by macro's (either recorded or programmed in VBA).

6.42.4 Importing sets

Sets can be directly imported if they are organized vertically. The following picture shows a spreadsheet with two sets with elements {a,b,c} organized vertically (A1:A3) and horizontally (B5:D5).

	A	B	C	D	E
1	a				
2	b				
3	c				
4					
5		a	b	c	
6					

The first set can be imported directly using:

```
Set i /
$call =xls2gms r=a1:a3 i=book4.xls o=set1.inc
$include set1.inc
/;
```

```
display i;
```

The second set is somewhat more difficult, as we need to add a separating comma between the elements. This can be accomplished by:

```
Set j /
$call =xls2gms r=b5:d5 s="," i=book4.xls o=set2.inc
$include set2.inc
/;
```

```
display j;
```

This will generate the include file:

```
* -----
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----
* Application: Microsoft Excel
* Version:      9.0
* Workbook:     D:\gams projects\xls2gms\ver2.0\Book4.xls
* Sheet:        Sheet1
* Range:        $B$5:$D$5
* -----
a,b,c
* -----
```

6.42.5 Importing sets and tables

The table

	A	B	C	D	E	F
1	table d(i,j) 'distance in thousands of miles'					
2		new-york	chicago	topeka		
3	seattle	2.5	1.7	1.8		
4	san-diego	2.5	1.8	1.4		
5	;					
6						
7						

can be considered to contain three pieces of GAMS data:

- The set *i* (seattle, san-diego)
- The set *j* (new-york, chicago, topeka)
- The distances

All this information can be read as follows:

```
Set i /
$call =xls2gms r=a3:a4 i=book3.xls o=seti.inc
$include seti.inc
/;
```

```
Set j /
$call =xls2gms r=b2:d2 s="," i=book3.xls o=setj.inc
$include setj.inc
/;
```

```
Table d(i,j)
$call =xls2gms r=a2:d4 i=book3.xls o=pard.inc
$include pard.inc
;
```

```
display i, j, d;
```

The above \$call statements can be combined onto one as follows:

```
$onEcho > book3a.txt
i=%system.fp%book3.xls
r1=a3:a4
o1=seti.inc
r2=b2:d2
o2=setj.inc
s2=","
r3=a2:d4
o3=pard.inc
$offEcho

$call =xls2gms @book3a.txt

Set i /
```

In this spreadsheet the first two columns are index columns. To make this valid GAMS syntax we need to insert a dot between the index elements. A simple way is to insert a (narrow) column with a dot in each cell. This way we can import this table as:

```
Set
  l 'livestock types'      / sheep, goat, angora, cattle, buffalo, mule, poultry /
  cl 'livestk comm'       / meat, milk, wool, hide, egg /
  ty 'time periods - years' / 1974*1979 /;

$onEcho > yield.txt
I="%system.fp%yield.xls"
R=data!B2:J23
O=yield.inc
$offEcho

$call =xls2gms @yield.txt

Table yieldt1(l,cl,ty) 'livestock "yield" time series (kg per head)'
$include yield.inc
;

display yieldt1;
```

6.42.7 Interactive use

When the tool is called without command line parameters, it will startup interactively. Using it this way, one can specify the spreadsheet file (.XLS file), the range and the final destination file (a GAMS include file) using the built-in interactive environment. The main screen contains a number of buttons and edit boxes, which are explained below.

- **Input file (*.XLS).** This is the combo box to specify the input file. The file must be a valid MS Excel spreadsheet file (*.XLS). The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation `\machine\directory\file.xls`.

- **Range.** The range can be left empty in which case the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). The range can also be a name if the spreadsheet contains named ranges. The browse button will start Excel allowing you to interactively select a range.

- **Output GAMS Include file (*.INC).** If you want to create a GAMS include file, then specify here the destination file. The include file will be an ASCII file that can be read by GAMS using the `$include` command. If the include file already exists, it will be overwritten.

- **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

- **options button** will pop up a window where you can specify a number of options.

- **help button** will show this help.

- the **OK button** is pressed the query will be executed and an include file will be generated.

- the **batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press Ctrl-C or choose Edit|Paste to copy the contents of the clipboard to a GAMS text file.

- **close button** will exit the application. The current settings will be saved in an INI file so when you run XLS2GMS again all current settings will be restored.

6.42.8 Options

The **Options** window can be created by pressing the options button:

The following options are available in the options window:

- **Quote blanks:** Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. (In the special case the string contains both, double quotes are replaced by single quotes). For more information see this example.

Quote blanks

- **Mute:** Don't include the extra informational text (such as used query etc.) in the include file.

Mute

- **No listing:** Surround the include file by `$offlisting` and `$onlisting` so that the data will not be echoed to the listing file. This can be useful for very large data files, where the listing file would become too large to be handled comfortably.

No listing

- **Separator.** This option allows you to set a separator string to be written between cell entries. By default this is a blank. In some cases it can be useful to make this a comma. See [example](#) for an example where this is used to import sets. Note: when this option is set to an empty string, the results may not be syntactically correct for GAMS. As it is difficult to see the difference between a single blank and an empty string, the user interface will give some feedback for these cases. When an empty string is used, a warning is written to the include file.

Output Separator

- **Range Separator.** Multiple ranges can be separated by a range separator symbol. By default this is a semi-colon. When certain non-US locales are used, the semi-colon is a list separator symbol which can be used in multi-area ranges. In case of such a conflict, it is possible to change the range separator symbol.

Range Separator

- **Append.** Append to the output file.

Append

- **Browse Read-Only.** When the Browse Range button is pressed, we launch Excel and try to load the currently specified input file. If this option is checked then the input file is loaded as read-only. If this option is not checked the file is loaded normally, in which case you can change and save it.

Browse Read-Only

The buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made, and all option settings will revert to their previous values.

- **Help button** will show this help text.

6.42.9 Batch use

When calling **XLS2GMS** directly from GAMS we want to specify all command and options directly from the command line or from a command file. An example is:

```
C:\tmp>xls2gms "I=c:\My Documents\test.xls" O=test.inc
```

This call will perform its task without user intervention. The batch facility can be used from inside a GAMS model, e.g.:

```
Table c(i,j) 'data from spreadsheet' /
$call =xls2gms I=C:\tmp\test.xls O=C:\tmp\data.inc R=B1:E10
$include C:\tmp\data.inc
/;
```

The [\\$call statement](#) is rather error prone and you will need to spend a little bit of time to get the call correct and reliable.

All the possible command line options are listed in command line arguments section. A proper batch call will at least contain the following command line parameters:

1. I=inputfilename
2. O=outputincludefile

If you only specify **I=inputfilename** then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command line argument. Only if an input file and an output file is provided, the call will be considered a batch invocation.

6.42.10 Command-line Arguments

Argument	Description
I=inputfile	This option is required and specifies the name of the .XLS file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. If only the file name is used without a path, the file is searched in the current directory (this is the project directory when running under the IDE). On a network UNC names can be used, and files from another computer can be accessed, e.g. "\\hostname\c\my documents\a.xls." This option is required for batch processing.
O=outputincludefile	option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter statement. Make sure the directory is writable. UNC names can be used. An output file must be specified for batch operation.
R=range	range is an optional argument. If not specified the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). To specify a whole sheet use: Sheet2!. The range can also be a name if the spreadsheet contains named ranges. Both global names (e.g. R=rangename) and sheet specific range names (e.g. R=Sheet2!rangename) are recognized. To select multiple ranges in one go, you can specify: R=range1;range2;range3. This is just a short-hand for three separate invocations of xls2gms. A multiple-area range can be specified by R=area1,area2,area3. Before exporting, a new range is created consisting of the union of the areas. This can be used to drop certain rows or columns from a table.
D	Debug. This option can be used for debugging purposes. If specified the import filter will no run minimized but "restored", i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of xls2gms .
B	If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off.
M	Run in modest or mute mode: no additional information, such as version number etc. is written to the listing file.
L	Embed the data in \$offlisting, \$onlisting. A quick way to reduce the size of the listing file.
@filename @"file name"	Causes the program to read options from a file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if it were specified on the command line.
N=inifilename	Use a different Inifile than the standard xls2gms.ini located in the same directory as the executable xls2gms.exe .
A	Append to output files instead of overwriting them.
G="x"	Sets the range separator symbol
S="x"	Sets the output separator symbol

As invocations of **xls2gms** are reasonably expensive (a copy of Excel is started), there is a way to optimize related calls. From version 1.4, xls2gms allows multiple ranges to be read and multiple include files to be written in one swoop. The syntax is best explained by showing an illustrative example:

```
$call =xls2gms I=c:\tmp\x.xls R1=range1 R1=range2 R2=range3 O1=c:\tmp\f1.inc O2=c:\tmp\f2.inc
```

In this example the ranges 'range1' and 'range2' are written to the file 'f1.inc' while the range 'range3' will go to file 'f2.inc'. In general the ranges specified with Rn will be written to the file specified with On. If multiple ranges are specified, they are written sequentially to the output file.

```
$call =xls2gms I=c:\tmp\x.xls R=range1 R=range2 O=c:\tmp\f1.inc
```

In this example the ranges 'range1' and 'range2' are written to 'f1.inc'.

6.42.11 \$CALL command

The **\$CALL** command in GAMS will execute an external program at compile time. There are two forms:

```
$call externalprogram
```

```
$call =externalprogram
```

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=', bypasses the command processor and directly executes the external program. We mention some of the differences:

- Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE.
- If you want to execute these commands you will need to use the form `$call externalprogram` which uses the command processor. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form `$call externalprogram`.
- If it is important to stop with an appropriate error message if the external program does not exist, only use the form `$call =externalprogram`. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: `$call =externalprogram`.
- When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: `$call start /w externalwindowsprogram`. Otherwise, it is preferred to use: `$call =externalwindowsprogram`.

Attention

In general it is recommended to use the `$call =externalprogram` version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

```
$call externalprogram parameter1 parameter2
```

```
$call =externalprogram parameter1 parameter2
```

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

```
$call 'external program' "parameter 1" "parameter 2"
```

```
$call ="external program" "parameter 1" "parameter 2"
```

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the \$call in GAMS. The second form work without additional quotes only if the = appears outside the double quotes.

6.42.12 Command files

Parameters can be specified in a command file. This is important if the length of the command line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command lines. Instead of specifying a long command line as in:

```
$call =xls2gms I="c:\My Documents\test.xls" O="c:\My Documents\data.inc" R="Sheet2!A1:F15"
```

we can use a command line like:

```
$call =xls2gms @"c:\My Documents\options.txt"
```

The command file `c:\My Documents\options.txt` can look like:

```
I=c:\My Documents\test.xls
O=c:\My Documents\data.inc
R=Sheet2!A1:F15
```

It is possible to write the command file from inside a GAMS model using the `$echo` command. The following example will illustrate this:

```
$set cmdfile "transport.txt"
$echo "I=transport.xls" > "%cmdfile%"
$echo "O=transport.inc" >> "%cmdfile%"
$call =xls2gms @"%cmdfile%"

$include transport.inc
```

Newer versions of GAMS allow:

```
$set cmdfile transport.txt
$onEcho > "%cmdfile%"
I=transport.xls
O=transport.inc
$offEcho
$call =xls2gms @"%cmdfile%"

$include transport.inc
```

6.42.13 Multiple-area ranges and post-processing

The following fragment is from a spreadsheet from Unesco:

unesco.xls [Read-Only]										
	A	B	C	D	E	F	G	H	I	J
1	Table 11									
2	Public current expenditure on education									
3										
4						Percentage distribution of current expenditure by level				
5						1990			1996	
6						Pre			Pre-	
7	Country or territory		Teachers' emoluments as percentage of total current expenditure			prim.			prim.	
8						+			+	
9						prim.	Sec.	Tert.	prim.	Sec.
10			1996							
11										
12	Africa									
13										
14	Algeria	
15	Angola		...		96.3	1.	3.7	
16	Benin		♦ 78.6			59.1	21.7
17	Botswana		...		31.1	48.8	12.2	
18	Burkina Faso		52.7		41.7	25.8	32.1		56.6	25.1
19	Burundi		...		46.8	29.1	22.0		42.7	36.7
20										
21	Cameroon		...		70.5	1.	29.5		86.8	1.
22	Cape Verde		...		54.7	17.5	2.7	
23	Central African Republic		...		52.7	14.6	21.5		53.2	16.5
24	Chad		64.4		47.1	20.9	8.2		43.5	24.2
25	Comoros		70.3		42.4	28.2	17.3		36.6	35.1
26	Congo		♦ 83.7			50.4	11.6
27										

Assume we want to extract the 1990 percentage distribution of current expenditure for the countries Algeria through Congo. The range to select is not a contiguous area but consists of several pieces. In Excel we can use the mouse and the Ctrl key to make a multiple selection:

unesco.xls [Read-Only]										
	A	B	C	D	E	F	G	H	I	J
1	Table 11									
2	Public current expenditure on education									
3										
4							Percentage distribution			
5							of current expenditure by level			
6							1990		1996	
7	Country or territory	Teachers' emoluments as percentage of total current expenditure					Pre-prim.			Pre-prim.
8							+		+	
9							prim.	Sec.	Tert.	prim.
10		1996					prim.	Sec.	Tert.	Sec.
11										
12	Africa									
13										
14	Algeria
15	Angola	...			96.3	./.	3.7
16	Benin	♦ 78.6			59.1	21.7	...
17	Botswana	...			31.1	48.8	12.2
18	Burkina Faso	...	52.7		41.7	25.8	32.1	56.6	25.1	...
19	Burundi		46.8	29.1	22.0	42.7	36.7	...
20										
21	Cameroon		70.5	./.	29.5	86.8	./.	...
22	Cape Verde		54.7	17.5	2.7
23	Central African Republic		52.7	14.6	21.5	53.2	16.5	...
24	Chad	...	64.4		47.1	20.9	8.2	43.5	24.2	...
25	Comoros	...	70.3		42.4	28.2	17.3	36.6	35.1	...
26	Congo	♦ 83.7	50.4	11.6	...
27										

The range is A10,E10:G10,A14:A19,E14:G19,A21:A26,E21:G26, where the comma's indicate the range is a multiple-area range. In this case we have six pieces. It is important that Excel understands that the union of the pieces forms a rectangular area. If this is not the case an error will be raised. (You can check this yourself by selecting a multi-area range and copying it to a new sheet: this operation will fail if the areas together don't form a rectangle).

The extracted text file will look like:

```
* -----
* XLS2GMS Version 2.3, March 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----
* Application: Microsoft Excel
* Version: 9.0
* Workbook: D:\gams projects\xls2gms\ver2.0\unesco.xls
* Sheet: Sheet1
* Range: $A$10,$E$10:$G$10,$A$14:$A$19,$E$14:$G$19,$A$21:$A$26,$E$21:$G$26
* -----
```

```
prim. Sec. Tert.
Algeria ... ..
Angola 96.3 ./ 3.7
Benin ... ..
Botswana 31.1 48.8 12.2
'Burkina Faso' 41.7 25.8 32.1
Burundi 46.8 29.1 22
Cameroon 70.5 ./ 29.5
'Cap Verde' 54.7 17.5 2.7
```

```
'Central African Republic' 52.7 14.6 21.5
Chad                        47.1 20.9 8.2
Comoros                     42.4 28.2 17.3
Congo                       ...  ...  ...
```

* -----

This file is not completely suitable for using in a GAMS model. The following edits would need to be made:

1. The header labels should get rid of the trailing dot.
2. Cells with ... should be replaced by blanks.
3. Cells with ./ should be replaced by blanks

In the GAMS distribution a subdirectory **gbin** contains lots of interesting Unix utilities. Some of these are very suited to do string processing on text files, such as **sed** and **awk**. In this case we can use sed with some substitution commands:

Command	Description
s/prim\./prim /	Replace "prim." by "prim ". We need to be careful to keep the table alignment correctly, so we replace the dot by a blank instead of just removing the dot. A dot is a special character in sed (it means "any character") so we escape it by specifying "\."
s/Sec\./sec /	Replace "Sec." by "sec ".
s/Tert\./tert /	Replace "Tert." by "tert ".
s/\.\.\./ /g	Replace "... " by " ". The dots are escaped. We add g to indicate there there may be multiple instances on a line that must be replaced.
s/\./\./ /g	Replace ". ." by " ". Both dots and '/' needs to be escaped.

The complete GAMS formulation can look like:

```
$onText
New version XLS2GMS ver 2.1 can handle
multiple-area ranges.
$offText

Set
  c   'countries'
      / Algeria, Angola, Benin, Botswana, 'Burkina Faso', Burundi, Cameroon
      'Cape Verde', 'Central African Republic', Chad, Comoros, Congo /
  exp 'percentage distribution of current expenditure'
      / prim, sec, tert /;

$onEcho > commands.txt
I=%system.fp%unesco.xls
R=A10,E10:G10,A14:A19,E14:G19
O=unesco.inc
B
$offEcho

$call =xls2gms @commands.txt

$onEcho > sedcommands.txt
```

```

s/prim\./prim /
s/Sec\./sec /
s/Tert\./tert /
s/\.\.\./ /g
s/\.\.\.\./ /g
$offEcho

$call sed.exe -f sedcommands.txt unesco.inc > unescocx.inc

Table distr(c,exp)
$include unescocx.inc
;

display distr;

```

6.43 XLSDUMP

Note

The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only [GDXXRW](#) is under active development. Therefore, we strongly recommend using [GDXXRW](#) for data exchange with Excel.

This program will write all worksheets of an Excel workbook to a.gdx file. Unlike [GDXXRW](#), the program does not require that Excel is installed. Windows platforms only.

6.43.1 Usage

```
XLSDump infile outfile
```

where

infile

A valid Excel workbook

outfile

Optional. The output.gdx file. If no output file is specified, the name of the input file will be used to construct the name the output file.

6.43.2 Example

Consider the following working file 'test2.xlsx'.

Converting this workbook using xlsdump:

```
xlsdump test2.xlsx
```

Will generate the file `test2.gdx`. Showing this.gdx file in the GAMS IDE:

The parameter VF:

6.44 XLSTALK

XLSTalk is not a GDX utility, but as the program is often used with [GDXXRW](#), it is discussed here.

6.44.1 Usage

```
xlstalk <option> {-V} <file> {<parameters>}
```

where

<file>

Excel file name with file extension

<option>

One of the following options; see following table:

Option	Action	Parameter	Return code
-A	Test if Excel is running		0 Excel not running 1 Excel is running
-C	Close file; do not save changes.	<file>	
-E	Test if file exists	<file>	0 File does not exist 1 File exists
-M	Status of file	<file>	0 Not open in Excel 1 File is open and is not modified 2 File is open and has been modified
-O	Open file but do not reload	<file>	
-Q	Quit Excel if no workbooks have been modified	<file>	0 Excel is closed 1 Excel is still running
-R	Run a macro	<file> <macro-name> {<macro-param>}	
-S	Save and close the file	<file>	
-V	Verbose mode		
-W	Wait for the user to close the file	<file>	
-X	Excel version		0 Excel is not installed 1 Excel is installed; version 2003 or earlier 2 Excel is installed; version 2007 or later

6.44.2 Example

In GAMS, the return value can be obtained by using 'errorlevel'.

```
execute 'xlstalk.exe -X';
```

```
Scalar x;  
x = errorLevel;  
display x;
```

Chapter 7

Application Programming Interfaces

The Application Programming Interfaces (APIs) to GAMS allow the seamless integration of GAMS into an application. The APIs provide appropriate classes for the interaction with GAMS. The `GAMSDatabase` class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the `GAMSJob` class and by using the `GAMSModelInstance` class a sequence of closely related model instances can be solved in the most efficient way. Note that the GAMS object-oriented API was not designed to offer modeling capability. The model needs to be formulated in GAMS and passed on to the `GAMSJob` class.

Four versions of [object-oriented GAMS APIs](#) :

- [.NET API](#) with Target Framework Version 4.0,
- [C++ API](#) works with C++11 or later,
- [Java API](#) works with Java SE 8 or later, and
- [Python API](#) works with Python ≥ 3.6 .
- [Matlab API](#) works with Matlab 2017b (or later) and Octave 5.2 (or later).

In addition to the [object-oriented GAMS APIs](#), there exist [expert-level \(or low-level\) GAMS APIs](#) in which its usage requires advanced knowledge of GAMS component libraries. See [Executing GAMS from other Environments](#) if you want to execute GAMS directly from an application without using APIs.

7.1 Object-oriented APIs

The [Reference Manuals](#) give an overview of the features provided by GAMS APIs, release notes, and a list of all classes with descriptions. The [Tutorials](#) provide an overview of the basic functionality of the GAMS APIs and the [Examples](#) provides a list of examples available with GAMS distribution with detailed description. See also [Release Notes](#) and [Supported Platforms](#).

7.1.1 Reference Manuals

The GAMS APIs reference manuals give an overview of the features provided by GAMS APIs, release notes, and a list of all classes with descriptions.

- [.NET API](#)
- [C++ API](#)
- [Java API](#)
- [Python API](#)
- [Matlab API](#)

7.1.2 Tutorials

GAMS API Tutorials provide an overview of basic functionalities of GAMS APIs and allow a user to get started to work with the GAMS API.

- [.NET API Tutorial](#)
- [C++ API Tutorial](#)
- [Java API Tutorial](#)
- [Python API Tutorial](#)
- [Matlab API Tutorial](#)

7.1.3 Examples

There are several examples available for the different programming languages: [.NET](#), [C++](#), [Java](#), and [Python](#). Below we give a description of each example together with its link to the detailed page in different languages.

Examples	.NET	C++	Java	Python
Alias	Alias		Alias	alias.py
Benders2Stage	Benders2Stage, Benders2StageMT		Benders2Stage, Benders2StageMT	benders_2stage.py, benders_2stage_mt.py
Clad	Clad		Clad	clad.py
CutStock	Cutstock, SimpleCutstock		Cutstock-Model, SimpleCutstock, Cutstock	cutstock_class.py, simple_cutstock.py, cutstock.py
Domain Checking	DomainChecking	domainchecking.cpp	DomainCheck	domain_checking.py
Graphical User Interface (GUI)				
- CutstockGUI	CutStockGUI			
- FarmGUI	FarmGUI			
- InterruptGUI	InterruptGui		InterruptGUI	interrupt_gui.py
- TransportGUI	TransportGUI		TransportGUI	
GAMS Remote Object	GAMSServer, GAMSCient			
Interrupt	Interrupt		ConsoleInterrupt	interrupt.py
Markowitz	Markowitz			markowitz.py
MessageReceiver Window	MessageReceiverWindow			
Special Values	SpecialValues		SpecialValues	special_values.py
Transport Model Sequence	Transport, Transport1 - Transport14	transport.cpp, transport1.cpp - transport14.cpp	Transport-Model, Transport1 - Transport14	transport_class.py, transport1.py - transport14.py

Examples	.NET	C++	Java	Python
Traveling Salesman Problem	Tsp		Tsp	tsp.py
Warehouse	Warehouse	warehouse.cpp	Warehouse	warehouse.py
Unit Test	NUnitTest			

These examples are available with the GAMS distribution in [Path/To/GAMS]/apifiles/ directory. In that directory, the file `readme.txt` describes how to build and execute these examples. A GAMS script to compile and execute each example is available in [Path/To/GAMS]/apilib.ml/ directory with a **table of contents**.

7.1.3.1 Alias

The Object-oriented API does not have the concept of a GAMS alias. An alias cannot be entered into a GAMSDatabase by API methods. Nevertheless, if the GAMSDatabase is loaded from a GDX container (e.g. the GAMSJob.OutDB), the database can contain aliases. Such an alias can be retrieved as a GAMSSet and consists of the elements of the aliased set. The method to find out if a GAMSSet in a GAMSDatabase is indeed an alias is to check if the symbol name is different from the lookup name (i.e. `bool isAlias = db.GetSet("ii").Name != "ii"`). This example model goes through the logic of how aliases are handled in the Object-oriented API.

See Alias example in [[.NET](#), [Java](#), [Python](#)].

7.1.3.2 Benders2Stage

This example implements a simple Benders decomposition method for a stochastic linear program. The underlying model implements a simple distribution system with stochastic demand data. This example actually consists of two programs: A sequential and a parallel implementation. In the sequential version, the master and the subproblems are implemented with the GAMSModelInstance object which allows resolving the model with modified input without regenerating the model. A GAMSModelInstance has a fixed model rim, so this provides a challenge for Benders master problem because every iteration adds new constraints (the Benders cuts) to the master. We get around this limitation of GAMSModelInstance by initializing the GAMSModelInstance of the master with a fixed number of empty (i.e. non-binding) placeholder constraints and during the run of the algorithm turn these placeholder constraints into valid Benders cuts. The parallel version extends the Benders2Stage example by solving the independent subproblems in parallel. For that we need to instantiate a separate GAMSModelInstance for each parallel worker. We use the efficient GAMSModelInstance.CopyInstance method to accomplish this in the most effective way. The number of demand scenarios can be larger than the number of parallel workers. The distribution of work is handles through a work queue. The parallel execution of the subproblems is done in separate threads (the MT in the name of the example stands for Multi Threading), so there is very little overhead from disk activity.

See Bender2Stage example in [[.NET](#), [Java](#), [Python](#)] and Bender2StageMT example in [[.NET](#), [Java](#), [Python](#)].

7.1.3.3 Clad

This example demonstrates how to implement a complex termination criterion for a difficult MIP using GAMS/Cplex. We would like to achieve a globally optimal solution (relative gap 0%) but if solution time becomes larger than n1 seconds, we can compromise for a 10% gap, and if this is not achieved after n2 seconds, we compromise for a 20% gap, and again if this is not accomplished in n3 seconds we take whatever the solver has done so far and terminate the solve. This is implemented by executing GAMSJob.run in an independent thread and providing new tolerances for the relative gap in the main thread by supplying new GAMS/Cplex option files and triggers the processing of the new tolerance option by GAMS/Cplex through the GAMSJob.Interrupt method.

See Clad example in [[.NET](#), [Java](#), [Python](#)].

7.1.3.4 CutStock

This example contains two programs that implement a column generation approach to solve the cutting stock problem. In the program SimpleCutstock, the column generation scheme has been implemented in GAMS. Moreover the GAMS model with the input and output data has been wrapped in a class that separates all interaction with GAMS from the driving application. In the second example, the column generation approach has been entirely implemented in the program using GAMSJob for the master and GAMSModelInstance for the pricing problem. GAMS is used to build the master and pricing problems. The logic of the column generation method is in the application program.

See Cutstock Model example in [[.NET](#), [Java](#), [Python](#)], SimpleCustock example in [[.NET](#), [Java](#), [Python](#)], and Custock example in [[.NET](#), [Java](#), [Python](#)].

7.1.3.5 Domain Checking

Enforcing referential integrity also known in the GAMS lingo as domain checking is an essential and important part of GAMS. The Object-oriented API does a delayed domain checking of symbols. So you can add records to a domain controlled parameter (e.g. p(i)) even though the GAMSSet i does not contain the label (yet). The user can trigger an explicit check of the referential integrity by calling the GAMSDatabase.CheckDomains (or GAMSSymbol.CheckDomains). The Object-oriented API provides methods to access the records that violate the referential integrity (see GAMSDatabaseDomainViolation for details). Domain checking is implicitly done when the GAMSDatabase is exported to a GDX file via the GAMSDatabase.Export method or for databases provided in the GAMSJob.Run method. The implicit domain check can be suppressed (and left to GAMS when importing data) via the GAMSDatabase.SuppressAutoDomainChecking property. This example demonstrates how to trigger domain checking and how to access the records that violate the referential integrity.

See Domain checking example in [[.NET](#), [C++](#), [Java](#), [Python](#)].

7.1.3.6 GUI Examples

Modern development frameworks like Microsoft's Visual Studio, Python, and Java allow to quickly build graphical user interfaces. Every example consists of a simple GUI that provides data entry, executing of a GAMSJob and graphically represents the results of a GAMS model.

- **CutstockGUI:** This example allows to either load data from a database or to enter data manually. A cutting stock problem is solved by using both the GAMSJob and the GAMSModelInstance class in order to implement a decomposition approach. See also [CutStock Example](#). See this example in [[.NET](#)].
 - **InterruptGUI:** This small example demonstrates how to run a GAMS model in a graphical user interface. This has all rudimentary features we know from the GAMS IDE: starting a job, capture the GAMS log in a window, and providing a button to interrupt. The underlying mechanism to interrupt the job is similar to the [Interrupt Example](#) (GAMSJob.Interrupt), but the trigger mechanism is very different. See this example in [[.NET](#), [Java](#), [Python](#)].
 - **FarmGUI:** For this farming model, the input data can be entered directly into several tables. The GAMS model itself is executed by using one single GAMSJob instance. Results are displayed in different charts and tables. See this example in [[.NET](#)].
 - **TransportGUI:** In this example a series of transportation problems is solved using GAMSModelInstance. Data can be entered into tables or can be loaded from a database. When data is entered into a table, related tables are updated automatically. Results are shown in tables and/or a bar chart. See also [Transport Model Sequence Example](#). See this example in [[.NET](#), [Java](#)].
-

7.1.3.7 GAMS Remote Object

This example demonstrates how to implement a simple GAMS Server. The example has two parts: GAMSSErver and GAMSClient. The example is configured to run the client and server on the same machine, but can easily be altered to run on different machines. Both client and server need access to the GAMSRemoteClass that implements the server. The method to communicate is very simple. The client sets up the ingredients for a GAMSJob (model text, GDX input, parameters) and sends them serialized (via a byte representation of the GDX and parameter file) to the server. The server recreates the GAMS objects from the serialized representations, runs the model, and ships GAMSJob.OutDB serialized back to the client for further processing.

See GAMSSErver example in [[.NET](#)] and GAMSClient in [[.NET](#)].

7.1.3.8 Interrupt

Ctrl-C in a regular console application results in the interrupt of the entire job. GAMS users are used to the fact that Ctrl-C interrupts a solve but then continues with the execution of the remaining GAMS job. The example demonstrates how to alter some console properties to get this behavior of Ctrl-C.

See Interrupt example in [[.NET](#), [Java](#), [Python](#)].

7.1.3.9 Markowitz

This is a small graphical program that plots the efficient frontier of Markowitz' portfolio selection problem with the two objectives return and risk. The example utilizes the GAMSModelInstance class to solve the parameterized objective $\max \lambda \text{return} - (1-\lambda) \text{risk}$ in the most efficient way.

See Markowitz example in [[.NET](#), [Python](#)].

7.1.3.10 MessageReceiver Window

The little example demonstrates how to implement a custom visual log. From GAMS one can send messages to the form started by this program via the put_utility "winmsg". The form also understands some commands (a message that starts with @) to save the content of the form, to put the content into the clipboard, or to terminate the program. The MessageReceiverWindow is also distributed as an executable in the GAMS system directory ready to be used. The model mrw01 in the GAMS Test Library demonstrates the use of the program.

See MessageReceiver Window example in [[.NET](#)].

7.1.3.11 Special Values

This example shows how special values of the programming language (e.g. infinity) percolate down to GAMS. Infinity and NaN (not a number) are well defined. The GAMS Undefined and EPS need special considerations.

See Special Values example in [[.NET](#), [Java](#), [Python](#)].

7.1.3.12 Transport Model Sequence

This set of examples demonstrates the use of the Object-oriented API on the simple transport model **transport.gms : A Transportation Problem** [transport]. The detailed description of the various examples is provided in the Object-oriented API tutorials in the GAMS documentation.

See Transport Model example in [[.NET](#), [C++](#), [Java](#), [Python](#)].

7.1.3.13 Traveling Salesman Problem

This example demonstrates how to use a GAMSModelInstance to implement the subtour elimination algorithm for the Traveling Salesman Problem (TSP) problem. Similar to [Benders2Stage example](#), we have a placeholder for the subtour elimination constraint that gets generated in each iteration of the algorithm. In contrast to the Benders example, here we regenerate the GAMSModelInstance if the original number of placeholders was not big enough. We continue this process until all subtours are eliminated.

See Traveling Salesman Problem example in [[.NET](#), [Java](#), [Python](#)].

7.1.3.14 Unit Test

This example contains all the unit tests we run on the .Net Object-oriented API. See Unit Test example in [[.NET](#)].

7.1.3.15 Warehouse

This example demonstrates how to solve a simple GAMS model to assign stores to warehouses for different data sets in parallel. The model has been parameterized. The data can be derived from a few numbers namely the number of warehouses, stores, and some fixed cost scalar. The results of the model are written into a single result database that is protected across the parallel threads via a mutex.

See Warehouse example in [[.NET](#), [C++](#), [Java](#), [Python](#)].

7.1.4 Release Notes

GAMS API Release Notes provide an overview of changes to the GAMS APIs in releases of the GAMS distribution.

- [.NET API Release Notes](#)
- [Java API Release Notes](#)
- [Python API Release Notes](#)

7.1.5 Supported Platforms

	x86 64bit MS Windows	x86 64bit Linux	x86 64bit Mac OS X
GAMS C++	✓	✓	✓
GAMS Java	✓	✓	✓
GAMS.NET	✓	✓	✓
GAMS Python	✓	✓	✓
GAMS Matlab	✓	✓	✓

7.2 Expert-Level APIs

In addition to the object-oriented GAMS API, there exist expert-level (or low-level) APIs to some component libraries of the GAMS system. These APIs are used internally in GAMS for a long time and help in the deployment of GAMS models. While they offer high performance and flexibility, they also require advanced knowledge and it is recommended that the object-oriented GAMS API is used if possible. The expert-level APIs are offered for *C*, *C#*, *Delphi*, *Fortran*, *Java*, *Python*, and *Visual Basic*.

The DCT, GEV, and GMO components are mainly used to build solver links to GAMS (see, e.g., the [GAMSLinks project](#)). In fact, all professional GAMS solver links are based on these components. They provide access to an instance of a model generated by a `solve` statement. If you plan to build advanced algorithms for models or need to solve a sequence of very similar models these components might represent an alternative to an implementing using the GAMS language.

While we also strive for backward compatibility with our component libraries, but programming interfaces are commonly subject to change, so programs based on these APIs might require adjustment when updating to a new GAMS version. The [Release Notes](#) have a section on these API changes.

Overviews of the exported function in pseudo code are available in the following summary pages:

- [CFG API](#) (GAMS Configuration Object)
- [DCT API](#) (GAMS Dictionary Object)
- [GDx API](#) (GAMS Data Exchange Object) with additional information available as [PDF](#) and [CHM](#).
- [GEV API](#) (GAMS Environment Object) with additional [GAMS Environment Object Options](#).
- [GMO API](#) (GAMS Modeling Object) with additional information on [philosophy and design](#).
- [IDX API](#) (GAMS IDX Object)
- [OPT API](#) (GAMS Option Object)
- [PAL API](#) (GAMS Auditing and Licensing Object)

Note

Without having a GAMS system directory in the `PATH` environment variable, the `xyzCreated` functions (e.g. `gdxCreated`, `optCreated`, ...) might cause some issues finding libraries that are only in the GAMS system directory on Windows.

7.2.1 Supported Platforms

	x86 64bit MS Windows	x86 64bit Linux	x86 64bit Mac OS X
C	✓	✓	✓
C#	✓		
Delphi	✓		
Fortran*	✓	✓	✓
Java	✓	✓	✓
Python	✓	✓	✓
VBA	✓		
VB.NET	✓		

- Fortran API files are based on C code to load dynamic libraries. For Windows pure Fortran API files for Intel and Lahey Fortran compilers are included

7.3 C++ API

GAMS C++ API provides a convenient way to exchange input data and model results with in-memory representation of data (**GAMSDatabase**), and to create and run GAMS models (**GAMSJob**) that can be customized by GAMS options (**GAMSOptions**). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (**GAMSModelInstance**).

7.4 Java API

GAMS Java API provides a Java programming interface to the General Algebraic Model System (GAMS). GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

The underlying GAMS engine relies to some extent on file based communication (e.g. the listing file) and other unmanaged resources. The use of external resources in the Java environment requires special attention. Hence, some objects need to be properly disposed before the Java garbage collector does its job.

A GAMS program can include other source files (e.g. \$include), load data from GDX files (e.g. \$GDXIN or execute_load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base object GAMSWorkspace manages the anchor to the file system.

With the exception of GAMSWorkspace the objects in the gams namespace cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GAMSModelInstance class).

Note

If you use multiple instances of the GAMSWorkspace in parallel, you should avoid using the same WorkingDirectory. Otherwise you may end up with conflicting file names.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving GAMSModelInstances. Some solvers will not work in a multi-threaded application using GAMSModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, GAMSModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This version of the GAMS Java API also does not provide support for the following GAMS components: acronyms, GAMS compilation/execution errors, structured access to listing file, and solver options.

7.5 Python API

The `gams` namespace provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this namespace allow convenient exchange of input data and model results (`GamsDatabase`), help to create and run GAMS models (`GamsJob`), that can be customized by GAMS options (`GamsOptions`). Furthermore, it introduces a way to solve a sequence of closely related model instances in the most efficient way (`GamsModelInstance`).

A GAMS program can include other source files (e.g. `$include`), load data from GDX files (e.g. `$GDXIN` or `execute_load`), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base class `GamsWorkspace` manages the anchor to the file system. If external file communication is not an issue in a particular Python application, temporary directories and files will be managed by objects in the namespace.

With the exception of `GamsWorkspace` the objects in the `gams` namespace cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the `GamsModelInstance` class).

Note

If you use multiple instances of the `GamsWorkspace` in parallel, you should avoid using the same working directory. Otherwise you may end up with conflicting file names.

This version of the `gams` namespace lacks support for the following GAMS components:

Acronyms, support for GAMS compilation/execution errors (`GamsJob.run` just throws an exception), structured access to listing file, and proper support for solver options.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving `GamsModelInstances`. Some solvers will not even work in a multi-threaded application using `GamsModelInstances`. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, `GamsModelInstances` are not available for quadratic model types (QCP, MIQCP, RMIQCP).

The GAMS Python API collection contains further packages and modules for specific applications, some of which are currently in beta status. The [gams.magic API](#) (beta) allows to integrate GAMS into Jupyter notebooks. The API [gams2numpy](#) (beta) communicates data between GAMS and numpy arrays. [gamstransfer](#) (beta) simplifies the work of reading and writing GDX files. The used data structures allow data to be easily converted directly to Pandas DataFrames (or other native Python data types). The `gams_engine` API allows the creation of Python clients for [GAMS Engine](#).

7.5.1 Jupyter Notebooks

Note

This feature is currently in beta status.

7.5.1.1 Introduction

GAMS Jupyter Notebooks allow to use notebook technology in combination with GAMS. If you just want to learn GAMS there are probably better ways doing this. Notebooks allow you to combine GAMS and Python. The former works great with well structured data and optimization models, while the latter is very rich in features to retrieve, manipulate, and visualize data that comes in all sort of ways. Combining GAMS and Python in a notebook it is relatively easy to tell an optimization story with text, data, graphs, math, and models.

7.5.1.2 Getting Started

The first step in getting started with GAMS Jupyter Notebooks is to make your Python 3 installation aware of the GAMS Python API collection described in the [Getting started](#) section of the API tutorial. We recommend to follow the steps below which are specifically tailored for getting started with GAMS Jupyter notebooks. While any Python ≥ 3.6 installation is supported, we recommend the use of Anaconda or Miniconda Python distributions.

In addition to the GAMS Python API collection, the packages `jupyterlab`, `matplotlib`, `pandas`, and `tabulate` are required in order to enable GAMS Jupyter Notebooks and to run the provided examples which are located in `apifiles/Python/jupyter_examples`. The following code section shows how to create and set up a Miniconda Python environment for GAMS Jupyter notebooks:

Windows:

```
conda create -n gmsjupyter python=3.8 jupyterlab pandas tabulate matplotlib
conda activate gmsjupyter
cd C:\GAMS\33\apifiles\Python\api_38
python setup.py install (In case of permission problems run the following instead: python setup.py b
cd C:\jupyter (or another directory that should be used for your notebooks)
jupyter notebook (this will start the jupyter notebook server)
```

Linux:

```
conda create -n gmsjupyter python=3.8 jupyterlab pandas tabulate matplotlib
conda activate gmsjupyter
cd ~/gams/gams33.1_linux_x64_64_sfx/apifiles/Python/api_38
python setup.py install (In case of permission problems run the following instead: python setup.py b
cd ~/jupyter (or another directory that should be used for your notebooks)
jupyter notebook (this will start the jupyter notebook server)
```

macOS:

```
conda create -n gmsjupyter python=3.8 jupyterlab pandas tabulate matplotlib
conda activate gmsjupyter
python /Library/Frameworks/GAMS.framework/Resources/apifiles/Python/api_38/setup.py build -b $TMPDIR
cd ~/jupyter (or another directory that should be used for your notebooks)
jupyter notebook (this will start the jupyter notebook server)
```

The notebooks `Millco.ipynb` and `Introduction.ipynb` located in `apifiles/Python/jupyter_examples` are good starting points to get familiar with Jupyter notebooks and GAMS. The [Tutorial](#) in this documentation is derived from the `Introduction.ipynb` notebook.

7.5.1.3 Tutorial

GAMS Jupyter Notebooks allow to use notebook technology in combination with GAMS. If you *just* want to learn GAMS there are probably better ways doing this. Notebooks allow you to combine GAMS and Python. The former works great with well structured data and optimization models, while the latter is very rich in features to retrieve, manipulate, and visualize data that comes in all sort of ways. Combining GAMS and Python in a notebook it is relatively easy to tell an optimization *story* with text, data, graphs, math, and models.

The GAMS Jupyter Notebook builds on top of the Python 3 kernel. So by default the notebook cells are Python cells. Cells can be turned into GAMS cells, i.e. cells with GAMS syntax, using the Jupyter magic facility (first line in a cell is `%gams`). GAMS magic commands enable GAMS support in Python Jupyter notebooks. Beside running GAMS code, it is possible to transfer data between GAMS and Python. In order to enable the GAMS magic commands, it is required to load the extension `gams_magic`:

```
In:
%load_ext gams_magic
```

There are a few other useful command in connection with running GAMS in a Jupyter notebook. Some transformation functions for pandas dataframes useful for exchange with GAMS have been collected in the `DataTransform.ipynb`. The next cell will execute that notebook and make such data transformation function, e.g. `gt_from2dim` (see below) available in this notebook. `%capture` captures the output from the execution of the notebook and does not clutter your output.

```
In:
%%capture
%run ~/share/DataTransform.ipynb
```

Somehow one output from a cell is sometimes not enough, e.g. if you want to display a couple of tables. The display function allows you to do this but needs to be imported. As an example, we display a Python list:

```
In:
from IPython.display import display
display([1,2,3])
```

```
[1, 2, 3]
```

7.5.1.3.1 Running GAMS code Running GAMS code can be done by using either `gams` (line magic) or `%gams` (cell magic). While `gams` can be used for running a single line of GAMS code, `%gams` makes the whole cell a GAMS cell.

```
In:
%gams set i;
```

```
In:
%%gams
set j;
parameter p(i,j);
parameter p2(i,j);
```

The GAMS compiler and execution system has been adjusted so one can run a GAMS cell multiple time, even if it contains a declaration or an equation definition, which is normally not possible in the GAMS system. The execution of the next two cells does not create a problem, which mimics the execution, modification, and reexecution of a cell.

```
In:
%%gams
set i / peter,paul,mary /, j / A,B,C /;
parameter p2(i,j) / set.i.set.j 1 /;
```

```
In:
%%gams
set i / i1*i5 /, j / j1*j5 /;
parameter p2(i,j) / set.i.set.j 1 /;
```

You won't see any output from a GAMS cell (unless there is a solve executed in the cell, see below). All output goes to the log and lst file. If you really need to see this you can use magic command `gams_log` and `gams_lst` to display the content of the log and listing file of the most recent GAMS execution. The next cell displays the content of listing file of the last run GAMS cell or line magic. The `-e` only display the section of the listing file associated with the execution:

```
In:
%gams display p2;
%gams.lst -e
```

E x e c u t i o n

```

-----      11 PARAMETER p2

              j1          j2          j3          j4          j5

i1          1.000        1.000        1.000        1.000        1.000
i2          1.000        1.000        1.000        1.000        1.000
i3          1.000        1.000        1.000        1.000        1.000
i4          1.000        1.000        1.000        1.000        1.000
i5          1.000        1.000        1.000        1.000        1.000

```

There is a limit to the execution, modification, and reexecution of GAMS cells. If the type or the dimensionality of a symbol changes, you will need to execute the notebook from scratch and do a controlled reset of the entire GAMS database via `gams_reset`. For example, since we declared parameter `p2` already over `(i,j)` we cannot change our mind and redeclare `p2` as `parameter p2(i,i,j)`:

In:

```
%gams parameter p2(i,i,j);
```

This will give you a compilation error and an exception in the cell execution (uncomment the line in the next cell to do so):

In:

```

#%gams parameter p2(i,i,j);
#%gams.lst

```

With a `gams_reset` we can reset the GAMS database and can declare symbols with a different type and domain/dimension. All other things in the GAMS database are gone, too. So we need to redeclare the sets `i` and `j`, too. The state of the GAMS database is kept in various files that can easily clutter your directory. The `gams_cleanup` call helps you to clean the directory of temporary files. The option `-k` keeps the most recent GAMS database, hence the `gams_cleanup -k` is a save call anywhere in your notebook.

In:

```

%gams_reset
%gams set i,j; parameter p(i,j), p2(i,i,j);
%gams_cleanup -k

```

7.5.1.3.2 Pushing Data from Python to GAMS `gams_push` transfers data from Python to GAMS. Supported data types for pushing data are lists, `pandas.DataFrame` and `numpy` arrays:

In:

```

# Define Python lists with data
i = ['i1', 'i2', 'i3']
j = ['j1', 'j2']
p = [('i1', 'j1', 1.1), ('i1', 'j2', 2.2), ('i2', 'j1', 3.3), ('i2', 'j2', 4.4), ('i3', 'j1', 5.5), ('i3', 'j2', 6.6)]
%gams_push i j p

```

As mentioned above the execution of a `%gams` cell or `gams` and `gams_push` line magic does not produce output. If one wants to verify that the data ended up in GAMS we can `display` the symbols in GAMS and output the corresponding part of the listing file:

In:

```

%gams display i,j,p;
%gams.lst -e

```

E x e c u t i o n

```

----      12 SET i

i1,      i2,      i3

----      12 SET j

j1,      j2

----      12 PARAMETER p

                j1          j2

i1          1.100          2.200
i2          3.300          4.400
i3          5.500          6.600

```

The next cell turns a Python list into a pandas.DataFrame, multiplies the value by 2 and displays the dataframe with IPython's `display`. We actually display the transformed `p2` (via function `gt_pivot2d` found in the `DataTransformation` notebook run at the top of the notebook), so the table looks nicer. Next, we send the pandas.DataFrame down to GAMS via the `gams_push` command. Via the GAMS `display` and the output of the relevant part of the listing file we see that the `gams_push` succeeded:

In:

```

import pandas as pd
# turn the Python list p into a pandas.DataFrame p2 and send this down to GAMS
pp = pd.DataFrame(p)
# multiply the value by 2:
pp[2] = 2*pp[2]
# display a nicer version of the dataframe:
display(gt_pivot2d(pp))
%gams parameter pp(i,j)
%gams.push pp
%gams.display pp;
%gams.lst -e

```

	j1	j2
i1	2.2	4.4
i2	6.6	8.8
i3	11.0	13.2

E x e c u t i o n

```

----      18 PARAMETER pp

                j1          j2

i1          2.200          4.400
i2          6.600          8.800
i3          11.000         13.200

```

When using numpy arrays in order to push data into GAMS, the data is assumed to be dense. The corresponding sets are defined automatically from `1..n`, `1..m`, etc depending on the data that is pushed.

In:

```
import numpy as np
data = [[[1.1,-1.1], [2.2,-2.2]], [[3.3,-3.3], [4.4,-4.4]], [[5.5,-5.5], [6.6,-6.6]]]
p3 = np.array(data)
```

In:

```
%gams set i, j, k; parameter p3(i,j,k);
%gams.push p3
%gams display i,j,k,p3;
%gams.lst -e
```

E x e c u t i o n

```
----      23 SET i

1,      2,      3

----      23 SET j

1,      2

----      23 SET k

1,      2

----      23 PARAMETER p3  3-dim Matrix

              1              2

1.1          1.100          -1.100
1.2          2.200          -2.200
2.1          3.300          -3.300
2.2          4.400          -4.400
3.1          5.500          -5.500
3.2          6.600          -6.600
```

7.5.1.3.3 Pulling Data from GAMS to Python The line magic `gams_pull` transfers data from GAMS to Python in different formats. Supported formats are lists (default), `pandas.DataFrame` and `numpy` arrays. The following example pulls the sets `i`, `j`, and parameter `p3` from GAMS into lists. For multi-dimensional symbols the records become Python tuples. Currently, the renaming functionality `gams_pull gamsSym=pySymbol` is not yet supported.

In:

```
%gams.pull p3 i j
display(i,j,p3)
```

```
['1', '2', '3']

['1', '2']

[('1', '1', '1', 1.1),
 ('1', '1', '2', -1.1),
 ('1', '2', '1', 2.2),
 ('1', '2', '2', -2.2),
 ('2', '1', '1', 3.3),
```

```
( '2', '1', '2', -3.3),
( '2', '2', '1', 4.4),
( '2', '2', '2', -4.4),
( '3', '1', '1', 5.5),
( '3', '1', '2', -5.5),
( '3', '2', '1', 6.6),
( '3', '2', '2', -6.6)]
```

The switch `-d` will populate `pandas.DataFrames` instead of lists with the GAMS data. The dataframes that are pushed into or pulled from GAMS have a very specific layout. There is a record index and the GAMS domains show up as columns in the dataframe. For parameters, there is an extra `value` column. For variables and equations we find extra columns `level`, `marginal`, `lower`, `upper`, and `scale`. The method `head()` used in the IPython `display` provides only the first 5 records of a `pandas.DataFrame`:

In:

```
%gams variable x(i) /1.1 1, 2.m 3/;
%gams.pull -d i j p3 x
display(i, j, p3.head(), x)
```

	i
0	1
1	2
2	3

	j
0	1
1	2

	i	j	k	value
0	1	1	1	1.1
1	1	1	2	-1.1
2	1	2	1	2.2
3	1	2	2	-2.2
4	2	1	1	3.3

	i	level	marginal	lower	upper	scale
0	1	1.0	0.0	-inf	inf	1.0
1	2	0.0	3.0	-inf	inf	1.0

The data transformation functions available from `DataTransformations.ipynb` help to convert between this format and formats more suitable for display of other transformations in Python. The following lines give a quick overview of the transformation functionality:

In:

```
%gams parameter r(i,j); r(i,j) = uniformInt(1,10);
%gams.pull -d r
display(r,gt.pivot2d(r),gt_from2dim(gt.pivot2d(r),['i','j'],'value'))
```

	i	j	value
0	1	1	2.0
1	1	2	9.0
2	2	1	6.0
3	2	2	4.0

	i	j	value
4	3	1	3.0
5	3	2	3.0

	1	2
0	2.0	9.0
1	6.0	4.0
2	3.0	3.0

	i	j	value
0	1	1	2.0
1	1	2	9.0
2	2	1	6.0
3	2	2	4.0
4	3	1	3.0
5	3	2	3.0

The switch `-n` will populate numpy arrays instead lists with the GAMS parameters. This format works with parameters only! The GAMS data will be dropped into a dense numpy array:

In:

```
%gams parameter p4(i,j) / 1.1 1, 2.2 2 /;
%gams.pull -n p4
display(p4)
```

```
array([[1., 0.],
       [0., 2.],
       [0., 0.]])
```

7.5.1.3.4 Troubleshooting and Hints

- Paths to notebooks must not contain whitespaces. A notebook file itself (*.ipynb) can.
- The directory containing the notebook will clutter up with temporary files. A `gams_cleanup` or `gams_cleanup -k` if you want to continue working in this session
- The temporary file are useful for debugging, see below. The naming of the temporary files is not very sophisticated, so it can come to file nameing conflicts if you run two notebooks in the same directory at the same time (in different browser tabs). Create subdirectories and move the notebook into the subdirectories if you run into this problem.
- As soon as an error occurs while running GAMS code (the notebook exception is a `GamsException`), it can be useful to examine the listing file (*.lst) using `cat path/to/listing.lst` or `gams.lst`. The path of the listing file can be found in the last line of the output of a failing cell.

In:

```
%gams Parameter p5(i,j,l);
```

7.5.2 GAMS Transfer

GAMS Transfer is a package to maintain GAMS data outside a GAMS script in a programming language like Python or Matlab. It allows the user to add GAMS symbols (Sets, Parameters, Variables and Equations), to manipulate GAMS symbols, as well as read/write symbols to different data endpoints. GAMS Transfer's main focus is the highly efficient transfer of data between GAMS and the target programming language, while keeping those operations as simple as possible for the user. In order to achieve this, symbol records – the actual and potentially large-scale data sets – are stored in native data structures of the corresponding programming languages. The benefits of this approach are threefold: (1) The user is usually very familiar with these data structures, (2) these data structures come with a large tool box for various data operations, and (3) optimized methods for reading from and writing to GDX can transfer the data as a bulk – resulting in the high performance of this package. This tutorial describes, in detail, the use of GAMS Transfer within a Python environment.

Data within GAMS Transfer will be stored as Pandas DataFrame. The flexible nature of Pandas DataFrames makes them ideal for storing/manipulating sparse data. Pandas includes advanced operations for [indexing and slicing](#), [reshaping](#), [merging](#) and even [visualization](#).

Pandas also includes a number of advanced data [I/O tools](#) that allow users to generate DataFrames directly from CSV ([.csv](#)), JSON ([.json](#)), HTML ([.html](#)), Microsoft Excel ([.xls](#), [.xlsx](#)), SQL, pickle ([.pkl](#)), SPSS ([.sav](#), [.zsav](#)), SAS ([.xpt](#), [.sas7bdat](#)), etc.

Centering GAMS Transfer around the Pandas DataFrame gives GAMS users (on a variety of platforms – MacOS, Windows, Linux) access to tools to move data back and forth between their favorite environments for use in their GAMS models.

The goal of this tutorial is to introduce the user to GAMS Transfer and its functionality. This tutorial is not designed to teach the user how to effectively manipulate Pandas DataFrames; users seeking a deeper understanding of Pandas are referred to the extensive [documentation](#).

7.5.2.1 Install

The user must download and install the latest version of GAMS in order to install GAMS Transfer. GAMS Transfer is installed when the GAMS Python API is built and installed. The user is referred [HERE](#) for instructions on how to install the Python API files. GAMS Transfer and all GAMS Python API files are compatible with environment managers such as Anaconda.

7.5.2.2 Design

Storing, manipulating, and transforming sparse data requires that it live within an environment – this data can then be linked together to enable various operations. In GAMS Transfer we refer to this "environment" as the **Container**, it is the main repository for storing and linking our sparse data. Symbols can be added to the **Container** from a variety of GAMS starting points but they can also be generated directly within the Python environment using convenient function calls that are part of the GAMS Transfer package; a symbol can only belong to one container at a time.

The process of linking symbols together within a container was inspired by typical GAMS workflows but leverages aspects of object oriented programming to make linking data a natural process. Linking data enables data operations like implicit set growth, domain checking, data format transformations (to dense/sparse matrix formats), etc. All of these details will be discussed in the following sections. For now, we highlight a few key aspects of GAMS Transfer that will help lay the foundation. Users can skip directly to examples using the Table of Contents.

7.5.2.2.1 GAMS Special Values The GAMS system contains five **special values**: UNDEF (undefined), NA (not available), EPS (epsilon), +INF (positive infinity), -INF (negative infinity). These special values must be mapped to their Python equivalents. GAMS Transfer follows the following convention to generate the 1:1 mapping:

- +INF is mapped to `float("inf")`
- -INF is mapped to `float("-inf")`
- EPS is mapped to `-0.0` (mathematically identical to zero)
- NA is mapped to a special `NaN`
- UNDEF is mapped to `float("nan")`

GAMS Transfer syntax is designed to quickly get data into a form that is usable in further analyses or visualization; this mapping also highlights the preference for data that is of type `float`, which offers performance benefits within Pandas/NumPy. The user does not need to remember these constants as they are provided within the class `SpecialValues` as `SpecialValues.POSINF`, `SpecialValues.NEGINF`, `SpecialValues.EPS`, `SpecialValues.NA`, and `SpecialValues.UNDEF`. The `SpecialValues` class also contains methods to test for these special values. Some examples are shown below; already, we, begin to introduce some of the GAMS Transfer syntax.

Example (special values in a parameter)

```
from gamstransfer import *
m = Container()
x = Parameter(
    m,
    "x",
    ["*"],
    records=[
        ("i1", 1),
        ("i2", SpecialValues.POSINF),
        ("i3", SpecialValues.NEGINF),
        ("i4", SpecialValues.EPS),
        ("i5", SpecialValues.NA),
        ("i6", SpecialValues.UNDEF),
    ],
    description="special values",
)
```

The following DataFrame for `x` would look like:

```
In [1]: x.records
Out[1]:
```

```

uni_0 value
0  i1  1.0
1  i2  inf
2  i3  -inf
3  i4  -0.0
4  i5  NaN
5  i6  NaN

```

The user can now easily test for specific special values in the `value` column of the DataFrame (returns a boolean array):

```

In [1]: SpecialValues.isNA(x.records["value"])
Out[1]: array([False, False, False, False,  True, False])

```

Other data structures can be passed into these methods as long as these structures can be converted into a numpy array with `dtype=float`. It follows that:

```

In [1]: SpecialValues.isEps(SpecialValues.EPS)
Out[1]: True
In [2]: SpecialValues.isPosInf(SpecialValues.POSINF)
Out[2]: True
In [3]: SpecialValues.isNegInf(SpecialValues.NEGINF)
Out[3]: True
In [4]: SpecialValues.isNA(SpecialValues.NA)
Out[4]: True
In [5]: SpecialValues.isUndef(SpecialValues.UNDEF)
Out[5]: True
In [6]: SpecialValues.isUndef(SpecialValues.NA)
Out[6]: False
In [6]: SpecialValues.isNA(SpecialValues.UNDEF)
Out[6]: False

```

Pandas DataFrames allow data columns to exist with mixed type (`dtype=object`). As such, GAMS Transfer allows special string representations ("`+inf`", "`-inf`", "`eps`", "`na`", or "`undef`") of these special values when setting symbol records as seen in the following example.

Example (special values defined by strings)

```

from gamstransfer import *
m = Container()
x = Parameter(
    m,
    "x",
    ["*"],
    records=[
        ("i1", 1),
        ("i2", "+inf"),
        ("i3", "-inf"),
        ("i4", "eps"),
        ("i5", "na"),
        ("i6", "undef"),
    ],
    description="special values",
)

```

These special strings will be immediately mapped to their float equivalents from the `SpecialValues` class in order to ensure that all data entries are float types.

Note

Python is case sensitive. GAMS Transfer is strict such that `EPS` will not map to `-0.0` and an error will be generated; the user is responsible for transforming their data to use the lower case representations of special values.

7.5.2.2.2 GAMS Transfer Standard Data Formats This section is meant to introduce the standard format that GAMS Transfer expects for symbol records. It has already been mentioned that we store data as a Pandas DataFrame, but there is an assumed structure to the column headings and column types that will be important to understand. GAMS Transfer includes convenience functions in order to ease the burden of converting data from a user-centric format to one that is understood by GAMS Transfer. However, advanced users will want to convert their data first and add it directly to the Container to avoid making extra copies of (potentially large) data sets.

Set Records Standard Format

All set records (including singleton sets) are stored as a Pandas DataFrame with n number of columns, where n is the dimensionality of the symbol + 1. The first $n-1$ columns include the domain elements while the last column includes the set element explanatory text. Records are organized such that there is one record per row.

The names of the domain columns follow a pattern of `<set_name>_<index_position>`; a symbol dimension that is referenced to the universe is labeled `uni_<index_position>`. The explanatory text column is called `element_text` and must take the last position in the DataFrame.

All domain columns must be a categorical data type and the `element_text` column must be a `object` type. Pandas allows the categories (basically the unique elements of a column) to be various data types as well, however GAMS Transfer requires that all these are type `str`. All rows in the `element_text` column must be type `str`.

Some examples:

```
m = Container()
i = Set(m, "i", records=["seattle", "san-diego"])
j = Set(m, "j", [i, "*"], records=[("seattle", "new-york"), ("san-diego", "st-louis")])
k = Set(m, "k", [i], is_singleton=True, records=["seattle"])
In [1]: i.records
Out[1]:
      uni_0 element_text
0  seattle
1 san-diego
In [2]: j.records
Out[2]:
      i_0      uni_1 element_text
0  seattle new-york
1 san-diego st-louis
In [3]: k.records
Out[3]:
      i_0 element_text
0  seattle
```

Parameter Records Standard Format

All parameter records (including scalars) are stored as a Pandas DataFrame with n number of columns, where n is the dimensionality of the symbol + 1. The first $n-1$ columns include the domain elements while the last column includes the numerical value of the records. Records are organized such that there is one record per row. Scalar parameters have zero dimension, therefore they only have one column and one row.

The names of the domain columns follow a pattern of `<set_name>_<index_position>`; a symbol dimension that is referenced to the universe is labeled `uni_<index_position>`. The value column is called `value` and must take the last position in the DataFrame.

All domain columns must be a categorical data type and the `value` column must be a `float` type. Pandas allows the categories (basically the unique elements of a column) to be various data types as well, however GAMS Transfer requires that all these are type `str`.

Some examples:

```
m = Container()
i = Set(m, "i", records=["seattle", "san-diego"])
a = Parameter(m, "a", [i, "*"], records=[("seattle", 50), ("san-diego", 100)])
b = Parameter(
    m,
    "b",
    [i, "*"],
    records=[("seattle", "new-york", 32.2), ("san-diego", "st-louis", 123)],
)
c = Parameter(m, "c", records=90)
In [1]: a.records
Out[1]:
```

```

    uni.0 value
0 seattle 50.0
1 san-diego 100.0
In [2]: b.records
Out[2]:
    i.0 uni.1 value
0 seattle new-york 32.2
1 san-diego st-louis 123.0
In [3]: c.records
Out[3]:
    value
0 90.0

```

Variable/Equation Records Standard Format

Variables and equations share the same standard data format. All records (including scalar variables/equations) are stored as a Pandas DataFrame with n number of columns, where n is the dimensionality of the symbol + 5. The first $n-5$ columns include the domain elements while the last five columns include the numerical values for different attributes of the records. Records are organized such that there is one record per row. Scalar variables/equations have zero dimension, therefore they have five columns and one row.

The names of the domain columns follow a pattern of `<set_name>_<index position>`; a symbol dimension that is referenced to the universe is labeled `uni_<index position>`. The attribute columns are called `level`, `marginal`, `lower`, `upper`, and `scale`. These attribute columns must appear in this order. Attributes that are not supplied by the user will be assigned the default GAMS values for that variable/equation type; it is possible to not pass any attributes, GAMS Transfer would then simply assign default values to all attributes.

All domain columns must be a categorical data type and all the attribute columns must be a `float` type. Pandas allows the categories (basically the unique elements of a column) to be various data types as well, however GAMS Transfer requires that all these are type `str`.

Some examples:

```

from gamstransfer import *
import pandas as pd
m = Container()
i = Set(m, "i", records=["seattle", "san-diego"])
a = Variable(
    m,
    "a",
    "free",
    domain=[i],
    records=pd.DataFrame(
        [{"seattle", 50}, {"san-diego", 100}], columns=["city", "level"]
    ),
)
In [1]: a.records
Out[1]:
    i.0 level marginal lower upper scale

7.5.2.3 Core Functionality

The reader has already had glimpses of the GAMS Transfer syntax, but in this section we will present more details about the core functionality and dig further into the syntax. Specifically, we will discuss:

1. How to create a `Container`
2. How to add symbols to a `Container`
3. How to validate the data that is in the `Container`

4. How to defined domains implicitly with `domain_forwarding`
5. How to describe the data that is in the `Container`
6. How to transform data that is in the `Container`
7. Understand what the universe set is (UEL list)
8. How to reorder symbols in the `Container`
9. How to remove symbols from the `Container`
10. Tips for debugging data

All of these operations pertain specifically to the `Container` and the symbols within the `Container`. We will leave a detailed discussion about reading/writing data from/to GDX files until the next section.

7.5.2.3.1 Creating a Container The main object class within GAMS Transfer is called `Container`. The `Container` is the vessel that allows symbols to be linked together (through their domain definitions), it enables implicit set definitions, it enables structural manipulations of the data (matrix generation), and it allows the user to perform different read/write operations.

Container constructor

Argument	Type	Description	Required	Default
<code>load_from</code>	<code>str</code> , GMD Object Handle, <code>ConstContainer</code>	Points to the source of the data being read into the <code>Container</code>	No	None
<code>system_directory</code>	<code>str</code>	Absolute path to GAMS Resources folder	No	Attempts to find the GAMS installation by creating a <code>GamsWorkspace</code> object and loading the <code>system_directory</code> attribute.

Creating a `Container` is a simple matter of initializing an object. For example:

```
from gamstransfer import *
m = Container()
```

This new `Container` object, here called `m`, contains a number of convenient properties and methods that allow the user to interact with the symbols that are in the `Container`. Some of these properties are simply used to filter out different types of symbols, other methods are used to numerically characterize the data within each symbol.

Symbols are organized in the `Container` under the `data Container` attribute. The dot notation (`m.data`) is used to access the underlying `dict`; symbols in this `dict` can then be retrieved with the standard bracket notation (`m.data[<symbol_name>]`). For convenience, there are `list*` methods that will filter the different types of symbols and return a list. Those methods and their arguments are described below:

Method	Argument	Type	Description	Required	Default
<code>listSymbols</code>	<code>is_valid</code>	<code>bool</code>	returns a list of symbols that are valid (<code>is_valid=True</code>), invalid (<code>is_valid=False</code>), or all symbols (<code>is_valid=None</code>)	No	None
<code>listSets</code>	<code>is_valid</code>	<code>bool</code>	returns a list of sets (excluding aliases) that are valid (<code>is_valid=True</code>), invalid (<code>is_valid=False</code>), or all symbols (<code>is_valid=None</code>)	No	None
<code>listAliases</code>	<code>is_valid</code>	<code>bool</code>	returns a list of aliases that are valid (<code>is_valid=True</code>), invalid (<code>is_valid=False</code>), or all symbols (<code>is_valid=None</code>)	No	None
<code>listParameters</code>	<code>is_valid</code>	<code>bool</code>	returns a list of parameters that are valid (<code>is_valid=True</code>), invalid (<code>is_valid=False</code>), or all symbols (<code>is_valid=None</code>)	No	None
<code>listVariables</code>	<code>is_valid</code>	<code>bool</code>	returns a list of variables that are valid (<code>is_valid=True</code>), invalid (<code>is_valid=False</code>), or all symbols (<code>is_valid=None</code>)	No	None
	<code>types</code>	<code>str</code>	filters returned list of variables to a specific type (valid types are <code>binary, integer, positive, negative, free, sos1, sos2, semi cont, semi int</code>)	No	All types
<code>listEquations</code>	<code>is_valid</code>	<code>bool</code>	returns a list of equations that are valid (<code>is_valid=True</code>), invalid (<code>is_valid=False</code>), or all symbols (<code>is_valid=None</code>)	No	None
	<code>types</code>	<code>str</code>	filters returned list of equations to a specific type (valid types are <code>eq, geq, nonbinding, cone, external, boolean</code> , or their synonyms)	No	All types

A valid symbol is one that has passed a number of internal quality checks to ensure that this data is in the GAMS Transfer standard format and is self-consistent. More details on data validity will be provided in [Validating Data](#).

As an example, a `Container` that has been populated with symbol data from the `trnsport.gms` (we will discuss how to exchange data with GDX in [Data Exchange with GDX](#)) model would look like:

```
In [1]: m.data
Out[1]:
{'i': <src.gamstransfer.Set at 0x7fa2387750a0>,
 'j': <src.gamstransfer.Set at 0x7fa238e74fa0>,
 'a': <src.gamstransfer.Parameter at 0x7fa238e74cd0>,
 'b': <src.gamstransfer.Parameter at 0x7fa238e746a0>,
 'd': <src.gamstransfer.Parameter at 0x7fa23876b370>,
 'f': <src.gamstransfer.Parameter at 0x7fa23876b400>,
 'c': <src.gamstransfer.Parameter at 0x7fa23876b5e0>,
 'x': <src.gamstransfer.Variable at 0x7fa23876b340>,
 'z': <src.gamstransfer.Variable at 0x7fa23876b640>,
 'cost': <src.gamstransfer.Equation at 0x7fa23876b2b0>,
 'supply': <src.gamstransfer.Equation at 0x7fa23876b310>,
 'demand': <src.gamstransfer.Equation at 0x7fa23876b460>}
```

We can then call the `list*` methods to explore the different types of symbols. The order of these lists mirror the order of appearance in the `m.data` dict.

```

In [2]: m.listSets()
Out[2]: ['i', 'j']
In [3]: m.listParameters()
Out[3]: ['a', 'b', 'd', 'f', 'c']
In [4]: m.listVariables()
Out[4]: ['x', 'z']
In [5]: m.listEquations()
Out[5]: ['cost', 'supply', 'demand']
In [6]: m.listAliases()
Out[6]: []

```

7.5.2.3.2 Creating a Symbol There are two different ways to create a symbol and add it to a Container.

- Use Container methods `addSet`, `addAlias`, `addParameter`, `addVariable`, and `addEquation`
- Use symbol constructors `Set`, `Alias`, `Parameter`, `Variable` and `Equation` The following tables detail the arguments used to create each symbol type and their default values.

The following table detail the argument and their default values for the symbol constructors.

Set constructor

Argument	Type	Description	Required	Default
container	Container	A reference to the Container object that the symbol is being added to	Yes	-
name	str	Name of symbol	Yes	-
domain	list	List of domains given either as string ('*' for universe set) or as reference to a Set object	No	['*']
is_singleton	bool	Indicates if set is a singleton set (True) or not (False)	No	False
records	many	Symbol records	No	None
domain_forwarding	bool	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth)	No	False
description	str	Description of symbol	No	""

Alias constructor

Argument	Type	Description	Required	Default
container	Container	A reference to the Container object that the symbol is being added to	Yes	-
name	str	Name of symbol	Yes	-
alias_with	Set or Alias	Set an alias is linked to	Yes	-

Parameter constructor

Argument	Type	Description	Required	Default
container	Container	A reference to the Container object that the symbol is being added to	Yes	-
name	str	Name of symbol	Yes	-
domain	list	List of domains given either as string ('*' for universe set) or as reference to a Set object, an empty domain list will create a scalar parameter	No	[]
records	many	Symbol records	No	None
domain_forwarding	bool	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth)	No	False
description	str	Description of symbol	No	""

Variable constructor

Argument	Type	Description	Required	Default
container	Container	A reference to the Container object that the symbol is being added to	Yes	-
name	str	Name of symbol	Yes	-
type	str	Type of variable being created ["binary", "integer", "positive", "negative", "free", "sos1", "sos2", "semicont", "semiint"]	No	"free"
domain	list	List of domains given either as string ('*' for universe set) or as reference to a Set object, an empty domain list will create a scalar variable	No	[]
records	many	Symbol records	No	None
domain_forwarding	bool	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth)	No	False
description	str	Description of symbol	No	""

Equation constructor

Argument	Type	Description	Required	Default
container	Container	A reference to the Container object that the symbol is being added to	Yes	-
name	str	Name of symbol	Yes	-
type	str	Type of equation being created ['eq' (or 'E'/'e'), 'geq' (or 'G'/'g'), 'leq' (or 'L'/'l'), 'nonbinding' (or 'N'/'n'), 'cone' (or 'C'/'c'), 'external' (or 'X'/'x'), 'boolean' (or 'B'/'b')]	Yes	-

Argument	Type	Description	Required	Default
domain	list	List of domains given either as string ('*' for universe set) or as reference to a Set object, an empty domain list will create a scalar equation	No	[]
records	many	Symbol records	No	None
domain_forwarding	bool	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth)	No	False
description	str	Description of symbol	No	""

The other symbol properties are implied by the arguments that the user specifies. For example, dimension is the number of elements in the domain list. All the above symbol properties can be modified at any time after the addition to the container, however, any changes could result in an invalid symbol. Care must be taken when modifying data directly.

Note

If any domain element is passed as string except for "*" (universe set), the `domain_type` of the symbol will be labeled as a **relaxed** symbol rather than **regular**. This means that domain checking will not be performed.

When using the Container methods to create new symbols (`addSet`, `addParameter`, `addAlias`, `addVariable`, `addEquation`) it is not necessary to pass the container reference as an argument. All other arguments have the same structure as in the tables above.

7.5.2.3.3 Adding Set Records

Three possibilities exist to assign symbol records to a set:

- Setting the property `records` directly
- Using the symbol method `setRecords`
- Setting the argument records in a symbol constructor/container method (internally calls `setRecords`)

If data is assigned to the `records` property directly, the user must take care that the data follow the standard format. If the user does not follow this format the symbol will be marked as invalid and therefore cannot be written to the data endpoint. Users that are concerned about memory use may want to set the records directly because this avoids creating a copy of the data in memory.

The symbol method `setRecords` is a convenience method that transforms the given data into an approved Pandas DataFrame format. Many native python data types can be easily transformed into DataFrames, so the `setRecords` method for `Set` objects will accept a number of different types for input. The `setRecords` method is called internally on any data structure that is passed through the `records` argument.

Example (create a 1D set from a list)

```
m = Container()
i = Set(m, "i", records=["seattle", "san-diego"])
In [1]: i.records
Out[1]:
   uni_0 element_text
0    seattle
1  san-diego
```

Example (create a 1D set from a tuple)

```
j = Set(m, "j", records=("seattle", "san-diego"))
In [1]: j.records
Out[1]:
      uni_0 element_text
0      seattle
1  san-diego
```

Example (create a 2D set from a list of tuples)

```
k = Set(m, "k", ["*", "*"], records=[("seattle", "san-diego")])
In [1]: k.records
Out[1]:
      uni_0      uni_1 element_text
0  seattle  san-diego
```

Example (create a 1D set from a DataFrame slice + unique())

```
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
l = Set(m, "l", records=dist["from"].unique())
In [1]: l.records
Out[1]:
      uni_0 element_text
0      seattle
1  san-diego
```

Note

The `.unique()` method preserves the order of appearance, unlike `set()`.

Set element text is very handy when labeling specific set elements within a set. A user can add a set element text directly with a set element. Note that it is not required to label all set elements, as can be seen in the following example.

Example (adding set element text)

```
m = Container()
i = Set(
    m,
    "i",
    records=[
        ("seattle", "home of sub pop records"),
        ("san-diego",),
        ("washington_dc", "former gams hq"),
    ],
)
In [1]: i.records
Out[1]:
      uni_0      element_text
0      seattle  home of sub pop records
1      san-diego
2  washington_dc      former gams hq
```

Note

It is not possible to "add records" to an alias because an alias simply points to another set. If an alias is made from another alias, GAMS Transfer will recursively search for the root set and point directly to this set.

7.5.2.3.4 Adding Parameter Records Three possibilities exist to assign symbol records to a parameter:

- Setting the property `records` directly
- Using the symbol method `setRecords`
- Setting the argument records in a symbol constructor/container method (internally calls `setRecords`)

If data is assigned to the `records` property directly, the user must take care that the data follow the standard format. If the user does not follow this format the symbol will be marked as invalid and therefore cannot be written to the data endpoint. Users that are concerned about memory use may want to set the records directly because this avoids creating a copy of the data in memory.

The symbol method `setRecords` is a convenience method that transforms the given data into an approved Pandas DataFrame format. Many native python data types can be easily transformed into DataFrames, so the `setRecords` method for `Parameter` objects will accept a number of different types for input. The `setRecords` method is called internally on any data structure that is passed through the `records` argument.

Example (create a 1D parameter from a list of tuples)

```
m = Container()
a = Parameter(m, "a", ["*"], records=[("seattle", 100), ("san-diego", 64)])
In [1]: a.records
Out[1]:
      uni_0  value
0  seattle  100.0
1  san-diego  64.0
```

Example (create a 2D parameter from a tuple)

```
b = Parameter(
    m,
    "b",
    ["*", "*"],
    records=[("seattle", "san-diego", 143), ("chicago", "madison", 147.3)],
)
In [1]: b.records
Out[1]:
      uni_0  uni_1  value
0  seattle  san-diego  143.0
1  chicago  madison   147.3
```

Example (create a 2D set from a DataFrame)

```
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
c = Parameter(m, "c", ["*", "*"], records=dist)
In [1]: c.records
Out[1]:
      uni_0  uni_1  value
0  seattle  new-york    2.5
1  seattle  chicago    1.7
2  seattle  topeka     1.8
3  san-diego  new-york    2.5
4  san-diego  chicago    1.8
5  san-diego  topeka     1.4
```

Note

When passing a DataFrame in the `records` argument a deep copy of the data will be made. This copy will be converted to the GAMS Transfer standard format leaving the other copy untouched.

7.5.2.3.5 Adding Variables Three possibilities exist to assign symbol records to a variable:

- Setting the property `records` directly
- Using the symbol method `setRecords`
- Setting the argument records in a symbol constructor/container method (internally calls `setRecords`)

If data is assigned to the `records` property directly, the user must take care that the data follow the standard format. If the user does not follow this format the symbol will be marked as invalid and therefore cannot be written to the data endpoint. Users that are concerned about memory use may want to set the records directly because this avoids creating a copy of the data in memory.

The symbol method `setRecords` is a convenience method that transforms the given data into an approved Pandas DataFrame format. The `setRecords` method is called internally on any data structure that is passed through the `records` argument. The structure for `Variable` symbols is more complicated so the user must present `setRecords` with a DataFrame, however the user does not need to supply all necessary columns (i.e., "level", "marginal", "lower", "upper" and "scale"). Any columns that are not supplied will be created and filled with their GAMS default values.

Example (create a 1D free variable, specifying only level values)

```
m = Container()
x = Variable(
    m,
    "x",
    "free",
    ["*"],
    records=pd.DataFrame(
        [{"seattle", 100}, {"san-diego", 64}], columns=["cities", "level"]
    ),
)
In [1]: x.records
Out[1]:
```

	uni_0	level	marginal	lower	upper	scale
0	seattle	100.0	0.0	-inf	inf	1.0
1	san-diego	64.0	0.0	-inf	inf	1.0

Example (create a scalar variable)

```
z = Variable(m, "z", "free", records=pd.DataFrame([100], columns=["level"]))
In [1]: z.records
Out[1]:
```

	level	marginal	lower	upper	scale
0	100.0	0.0	-inf	inf	1.0

Example (create a 2D positive variable, specifying no numerical data)

```
b = Variable(
    m,
    "b",
    "positive",
    ["*", "*"],
    records=pd.DataFrame([{"seattle", "san-diego"}, {"chicago", "madison"}]),
)
In [1]: b.records
Out[1]:
```

	uni_0	uni_1	level	marginal	lower	upper	scale
0	seattle	san-diego	0.0	0.0	0.0	inf	1.0
1	chicago	madison	0.0	0.0	0.0	inf	1.0

7.5.2.3.6 Adding Equations Three possibilities exist to assign symbol records to an equation:

- Setting the property `records` directly
- Using the symbol method `setRecords`
- Setting the argument records in a symbol constructor/container method (internally calls `setRecords`)

If data is assigned to the `records` property directly, the user must take care that the data follow the standard format. If the user does not follow this format the symbol will be marked as invalid and therefore cannot be written to the data endpoint. Users that are concerned about memory use may want to set the records directly because this avoids creating a copy of the data in memory.

The symbol method `setRecords` is a convenience method that transforms the given data into an approved Pandas DataFrame format. The `setRecords` method is called internally on any data structure that is passed through the `records` argument. The structure for `Equation` symbols is more complicated so the user must present `setRecords` with a DataFrame, however the user does not need to supply all necessary columns (i.e., "level", "marginal", "lower", "upper" and "scale"). Any columns that are not supplied will be created and filled with their GAMS default values.

Example (create a 1D =L= equation, specifying only level values)

```
m = Container()
t = Equation(
    m,
    "t",
    "leq",
    ["*"],
    records=pd.DataFrame(
        [{"seattle", 100}, {"san-diego", 64}], columns=["cities", "level"]
    ),
)
In [1]: t.records
Out[1]:
```

	uni.0	level	marginal	lower	upper	scale
0	seattle	100.0	0.0	-inf	inf	1.0
1	san-diego	64.0	0.0	-inf	inf	1.0

Example (create a scalar =E= equation)

```
obj = Equation(m, "obj", "eq", records=pd.DataFrame([100], columns=["level"]))
In [1]: obj.records
Out[1]:
```

	level	marginal	lower	upper	scale
0	100.0	0.0	-inf	inf	1.0

7.5.2.3.7 Validating Data GAMS Transfer requires that the records for all symbols exist in a standard format ([GAMS Transfer Standard Data Formats](#)) in order for them to be understood and written successfully. It is certainly possible that the data could end up in a state that is inconsistent with the standard format (especially if setting symbol attributes directly). GAMS Transfer includes the `.isValid()` method in order to determine if a symbol is valid and ready for writing; this method returns a `bool`. For example, we create two valid sets and then check them with `.isValid()` to be sure.

Note

It is possible to run `.isValid()` on both the `Container` as well as the symbol object – `.isValid()` will also return a `bool` if there are any invalid symbols in the `Container` object.

Example (valid data)

```
from gamstransfer import *
m = Container()
i = Set(m, "i", records=["seattle", "san-diego", "washington_dc"])
j = Set(m, "j", i, records=["san-diego", "washington_dc"])
In [1]: i.isValid()
Out[1]: True
In [2]: j.isValid()
Out[2]: True
In [3]: m.isValid()
Out[3]: True
```

Now we create some data that is invalid due to domain violations in the set j.

Example (intentionally create domain violations)

```
from gamstransfer import *
m = Container()
i = Set(m, "i", records=["seattle", "san-diego", "washington_dc"])
j = Set(m, "j", i, records=["grayslake", "washington_dc"])
In [1]: i.isValid()
Out[1]: True
In [2]: j.isValid()
Out[2]: False
In [3]: m.isValid()
Out[3]: False
```

In this example, we know that the validity of the data is compromised by the domain violations, but there could be other subtle discrepancies that must be remedied before writing data. The user can get more detailed error reporting if the `verbose` argument is set to `True`. For example:

```
In [1]: j.isValid(verbose=True)
Exception: Symbol 'records' contain domain violations; ensure that all domain elements have been mapped properly to a category
```

7.5.2.3.8 Domain Forwarding GAMS includes the ability to define sets directly from data using the implicit set notation (see: [Implicit Set Definition \(or: Domain Defining Symbol Declarations\)](#)). This notation has an analogue in GAMS Transfer called `domain_forwarding`.

Note

It is possible to recursively update a subset tree in GAMS Transfer.

Domain forwarding is available as an argument to all symbol object constructors; the user would simply need to pass `domain_forwarding=True`.

In this example we have raw data that in the `dist` DataFrame and we want to send the domain information into the `i` and `j` sets – we take care to pass the set objects as the domain for parameter `c`.

```
m = Container()
i = Set(m, "i")
j = Set(m, "j")
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
c = Parameter(m, "c", [i, j], records=dist, domain_forwarding=True)
In [1]: i.records
Out[1]:
      uni_0 element.text
0      seattle
```

```

1 san-diego
In [2]: j.records
Out[2]:
  uni.0 element.text
0 new-york
1 chicago
2 topeka
In [3]: c.records
Out[3]:
   i.0      j.1  value
0  seattle new-york  2.5
1  seattle  chicago  1.7
2  seattle  topeka   1.8
3 san-diego new-york  2.5
4 san-diego  chicago  1.8
5 san-diego  topeka   1.4

```

Note

The element order in the sets `i` and `j` mirrors that in the raw data.

In this example we show that domain forwarding will also work recursively to update the entire set lineage – the domain forwarding occurs at the creation of every symbol object. The correct order of elements in set `i` is `[z, a, b, c]` because the records from `j` are forwarded first, and then the records from `k` are propagated through (back to `i`).

```

m = Container()
i = Set(m, "i")
j = Set(m, "j", i, records=["z"], domain_forwarding=True)
k = Set(m, "k", j, records=["a", "b", "c"], domain_forwarding=True)
In [1]: i.records
Out[1]:
  uni.0 element.text
0 z
1 a
2 b
3 c
In [2]: j.records
Out[2]:
  i.0 element.text
0 z
1 a
2 b
3 c
In [3]: k.records
Out[3]:
  j.0 element.text
0 a
1 b
2 c

```

7.5.2.3.9 Describing Data The methods `describeSets`, `describeParameters`, `describeVariables`, and `describeEquations` allow the user to get a summary view of key data statistics. The returned `DataFrame` aggregates the output for a number of other methods (depending on symbol type). Column descriptions are tabulated below:

Property / Statistic	Description	Set	Alias	Parameter	Variable	Equation
<code>name</code>	name of the symbol	x	x	x	x	x
<code>is_alias</code>	indicates if set is an alias (true) or not (false)	x	x	x	x	x
<code>is_singleton</code>	indicates if set is a singleton set (true) or not (false)	x	x	x	x	x
<code>domain</code>	domain labels (not object references) for the symbol	x	x	x	x	x
<code>domain_type</code>	domain types (i.e., relaxed or regular)	x	x	x	x	x

Property / Statistic	Description	Set	Alias	Parameter	Variable	Equation
dim	dimension of the symbol	x	x	x	x	x
num_recs	number of symbol records	x	x	x	x	x
cardinality	full cartesian product of domain possibilities	x	x	x	x	x
sparsity	sparsity of symbol records w.r.t. to cardinality	x	x	x	x	x
is_scalar	indicates if the parameter is a scalar (true) or not (false)			x		
min_value	minimum value			x		
mean_value	mean value			x		
max_value	maximum value			x		
where_min	domain entry of record with min_value (first appearance)			x		
where_max	domain entry of record with max_value (first appearance)			x		
count_eps	number of EPS special values			x		
count_na	number of NA special values			x		
count_undef	number of UNDEF special values			x		
type	variable or equation type				x	x
min_level	minimum level value				x	x
mean_level	mean level value				x	x
max_level	maximum level value				x	x
where_max_abs_level	domain entry of records with maximum absolute level value (first appearance)				x	x
count_eps_level	number of EPS special values in the level				x	x
min_marginal	minimum marginal value				x	x
mean_marginal	mean marginal value				x	x
max_marginal	maximum marginal value				x	x

Property / Statistic	Description	Set	Alias	Parameter	Variable	Equation
where_max_abs_marginal	domain entry of records with maximum absolute marginal value (first appearance)				x	x
count_eps_marginal	number of EPS special values in the marginal				x	x

The methods used to generate these tables are also available directly to the user. These methods (and their arguments) are tabulated:

Method	Description	Argument	Default
getCardinality	get the full cartesian product of the domain	-	-
getSparsity	get the sparsity of the symbol w.r.t the cardinality	-	-
getMaxValue	get the maximum value	columns	value (parameter), level (variable/equation)
getMinValue	get the minimum value	columns	value (parameter), level (variable/equation)
getMeanValue	get the mean value	columns	value (parameter), level (variable/equation)
getMaxAbsValue	get the maximum absolute value	columns	value (parameter), level (variable/equation)
whereMax	find the domain entry of records with a maximum value (return first instance only)	columns	value (parameter), level (variable/equation)
whereMaxAbs	find the domain entry of records with a maximum absolute value (return first instance only)	columns	value (parameter), level (variable/equation)
whereMin	find the domain entry of records with a minimum value (return first instance only)	columns	value (parameter), level (variable/equation)
countNA	number of NA special values in a column	columns	value (parameter), level (variable/equation)
countEps	number of EPS special values in a column	columns	value (parameter), level (variable/equation)
countUndef	number of UNDEF special values in a column	columns	value (parameter), level (variable/equation)
countPosInf	number of +INF special values in a column	columns	value (parameter), level (variable/equation)
countNegInf	number of -INF special values in a column	columns	value (parameter), level (variable/equation)

7.5.2.3.10 Transforming Data GAMS Transfer stores data in a "flat" format, that is, one record entry per DataFrame row. However, it is often necessary to convert this data format into a matrix format – GAMS Transfer enables users to do this with relative ease using the `toDense` and the `toSparseCoo` symbol methods. The `toDense` method will return a dense N-dimensional numpy array with each dimension

corresponding to the GAMS symbol dimension; it is possible to output an array up to 20 dimensions (a GAMS limit). The `toSparseCoo` method will return the data in a sparse scipy COOrdinate format, which can then be efficiently converted into other sparse matrix formats.

Attention

Both the `toDense` and `toSparseCoo` methods do not transform the underlying DataFrame in any way, they only return the transformed data.

Note

`toSparseCoo` will only convert 2-dimensional data to the scipy COOrdinate format. A user interested in sparse data for an N-dimensional symbol will need to decide how to reshape the dense array in order to generate the 2D sparse format.

Attention

In order to use the `toSparseCoo` method the user will need to install the scipy package. Scipy is not provided with GMSPython.

Both the `toDense` and `toSparseCoo` method leverage the indexing that comes along with using categorical data types to store domain information. This means that linking symbols together (by passing symbol objects as domain information) impacts the size of the matrix. This is best demonstrated by a few examples.

Example (1D data w/o domain linking (i.e., a relaxed domain))

```
m = Container()
a = Parameter(m, "a", "i", records=[("a", 1), ("c", 3)])
In [1]: a.records
Out[1]:
   i_0  value
0    a    1.0
1    c    3.0
In [2]: a.toDense()
Out[2]:
array([[1.],
       [3.]])
In [3]: a.toSparseCoo()
Out[3]:
<2x1 sparse matrix of type '<class 'numpy.float64''>'
with 2 stored elements in COOrdinate format>
```

Note that the parameter `a` is not linked to another symbol, so when converting to a matrix, the indexing is referenced to the data structure in `a.records`. Defining a sparse parameter `a` over a set `i` allows us to extract information from the `i` domain and construct a very different dense matrix, as the following example shows:

Example (1D data w/ domain linking (i.e., a regular domain))

```
m = Container()
i = Set(m, "i", records=["a", "b", "c", "d"])
a = Parameter(m, "a", i, records=[("a", 1), ("c", 3)])
In [1]: i.records
Out[1]:
   uni_0  element_text
0      a
1      b
2      c
3      d
In [2]: a.records
```

```

Out[2]:
   i_0 value
0    a   1.0
1    c   3.0
In [3]: a.toDense()
Out[3]:
array([[1.,
        0.],
       [3.,
        0.]])
In [4]: a.toSparseCoo()
Out[4]:
<4x1 sparse matrix of type '<class 'numpy.float64''>'
  with 2 stored elements in COOrdinate format>

```

Example (2D data w/ domain linking)

```

m = Container()
i = Set(m, "i", records=["a", "b", "c", "d"])
a = Parameter(m, "a", [i, i], records=[("a", "a", 1), ("c", "c", 3)])
In [1]: i.records
Out[1]:
   uni_0 element_text
0      a
1      b
2      c
3      d
In [2]: a.records
Out[2]:
   i_0 i_1 value
0    a  a   1.0
1    c  c   3.0
In [3]: a.toDense()
Out[3]:
array([[1., 0., 0., 0.],
       [0., 0., 0., 0.],
       [0., 0., 3., 0.],
       [0., 0., 0., 0.]])
In [4]: a.toSparseCoo()
Out[4]:
<4x4 sparse matrix of type '<class 'numpy.float64''>'
  with 2 stored elements in COOrdinate format>

```

7.5.2.3.11 The Universe Set A Unique Element List (UEL) (aka the "universe" or "universe set") is an (i, s) pair where i is an identification number for a string s . GAMS uses UELs to efficiently store domain entries of a record by storing the UEL ID i of a domain entry instead of the actual string s . This avoids storing the same string multiple times. The concept of UELs also exists in Python/Pandas and is called a "categorical array". GAMS Transfer leverages these types in order to efficiently store strings and enable domain checking within the Python environment.

Each domain column in a DataFrame can be assigned a unique categorical type, the effect is that each symbol maintains its own list of UELs per dimension. The UEL IDs are numbered from 1 to the number of UELs stored independently for each dimension. It is possible to convert a categorical column to its ID number representation by using the categorical accessor `x.records[<domain_column_label>].cat.codes`; however, this type of data manipulation is not necessary within GAMS Transfer, but could be handy when debugging data.

Pandas offers the possibility to create categorical column types that are `ordered` or not; GAMS Transfer relies exclusively on `ordered` categorical data types. By using ordered categories, GAMS Transfer will order the UEL such that elements appear in the order in which they appeared in the data (which is how GAMS defines the UEL). There is a feature to `GAMSTransfer` that allows the user to make last minute modifications to the UEL order, should they desire.

GAMS Transfer does not actually keep track of the UEL separately from other symbols in the `Container`, it will be created at the last minute based on the order in which data is added to the container. However, the user can access the current state of the UEL with the `.getUniverseSet()` container method. For example, we set a two dimensional set:

```

from gamstransfer import *
m = Container()

```

```

j = Set(m, "j", ["*", "*"], records=[("i" + str(n), "j" + str(n)) for n in range(2)])
In [1]: j.records
Out[1]:
  uni_0 uni_1 element.text
0    i0    j0
1    i1    j1
In [2]: m.getUniverseSet()
Out[2]: ['i0', 'j0', 'i1', 'j1']

```

Pandas also includes a number of methods that allow categories to be **renamed, appended, etc.** These methods may be useful for advanced users, but most users will probably find that modifying the original data structures and resetting the symbol records provides a simpler solution. The design of GAMS Transfer should enable to user to quickly move data back and forth, without worrying about the deeper mechanics of categorical data.

7.5.2.3.12 Reordering Symbols The order of the Container file requires the symbols to be sorted such that, for example, a Set used as domain of another symbol appears before that symbol. The Container will try to establish a valid ordering when writing the data. However, this operation can also be invoked manually by calling the method `reorderSymbols`.

7.5.2.3.13 Rename Symbols It is possible to rename a symbol even after it has been added to a Container. There are two methods that can be used to achieve the desired outcome:

- using the container method `renameSymbol`
- directly changing the `name` symbol property

We create a Container with two sets:

```

m = Container()
i = Set(m, "i", records=["seattle", "san-diego"])
j = Set(m, "j", records=["new-york", "chicago", "topeka"])

```

Example (changing the name of a symbol with the container method)

```

In [1]: m.renameSymbol("i","h")
In [2]: m.data
Out[2]:
{'h': <src.gamstransfer.Set at 0x7f9fc01fc070>,
 'j': <src.gamstransfer.Set at 0x7f9f9080a220>}

```

Example (changing the name of a symbol with the container method)

```

In [1]: i.name = "h"
In [2]: m.data
Out[2]:
{'h': <src.gamstransfer.Set at 0x7f9fc01fc070>,
 'j': <src.gamstransfer.Set at 0x7f9f9080a220>}

```

Note

Note that the renamed symbols maintain the original symbol order, this will prevent unnecessary reordering operations later in the workflow.

7.5.2.3.14 Removing Symbols Removing symbols from a container is easy when using the `removeSymbols` container method; this method accepts either a `str` or a `list` of `str`.

Attention

Once a symbol has been removed, it is possible to have hanging references as domain links in other symbols. The user will need to repair these other symbols with the proper domain links in order to avoid validity errors.

7.5.2.3.15 Debugging Data Several methods are provided as part of GAMS Transfer that enable operations that could be classified as "data debugging" rather than "describe" operations. These are: `findDomainVolations`, `findEps`, `findNA`, `findUndef`, `findPosInf`, and `findNegInf`. These methods and their arguments are tabulated below:

Method	Description	Argument	Required	Default
<code>findDomainVolations</code>	find the index position of all records that contain a domain violation	-	-	-
<code>findEps</code>	find the index position of all records that contain an EPS special value	None (parameter), column (variable/equation)	Yes (variable/equation)	-
<code>findNA</code>	find the index position of all records that contain an NA special value	None (parameter), column (variable/equation)	Yes (variable/equation)	-
<code>findUndef</code>	find the index position of all records that contain an UNDEF special value	None (parameter), column (variable/equation)	Yes (variable/equation)	-
<code>findPosInf</code>	find the index position of all records that contain an +INF special value	None (parameter), column (variable/equation)	Yes (variable/equation)	-
<code>findNegInf</code>	find the index position of all records that contain an -INF special value	None (parameter), column (variable/equation)	Yes (variable/equation)	-

7.5.2.3.16 Full Example It is possible to use everything we now know about GAMS Transfer to recreate the `trnsport.gms` results in GDX form. As part of this example we also introduce the `write` method (and generate `new.gdx`). We will discuss in more detail in the following section: [Data Exchange with GDX](#).

```

from gamstransfer import *
# create an empty Container object
m = Container()
# add sets
i = Set(m, "i", records=["seattle", "san-diego"], description="supply")
j = Set(m, "j", records=["new-york", "chicago", "topeka"], description="markets")
# add parameters
a = Parameter(m, "a", ["*"], description="capacity of plant i in cases")
b = Parameter(m, "b", j, description="demand at market j in cases")
d = Parameter(m, "d", [i, j], description="distance in thousands of miles")
f = Parameter(
    m, "f", records=90, description="freight in dollars per case per thousand miles"
)
c = Parameter(
    m, "c", [i, j], description="transport cost in thousands of dollars per case"
)
# set parameter records

```

```

cap = pd.DataFrame([("seattle", 350), ("san-diego", 600)], columns=["plant", "n_cases"])
a.setRecords(cap)
dem = pd.DataFrame(
    [("new-york", 325), ("chicago", 300), ("topeka", 275)],
    columns=["market", "n_cases"],
)
b.setRecords(dem)
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
d.setRecords(dist)
# c(i,j) = f * d(i,j) / 1000;
cost = d.records.copy(deep=True)
cost["value"] = f.records.loc[0, "value"] * cost["value"] / 1000
c.setRecords(cost)
# add variables
q = pd.DataFrame(
    [
        ("seattle", "new-york", 50, 0),
        ("seattle", "chicago", 300, 0),
        ("seattle", "topeka", 0, 0.036),
        ("san-diego", "new-york", 275, 0),
        ("san-diego", "chicago", 0, 0.009),
        ("san-diego", "topeka", 275, 0),
    ],
    columns=["to", "from", "level", "marginal"],
)
x = Variable(
    m, "x", "positive", [i, j], records=q, description="shipment quantities in cases",
)
z = Variable(
    m,
    "z",
    records=pd.DataFrame(data=[153.675], columns=["level"]),
    description="total transportation costs in thousands of dollars",
)
# add equations
cost = Equation(m, "cost", "eq", description="define objective function")
supply = Equation(m, "supply", "leq", i, description="observe supply limit at plant i")
demand = Equation(m, "demand", "geq", j, description="satisfy demand at market j")
# set equation records
cost.setRecords(
    pd.DataFrame(data=[[0, 1, 0, 0]], columns=["level", "marginal", "lower", "upper"])
)
supplies = pd.DataFrame(
    [
        ("seattle", 350, "eps", float("-inf"), 350),
        ("san-diego", 550, 0, float("-inf"), 600),
    ],
    columns=["from", "level", "marginal", "lower", "upper"],
)
supply.setRecords(supplies)
demands = pd.DataFrame(
    [
        ("new-york", 325, 0.225, 325),
        ("chicago", 300, 0.153, 300),
        ("topeka", 275, 0.126, 275),
    ],
    columns=["from", "level", "marginal", "lower"],
)
demand.setRecords(demands)
m.write("new.gdx")

```

7.5.2.4 ConstContainer (Rapid Read)

In the [Core Functionality](#) section we describe how to use the main object class of GAMS Transfer – the **Container**. Many users of GAMS Transfer will rely on the **Container** for building their data pipeline, however some users will only be interested in post-processing data from a GAMS model run. This one-directional flow of data means that these users do not need some of the advanced **Container** features such as domain linking, matrix generation, domain checking, etc. The **ConstContainer** (i.e., a Constant Container) object class is a data-focused read-only object that will provide a snapshot of the data target being read – the **ConstContainer** can be created by reading a GDX file or a GMD object (an in memory representation of data used in embedded Python code).

7.5.2.4.1 Creating a ConstContainer The `ConstContainer` shares many of the same methods and attributes that are in the `Container` class, which makes moving between the `ConstContainer` and the `Container` very simple. There are some important differences though:

1. The `ConstContainer` does not link any symbol data
2. The `ConstContainer` can only read from one source at a time – every new call of `.read()` will clear the data dict
3. The `ConstContainer` constructor will not read in any symbol records – this enables users to browse an unknown data source quickly (similar behavior to `gdxdump`).
4. The `ConstContainer` does not have a `.write()` method – a `ConstContainer` can be passed to the constructor of a `Container` which will enable data writing (however a copy of the data will be generated).
5. The user will never need to instantiate a symbol object and add it to the `ConstContainer` – the `ConstContainer` will internally generate its own set of (simplified) symbol classes and hold them in the `.data` attribute.

All of these differences were inspired by users that want to read the data as fast as possible and probe unknown data files without worrying about memory issues – `ConstContainer` provides users with a high level view of the data very quickly.

`ConstContainer` constructor

Creating a `ConstContainer` is a simple matter of initializing an object. For example:

```
from gamstransfer import *
h = ConstContainer("out.gdx")
```

Note

This new `ConstContainer` object, here called `h`, will load all the symbol data from `out.gdx` but it will not load any of the records. To load records, users must use the `.read()` method.

The `ConstContainer` constructor arguments are:

Argument	Type	Description	Required	Default
<code>load_from</code>	<code>str</code> or GMD Object Handle	Points to the source of the data being read into the <code>ConstContainer</code>	No	None
<code>system_directory</code>	<code>str</code>	Absolute path to GAMS Resources folder	No	Attempts to find the GAMS installation by creating a <code>GamsWorkspace</code> object and loading the <code>system_directory</code> attribute.

The `ConstContainer` contains many of the same methods that are in the `Container` class, specifically:

Method	Argument	Type	Description	Required	Default
read	load_from	str or GMD Object Handle	Points to the source of the data being read into the ConstContainer	No	None
	symbols	str or list	controls which symbols are read into the ConstContainer	No	All symbols
	records	bool	controls if records will be loaded as well as metadata	No	True
listSymbols	None		returns a list of all symbols		
listSets	None		returns a list of sets (excluding aliases)		
listAliases	None		returns a list of aliases		
listParameters	None		returns a list of parameters		
listVariables	types	str	filters returned list of variables to a specific type (valid types are binary, integer, positive, negative, free, sos1, sos2, semicont, se	No	All types
listEquations	types	str	filters returned list of equations to a specific type (valid types are eq, geq, nonbinding, cone, external, boolean, or their synonyms)	No	All types
describeSets	symbols	str or list	returns a DataFrame of summary statistics symbols that are Sets	No	All sets
describeParameters	symbols	str or list	returns a DataFrame of summary statistics symbols that are Parameters	No	All parameters
describeVariables	symbols	str or list	returns a DataFrame of summary statistics symbols that are Variables	No	All variables

Method	Argument	Type	Description	Required	Default
<code>describeEquations</code>	symbols	str or list	returns a DataFrame of summary statistics symbols that are Equations	No	All equations

The structure of the DataFrames that are returned from the `describe*` methods mirrors that in the `Container`; the user should reference [Describing Data](#) for detailed descriptions of the columns.

7.5.2.4.2 ConstContainer Symbol Objects The `ConstContainer` uses a simplified symbol class structure to hold symbol specific information. The user will never need to directly instantiate these symbol classes (called `SimpleSet`, `SimpleParameter`, `SimpleVariable`, `SimpleEquation` and `SimpleAlias`); these symbol classes are nested under the `ConstContainer` class. This class structure is used to provide the feel of a read-only object.

While users do not need to instantiate any of the `Simple*` symbol object directly they are available for users to probe. Many of the same `Container` symbol methods that generate summary statistics exist for the `ConstContainer` symbols. Specifically:

Method	Description	Argument	Default
<code>summary</code>	get a quick summary of symbol metadata	-	-
<code>getMaxValue</code>	get the maximum value	columns	value (parameter), level (variable/equation)
<code>getMinValue</code>	get the minimum value	columns	value (parameter), level (variable/equation)
<code>getMeanValue</code>	get the mean value	columns	value (parameter), level (variable/equation)
<code>getMaxAbsValue</code>	get the maximum absolute value	columns	value (parameter), level (variable/equation)
<code>whereMax</code>	find the domain entry of records with a maximum value (return first instance only)	columns	value (parameter), level (variable/equation)
<code>whereMaxAbs</code>	find the domain entry of records with a maximum absolute value (return first instance only)	columns	value (parameter), level (variable/equation)
<code>whereMin</code>	find the domain entry of records with a minimum value (return first instance only)	columns	value (parameter), level (variable/equation)
<code>countNA</code>	number of NA special values in a column	columns	value (parameter), level (variable/equation)
<code>countEps</code>	number of EPS special values in a column	columns	value (parameter), level (variable/equation)
<code>countUndef</code>	number of UNDEF special values in a column	columns	value (parameter), level (variable/equation)
<code>countPosInf</code>	number of +INF special values in a column	columns	value (parameter), level (variable/equation)
<code>countNegInf</code>	number of -INF special values in a column	columns	value (parameter), level (variable/equation)

Example (reading only meta data w/ ConstContainer constructor)

```
h = ConstContainer("transport.gdx")
In [1]: h.data
Out[1]:
{'i': <src.gamstransfer.ConstContainer.SimpleSet at 0x7fba484bf5b0>,
 'j': <src.gamstransfer.ConstContainer.SimpleSet at 0x7fba484bff40>,
 'a': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba484bf880>,
 'b': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0f460>,
 'd': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0ff40>,
 'f': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0fa00>,
 'c': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0f160>,
 'x': <src.gamstransfer.ConstContainer.SimpleVariable at 0x7fba48b0f7c0>,
 'z': <src.gamstransfer.ConstContainer.SimpleVariable at 0x7fba48b0f3a0>,
 'cost': <src.gamstransfer.ConstContainer.SimpleEquation at 0x7fba48b0f7f0>,
 'supply': <src.gamstransfer.ConstContainer.SimpleEquation at 0x7fba48b0fd30>,
 'demand': <src.gamstransfer.ConstContainer.SimpleEquation at 0x7fba48b0fc70>}
In [2]: h.describeParameters()
Out[2]:
   name  is_scalar  domain  domain_type  dim  num_recs  sparsity  min_value  mean_value  max_value  where_min  where_max  count_eps
count_na  count_undef
0  a      False    [i]      regular    1      2      0.0      None      None      None      None      None
   None      None      None
1  b      False    [j]      regular    1      3      0.0      None      None      None      None      None
   None      None      None
2  c      False    [i, j]    regular    2      6      0.0      None      None      None      None      None
   None      None      None
3  d      False    [i, j]    regular    2      6      0.0      None      None      None      None      None
   None      None      None
4  f      True     []       none       0      1      0.0      None      None      None      None      None
   None      None      None
```

Note that in this example we make use of the convenience notation contained in the constructor to read in only the metadata of the `transport.gdx` file. This allows users to quickly explore the symbols contained in a file (or in-memory object) and it also explains why there are many `None` values in the columns of the `.describeParameters()` method.

Example (reading all data w/ ConstContainer.read() method)

```
h = ConstContainer()
h.read("transport.gdx")
In [1]: h.data
Out[1]:
{'i': <src.gamstransfer.ConstContainer.SimpleSet at 0x7fba484bf5b0>,
 'j': <src.gamstransfer.ConstContainer.SimpleSet at 0x7fba484bff40>,
 'a': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba484bf880>,
 'b': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0f460>,
 'd': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0ff40>,
 'f': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0fa00>,
 'c': <src.gamstransfer.ConstContainer.SimpleParameter at 0x7fba48b0f160>,
 'x': <src.gamstransfer.ConstContainer.SimpleVariable at 0x7fba48b0f7c0>,
 'z': <src.gamstransfer.ConstContainer.SimpleVariable at 0x7fba48b0f3a0>,
 'cost': <src.gamstransfer.ConstContainer.SimpleEquation at 0x7fba48b0f7f0>,
 'supply': <src.gamstransfer.ConstContainer.SimpleEquation at 0x7fba48b0fd30>,
 'demand': <src.gamstransfer.ConstContainer.SimpleEquation at 0x7fba48b0fc70>}

```

In this example we make use of the `.read()` method to retrieve both the metadata and the numerical records for all symbols in the GDX file – the `.describeParameters()` method will now populate the DataFrame with additional summary statistics.

7.5.2.5 Data Exchange with GDX

Up until now, we have been focused on using GAMS Transfer to create symbols in an empty `Container` using the symbol constructors (or their corresponding container methods). These tools will enable users to ingest data from many different formats and add them to a `Container` – however, it is also possible to read in symbol data directly from GDX files using the `read` container method. In the following sections, we will discuss this method in detail as well as the `write` method, which allows users to write out to new GDX files.

7.5.2.5.1 Reading from GDX

There are two main ways to read in GDX based data.

- Pass the file path directly to the `Container` constructor (will read all symbols and records)
- Pass the file path directly to the `read` method (default read all symbols, but can read partial files)

The first option here is provided for convenience and will, internally, call the `read` method. This method will read in all symbols as well as their records. This is the easiest and fastest way to get data out of a GDX file and into your Python environment. For the following examples we leverage the GDX output generated from the `trnsport.gms` model file.

Example (reading full data w/ `Container` constructor)

```
m = Container("trnsport.gdx")
In [1]: m.data
Out[1]:
{'i': <src.gamstransfer.Set at 0x7fdd21858d60>,
 'j': <src.gamstransfer.Set at 0x7fdd21858dc0>,
 'a': <src.gamstransfer.Parameter at 0x7fdd21858df0>,
 'b': <src.gamstransfer.Parameter at 0x7fdd21858d90>,
 'd': <src.gamstransfer.Parameter at 0x7fdd21858e80>,
 'f': <src.gamstransfer.Parameter at 0x7fdd21858eb0>,
 'c': <src.gamstransfer.Parameter at 0x7fdd21858ee0>,
 'x': <src.gamstransfer.Variable at 0x7fdd21858f10>,
 'z': <src.gamstransfer.Variable at 0x7fdd21858e50>,
 'cost': <src.gamstransfer.Equation at 0x7fdd21858f70>,
 'supply': <src.gamstransfer.Equation at 0x7fdd21858fa0>,
 'demand': <src.gamstransfer.Equation at 0x7fdd21858fd0>}
In [2]: m.describeParameters()
Out[2]:
  name  is_scalar  domain  domain_type  dim  num_recs  min_value  mean_value  max_value  where_min
  where_max  count_eps  count_na  count_undef  cardinality  sparsity
0  a  False  [i]  regular  1  2  350.000  475.000  600.000  [seattle]
  [san-diego]  0  0  0  2  0.0
1  b  False  [j]  regular  1  3  275.000  300.000  325.000  [topeka]
  [new-york]  0  0  0  3  0.0
4  c  False  [i, j]  regular  2  6  0.126  0.176  0.225  [san-diego, topeka]  [seattle,
  new-york]  0  0  0  6  0.0
2  d  False  [i, j]  regular  2  6  1.400  1.950  2.500  [san-diego, topeka]  [seattle,
  new-york]  0  0  0  6  0.0
3  f  True  []  none  0  1  90.000  90.000  90.000  None
  None  0  0  0  None  None
```

A user could also read in data with the `read` method as shown in the following example.

Example (reading full data w/ read method)

```
m = Container()
m.read("trnsport.gdx")
In [1]: m.data
Out[1]:
{'i': <src.gamstransfer.Set at 0x7fdd21858d60>,
 'j': <src.gamstransfer.Set at 0x7fdd21858dc0>,
 'a': <src.gamstransfer.Parameter at 0x7fdd21858df0>,
 'b': <src.gamstransfer.Parameter at 0x7fdd21858d90>,
 'd': <src.gamstransfer.Parameter at 0x7fdd21858e80>,
 'f': <src.gamstransfer.Parameter at 0x7fdd21858eb0>,
 'c': <src.gamstransfer.Parameter at 0x7fdd21858ee0>,
 'x': <src.gamstransfer.Variable at 0x7fdd21858f10>,
 'z': <src.gamstransfer.Variable at 0x7fdd21858e50>,
 'cost': <src.gamstransfer.Equation at 0x7fdd21858f70>,
 'supply': <src.gamstransfer.Equation at 0x7fdd21858fa0>,
 'demand': <src.gamstransfer.Equation at 0x7fdd21858fd0>}
```

It is also possible to read in a partial GDX file with the `read` method, as shown in the following example:

```
m = Container()
m.read("trnsport.gdx", "x")
In [1]: m.data
Out[1]: {'x': <src.gamstransfer.Variable at 0x7fa728a2d9d0>}
In [2]: m.data["x"].records
Out[2]:
      i.0      j.1  level  marginal  lower  upper  scale
0  seattle  new-york  50.0    0.000    0.0    inf    1.0
1  seattle  chicago  300.0   0.000    0.0    inf    1.0
2  seattle  topeka    0.0    0.036    0.0    inf    1.0
3  san-diego  new-york  275.0   0.000    0.0    inf    1.0
4  san-diego  chicago   0.0    0.009    0.0    inf    1.0
5  san-diego  topeka   275.0   0.000    0.0    inf    1.0
```

This syntax assumes that the user will always want to read in both the metadata as well as the actual data records, but it is possible to skip the reading of the records by passing the argument `values=False`.

```
m = Container()
m.read("trnsport.gdx", "x", values=False)
In [1]: m.data
Out[1]: {'x': <src.gamstransfer.Variable at 0x7fa728a37220>}
In [2]: m.data["x"].summary
Out[2]:
{'name': 'x',
 'type': 'positive',
 'domain_objects': ['i', 'j'],
 'domain_names': ['i', 'j'],
 'dimension': 2,
 'description': 'shipment quantities in cases',
 'number_records': 6,
 'domain_type': 'relaxed'}
In [3]: m.data["x"].records
```

Attention

The `read` method attempts to link the domain objects together (in order to have a "regular" `domain_type`) but if domain sets are not part of the read operation there is no choice but to default to a "relaxed" `domain_type`. This can be seen in the last example where we only read in the variable `x` and not the domain sets (`i` and `j`) that the variable is defined over. All the data will be available to the user, but domain checking is no longer possible. The symbol `x` will remain with "relaxed" domain type even if the user were to read in sets `i` and `j` in a second `read` call.

7.5.2.5.2 Writing to GDX A user can write data to a GDX file by simply passing a file path (as a string). The `write` method will then create the GDX and write all data in the `Container`.

Note

It is not possible to write the `Container` when any of its symbols are invalid. If any symbols are invalid an error will be raised and the user will need to inspect the problematic symbols (perhaps using a combination of the `listSymbols(isValid=False)` and `isValid(verbose=True)` methods).

Example

```
m.write("path/to/file.gdx")
```

Example (write a compressed GDX file)

```
m.write("path/to/file.gdx", compress=True)
```

Advanced users might want to specify an order to their UEL list (i.e., the universe set); recall that the UEL ordering follows that dictated by the data. As a convenience, it is possible to prepend the UEL list with a user specified order using the `uel_priority` argument.

Example (change the order of the UEL)

```
m = Container()
i = Set(m, "i", records=["a", "b", "c"])
m.write("foo.gdx", uel_priority=["a", "c"])
```

The original UEL order for this GDX file would have been ["a", "b", "c"], but at the last minute, the UEL order was changed to swap the positions of b and c. This can be verified with the `gdxdump` utility (using the `uelTable` argument):

```
gdxdump foo.gdx ueltable=foo
Set foo /
  'a' ,
  'c' ,
  'b' /;
$onEmpty
Set i(*) /
  'a' ,
  'c' ,
  'b' /;
$offEmpty
```

7.5.2.6 Data Exchange with GMD (and Embedded Python)

We have discussed how to create symbols in an empty `Container` and we have discussed how to exchange data with GDX files, however it is also possible to read and write data directly in memory by interacting with a GMD object – this allows GAMS Transfer to be used to read/write data within an Embedded Python environment. There are some important differences when compared to data exchange with GDX since we are working with data representations in memory.

7.5.2.6.1 Reading from GMD Just as with a GDX, there are two main ways to read in data that is in a GMD object.

- Pass the GMD object directly to the `Container` constructor (will read all symbols and records)
- Pass the GMD object directly to the `read` method (default read all symbols, but can read partial files)

The first option here is provided for convenience and will, internally, call the `read` method. This method will read in all symbols as well as their records. This is the easiest and fastest way to get data out of a GMD object and into your Python environment. While it is possible to generate a custom GMD object from scratch (using the `gmdcc` API), most users will be interacting with a GMD object that has already been instantiated internally when he/she is using Embedded Python. Our examples will show how to access the GMD object – we leverage the some of the data from the `transport.gms` model file.

Example (reading full data w/ Container constructor)

```
m = Container(gams.db._gmd)
```

Note

Embedded Python users will want pass the GMD object that is part of the GAMS Database object – this will always be referenced as `gams.db._gmd` regardless of the model file.

The following example uses embedded python to create a new Container, read in all symbols, and display some summary statistics as part of the gams log output.

```
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets'        / new-york, chicago, topeka /;
Parameter
  a(i) 'capacity of plant i in cases'
    / seattle 350
    san-diego 600 /
  b(j) 'demand at market j in cases'
    / new-york 325
    chicago 300
    topeka 275 /;
Table d(i,j) 'distance in thousands of miles'
      new-york  chicago  topeka
seattle      2.5      1.7      1.8
san-diego    2.5      1.8      1.4;
$onembeddedCode Python:
from gamstransfer import *
print()
print()
m = Container(gams.db._gmd)
print(m.describeSets())
print()
print(m.describeParameters())
$offEmbeddedCode
```

The gams log output will then look as such (the extra `print` calls are just providing nice spacing for this example):

```
GAMS 38.0.0 Copyright (C) 1987-2021 GAMS Development. All rights reserved
--- Starting compilation
--- trnsport.gms(30) 3 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
  name is_alias is_singleton domain domain_type dim num_recs cardinality sparsity
0 i False False [*] none 1 2 None None
1 j False False [*] none 1 3 None None
  name is_scalar domain domain_type dim num_recs min_value ... where_min where_max count_eps
count_na count_undef cardinality sparsity
0 a False [i] regular 1 2 350.0 ... [seattle] [san-diego] 0
0 0 0 2 0.0
1 b False [j] regular 1 3 275.0 ... [topeka] [new-york] 0
0 0 0 3 0.0
2 d False [i, j] regular 2 6 1.4 ... [san-diego, topeka] [seattle, new-york] 0
0 0 0 6 0.0
[3 rows x 16 columns]
--- Starting execution - empty program
Status: Normal completion
```

A user could also read in a subset of the data located in the GMD object with the `read` method as shown in the following example. Here we only read in the sets `i` and `j`, as a result the `.describeParameters()` method will return `None`.

Example (reading subset of full data w/ `read` method)

```
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets'        / new-york, chicago, topeka /;
Parameter
  a(i) 'capacity of plant i in cases'
    / seattle 350
    san-diego 600 /
  b(j) 'demand at market j in cases'
```

```

    / new-york  325
      chicago  300
      topeka   275 /;
Table d(i,j) 'distance in thousands of miles'
      new-york  chicago  topeka
seattle      2.5      1.7      1.8
san-diego    2.5      1.8      1.4;
$onEmbeddedCode Python:
from gamstransfer import *
print()
print()
m = Container()
m.read(gams.db._gmd, symbols=["i","j"])
print(m.describeSets())
print()
print(m.describeParameters())
$offEmbeddedCode

None
--- Starting execution - empty program
      Status: Normal completion

```

All the typical functionality of the Container exists when working with GMD objects. This means that domain linking, matrix conversion, and other more advanced options are available to the user at either compilation time or execution time (depending on the Embedded Python syntax being used, see: [Syntax](#)). The next example generates a 1000x1000 matrix and then takes its inverse using the Numpy `linalg` package.

Example (Matrix Generation and Inversion)

```

set i / i1*i1000 /;
alias(i,j);
parameter a(i,j);
a(i,j) = 1 / (ord(i)+ord(j) - 1);
a(i,i) = 1;
embeddedCode Python:
from gamstransfer import *
import numpy as np
import time
print()
print()
s = time.time()
m = Container(gams.db._gmd)
print(f"read data: {round(time.time() - s, 3)} sec")
s = time.time()
A = m.data["a"].toDense()
print(f"create matrix A: {round(time.time() - s, 3)} sec")
s = time.time()
invA = np.linalg.inv(A)
print(f"generate inv(A): {round(time.time() - s, 3)} sec")
endEmbeddedCode

```

Note

In this example, the assignment of the `a` parameter is done during execution time so we must use the execution time syntax for embedded Python in order to get the numerical records properly.

read data: 1.427 sec
create matrix A: 0.022 sec
generate inv(A): 0.033 sec
      Status: Normal completion

```

7.5.2.6.2 Writing Data to GMD A user can write to a GMD object with the `.write()` method just as he/she would write a GDX file – however there are some important differences. When a user writes a GDX file the entire GDX file represents a complete data environment (all domains have been resolved, etc.) thus, GAMS Transfer does not need to worry about merge/replace operations. It is possible to merge/replace symbol records when a user is writing data to in-memory data representations with GMD. We show a few examples to illustrate this behavior.

Example (Populating a set in GAMS)

```

    note that we need to declare the set i over "*" in order to provide hints about the symbol dimensionality
set i(*);
$onEmbeddedCode Python:
from gamstransfer import *
m = Container()
i = Set(m, "i", records=["i"+str(i) for i in range(10)])
m.write(gams.db._gmd)
$offEmbeddedCode i
embeddedCode Python:
from gamstransfer import *
m = Container(gams.db._gmd)
print()
print()
print(m.data["i"].records)
endEmbeddedCode

```

Note

In general, it is possible to use GAMS Transfer to create new symbols in a GMD object (and not necessarily merge symbols) but embedded Python best practices necessitate the declaration of any GAMS symbols on the GAMS side first, then the records can be filled with GAMS Transfer.

If we break down this example we can see that the set `i` is declared within GAMS (with no records) and then the records for `i` are set by writing a `Container` to the `gams.db._gmd` GMD object (we do this at compile time). The second embedded Python code block runs at execution time and is simply there to read all the records on the set `i` – printing the sets this way adds the output to the `.log` file (we could also use the more common `display i`; operation in GAMS to display the set elements in the LST file).

```

--- Starting compilation
--- matrix.gms(10) 2 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
--- matrix.gms(21) 3 Mb
--- Starting execution: elapsed 0:00:01.630
--- matrix.gms(13) 4 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
uni_0 element.text
0  i0
1  i1
2  i2
3  i3
4  i4
5  i5
6  i6
7  i7
8  i8
9  i9
Status: Normal completion

```

Example (Merging set records)

```

set i / i1, i2 /;
$onmulti
$onEmbeddedCode Python:
from gamstransfer import *
m = Container()
i = Set(m, "i", records=["i"+str(i) for i in range(10)])
m.write(gams.db._gmd, merge_symbols="i")
$offEmbeddedCode i

```

```

$offmulti
embeddedCode Python:
from gamstransfer import *
m = Container(gams.db._gmd)
print()
print()
print(m.data["i"].records)
endEmbeddedCode

```

In this example we need to make use of `$onMulti/$offMulti` in order to merge new set elements into the the set `i` (the same would be true if we were merging other symbol types) – any symbol that already has records defined (in GAMS) and is being added to with Python (and GAMS Transfer) must be wrapped with `$onMulti/$offMulti`. As with the previous example, the second embedded Python code block runs at execution time and is simply there to read all the records on the set `i`. Note that the UEL order will be different in this case (`i1` and `i2` come before `i0`).

```

--- Starting compilation
--- matrix.gms(11) 3 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
--- matrix.gms(22) 3 Mb
--- Starting execution: elapsed 0:00:01.657
--- matrix.gms(14) 4 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
uni_0 element.text
0 i1
1 i2
2 i0
3 i3
4 i4
5 i5
6 i6
7 i7
8 i8
9 i9
Status: Normal completion

```

Example (Replacing set records)

```

set i / x1, x2 /;
$onmultiR
$onembeddedCode Python:
from gamstransfer import *
m = Container()
i = Set(m, "i", records=["i"+str(i) for i in range(10)])
m.write(gams.db._gmd)
$offEmbeddedCode i
$offmulti
embeddedCode Python:
from gamstransfer import *
m = Container(gams.db._gmd)
print()
print()
print(m.data["i"].records)
endEmbeddedCode

```

In this example we want to replace the `x1` and `x2` set elements and built up a totally new element list with set elements from the `Container`. Instead of `$onMulti/$offMulti` we must use `$onMultiR/$offMulti` to ensure that the replacement happens in GAMS; we also need to remove the set `i` from the `merge_symbols` argument.

Attention

If the user seeks to replace all records in a symbol they must use the `$onMultiR` syntax. It is not sufficient to simply remove them from the `merge_symbols` argument in GAMS Transfer. If the user mixtakenly uses `$onMulti` the symbols will end up merging without total replacement.

```

GAMS 38.0.0 Copyright (C) 1987-2021 GAMS Development. All rights reserved
--- Starting compilation
--- matrix.gms(11) 3 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
--- matrix.gms(22) 3 Mb

```

```

--- Starting execution: elapsed 0:00:01.558
--- matrix.gms(14) 4 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
uni_0 element.text
0 i0
1 i1
2 i2
3 i3
4 i4
5 i5
6 i6
7 i7
8 i8
9 i9
Status: Normal completion

```

Example (Merging parameter records)

```

set i;
parameter a(i<) /
i1 1.23
i2 5
/;
$onmulti
$onembeddedCode Python:
from gamstransfer import *
m = Container()
i = Set(m, "i", records=["i"+str(i) for i in range(10)])
a = Parameter(m, "a", domain=i, records=[("i"+str(i),i) for i in range(10)])
m.write(gams.db._gmd, merge_symbols="a")
$offEmbeddedCode i, a
$offmulti
embeddedCode Python:
from gamstransfer import *
m = Container(gams.db._gmd)
print()
print()
print(m.data["a"].records)
endEmbeddedCode

```

In this example we also need to make use of `$onMulti/$offMulti` in order to merge new set elements into the the set `i`, however the set `i` also needs to contain the elements that are defined in the parameter – here we make use of the `<` operator that will add the set elements from `a(i)` into the set `i`

Note

It would also be possible to run this example by explicitly defining the `set i /i1, i2/;` before the parameter declaration.

Attention

GAMS Transfer will overwrite all duplicate records when merging. The original values of `a("i1")` and `a("i2")` have been replaced with their new values when writing the Container in this example (see output below).

7.6 Matlab API

The Matlab API consists of the object-oriented [GAMS API](#) and [GAMS Transfer](#).

7.6.1 GAMS API

GAMS Matlab API provides a Matlab programming interface to the General Algebraic Model System (GAMS). GAMS Matlab API objects allow a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

Note

There also exist the data exchange tools [GDXMRW](#) and [GAMS Transfer](#) to exchange data between Matlab and GDX files. Note that [GDXMRW](#) and [GAMS Transfer](#) are likely to be more efficient in case of exchanging very large data sets. However, the GAMS Matlab API offers more features, for example, to start and modify a GAMS job.

The underlying GAMS engine relies to some extent on file based communication (e.g. the listing file) and other unmanaged resources. Since the GAMS Matlab API is based on the GAMS Java API, the use of external resources in the Java environment requires special attention. Hence, some objects need to be properly disposed before the Java garbage collector does its job.

A GAMS program can include other source files (e.g. `$include`), load data from GDX files (e.g. `$GDXIN` or `execute_load`), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base object `GAMSWorkspace` manages the anchor to the file system.

With the exception of `GAMSWorkspace` the objects in the `gams` package cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the `GAMSModelInstance` class).

Note

If you use multiple instances of the `GAMSWorkspace` in parallel, you should avoid using the same `WorkingDirectory`. Otherwise you may end up with conflicting file names.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving `GAMSModelInstances`. Some solvers will not work in a multi-threaded application using `GAMSModelInstances`. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, `GAMSModelInstances` are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This version of the GAMS Matlab API also does not provide support for the following GAMS components: acronyms, GAMS compilation/execution errors, structured access to listing file, and solver options.

7.6.2 GAMS Transfer

GAMS Transfer is a package to maintain GAMS data outside a GAMS script in a programming language like Python or Matlab. It allows the user to add GAMS symbols (Sets, Parameters, Variables and Equations), to manipulate GAMS symbols, read symbols from a GDX file or write them to one. While keeping those operations as simple as possible for the user, GAMS Transfer's main focus is the highly efficient transfer of data between GAMS and the target programming language. In order to achieve this, symbol records – the actual and potentially large-scale data sets – are stored in native data structures of the corresponding programming languages, e.g., dataframes, tables or (sparse) matrices. The benefits of this approach are threefold: (1) The user is usually very familiar with these data structures, (2) these data structures come with a large tool box for various data operations, and (3) optimized methods for reading from and writing to GDX can transfer the data as a bulk – resulting in the high performance of this package.

Note

In comparison to the [GAMS API](#), GAMS Transfer focuses on data exchange. For this it is more efficient and offers a richer set of features to read and write GDX files. Moreover, GAMS Transfer comes with a more user-friendly interface than [GDXMRW](#).

Navigate to the [Class Reference](#) or the [GAMS Transfer Matlab Tutorial](#) to learn more about how to use GAMS Transfer.

7.6.2.1 Tutorial

7.6.2.1.1 Install Simply add the GAMS Matlab API to the Matlab path by calling `addpath("[PathToGAMS]/apifiles/Matlab/api")`. The shipped GAMS Transfer Matlab package is compatible with Matlab R2018a or newer.

Note

In Matlab the GAMS Transfer package can be imported by `import GAMSTransfer.*`. It is then not required to call GAMS Transfer classes with the preceding `GAMSTransfer.`, see [Example](#).

7.6.2.1.2 Example As an introductory example, we consider to create a GDX file in Matlab with content equal to the GDX file written by the call `gams trnsport GDX=trnsport.gdx`, i.e. the solution data of model `trnsport`:

```
import GAMSTransfer.*
% create an empty container
m = Container();
% add sets
i = Set(m, 'i', 'records', {'seattle', 'san-diego'}, 'description', 'canning plants');
j = Set(m, 'j', 'records', {'new-york', 'chicago', 'topeka'}, 'description', 'markets');
% add parameters
a = Parameter(m, 'a', i, 'description', 'capacity of plant i in cases');
b = Parameter(m, 'b', j, 'description', 'demand at market j in cases');
d = Parameter(m, 'd', {i,j}, 'description', 'distance in thousands of miles');
f = Parameter(m, 'f', 'description', 'freight in dollars per case per thousand miles');
c = Parameter(m, 'c', {i,j}, 'description', 'transport cost in thousands of dollars per case');
% set parameter records
a.setRecords([350, 600]);
b.setRecords([325, 300, 275]);
d.setRecords([2.5, 1.7, 1.8; 2.5, 1.8, 1.4]);
f.setRecords(90);
c.setRecords([0.225, 0.153, 0.162; 0.225, 0.162, 0.126]);
% add variables
x = Variable(m, 'x', 'positive', {i,j}, 'description', 'shipment quantities in cases');
z = Variable(m, 'z', 'description', 'total transportation costs in thousands of dollars');
% set variable records
% Note: Argument order is: level, marginal, lower, upper, scale.
x.setRecords([50, 300, 0; 275, 0, 275], [0, 0, 0.036; 0, 0.009, 0]);
z.setRecords(153.675);
% (optional) transform records into different format
```

```

x.transformRecords('table');
% add equations
cost = Equation(m, 'cost', 'e', 'description', 'define objective function');
supply = Equation(m, 'supply', 'l', i, 'description', 'observe supply limit at plant i');
demand = Equation(m, 'demand', 'g', j, 'description', 'satisfy demand at market j');
% set equation records
cost.setRecords(0, 1, 0, 0);
supply.setRecords(struct('level', [350, 550], 'marginal', [SpecialValues.EPS, 0], 'upper', [350, 600]));
demand.setRecords([325, 300, 275], [0.225, 0.153, 0.126], [325, 300, 275]);
% write data to a GDX file
m.write('transport.gdx');

```

The example illustrates the general GAMS Transfer concept: A **Container** can be filled with different GAMS symbols, here are shown **Set**, **Parameter**, **Variable** and **Equation** (not shown: **Alias**). The created GAMS Transfer container is empty, but alternatively could be initialized by [Reading Data From GDX](#). Each GAMS symbol has multiple symbol records – the actual data – that can be provided at symbol creation (see for example set i), but [Adding and Modifying Data](#) thereafter is possible, too. Finally, once all the data has been collected in the container, [Writing Data To GDX](#) is a simple one-liner. A GAMS symbol, e.g. the variable x, stores its symbol records in `x.records`, but provides further meta data:

```

>> x
x =
  Variable with properties:
    name: 'x'
    description: 'shipment quantities in cases'
    type: 'positive'
    default_values: [1x1 struct]
    dimension: 2
    size: [2 3]
    domain: {[1x1 GAMSTransfer.Set] [1x1 GAMSTransfer.Set]}
    domain_names: {'i' 'j'}
    domain_labels: {'i.1' 'j.2'}
    domain_type: 'regular'
    domain_forwarding: 0
    records: [6x4 table]
    format: 'table'

>> x.records
ans =
  6x4 table
    i.1      j.2      level      marginal
    -----
seattle    new-york    50          0
seattle    chicago    300         0
seattle    topeka     0           0.036
san-diego  new-york    275         0
san-diego  chicago    0           0.009
san-diego  topeka     275         0

```

Besides `name` and `description` each GAMS symbol has modifyable meta data `dimension`, `size` and `domain` to define the symbol domain and shape as well as the possible dependency on other sets. Note that `size` is of particular importance when using matrix like [Record Formats](#) to store symbol records (compare property `format`) and/or a **Container** in [Indexed GDX](#) mode. GAMS Transfer provides several tools for [Analyzing Data](#), for example to check the symbol's validity or to detect the records format. The example further shows that in table like [Record Formats](#) the first `dimension` columns are the record's domain information with column names `domain_labels`. Added record value columns follow (`level` and `marginal`). Missing value columns, here `lower`, `upper` and `scale` are considered to hold default values specified by `default_values` – in this example 0, Inf and 1, respectively.

7.6.2.1.3 GAMS Transfer Design

7.6.2.1.3.1 Indexed GDX Two different GDX interfaces exist and are both supported by the Matlab version of GAMS Transfer: (default) GDX and indexed GDX (also called IDX). These two interfaces mainly differ in the characterization of symbols:

- Default GDX: Symbol **dimension** and shape are defined by **domain**. Symbol **records** are identified by UELs (see also [Unique Elements \(UELs\)](#)).
- Indexed GDX: Symbol **dimension** and shape are defined by **size**. UELs do not exist. Symbol **records** are identified by numerical indices.

The mode – default or indexed – can be specified when creating a **Container** and cannot be changed thereafter, e.g.:

```
m = Container('indexed', true);
```

In indexed mode, pass the shape of the symbol instead of the domain to the constructor:

```
d = Parameter(m, 'd', [2, 3], 'description', 'distance in thousands of miles');
```

Note

The only supported symbols in indexed mode are **Parameter**.

In indexed mode it is not possible to set the property **domain** or using the UEL related methods (e.g. **getUELs** or **setUELs**), while in default mode the property **size** cannot be set and is inferred from by the domain.

7.6.2.1.3.2 Container Types GAMS Transfer offers two different container types: **Container** and **ConstContainer**. The latter differs from the former in that it is read only. After creation, data cannot be altered anymore. This allows to use internal operations with better runtime performance. Being read only, however, implies that many features of a **Container** are not available in a **ConstContainer**. Hence, choose **ConstContainer**, when performance is key.

Further differences are:

- **ConstContainer** currently does not support writing to GDX.
- **ConstContainer** symbols are structs, not objects.
- **ConstContainer** symbols are linked by domain names, not **Set** object references.
- Number of records and size information in a **ConstContainer** refers to that information in the read GDX file and not on the records currently stored in the container. This allows to read a GDX file without records and inspect symbol sizes and sparsity etc.
- **ConstContainer** symbols do not offer methods to manage UELs, e.g. **getUELs**, see also [Unique Elements \(UELs\)](#).
- Properties supported by **ConstContainer** symbols only:
 - **symbol_type**: Symbol type, e.g. **set** or **variable**.
 - **number_records**: Number of records in read GDX file, not actually read records, see also **getNumberRecords**.
 - **number_values**: Number of values read, which differs to number of records due to chosen format, see also **getNumberValues**.
 - **sparsity**: Sparsity of symbol based on number of records read and symbol shape as in GDX file, see also **getSparsity**.
 - **uels** (optional): UELs used in symbol if categorical arrays are not supported.
- Properties supported by **Container** symbols only:
 - **default_values**.
 - **domain_forwarding**.

Advanced users:

Creation of categorical arrays can be a bottleneck. Reading performance can be increased for a **ConstContainer** (not **Container**) when disabling them:

```
c = ConstContainer('path/to/file.gdx', 'features', struct('categorical', false));
```

Domain entries are numerical IDs of UELs (see also [Unique Elements \(UELs\)](#)) and can be looked up in the **uels** field of a symbol.

7.6.2.1.3.3 Record Formats The Matlab version of GAMS Transfer can read and maintain the symbol records in four different formats: `struct`, `table`, `dense_matrix` and `sparse_matrix`.

Both `struct` and `table` are table-like formats storing the domain entries in the first **dimension** columns followed by value columns (**value** for **Parameter**, **text** for **Set** and **level**, **marginal**, **lower**, **upper**, **scale** for **Variable** and **Equation**) and the records as rows. Both `dense_matrix` and `sparse_matrix` are matrix-like formats where the matrices have $\max(2, d)$ dimensions, where **d** is the symbol **dimension**, and shape **size**. Domain entries cannot be stored in the matrix, but can be queried using the symbol method `getUELs` (see also [Unique Elements \(UELs\)](#)). Assume a symbol **s** has two dimensions. Then, a (**row**, **col**) matrix entry corresponds to the domain entry $\{s.getUELLabels(1, row), s.getUELLabels(2, col)\}$. The logic is analogue for different dimensions.

Each format has its advantages and disadvantages, see the following table (ratings ++ (very good), +, o, -, --, rated relatively for each category):

Record Format	Max Dimension	Efficiency	Memory (General)	Memory (Dense Data)	Display
<code>struct</code>	20 (GAMS limit)	++	+	-	-
<code>table</code>	20 (GAMS limit)	--	o	--	++
<code>dense_matrix</code>	20 (GAMS limit)	+	--	++	-
<code>sparse_matrix</code>	2 (Matlab limit)	o	++	+	--

Note

For scalar symbols (**dimension** equals 0), the formats `struct` and `dense_matrix` are equivalent. GAMS Transfer will usually prefer `struct` in case of ambiguity.

Sets can only be maintained in formats `struct` and `table`.

Attention

Matrix based formats do not store the domain UELs in its own symbol object. Instead, they are given by the elements of the domain set. This implies that changing the domain set records (e.g. in its order) will change the meaning of the matrix formats.

Example (table):

```
>> x.records
ans =
  6x7 table
      i.1      j.2      level      marginal      lower      upper      scale
-----
seattle    new-york      50          0          0          Inf        1
seattle    chicago      300         0          0          Inf        1
seattle    topeka        0          0.036      0          Inf        1
san-diego  new-york      275         0          0          Inf        1
san-diego  chicago        0          0.009      0          Inf        1
san-diego  topeka        275         0          0          Inf        1
```

Example (struct):

```
>> x.records
ans =
  struct with fields:
    i.1: [6x1 categorical]
    j.2: [6x1 categorical]
    level: [6x1 double]
    marginal: [6x1 double]
    lower: [6x1 double]
    upper: [6x1 double]
```

```

        scale: [6×1 double]
>> x.records.level
ans =
    50
    300
     0
    275
     0
    275

```

Example (dense_matrix):

```

>> x.records
ans =
  struct with fields:
    level: [2×3 double]
    marginal: [2×3 double]
    lower: [2×3 double]
    upper: [2×3 double]
    scale: [2×3 double]
>> x.records.level
ans =
    50    300     0
    275     0    275

```

Example (sparse_matrix):

```

>> x.records
ans =
  struct with fields:
    level: [2×3 double]
    marginal: [2×3 double]
    lower: [2×3 double]
    upper: [2×3 double]
    scale: [2×3 double]
>> x.records.level
ans =
    (1,1)     50
    (2,1)    275
    (1,2)    300
    (2,3)    275

```

Note that in the above examples the following holds, which can be used to get the domain entries for matrix elements as described in the beginning of this section.

```

x.getUELLabels(1, 1:2) equals {'seattle', 'san-diego'}
x.getUELLabels(2, 1:3) equals {'new-york', 'chicago', 'topeka'}

```

7.6.2.1.3.4 Special Values GAMS GDX offers five special values: **NA** (not available), **UNDEF** (undefined), **EPS** (explicit zero, a standard zero is usually not stored in the sparse GDX format), **PINF** or **POSINF** (positive infinity) and **MINF** or **NEGINF** (negative infinity). All special values can be queried and checked for using the class **SpecialValues**. While **UNDEF**, **POSINF** and **NEGINF** have natural counterparts in Matlab (NaN, Inf and -Inf, respectively), **NA** and **EPS** do not. The latter two are therefore mapped to a special NaN and -0, respectively.

Example:

```

>> a = [0, NaN, SpecialValues.NA, SpecialValues.UNDEF, SpecialValues.EPS, SpecialValues.POSINF,
        SpecialValues.NEGINF]
a =
    0 NaN NaN NaN 0 Inf -Inf
>> SpecialValues.isNA(a)
ans =
  1×7 logical array
    0 0 1 0 0 0 0
>> SpecialValues.isUnDef(a)
ans =
  1×7 logical array
    0 1 0 1 0 0 0
>> SpecialValues.isEps(a)
ans =
  1×7 logical array
    0 0 0 0 1 0 0

```

7.6.2.1.3.5 Unique Elements (UELs) A Unique Element (UEL) is an (i,s) pair where i is an identification number for a string s . GDX uses UELs to efficiently store domain entries of a record by storing the UEL ID i of a domain entry instead of the actual string s . This avoids storing the same string multiple times. The concept of UELs also exists in Matlab and is called a "categorical array". Hence, GAMS Transfer uses categorical arrays to store domain entries.

Each symbol maintains its own list of UELs per dimension, which can be accessed and modified via the methods `getUELs`, `setUELs`, `initUELs`, `addUELs`, `removeUELs` and `renameUELs` (or the Matlab functions for modifying categorical arrays). The UEL IDs are numbered from 1 to the number of UELs stored independently for each dimension. It is possible to convert a categorical array to its IDs by using any number conversion function like `int64()` in Matlab.

Usually, it is not necessary to explicitly add a UEL with `addUELs`. Simply using a new UEL in `records` will add it automatically to the UEL list. However, it is possible to store more UELs than those actually used in the `records`. Advanced users can use this fact to sort the universe set of a GDX file to their needs.

Attention

The methods `setUELs` and `removeUELs` may reassign different UEL IDs to the UEL labels. These changes are applied to the IDs used in `records`. This implies that removing a UEL that is used in the `records` will then lead to an invalid domain entry (displayed as `<undefined>` in Matlab). If these updates are not desired, use the method `initUELs` instead.

Note

Users with Matlab or Octave versions that do not support categorical arrays must store the UEL IDs in the domain columns of the `records`. Storing strings is not supported. For looking up the corresponding string, use the method `getUELLabels`.

Example (getting UEL IDs):

```
>> x.records.i.1'
ans =
    1×6 categorical array
    seattle    seattle    seattle    san-diego    san-diego    san-diego
>> x.records.j.2'
ans =
    1×6 categorical array
    new-york    chicago    topeka    new-york    chicago    topeka
>> x.getUELs(1)'
ans =
    1×2 cell array
    {'seattle'}    {'san-diego'}
>> x.getUELs(2)'
ans =
    1×3 cell array
    {'new-york'}    {'chicago'}    {'topeka'}
>> int64(x.records.i.1)'
ans =
     1     1     1     2     2     2
>> int64(x.records.j.2)'
ans =
    1×6 int64 row vector
     1     2     3     1     2     3
```

Example (changing UELs):

```
>> x.setUELs(1, {'madison', 'new-york', 'seattle'});
>> categories(x.records.i.1)
ans =
    3×1 cell array
    {'madison'}
    {'new-york'}
    {'seattle'}
>> x.records.i.1'
ans =
    1×6 categorical array
    seattle    seattle    seattle    <undefined>    <undefined>    <undefined>
```

Example (adding UELs via records):

```
>> x.records.i.1(end) = "houston";
>> categories(x.records.i.1)
ans =
  4×1 cell array
    {'madison' }
    {'new-york' }
    {'seattle' }
    {'houston' }
>> x.records.i.1'
ans =
  1×6 categorical array
    seattle    seattle    seattle    <undefined>    <undefined>    houston
```

7.6.2.1.4 Data Exchange With GDX

7.6.2.1.4.1 Reading Data From GDX For reading a GDX file, the file path can be specified when constructing a **Container**. This will read the whole GDX file. For more control over the read procedure, use the **read** method. It is possible to only read a subset of the symbols in the GDX file or to specify the format to read in. The method (optional) arguments are:

- **symbols:** List of symbol names to be read. All if empty list.
- **format:** [Records format](#) to read records in.
- **values:** Subset of `{'level', 'marginal', 'lower', 'upper', 'scale'}` to specify which of those values should be read.

Furthermore, instead of a GDX file **Container** can read from a **ConstContainer**.

Attention

When reading from different GDX files it can happen that two different symbols have the same name. It is currently not possible to rename a symbol on load or to merge symbol contents, for example. GAMS Transfer will simply raise an error.

Note

Changing the GDX file name of a **Container** and/or reading from multiple GDX files into the same container is not supported.

Example (full read with constructor):

```
m = Container('path/to/file.gdx');
```

Example (full read with read method):

```
m = Container();
m.read('path/to/file.gdx');
```

Example (partial read):

To read all records from symbols **x** and **c** as **dense_matrix**, but only **level** values for **d** in **struct** format, call:

```
m = Container();
m.read('path/to/file.gdx', 'symbols', {'x', 'c'}, 'format', 'dense_matrix');
m.read('path/to/file.gdx', 'symbols', {'d'}, 'format', 'struct', 'values', {'level'});
```

Example (read from ConstContainer):

```
mc = ConstContainer('path/to/file.gdx');
m1 = Container(mc);
m2 = Container();
m2.read(mc);
```

7.6.2.1.4.2 Accessing Data Symbols are stored in the struct **data** of the **Container**, with fieldnames equal to the symbol names. Within the symbol, symbol records are located in the table or struct (depending on the [Record Formats](#)) **records**. Further to accessing **data** directly, symbol handle lists can be queried via the method **getSymbols** given a list of symbol names. This can be particularly useful in combination with the functions **listSymbols**, **listSets**, **listAliases**, **listParameters**, **listVariables** and **listEquations** that list the names of symbols of the corresponding type.

Example:

```
>> m.data
ans =
  struct with fields:
    i: [1×1 GAMSTransfer.Set]
    j: [1×1 GAMSTransfer.Set]
    a: [1×1 GAMSTransfer.Parameter]
    b: [1×1 GAMSTransfer.Parameter]
    d: [1×1 GAMSTransfer.Parameter]
    f: [1×1 GAMSTransfer.Parameter]
    c: [1×1 GAMSTransfer.Parameter]
    x: [1×1 GAMSTransfer.Variable]
    z: [1×1 GAMSTransfer.Variable]
    cost: [1×1 GAMSTransfer.Equation]
    supply: [1×1 GAMSTransfer.Equation]
    demand: [1×1 GAMSTransfer.Equation]
>> m.listVariables()
ans =
  1×2 cell array
    {'x'}    {'z'}
>> vars = m.getSymbols(m.listVariables())
vars =
  1×2 cell array
    {1×1 GAMSTransfer.Variable}    {1×1 GAMSTransfer.Variable}
>> {vars{1}.name, vars{2}.name}
ans =
  1×2 cell array
    {'x'}    {'z'}
```

7.6.2.1.4.3 Writing Data To GDX The current **Container** with all its symbols and symbol records can be written to a GDX file using the **write** method. It is possible to write the GDX file in compressed format by setting the method argument **compress** to **true**.

Note

It is not possible to write the **Container** when any of its symbols is not valid (see also [Validate Symbol Records](#)). A symbol can be considered valid but still has domain violations, which would lead to an error when writing, see also [Handle Domain Violations](#).

Example:

```
m.write('path/to/file.gdx');
```

Example (write compressed GDX):

```
m.write('path/to/file.gdx', 'compress', true);
```

Advanced users:

GDX expects the symbol records to be sorted in a certain order. Since this can be difficult for the user to achieve, the records are sorted (without overwriting) on default when writing to GDX. Users who know that their symbol records are sorted correctly, can set the **write** method argument **sorted** to **true** in order to improve efficiency. Symbol records **dense_matrix** and **sparse_matrix** are sorted per definition (**sorted** has no effect). GDX expects the following order for **struct** and **table** formats. Symbol records are sorted by domain UEL IDs (see also [Unique Elements \(UEs\)](#)) in ascending order first w.r.t. dimension 1, then 2, etc. However, UEL IDs are here not relative to the symbol as described in [Unique Elements \(UEs\)](#), but global to the whole container where only the first occurrence is relevant. In result, symbol order implies UEL order and hence symbol record order. The method **getUniverseSet** returns this global UEL ordering.

7.6.2.1.5 Adding and Modifying Data

7.6.2.1.5.1 Adding Symbols Two equivalent ways of adding a symbol to the **Container** exist:

- **Container** methods `addSet`, `addAlias`, `addParameter`, `addVariable` and `addEquation`.
- **Symbol** constructors `Set`, `Alias`, `Parameter`, `Variable` and `Equation`.

The following table lists the possible arguments that are needed or possible for defining the symbol. Here, the argument can be either of type **required**, **optional** (argument is positional but not required) or **parameter** (argument name and value have to be passed as pair, argument is not required). A # indicates the position if the argument is positional and the value in brackets is the default value if the argument is not required.

Argument	Type	Description	Set	Alias	Parameter	Variable	Equation
name	string	Name of symbol	required #1	required #1	required #1	required #1	required #1
alias_with	Set	Set an alias is linked to	-	required #2	-	-	-
type	string, int	Variable or Equation type, see Variable-Type and Equation-Type	-	-	-	optional #2 ('free')	required #2
domain	cell, Set , string	List of domains given either as string ('*' for universe set) or as reference to a Set object	optional #2 ('*')	-	optional #2 ({})	optional #3 ({})	optional #3 ({})
description	string	Description of symbol	parameter (")	-	parameter (")	parameter (")	parameter (")
records	any	Symbol records, see also Assigning Symbol Records	parameter ([])	-	parameter ([])	parameter ([])	parameter ([])
is_singleton	logical	Indicates if set is a singleton set (true) or not (false)	parameter (false)	-	-	-	-

The other symbol properties are implied by those listed above. For example, **dimension** is the number of elements in **domain**. All the above symbol properties can be modified at any time after the addition to the container. Furthermore, changing the property **dimension** has the following effect: Decreasing the **dimension** will remove **domain** elements at the back, while increasing the **dimension** will append appropriately many universe set domains *. Changing symbol properties may cause reevaluation of validity once an operation requires this changed symbol to be valid.

Note

If any domain element is passed as string except for * (universe set), the domain is handled **relaxed** instead of **regular** as indicated by the property **domain_type**. This means that domain checking does not apply, see also [Handle Domain Violations](#).

Example (using container methods):

```
m = Container();
i = m.addSet('i', 'records', {'seattle', 'san-diego'}, 'description', 'canning plants');
a = m.addParameter('a', i, 'records', [350, 600], 'description', 'capacity of plant i in cases');
supply = m.addEquation('supply', 'l', i, ...
    'records', struct('level', [350, 550], 'marginal', [SpecialValues.EPS, 0], 'upper', [350, 600]), ...
    'description', 'observe supply limit at plant i');
```

Example (using symbol constructors):

See also the introductory [Example](#).

```
m = Container();
i = Set(m, 'i', 'records', {'seattle', 'san-diego'}, 'description', 'canning plants');
a = Parameter(m, 'a', i, 'records', [350, 600], 'description', 'capacity of plant i in cases');
supply = Equation(m, 'supply', 'l', i, ...
    'records', struct('level', [350, 550], 'marginal', [SpecialValues.EPS, 0], 'upper', [350, 600]), ...
    'description', 'observe supply limit at plant i');
```

7.6.2.1.5.2 Assigning Symbol Records Three possibilities exist to assign symbol records to a symbol:

- Setting the property **records**.
- Using the symbol method **setRecords**.
- Setting the argument **records** in a symbol constructor (internally calls **setRecords**).

If data is assigned to the **records** property directly, the user is in charge to format the data in any of the supported [Record Formats](#). If the user fails to do so, the symbol will be marked as invalid, see also [Validate Symbol Records](#). The method **setRecords** is a convenience method that transforms the given data either into the **struct**, **dense_matrix** or **sparse_matrix** format (e.g., depending on if the user supplies domain entries or not). The following transformations are supported:

- **string**: Interpreted as domain entry for first dimension.
- **cellstr**: First dimension of cellstr must be equal to symbol dimension and second will be the number of records. Row *i* is interpreted to hold the domain entries for dimension *i*.
- **numeric vector/matrix**: Interpreted to hold the **level** values (or **value** for Parameter). Must satisfy the shape given by symbol size since this can only be a matrix format (e.g. **dense_matrix** or **sparse_matrix**), because domain entries are not given.
- **cell**: If element is the *i*-th cellstr, then this is considered to be the domain entries for the *i*-th domain. If element is the *j*-th numeric vector/matrix, it is interpreted as the *j*-th element of the following: (1) **level** or **value**, (2) **marginal**, (3) **lower**, (4) **upper**, (5) **scale**. If symbol is a Set, the (**dim**+1)-th cellstr is considered to be the set element texts.

- **struct**: Fields which names match domain labels, are interpreted as domain entries of the corresponding domain. Other supported fields are `level`, `value`, `marginal`, `lower`, `upper`, `scale`, `text`. Unsupported fields are ignored.
- **table**: used as is, but checked for correctness.

Note

Instead of a `cell`, it is possible to provide the elements as separate arguments to the method `setRecords`.

Example (single string)

Consider the symbol `a` to be a 1-dim parameter with domain `i`, see the introductory [Example](#).

```
>> a.setRecords('seattle');
>> a.transformRecords('table'); % format was struct
>> a.records
ans =
    table
      i_1
    -----
    seattle
```

Example (strings)

Consider the symbol `a` to be a 1-dim parameter with domain `i`, see the introductory [Example](#).

```
>> a.setRecords({'seattle', 'san-diego'});
>> a.transformRecords('table'); % format was struct
>> a.records
ans =
    2x1 table
      i_1
    -----
    seattle
    san-diego
```

Example (numeric vector)

Consider the symbol `a` to be a 1-dim parameter with domain `i`, see the introductory [Example](#).

```
>> a.setRecords([300 400]);
>> a.transformRecords('table'); % format was dense_matrix
>> a.records
ans =
    2x2 table
      i_1      value
    -----
    seattle      300
    san-diego      400
```

Example (numeric vectors)

Consider the symbol `v` to be a 1-dim variable with domain `i`, where `i` is defined in the introductory [Example](#).

```
>> v.setRecords([1 2], [11 22], [111 222], [1111 2222]);
>> v.transformRecords('table'); % format was dense_matrix
>> v.records
ans =
    2x5 table
      i_1      level      marginal      lower      upper
    -----
    seattle      1      11      111      1111
    san-diego      2      22      222      2222
```

Example (cell)

Consider the symbol `x` to be a 2-dim variable with domain `{i,j}`, see the introductory [Example](#).

```
>> x.setRecords({'seattle', 'seattle'}, {'new-york', 'chicago'}, [1 2], [11 22], [111 222], [1111 2222]);
>> x.transformRecords('table'); % format was struct
>> x.records
ans =
    2x6 table
      i_1      j_2      level      marginal      lower      upper
    -----
    seattle      new-york      1      11      111      1111
    seattle      chicago      2      22      222      2222
```

7.6.2.1.5.3 Removing Symbols To remove a symbol from the **Container**, simply call the method `removeSymbols`.

Attention

If a **Set** is removed from the **Container**, a handle to that **Set** can still exist as a domain of another symbol or be linked to by an alias. This will make these other symbols invalid, see `isValid`.

Example:

```
>> m.removeSymbols('x');
>> m.removeSymbols({'a', 'b'});
```

7.6.2.1.5.4 Reordering Symbols The GDX file requires the symbols to be sorted such that, for example, a **Set** used as domain of another symbol appears before that symbol. The **Container** will try to establish a valid ordering when writing the data to GDX. However, this operation can also be invoked manually by calling the method `reorderSymbols`.

7.6.2.1.6 Analyzing Data

7.6.2.1.6.1 Data Overview The methods `describeSets`, `describeAliases`, `describeParameters`, `describeVariables` and `describeEquations` allow for an overview over the symbols of the corresponding type stored in the **Container**. These methods return a table listing for each symbol the properties / statistics given in the following table (here an x means that this property / statistic is available for the symbol type and note that `*_level` is called `*_value` or simply `*` for **Parameter**).

Property / Statistic	Description	Set	Alias	Parameter	Variable	Equation
name	Name of symbol	x	x	x	x	x
is_alias	Indicates if set is an alias (true) or not (false)	x	x			
is_singleton	Indicates if set is a singleton set (true) or not (false)	x	x			
alias_with	Set an alias is linked to		x			
type	Variable or Equation type, see VariableType and EquationType				x	x
format	Format records are stored in, see Record Formats	x	x	x	x	x
dim	Dimension of symbol	x	x	x	x	x
domain_type	Type of domain, e.g. relaxed or regular	x	x	x	x	x
domain	Domain of symbol	x	x	x	x	x
size	Size or shape of symbol	x	x	x	x	x

Property / Statistic	Description	Set	Alias	Parameter	Variable	Equation
num_recs	Number of symbol GDX records	x	x	x	x	x
num_vals	Number of stored records values	x	x	x	x	x
sparsity	Sparsity of symbol records w.r.t. to count	x	x	x	x	x
min_level	Minimum value of level values			x	x	x
mean_level	Mean value of level values			x	x	x
max_level	Maximum value of level values			x	x	x
where_max_abs_level	Domain entry of record with maximum absolute level value			x	x	x
count_na_level	Number of GAMS special values NA in level values			x	x	x
count_undef_level	Number of GAMS special values UNDEF in level values			x	x	x
count_eps_level	Number of GAMS special values EPS in level values			x	x	x
min_marginal	Minimum value of marginal values				x	x
mean_marginal	Mean value of marginal values				x	x
max_marginal	Maximum value of marginal values				x	x
where_max_abs_marginal	Domain entry of record with maximum absolute marginal value				x	x
count_na_marginal	Number of GAMS special values NA in marginal values				x	x
count_undef_marginal	Number of GAMS special values UNDEF in marginal values				x	x
count_eps_marginal	Number of GAMS special values EPS in marginal values				x	x

Example:

```
>> tbl = m.describeVariables();
>> tbl(:,1:10)
ans =
2x10 table
   name      type    format  dim  domain_type  domain  size  num_recs  num_vals  sparsity
-----
   x      positive  table    2    regular    [i,j]  [2,3]    6         12      0.6
```

```

z      free      struct      0      none      []      []      1      1      0.8
>> tbl(:,11:17)
ans =
2×7 table
   min_level  mean_level  max_level  where_max_abs_level  count_na_level  count_undef_level
count_eps_level
-----
      0         150         300      [seattle,chicago]         0         0         0
153.68      153.68      153.68      []         0         0         0
>> tbl(:,18:24)
ans =
2×7 table
   min_marginal  mean_marginal  max_marginal  where_max_abs_marginal  count_na_marginal
count_undef_marginal  count_eps_marginal
-----
      0         0.0075         0.036      [seattle,topeka]         0         0
NaN         0         NaN         NaN      <undefined>         0         0

```

7.6.2.1.6.2 Handle Domain Violations Domain violations occur when a symbol uses other **Set(s)** as **domain(s)** and a domain entry in its **records** that is not present in the corresponding set. Such a domain violation will lead to a GDX error when writing the data. The method **getDomainViolations** returns a list of **DomainViolation** objects w.r.t. each dimension of the symbol which can be used to resolve the domain violations. The GAMS Transfer methods **resolveDomainViolations** and **resolve** offer an automatic expansion of the domain sets with the violated entries in order to eliminate domain violations. This resolving feature can further be triggered automatically by setting the symbol property **domain_forwarding** to **true**. If **records** are updated by direct access, the domain update will happen delayed for improved efficiency, but can be forced by calling **isValid** or the resolving methods mentioned above.

Note

The method for automatically resolving the domain violations can be convenient, but it effectively disables domain checking, which is a valuable tool for error detection. We encourage to use **resolveDomainViolations**, **resolve** or **domain_forwarding** enabled as rarely as possible. The same holds for using **relaxed** domain information when **regular** domain information would be possible, see **domain_type**.

Example (domain violation when writing):

```

Consider the symbol x to have domains {i,j}, where i and j are Sets. The label madison is not
part of set i. See Example.
>> x.records.i.1(end) = "madison";
>> i.records.uni.1'
ans =
1×2 categorical array
   seattle    san-diego
>> m.write();
Error using gt.gdx.write
GDX error in record x(madison,topeka): Domain violation
Error in GAMSTransfer.Container/write (line 341)
    GAMSTransfer.gt.gdx.write(obj.system_directory, filename, obj.data, ...

```

Example (automatically resolving domain violations):

```

Consider the symbol x to have domains {i,j}, where i and j are Sets. The label madison is not
part of set i (in the beginning). See Example.
>> x.records.i.1(end) = "madison";
>> i.records.uni.1'
ans =
1×2 categorical array
   seattle    san-diego
>> dv = x.getDomainViolations();
>> dv{1}
ans =
DomainViolation with properties:
   symbol: [1×1 GAMSTransfer.Variable]

```

```

    dimension: 1
      domain: [1x1 GAMSTransfer.Set]
      violations: {'madison'}
  >> x.resolveDomainViolations();
  >> dv = x.getDomainViolations()
  dv =
    0x0 empty cell array
  >> i.records.uni_1'
  ans =
    1x3 categorical array
      seattle    san-diego    madison

```

7.6.2.1.6.3 Validate Symbol Records GAMS Transfer requires the symbol records to be stored in one of the supported [Record Formats](#) in order to understand and write them to GDX. However, it can easily happen that a certain criteria of the format is not met and the symbol is marked as invalid, i.e., the symbol method `isValid` returns `false`. In that case setting the argument `verbose` of `isValid` to `true` will print the reason for invalidity and can thus help to resolve the issue.

Note

Performance hint: In case symbol records are updated within a loop, try to avoid checking the symbol validity within the loop. Note that symbol methods to query, for example, the number of records will call `isValid` internally.

Example (incorrect shape of value field):

Consider variable `x` to be as in the introductory [Example](#).

```

>> x.transformRecords('struct');
>> x.isValid(true)
ans =
    logical
     1
>> x.records.level = x.records.level';
>> x.isValid(true)
Warning: Value fields must all have the same size.
> In GAMSTransfer/Symbol/isValid (line 840)
ans =
    logical
     0
>> x.records.marginal = x.records.marginal';
>> x.isValid(true)
Warning: Fields need to match matrix format or to be dense column vectors.
> In GAMSTransfer/Symbol/isValid (line 840)
ans =
    logical
     0

```

Example (incorrect value field name):

Consider variable `x` to be as in the introductory [Example](#).

```

>> x.transformRecords('struct');
>> x.isValid(true)
ans =
    logical
     1
>> x.records.LEVEL = x.records.level;
>> x.isValid(true)
Warning: Field 'LEVEL' not allowed.
> In GAMSTransfer/Symbol/isValid (line 840)
ans =
    logical
     0

```

7.7 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C# API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known [transportation problem](#). These examples introduce several API features step by step.

- [Getting Started](#) A quick introduction about how to create and configure C# project
- [Important Classes of the API](#) Overview of some fundamental classes of the GAMS C# API
- [How to use API](#) An extensive set of examples how to use API components

7.7.1 Getting Started

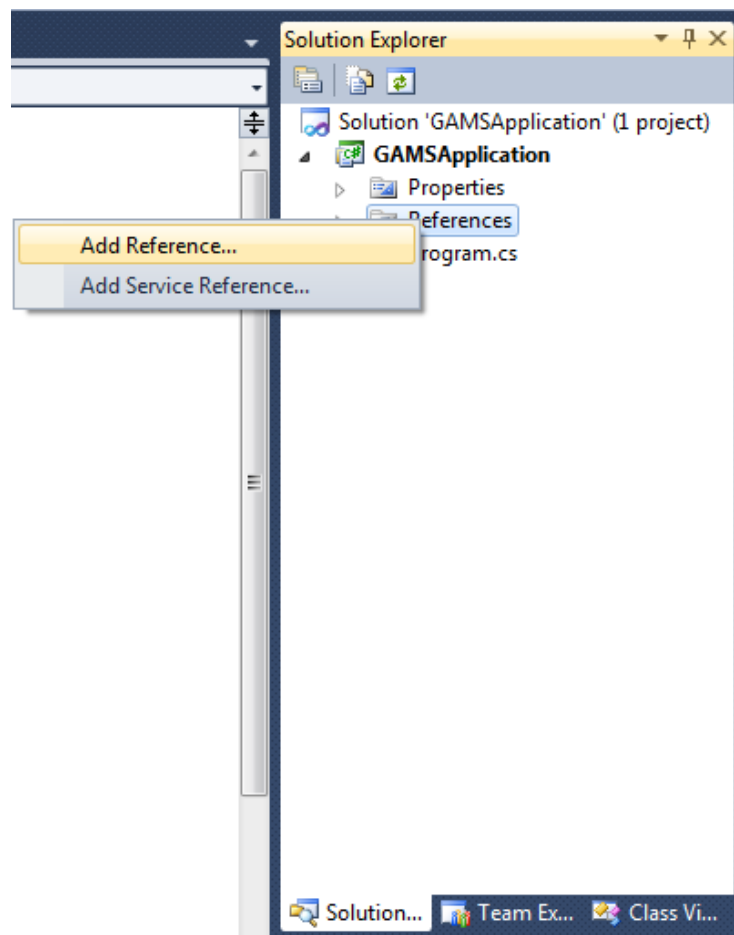

This section takes you through the basic steps of creating and configuring a C# project in Visual Studio 2010 for use with the GAMS C# API. At the end of this section there is also a paragraph about [Mono](#) as an alternative to Microsoft Visual Studio.

7.7.1.1 Open a new Project

After opening Microsoft Visual Studio you can open the New Project wizard by choosing **File > New > Project** from the ribbon menu and type a name for your application, e.g. GAMSApplication.

7.7.1.2 Add a Reference to a Project

Once you opened the project add a reference by a right click on **References** inside the solution explorer. Then choose **Add Reference..** and select the **Browse** tab. Next navigate to the location where you installed `GAMS.net4.dll`, typically the GAMS system directory, e.g. `C:\GAMS\win64\38.0`. Then choose `GAMS.net4.dll` and click **OK**.

7.7.1.3 Solving your first Model

This section illustrates how a model from the GAMS model library can be imported and solved.

Open a new project and reference the `GAMS.net4.dll` in your project as explained above. Open `Program.cs` which should be part of your project and replace the content by:

```
using System;
using System.IO;
using System.Collections.Generic;
using System.Text;
using GAMS;
namespace TransportSeq
{
    class Transport0
    {
        static void Main(string[] args)
        {
            GAMSWorkspace ws = new GAMSWorkspace();
            ws.GamsLib("transport");
            // create a GAMSJob from file and run it with default settings
            GAMSJob t0 = ws.AddJobFromFile("transport.gms");
            t0.Run();
            Console.WriteLine("Ran with Default:");
            foreach (GAMSVariableRecord rec in t0.OutDB.GetVariable("x"))
                Console.WriteLine("x(" + rec.Keys[0] + ", " + rec.Keys[1] + "): level=" + rec.Level + " marginal=" +
                    rec.Marginal);
            Console.WriteLine("z=" + t0.OutDB.GetVariable("z").LastRecord().Level);
        }
    }
}
```

Then click the highlighted button from figure (a) down below or press **F5** to start debugging. You can also start the program without debugging by pressing **Control + F5** or choosing **Debug > Start Without Debugging** from the ribbon menu as illustrated in figure (b).

Figure (a)

Figure(b)

By following the latter instruction the command line shell remains open and show the produced output.

7.7.1.4 Mono

The GAMS .NET API works also on non-Windows platforms where no Visual Studio is available. It can be used for example with the open source .Net framework Mono (<http://www.mono-project.com>). Mono offers a IDE that could be used similarly to Visual Studio. If one prefers to compile and execute from a shell, the following code shows how this can be done using the example Transport1 which comes with the GAMS system (this assumes that xbuild and mono are in the PATH):

```
cd <GAMS Dir>/apifiles/CSharp/Transport1
xbuild /t:rebuild /p:Configuration=Release Transport1.csproj
mono bin/Release/Transport1.exe ../../..
```

7.7.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of [examples](#).

- **GAMS Namespace**
- **GAMSWorkspace Class**
- **GAMSJob Class**
- **GAMSDatabase Class**
- **GAMSOptions Class**
- **GAMSModelInstance Class**

7.7.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C# API. `<GAMS system directory>\apifiles\CSharp` contains a file `TransportSeq.sln` that can be opened in Microsoft Visual Studio. The contained projects deal with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- [How to choose the GAMS system \(Transport1\)](#)
 - [How to export data to GDX \(TransportGDX\)](#)
 - [How to import data from GDX \(TransportGDX\)](#)
 - [How to run a GAMSJob from file \(Transport1\)](#)
 - [How to specify the solver \(Transport1\)](#)
 - [How to run a job with a solver option file and capture its log output \(Transport1\)](#)
-

- [How to use include files \(Transport2\)](#)
- [How to read data from string and export to GDX \(Transport3\)](#)
- [How to run a job using data from GDX \(Transport3\)](#)
- [How to run a job using implicit database communication \(Transport3\)](#)
- [How to define data using C# data structures \(Transport4\)](#)
- [How to prepare a GAMSDatabase from C# data structures \(Transport4\)](#)
- [How to initialize a GAMSCheckpoint by running a GAMSJob \(Transport5\)](#)
- [How to initialize a GAMSJob from a GAMSCheckpoint \(Transport5\)](#)
- [How to run multiple GAMSJobs in parallel using a GAMSCheckpoint \(Transport6\)](#)
- [How to create a GAMSModelInstance from a GAMSCheckpoint \(Transport7\)](#)
- [How to modify a parameter of a GAMSModelInstance using GAMSModifier \(Transport7\)](#)
- [How to modify a variable of a GAMSModelInstance using GAMSModifier \(Transport7\)](#)
- [How to use a queue to solve multiple GAMSModelInstances in parallel \(Transport8\)](#)
- [How to fill a GAMSDatabase by reading from MS Access \(Transport9\)](#)
- [How to fill a GAMSDatabase by reading from MS Excel \(Transport10\)](#)
- [How to create and use a save/restart file \(Transport11\)](#)

7.7.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing `Transport1.exe` with `C:/GAMS/win64/38.0` we use the 64-bit version of GAMS 38.0 to run `Transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
GAMSWorkspace ws;
if (Environment.CommandLineArgs().Length > 1)
    ws = new GAMSWorkspace(systemDirectory: Environment.CommandLineArgs()[1]);
else
    ws = new GAMSWorkspace();
...
```

Remember that the bitness of the GAMS system has to match the bitness of your .NET program.

7.7.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented .NET API offers much more than exchanging data between .NET and GDX, a common use case is the export and import of GDX files. The central class for this purpose is `GAMSDatabase`. We assume that the data to be exported is available in .NET data structures.

```
...
List<string> plants = new List<string>()
{
    "Seattle", "San-Diego"
};
List<string> markets = new List<string>()
{
    "New-York", "Chicago", "Topeka"
};
Dictionary<string, double> capacity = new Dictionary<string, double>()
{
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
}
```

```

};
Dictionary<string, double> demand = new Dictionary<string, double>()
{
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
Dictionary<Tuple<string, string>, double> distance = new Dictionary<Tuple<string, string>, double>()
{
    { new Tuple<string, string> ("Seattle", "New-York"), 2.5 },
    { new Tuple<string, string> ("Seattle", "Chicago"), 1.7 },
    { new Tuple<string, string> ("Seattle", "Topeka"), 1.8 },
    { new Tuple<string, string> ("San-Diego", "New-York"), 2.5 },
    { new Tuple<string, string> ("San-Diego", "Chicago"), 1.8 },
    { new Tuple<string, string> ("San-Diego", "Topeka"), 1.4 }
};
...

```

Different GAMS symbols are represented using different .NET data structures. The data for the GAMS sets is represented using lists of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by dictionaries (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with .NET data structures.

A new `GAMSDatabase` instance can be created using `GAMSWorkspace.AddDatabase`.

```

...
// prepare a GAMSDatabase with data from the C# data structures
GAMSDatabase db = ws.AddDatabase();
...

```

We start adding GAMS sets using the method `GAMSDatabase.AddSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A `foreach`-loop iterates through `plants` and adds new records to the recently created `GAMSSet` instance `i` using `GAMSSet.AddRecord`.

```

...
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.AddSet("i", 1, "canning plants");
foreach (string p in plants)
    i.AddRecord(p);
...

```

`GAMSPParameter` instances can be added by using the method `GAMSDatabase.AddParameter`. It has the same signature as `GAMSDatabase.AddSet`. Anyhow, in this example we use an overload of the method which takes a list of `GAMSSet` instances instead of the dimension for creating a parameter with domain information.

```

...
// add parameter 'a' with domain 'i'
GAMSPParameter a = db.AddParameter("a", "capacity of plant i in cases", i);
foreach (string p in plants)
    a.AddRecord(p).Value = capacity[p];
...

```

As soon as all data is prepared in the `GAMSDatabase`, the method `GAMSDatabase.Export` can be used to create a GDX file.

```

...
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSWorkspace
db.Export("data.gdx");
...

```

7.7.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.AddDatabaseFromGDX`. The method takes a path to a GDX file and creates a `GAMSDatabase` instance.

```

...
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.AddDatabaseFromGDX("data.gdx");
...

```

Reading the data from the `GAMSSet` `i` into a list can be done as follows:

```

...
// read data from symbols into .NET data structures
List<string> plants2 = new List<string>();
foreach (GAMSSetRecord item in db2.GetSet("i"))

```

```
plants2.Add(item.Key(0));
...
```

A new list `plants2` is created. `i` is retrieved by calling `GAMSDatabase.GetSet` on `db2`. The returned `GAMSSet` object can be iterated using a `foreach`-loop to access the records of the set. Each record is of type `GAMSSetRecord` and can be asked for its keys.

You can do the same for `GAMSPParameters`. Instead of creating a list, we want to have the data in the form of a dictionary. `GAMSPParameterRecords` can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a `Dictionary<string, double>`.

```
...
Dictionary<string, double> capacity2 = new Dictionary<string, double>();
foreach (GAMSPParameterRecord item in db2.GetParameter("a"))
    capacity2.Add(item.Key(0), item.Value);
...
```

For multi dimensional symbols, we choose the dictionary keys to be tuples instead of string.

```
...
Dictionary<Tuple<string, string>, double> distance2 = new Dictionary<Tuple<string, string>, double>();
foreach (GAMSPParameterRecord item in db2.GetParameter("d"))
    distance2.Add(new Tuple<string, string>(item.Key(0), item.Key(1)), item.Value);
...
```

7.7.3.4 How to run a GAMSJob from file (Transport1)

Here we load the model `trnsport` from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the `GAMSWorkspace.AddJobFromFile` Method afterwards. Apparently this method also works with any other `gms` file you might have created on your own as long as it is located in the current working directory. Then the `GAMSJob t1` is defined from that file and run by the `GAMSJob.Run` method.

The following lines create the solution output and illustrate the usage of the `GAMSJob.OutDB` property to get access to the `GAMSDatabase` created by the `Run` method. To retrieve the content of variable `x` we use the `GAMSVariableRecord` class and the `GAMSDatabase.GetVariable` method.

```
...
ws.GamsLib("trnsport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.AddJobFromFile("trnsport.gms");
t1.Run();
Console.WriteLine("Ran with Default:");
foreach (GAMSVariableRecord rec in t1.OutDB.GetVariable("x"))
    Console.WriteLine("x(" + rec.Keys[0] + ", " + rec.Keys[1] + "): level=" + rec.Level + " marginal=" + rec.Marginal);
...
```

7.7.3.5 How to specify the solver (Transport1)

The solver can be specified via the `GAMSOptions` class and the `GAMSWorkspace.AddOptions` method. The `GAMSOptions.AllModelTypes` property sets `xpress` as default solver for all model types which the solver can handle.

```
...
// run the job again with another solver
using (GAMSOptions opt = ws.AddOptions())
{
    opt.AllModelTypes = "xpress";
    t1.Run(opt);
}
...
```

7.7.3.6 How to run a job with a solver option file and capture its log output (Transport1)

At first we use the `StreamWriter` to create the file `xpress.opt` which will be used as solver option file and is stored in the current working directory. Then we write `algorithm=barrier` to this file and specify the barrier algorithm as algorithm before we close the solver option file. We choose `xpress` as solver just like in the preceding example and set the `GAMSOptions.OptFile` Property to 1 to tell the solver to look for a solver option file. In addition, we specify the argument `output` in order to write the log of the `GAMSJob` into the file `transport1_xpress.log`.

```
...
using (StreamWriter optFile = new StreamWriter(Path.Combine(ws.WorkingDirectory, "xpress.opt")))
using (TextWriter logFile = new StreamWriter(Path.Combine(ws.WorkingDirectory, "transport1_xpress.log")))
using (GAMSOptions opt = ws.AddOptions())
{
    optFile.WriteLine("algorithm=barrier");
    optFile.Close();
    opt.AllModelTypes = "xpress";
    opt.OptFile = 1;
    t1.Run(opt, output: logFile);
}
...
```

Instead of writing the log output to a file, it can be written into any `TextWriter`. In order to write the log directly to `Console.Out`, we can use the following code:

```
...
    t1.Run(opt, output: Console.Out);
...
```

7.7.3.7 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings `GetDataText` and `GetModelText` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
...
using (StreamWriter writer = new StreamWriter(ws.WorkingDirectory + Path.DirectorySeparatorChar + "tdata.gms"))
{
    writer.Write(GetDataText());
}
...
```

Afterwards we create a `GAMSJob` using the `GAMSWorkspace.AddJobFromString` method. The `GAMSOptions.Defines` field is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line.

```
...
using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t2 = ws.AddJobFromString(GetModelText());
    opt.Defines.Add("incname", "tdata");
    t2.Run(opt);
    ...
}
...
```

Note that the string `GetModelText` contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

7.7.3.8 How to read data from string and export to GDX (Transport3)

We read the data from the string `GetDataText` as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding `GAMSJob` a `GAMSDatabase` is created that is available via the `GAMSJob.OutDb` property. We can use the `GAMSDatabase.Export` method to write the content of this database to a `gdx` file `tdata.gdx`.

```
...
GAMSJob t3 = ws.AddJobFromString(GetDataText());
t3.Run();
t3.OutDB.Export(ws.WorkingDirectory + Path.DirectorySeparatorChar + "tdata.gdx");
...
```

7.7.3.9 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in [Transport2 - How to use include files \(Transport2\)](#).

```
...
t3 = ws.AddJobFromString(GetModelText());
using (GAMSOptions opt = ws.AddOptions())
{
    opt.Defines.Add("gdxincname", "tdata");
    opt.AllModelTypes = "xpress";
    t3.Run(opt);
    ...
}
...
```

Note that there are some changes in `GetModelText` due to the usage of a GDX file instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

7.7.3.10 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two `GAMSJobs` `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `OutDB` can be read in directly just like a `gdx` file. Note that the database needs to be passed to the `GAMSJob.Run` method as additional argument.

```
...
using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t3a = ws.AddJobFromString(GetDataText());
    GAMSJob t3b = ws.AddJobFromString(GetModelText());
    t3a.Run();
    opt.Defines.Add("gdxincname", t3a.OutDB.Name);
    opt.AllModelTypes = "xpress";
    t3b.Run(opt, t3a.OutDB);
    ...
}
...
```

7.7.3.11 How to define data using C# data structures (Transport4)

We use the `List<T>` class, the `Dictionary<TKey, TValue>` class and the `Tuple<T1, T2>` class to define C# data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
...
List<string> plants = new List<string>()
{
    "Seattle", "San-Diego"
};
List<string> markets = new List<string>()
{
    "New-York", "Chicago", "Topeka"
};
Dictionary<string, double> capacity = new Dictionary<string, double>()
{
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
Dictionary<string, double> demand = new Dictionary<string, double>()
{
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
Dictionary<Tuple<string,string>, double> distance = new Dictionary<Tuple<string,string>, double>()
{
    { new Tuple<string,string> ("Seattle", "New-York"), 2.5 },
    { new Tuple<string,string> ("Seattle", "Chicago"), 1.7 },
    { new Tuple<string,string> ("Seattle", "Topeka"), 1.8 },
    { new Tuple<string,string> ("San-Diego", "New-York"), 2.5 },
    { new Tuple<string,string> ("San-Diego", "Chicago"), 1.8 },
    { new Tuple<string,string> ("San-Diego", "Topeka"), 1.4 }
};
...
```

7.7.3.12 How to prepare a GAMSDatabase from C# data structures (Transport4)

At first we create an empty GAMSDatabase db using the GAMSWorkspace.AddDatabase method. Afterwards we prepare the database. To add a set to the database we use the GAMSSet class and the GAMSDatabase.AddSet method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C# data structure and add them by using the GAMSSet.AddRecord method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The GAMSJob can be run like explained in the preceding example about implicit database communication.

```

...
GAMSDatabase db = ws.AddDatabase();
GAMSSet i = db.AddSet("i", 1, "canning plants");
foreach (string p in plants)
    i.AddRecord(p);
...
GAMSParameter a = db.AddParameter("a", 1, "capacity of plant i in cases");
foreach (string p in plants)
    a.AddRecord(p).Value = capacity[p];
...
GAMSParameter d = db.AddParameter("d", 2, "distance in thousands of miles");
foreach (Tuple<string,string> t in distance.Keys)
    d.AddRecord(t.Item1,t.Item2).Value = distance[t];
GAMSParameter f = db.AddParameter("f", 0, "freight in dollars per case per thousand miles");
f.AddRecord().Value = 90;
// run a job using data from the created GAMSDatabase
GAMSJob t4 = ws.AddJobFromString(GetModelText());
using (GAMSOptions opt = ws.AddOptions())
{
    opt.Defines.Add("gdxincname", db.Name);
    opt.AllModelTypes = "xpress";
    t4.Run(opt, db);
    ...
}
...

```

7.7.3.13 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following two lines of code conduct several operations. While the first line simply creates a GAMS Checkpoint, the second one uses the GAMSWorkspace.AddJobFromString method to create a GAMSJob containing the model text and data but no solve statement. In contrast to the preceding examples it runs the job immediately using the GAMSJob.Run method. Furthermore, it passes an additional checkpoint argument to the Run method. That means the GAMSCheckpoint cp captures the state of the GAMSJob.

```

...
GAMSCheckpoint cp = ws.AddCheckpoint();
...
ws.AddJobFromString(GetModelText()).Run(cp);
...

```

This creates the same checkpoint as for example the following code snippet:

```

GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob t5a = ws.AddJobFromString(GetModelText());
t5a.Run(cp);

```

7.7.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function GetModelText() contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```

...
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';
...

```

We create a list with eight different values for this demand multiplier.

```
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
```

For each entry of that list we create a GAMSJob `t5` using the `GAMSWorkspace.AddJobFromString` method. Besides the string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a GAMSJob combined from the checkpoint plus the content provided by the string.

We run the GAMSJob and echo some interesting data from the `OutDB` using the `GAMSDatabase.GetParameter` and `GAMSDatabase.GetVariable` methods, the `GAMSParameter.FindRecord` and `GAMSVariable.FindRecord` methods plus the `GAMSParameterRecord.Value` property and the `GAMSVariableRecord.Level` property.

```
...
foreach (double b in bmultlist)
{
    GAMSJob t5 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat;
        ss=transport.solvestat;", cp);
    t5.Run();
    Console.WriteLine("Scenario bmult=" + b + ":");
    Console.WriteLine(" Modelstatus: " + t5.OutDB.GetParameter("ms").FindRecord().Value);
    Console.WriteLine(" Solvestatus: " + t5.OutDB.GetParameter("ss").FindRecord().Value);
    Console.WriteLine(" Obj: " + t5.OutDB.GetVariable("z").FindRecord().Level);
}
...
```

Note

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the `model status` and the `solve status` provide important information for a correct solution interpretation.

7.7.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs known from `Transport5` in parallel. We initialize the `GAMSCheckpoint cp` and introduce a demand multiplier as we did before :

```
...
GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object `ioMutex` that will be used to avoid mixed up output from the parallel jobs. For each element `b` from the list of demand multipliers we call a delegate of the function `RunScenario`. Note that these calls are parallel!

```
...
// run multiple parallel jobs using the created GAMSCheckpoint
Object ioMutex = new Object();
System.Threading.Tasks.Parallel.ForEach(bmultlist, delegate(double b) { RunScenario(ws, cp, ioMutex, b); });
...
```

In function `RunScenario` a GAMSJob is created and run just like in the preceding example of `Transport5`. The output section is also the same except for the fact that it is marked as critical section by the `lock` keyword. That means the delegates of `RunScenario` are running in parallel but the output block of different delegates cannot be executed in parallel since it is 'locked' by the same object `ioMutex` for all delegates.

```
...
static void RunScenario(GAMSWorkspace ws, GAMSCheckpoint cp, object ioMutex, double b)
{
    GAMSJob t6 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat;
        ss=transport.solvestat;", cp);
    t6.Run();
    // we need to make the ouput a critical section to avoid messed up report information
    lock (ioMutex)
    {
        Console.WriteLine("Scenario bmult=" + b + ":");
        Console.WriteLine(" Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
        Console.WriteLine(" Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
        Console.WriteLine(" Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
    }
}
```

...

While the output in `Transport5` is strictly ordered subject to the order of the elements of `bmultlist`, in `Transport6` the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lock` keyword.

If you want a further impression of the impact of the `lock` keyword, just rerun `Transport6` but comment out the `lock` as follows and compare the output.

```
...
//lock (ioMutex)
//{
    Console.WriteLine("Scenario bmult=" + b + ":");
    Console.WriteLine("  Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
    Console.WriteLine("  Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
    Console.WriteLine("  Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
//}
...
```

7.7.3.16 How to create a `GAMSModelInstance` from a `GAMSCheckpoint` (`Transport7`)

In `Transport7` the usage of `GAMS::GAMSModelInstance` is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Then we create the `GAMSModelInstance` `mi` using the `GAMSCheckpoint.AddModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```
...
GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob t7 = ws.AddJobFromString(GetModelText());
t7.Run(cp);
GAMSModelInstance mi = cp.AddModelInstance();
...
```

7.7.3.17 How to modify a parameter of a `GAMSModelInstance` using `GAMSModifier` (`Transport7`)

A `GAMSModelInstance` uses a `SyncDB` to maintain the data. We define `bmult` as `GAMSPParameter` using the `GAMSDatabase.AddParameter` method and specify `gurobi` as solver. Afterwards the `GAMSModelInstance` is instantiated with arguments `opt` and `GAMSModifier bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of `ModelInstance mi` stay unchanged. We use the `GAMSPParameter.AddRecord` method to assign a value to `bmult` that can be varied afterwards using the `GAMSPParameter.FirstRecord` method to reproduce our well-known example with different demand multipliers.

```
...
GAMSPParameter bmult = mi.SyncDB.AddParameter("bmult", 0, "demand multiplier");
GAMSOptions opt = ws.AddOptions();
opt.AllModelTypes = "gurobi";
mi.Instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
bmult.AddRecord().Value = 1.0;
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
foreach (double b in bmultlist)
{
    bmult.FirstRecord().Value = b;
    mi.Solve();
    Console.WriteLine("Scenario bmult=" + b + ":");
    Console.WriteLine("  Modelstatus: " + mi.ModelStatus);
    Console.WriteLine("  Solvestatus: " + mi.SolveStatus);
    Console.WriteLine("  Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
}
...
```

7.7.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a `GAMSModelInstance` just like in the next to last example. We define `x` as `GAMSVariable` and its upper bound as `GAMSParameter xup`. At the following instantiate method `GAMSModifier` has three arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the `GAMSParameter` that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
...
mi = cp.AddModelInstance();
GAMSVariable x = mi.SyncDB.AddVariable("x", 2, VarType.Positive, "");
GAMSParameter xup = mi.SyncDB.AddParameter("xup", 2, "upper bound on x");
mi.Instantiate("transport use lp min z", modifiers: new GAMSModifier(x,UpdateAction.Upper,xup));
foreach (GAMSSetRecord i in t7.OutDB.GetSet("i"))
    foreach (GAMSSetRecord j in t7.OutDB.GetSet("j"))
    {
        xup.Clear();
        xup.AddRecord(i.Keys[0],j.Keys[0]).Value = 0;
        mi.Solve();
        Console.WriteLine("Scenario link blocked: " + i.Keys[0] + " - " + j.Keys[0]);
        Console.WriteLine(" ModelStatus: " + mi.ModelStatus);
        Console.WriteLine(" Solvestatus: " + mi.SolveStatus);
        Console.WriteLine(" Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
    }
...

```

7.7.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a `GAMSCheckpoint cp` from a `GAMSJob`. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out-principle. The objects `queueMutex` and `ioMutex` are used later to avoid messed up output. Then we call two delegates of the function `ScenSolve` in parallel that get the same queue as argument.

```
...
GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
Queue<double> bmultQueue = new Queue<double>(new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 });
Object queueMutex = new Object();
Object ioMutex = new Object();
Parallel.For(0, 2, delegate(int i) { ScenSolve(ws, cp, bmultQueue, queueMutex, ioMutex); });
...

```

In function `ScenSolve` we create and instantiate a `GAMSModelInstance` as in the preceding examples and make `bmult` modifiable. The two delegates of the function extract the elements of the queue using `bmultQueue.Dequeue`. Note that we chose `cplex` as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```
private static void ScenSolve(GAMSWorkspace ws, GAMSCheckpoint cp, Queue<double> bmultQueue, Object queueMutex, Object
    ioMutex, int i)
{
    GAMSModelInstance mi = cp.AddModelInstance();
    GAMSParameter bmult = mi.SyncDB.AddParameter("bmult", 0, "demand multiplier");
    GAMSOptions opt = ws.AddOptions();
    opt.AllModelTypes = "cplex";
    mi.Instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
    bmult.AddRecord().Value = 1.0;
    while (true)
    {
        double b;
        // dynamically get a bmult value from the queue instead of passing it to the different threads at creation time
        lock (queueMutex)
        {
            if(0 == bmultQueue.Count)
                return;
            b = bmultQueue.Dequeue();
        }
        bmult.FirstRecord().Value = b;
        mi.Solve();
        // we need to make the output a critical section to avoid messed up report informations
    }
}

```

```

    lock (ioMutex)
    {
        Console.WriteLine("Scenario bmult=" + b + ";");
        Console.WriteLine(" Modelstatus: " + mi.ModelStatus);
        Console.WriteLine(" Solvestatus: " + mi.SolveStatus);
        Console.WriteLine(" Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
    }
}
}

```

7.7.3.20 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a `GAMSDatabase`. We call a function `ReadFromAccess` that finally returns a `GAMSDatabase` as shown below.

```

...
GAMSDatabase db = ReadFromAccess(ws);
...

```

The data we are going to read can be found in `<GAMS system directory>\apifiles\Data\transport.accdb`. It might be helpful to open this file for a better understanding. The function begins with the creation of an empty `GAMSDatabase`. Afterwards we connect to the MS Access database by first specifying the provider and then defining the aforementioned file as data source. The `OleDbConnection` represents an open connection to a data source. The following lines initialize the connection and use a try and a catch block for potential exceptions, i.e. errors that occur during application execution. To finally read in GAMS sets and parameters we call the functions `ReadSet` and `ReadParameter`. We will use several classes of the `System.Data.OleDb` namespace that are documented here. Furthermore, we recommend the [OLE DB Tutorial](#).

```

static GAMSDatabase ReadFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.AddDatabase();
    // connect to database
    string strAccessConn = @"Provider=Microsoft.ACE.OLEDB.12.0;Data Source=..\..\..\Data\transport.accdb";
    OleDbConnection connection = null;
    try
    {
        connection = new OleDbConnection(strAccessConn);
    }
    catch (Exception ex)
    {
        Console.WriteLine("Error: Failed to create a database connection. \n{0}", ex.Message);
        Environment.Exit(1);
    }
    // read GAMS sets
    ReadSet(connection, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
    ReadSet(connection, db, "SELECT Market FROM Market", "j", 1, "markets");
    // read GAMS parameters
    ReadParameter(connection, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
    ReadParameter(connection, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
    ReadParameter(connection, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
    return db;
}

```

The function `ReadSet` incorporates a try and a catch block. In the try block we prepare the reading from the MS Access file. Then we add a set symbol to the `GAMSDatabase` that is filled with the data from the MS Access file afterwards. The function `ReadParameter` works quite similar.

```

static void ReadSet(OleDbConnection connect, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string setExp = "")
{
    try
    {
        OleDbCommand cmd = new OleDbCommand(strAccessSelect, connect);
        connect.Open();
        OleDbDataReader reader = cmd.ExecuteReader();
        if (reader.FieldCount != setDim)
        {
            Console.WriteLine("Number of fields in select statement does not match setDim");
            Environment.Exit(1);
        }
        GAMSSet i = db.AddSet(setName, setDim, setExp);
        string[] keys = new string[setDim];
        while (reader.Read())
        {
            for (int idx = 0; idx < setDim; idx++)
                keys[idx] = reader.GetString(idx);
            i.AddRecord(keys);
        }
    }
}

```

```

    }
}
catch (Exception ex)
{
    Console.WriteLine("Error: Failed to retrieve the required data from the DataBase.\n{0}", ex.Message);
    Environment.Exit(1);
}
finally
{
    connect.Close();
}
}
}

```

Once we read in all the data we can create a `GAMSJob` from the `GAMSDatabase` and run it as usual.

7.7.3.21 How to fill a `GAMSDatabase` by reading from MS Excel (`Transport10`)

This example illustrates how to read data from Excel, or to be more specific, from `<GAMS system directory>\apifiles\Data\transport.xlsx`. The model is given as string without data like in in many examples before. At first we have to add

```
using Excel = Microsoft.Office.Interop.Excel;
```

to the preamble to be able to use the `Microsoft.Office.Interop.Excel` namespace. Then we define `excelApp` as Excel application using the implicit variable type `var`, use the aforementioned file as workbook `wb` and define the Excel range that can represent a cell, a row, a column, a selection of cells containing one or more contiguous blocks of cells, or a 3-D range.

```

...
var excelApp = new Excel.Application();
Excel.Workbook wb = excelApp.Workbooks.Open(Directory.GetCurrentDirectory() + @"..\..\..\Data\transport.xlsx");
Excel.Range range;
...

```

The following lines address the different worksheets and read in the contained data. Afterwards we make an errorcheck to ensure that the number of plants and markets is the same in all worksheets.

```

...
Excel.Worksheet capacity = (Excel.Worksheet)wb.Worksheets.get_Item("capacity");
range = capacity.UsedRange;
Array capacityData = (Array)range.Cells.Value;
int iCount = capacity.UsedRange.Columns.Count;
Excel.Worksheet demand = (Excel.Worksheet)wb.Worksheets.get_Item("demand");
range = demand.UsedRange;
Array demandData = (Array)range.Cells.Value;
int jCount = range.Columns.Count;
Excel.Worksheet distance = (Excel.Worksheet)wb.Worksheets.get_Item("distance");
range = distance.UsedRange;
Array distanceData = (Array)range.Cells.Value;
// number of markets/plants have to be the same in all spreadsheets
Debug.Assert((range.Columns.Count - 1) == jCount && (range.Rows.Count - 1) == iCount,
    "Size of the spreadsheets doesn't match");
wb.Close();
...

```

If you have problems to see through the steps above, adding the following output section right after `wb.Close()` might be helpful to understand where which data is stored.

```

...
for (int ii = 1; ii <= iCount; ii++)
{
    Console.WriteLine("capacityData(1, " + ii + ") = " + capacityData.GetValue(1, ii));
    Console.WriteLine("capacityData(2, " + ii + ") = " + capacityData.GetValue(2, ii));
}
for (int jj = 1; jj <= jCount; jj++)
{
    Console.WriteLine("demandData(1, " + jj + ") = " + demandData.GetValue(1, jj));
    Console.WriteLine("demandData(2, " + jj + ") = " + demandData.GetValue(2, jj));
}
for (int ii = 1; ii <= iCount; ii++)
{
    for (int jj = 1; jj <= jCount; jj++)
        Console.WriteLine("distanceData(" + (ii+1) + ", " + (jj+1) + ") = " + distanceData.GetValue(ii+1, jj+1));
}
...

```

Now we can create the `GAMSWorkspace` as usual and afterwards create a `GAMSDatabase` and fill it with the workbook data as follows:

```

...
GAMSDatabase db = ws.AddDatabase();
GAMSSet Set1 = db.AddSet("i", 1, "Plants");
GAMSSet j = db.AddSet("j", 1, "Markets");
GAMSParameter capacityParam = db.AddParameter("a", 1, "Capacity");
GAMSParameter demandParam = db.AddParameter("b", 1, "Demand");
GAMSParameter distanceParam = db.AddParameter("d", 2, "Distance");
for (int ic = 1; ic <= iCount; ic++)
{
    Set1.AddRecord((string)capacityData.GetValue(1, ic));
    capacityParam.AddRecord((string)capacityData.GetValue(1, ic)).Value = (double)capacityData.GetValue(2, ic);
}
for (int jc = 1; jc <= jCount; jc++)
{
    j.AddRecord((string)demandData.GetValue(1, jc));
    demandParam.AddRecord((string)demandData.GetValue(1, jc)).Value = (double)demandData.GetValue(2, jc);
    for (int ic = 1; ic <= iCount; ic++)
    {
        distanceParam.AddRecord((string)distanceData.GetValue(ic + 1, 1), (string)distanceData.GetValue(1, jc + 1)).Value =
            (double)distanceData.GetValue(ic + 1, jc + 1);
    }
}
...

```

Note that we can name sets and parameters just like in the database but we don't have to. Now we finally set up the database and can run our GAMSJob as usual.

```

...
using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t10 = ws.AddJobFromString(GetModelText());
    opt.Defines.Add("gdxincname", db.Name);
    opt.AllModelTypes = "xpress";
    t10.Run(opt, db);
    foreach (GAMSVariableRecord rec in t10.OutDB.GetVariable("x"))
        Console.WriteLine("x(" + rec.Keys[0] + ", " + rec.Keys[1] + "): level=" + rec.Level + " marginal=" + rec.Marginal);
}
...

```

7.7.3.22 How to create and use a save/restart file (Transport11)

In `Transport11` we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a `GAMSCheckpoint`.

In the main function we start with the creation of a folder called `tmp` that internally is denoted as `wDir`. Then we call the function `CreateSaveRestart`.

```

...
string wDir = Path.Combine(".", "tmp");
CreateSaveRestart(Path.Combine(wDir, "tbase"));
...

```

In function `CreateSaveRestart` we choose the path of the file given as argument as working directory, so it should be `wDir`. Then we create a `GAMSJob` from a string. Note that the string given via `GetBaseModelText()` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a `GAMSOption` to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the `GAMSJob` and stored in the file given as argument to the function. This becomes possible because the `AddCheckpoint` method accepts identifiers as well as file names as argument.

```

static void CreateSaveRestart(string cpFileName)
{
    GAMSWorkspace ws;
    if (Environment.GetCommandLineArgs().Length > 1)
        ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName), systemDirectory:
            Environment.GetCommandLineArgs()[1]);
    else
        ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName));
    GAMSJob j1 = ws.AddJobFromString(GetBaseModelText());
    GAMSOptions opt = ws.AddOptions();
    opt.Action = GAMSOptions.EAction.CompileOnly;
    GAMSCheckpoint cp = ws.AddCheckpoint(Path.GetFileName(cpFileName));
    j1.Run(opt, cp);
    opt.Dispose();
}

```

So what you should keep in mind before we return to further explanations of the main function is, that now the file `tbase` in folder `tmp` which is denoted as `wDir` contains a checkpoint. Now in the main function we define some data using C# data structures as we already did in `Transport4` before we create the `GAMSWorkspace` with working directory `wDir`.

```
...
GAMSWorkspace ws;
if (Environment.GetCommandLineArgs().Length > 1)
    ws = new GAMSWorkspace(workingDirectory: wDir, systemDirectory: Environment.GetCommandLineArgs()[1]);
else
    ws = new GAMSWorkspace(workingDirectory: wDir);
...
```

Afterwards we set up the `GAMSDatabase` like we already did in `Transport4`. Once this is done we run a `GAMSJob` using this data plus the checkpoint stored in file `tbase`.

```
...
GAMSCheckpoint cpBase = ws.AddCheckpoint("tbase");
using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t4 = ws.AddJobFromString(GetModelText(), cpBase);
    opt.Defines.Add("gdxincname", db.Name);
    opt.AllModelTypes = "xpress";
    t4.Run(opt, db);
    foreach (GAMSVariableRecord rec in t4.OutDB.GetVariable("x"))
        Console.WriteLine("x(" + rec.Keys[0] + ", " + rec.Keys[1] + "): level=" + rec.Level + " marginal=" + rec.Marginal);
}
...
```

Note that the string from which we create job `t4` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the `GAMSDatabase` correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

7.8 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C++ API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known [transportation problem](#). These examples introduce several API features step by step. The GAMS distribution comes with a pre compiled binary version of the GAMS C++ API on Windows, Mac OS X and Linux. Furthermore, the C++ API itself and the provided examples are published under MIT license and are hosted at the [GAMS GitHub](#) organization. Therefore it is possible to compile the library manually (e.g. if a certain compiler is required) The GAMS C++ API is implemented and compatible with C++17.

- [Getting Started](#) A quick introduction about how to create and configure a C++ project using Qt Creator
- [Important Classes of the API](#) Overview of some fundamental classes of the GAMS C++ API
- [How to use API](#) An extensive set of examples how to use API components

7.8.1 Getting Started

This section guides you through the basic steps of compiling and running a program from scratch using either [Qt Creator](#) or [Microsoft Visual Studio](#). If you want to have a look at the API itself you can directly start with the [How to use API](#) section instead. Note that you need to use at least C++17 in order to be able to use the GAMS C++ API. While this tutorial uses Qt Creator and Microsoft Visual Studio, other IDE's can be used as well.

Note

When using the pre compiled binary distribution of the GAMS C++ API as done in this section, one needs to use a compiler that is compatible with the one that was used during compilation of the library. Depending on the platform, different versions of the pre build binaries can be found under `<GAMS system directory>/apifiles/C++/lib`. In GAMS versions before 25.0 the binaries can be found under `<GAMS system directory>`.

7.8.1.1 Getting Started using Qt Creator

After opening Qt Creator click on **File > New File or Project**. Choose **Non-Qt Project > Plain C++ Application** and click on **Choose...**. On the next page fill in the name and the location of the new project and click **Next**. Select the kits you want to use for the project and click again on **Next**. If you use the precompiled library on Windows, you need to use **MSVC2017** or **MSVC2019**. Confirm the creation of the new project by clicking on **Finish**.

As soon as the project is created open the file `GAMSApplication.pro` by double clicking on it in the pane on the left hand side. Add the following two lines to the `.pro` file:

```
unix : LIBS += -ldl -L$(HOME)/gams36.0_linux.x64_64_sfx/apifiles/C++/lib -lgamscpp
win32: LIBS += -LC:\GAMS\36\apifiles\C++\lib\vs2019 -lgamscpp
INCLUDEPATH += C:\GAMS\36\apifiles\C++\api
```

Note

Depending on your operating system and the location of your GAMS system you need to adjust the paths respectively. Furthermore, all pre build binaries are always located at `<GAMS system directory>\apifiles\C++\lib`, if GAMS 25.0 (or higher) is used. This location may contain additional sub directories, like `<GAMS system directory>\apifiles\C++\lib\vs2019`. In case a previous version of GAMS is used the binaries are located at `<GAMS system directory>`.

Save the changes, right click on the project and choose **Run qmake**.

The last step of creating a first small example is to write code that makes use of the GAMS C++ API. Open the file `main.cpp` and replace the content of the file with the following lines of code:

```
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;
int main(int argc, char* argv[])
{
    GAMSWorkspace ws;
    ws.gamsLib("trnsport");
    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << ", " << rec.key(1) << "):" << " level=" << rec.level() << " marginal=" <<
            rec.marginal() << endl;
}
```

Make sure that **MSVC2019 64bit** is chosen as kit using the **Release** mode.

Click on the **play** button below to run (and compile) the small example. If everything works, you should see the output of the example displaying results of the solved transportation problem.

7.8.1.2 Getting Started using Visual Studio 2019

After opening Visual Studio click on **File > New > Project ...**

Choose **Console App** and fill in the name and the location of the project and click on **Ok**.

As soon as the project is loaded, open the **Configuration Manager**:

Change the **Active solution configuration** to **Release** and the **Active solution platform** to **x64**.

The next step is to configure the project to find the GAMS C++ API. Right click on the project and choose **Properties** from the context menu. Go to **Configuration Properties > C/C++ > General** and add `<GAMS system directory>\apifiles\C++\api` to **Additional Include Directories**.

Select **Configuration Properties > C/C++ > Precompiled Headers** on the left. On the right open the dropdown of **Precompiled Header** and select **Not Using Precompiled Headers**.

Go to **Configuration Properties > Linker > General** and add the `apifiles` path to the matching version of your Visual Studio (e.g. `<GAMS system directory>\apifiles\C++\lib\vs2017`) to **Additional Library Directories**:

Note

Please mind that the pre build binaries for older GAMS versions (before GAMS 25.0) are located at `<GAMS system directory>`.

Choose **Input** and add `gamscpp.lib`; to **Additional Dependencies**. Make sure that all previous entries including `%(AdditionalDependencies)` are present as well.

The last required configuration step is to add a post-build event that copies required files next to the generated executable. Click on **Build Events** > **Post-Build Event** and add the following code to **Command Line**. It is helpful to select `<Edit...>` from the dropdown box as there are two command lines. Note that you might need to adjust the used path depending on the location of your GAMS installation:

```
xcopy /Y "C:\gams\36\apifiles\C++\lib\vs2017\gamscpp.dll" "$(OutDir)"
```

Open the file `GAMSApplication.cpp` and replace its content by the following code:

```
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;
int main(int argc, char* argv[])
{
    GAMSWorkspace ws;
    ws.gamsLib("trnsport");
    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << ", " << rec.key(1) << "):" << " level=" << rec.level() << " marginal=" <<
            rec.marginal() << endl;
}
```

Click on **Debug** > **Start Without Debugging** in order to compile and run the example. If everything works, you should see the output of the example displaying results of the solved transportation problem.

7.8.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the `gams` namespace. Their usage is demonstrated by an extensive set of [examples](#).

- `gams` Namespace
 - `gams::GAMSWorkspace` Class
 - `gams::GAMSJob` Class
 - `gams::GAMSDatabase` Class
 - `gams::GAMSOptions` Class
 - `gams::GAMSModelInstance` Class
 - `gams::GAMSSymbol` Class
-

7.8.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C++ API. `<GAMS system directory>\apifiles\C++` contains the Qt project `examples.pro` and several Visual Studio solutions for different versions of Visual Studio (e.g. `examples-vs2017.sln`, `examples-vs2019.sln`). The code snippets that are explained in this tutorial are taken from these examples. Furthermore there is a `CMakeLists.txt` file that can be used for building the examples using CMake. The well-known transportation problem is discussed step by step and each example introduces new elements of the GAMS C++ API.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

-

7.8.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing `Transport1.exe` with `C:/GAMS/38` we use the 64-bit version of GAMS 38.0 to run `Transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
GAMSWorkspaceInfo wsInfo;
if (argc > 1)
    wsInfo.setSystemDirectory(argv[1]);
GAMSWorkspace ws(wsInfo);
...
```

Remember that the bitness of the GAMS system has to match the bitness of your C++ program.

7.8.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented C++ API offers much more than exchanging data between C++ and GDX, a common use case is the export and import of GDX files. The central class for this purpose is `GAMSDatabase`. We assume that the data to be exported is available in C++ data structures.

```
...
vector<string> plants = {
    "Seattle", "San-Diego"
};
vector<string> markets = {
    "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
map<string, double> demand = {
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
map<tuple<string, string>, double> distance = {
    { make_tuple("Seattle", "New-York"), 2.5 },
    { make_tuple("Seattle", "Chicago"), 1.7 },
    { make_tuple("Seattle", "Topeka"), 1.8 },
    { make_tuple("San-Diego", "New-York"), 2.5 },
    { make_tuple("San-Diego", "Chicago"), 1.8 },
    { make_tuple("San-Diego", "Topeka"), 1.4 }
};
...
```

Different GAMS symbols are represented using different C++ data structures. The data for the GAMS sets is represented using vectors of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by maps (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with C++ data structures.

A new `GAMSDatabase` instance can be created using `GAMSWorkspace.addDatabase`.

```
...
// create new GAMSDatabase instance
GAMSDatabase db = ws.addDatabase();
...
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created `GAMSSet` instance `i` using `GAMSSet.addRecord`.

```
...
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
...
```

`GAMSParameter` instances can be added by using the method `GAMSDatabase.addParameter`. It has the same signature as `GAMSDatabase.addSet`. Anyhow, in this example we use an overload of the method

which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```
...
// add parameter 'a' with domain 'i'
GAMSPParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
...
```

As soon as all data is prepared in the GAMSDatabase, the method GAMSDatabase.doExport can be used to create a GDX file.

```
...
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSSpace
db.doExport("data.gdx");
...
```

7.8.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using GAMSSpace.addDatabaseFromGDX. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```
...
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.addDatabaseFromGDX("data.gdx");
...
```

Reading the data from the GAMSSet *i* into a vector can be done as follows:

```
...
// read data from symbols into C++ data structures
vector<string> iNew;
for(GAMSSetRecord rec : db2.getSet("i"))
    iNew.push_back(rec.key(0));
...
```

A new vector *iNew* is created. *i* is retrieved by calling GAMSDatabase.getSet on db2. The returned GAMSSet object can be iterated using a for-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSPParameters. Instead of creating a vector, we want to have the data in the form of a map. GAMSPParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter *a* into a `map<string, double>`.

```
...
map<string, double> aNew;
for(GAMSPParameterRecord rec : db2.getParameter("a"))
    aNew[rec.key(0)] = rec.value();
...
```

For multi dimensional symbols, we choose the map keys to be tuples instead of string. We access the individual keys by index and generate a tuple using `make_tuple`.

```
...
map<tuple<string, string>, double> dNew;
for(GAMSPParameterRecord rec : db2.getParameter("d"))
    dNew[make_tuple(rec.key(0), rec.key(1))] = rec.value();
...
```

Scalars can be read into a variable of type double by accessing the value of the first and only record.

```
...
double fNew = db2.getParameter("f").firstRecord().value();
...
```

7.8.3.4 How to run a GAMSJob from file (Transport1)

At first we create a `GAMSWorkspace`. Afterwards we load the model `trnsport` from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the `GAMSWorkspace.AddJobFromFile` Method afterwards. Apparently this method also works with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GAMSJob `t1` is defined from that file and run by the `GAMSJob.run` method. The following lines create the solution output and illustrate the usage of the `GAMSJob.outDB` method to get access to the `GAMSDatabase` created by the `run` method. To retrieve the content of variable `x` we use the `GAMSVariableRecord` class and the `GAMSDatabase.getVariable` method.

```
...
GAMSWorkspace ws;
ws.gamsLib("trnsport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
// Default run
t1.run();
cout << "Ran with Defaults:" << endl;
for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
    cout << "x(" << rec.key(0) << ", " << rec.key(1) << "):" << " level=" << rec.level() << " marginal=" << rec.marginal()
        << endl;
...

```

7.8.3.5 How to specify the solver (Transport1)

The solver can be specified via the `GAMSOptions` class and the `GAMSWorkspace.addOptions` method. The `GAMSOptions.setAllModelTypes` method sets `xpress` as default solver for all model types which the solver can handle.

```
...
// Run the job again with another solver
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("xpress");
t1.run(opt);
...

```

7.8.3.6 How to run a job with a solver option file (Transport1)

At first create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. We choose `xpress` as solver just like in the preceding example and call `GAMSOptions.setOptFile` in order to tell the solver to look for a solver option file.

```
...
// Run the job with a solver option file
ofstream xpressopt(ws.workingDirectory() + cPathSep + "xpress.opt");
xpressopt << "algorithm=barrier" << endl;
xpressopt.close();
opt.setAllModelTypes("xpress");
opt.setOptFile(1);
t1.run(opt);
...

```

7.8.3.7 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings provided by the methods `getDataText` and `getModelText` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
...
ofstream tdata(ws.workingDirectory() + cPathSep + "tdata.gms");
tdata << getDataText();
tdata.close();
...

```

Afterwards we create a `GAMSJob` using the `GAMSWorkspace.addJobFromString` method. The `GAMSOptions.setDefine` method is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line.

```
...
GAMSOptions opt = ws.addOptions();
GAMSJob t2 = ws.addJobFromString(getModelText());
opt.setDefine("incname", "tdata");
t2.run(opt);
...
```

Note that the string provided by `getModelText` contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

7.8.3.8 How to read data from string and export to GDX (Transport3)

We read the data from the string provided by `getDataText` as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding `GAMSJob` a `GAMSDatabase` is created that is available via the `GAMSJob.outDB` method. We can use the `GAMSDatabase.doExport` method to write the content of this database to a gdx file `tdata.gdx`.

```
...
// data from a string with GAMS syntax with explicit export to GDX file
GAMSJob t3 = ws.addJobFromString(getDataText());
t3.run();
t3.outDB().doExport(ws.workingDirectory() + cPathSep + "tdata.gdx");
...
```

7.8.3.9 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in [Transport2 - How to use include files \(Transport2\)](#).

```
...
t3 = ws.addJobFromString(getModelText());
GAMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", "tdata");
opt.setAllModelTypes("xpress");
t3.run(opt);
...
```

Note that there are some changes in `getModelText` due to the usage of a GDX file instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

7.8.3.10 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two `GAMSJobs` `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `outDB` can be read in directly just like a gdx file. Note that the database needs to be passed to the `GAMSJob.run` method as additional argument.

```
...
GAMSJob t3a = ws.addJobFromString(getDataText());
GAMSJob t3b = ws.addJobFromString(getModelText());
t3a.run();
opt.setDefine("gdxincname", t3a.outDB().name());
t3b.run(opt, t3a.outDB());
...
```

7.8.3.11 How to define data using C++ data structures (Transport4)

We use the `vector<T>` and `map<Key, Value>` to define C++ data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
...
vector<string> plants = {
    "Seattle", "San-Diego"
};
vector<string> markets = {
    "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
map<string, double> demand = {
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
map<tuple<string, string>, double> distance = {
    { make_tuple("Seattle", "New-York"), 2.5 },
    { make_tuple("Seattle", "Chicago"), 1.7 },
    { make_tuple("Seattle", "Topeka"), 1.8 },
    { make_tuple("San-Diego", "New-York"), 2.5 },
    { make_tuple("San-Diego", "Chicago"), 1.8 },
    { make_tuple("San-Diego", "Topeka"), 1.4 }
};
...
```

7.8.3.12 How to prepare a GAMSDatabase from C++ data structures (Transport4)

At first we create an empty GAMSDatabase `db` using the `GAMSWorkspace.addDatabase` method. Afterwards we prepare the database. To add a set to the database we use the `GAMSSet` class and the `GAMSDatabase.addSet` method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C++ data structure and add them by using the `GAMSSet.addRecord` method. We do pretty much the same thing for the parameters.

Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that the scalars can be treated as parameter with dimension 0.

The `GAMSJob` can be run like explained in the preceding example about implicit database communication.

```
...
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
...
GMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
...
GMSParameter d = db.addParameter("d", "distance in thousands of miles", i, j);
for (auto t : distance)
    d.addRecord(get<0>(t.first), get<1>(t.first)).setValue(t.second);
GMSParameter f = db.addParameter("f", "freight in dollars per case per thousand miles");
f.addRecord().setValue(90);
// run a job using data from the created GAMSDatabase
GAMSJob t4 = ws.addJobFromString(getModelText());
GMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t4.run(opt, db);
...
```

7.8.3.13 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following two lines of code conduct several operations. While the first line simply creates a GAMS checkpoint, the second one uses the `GAMSWorkspace.addJobFromString` method to create a `GAMSJob` containing the model text and data but no solve statement. In contrast to the preceding examples it runs the job immediately using the `GAMSJob.run` method. Furthermore, it passes an additional checkpoint argument to the `run` method. That means the `GAMSCheckpoint cp` captures the state of the `GAMSJob`.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
...
ws.addJobFromString(getModelText()).run(cp);
...
```

7.8.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function `getModelText()` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
...
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';
...

```

We create a **vector** with eight different values for this demand multiplier.

```
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
```

For each entry of the vector we create a `GAMSJob` `t5` using the `GAMSWorkspace.addJobFromString` method. Besides the string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a `GAMSJob` combined from the checkpoint plus the content provided by the string.

We run the `GAMSJob` and echo some interesting data from the `outDB` using the `GAMSDatabase.getParameter` and `GAMSDatabase.getVariable` methods, the `GAMSPParameter.findRecord` and `GAMSVariable.findRecord` methods plus the `GAMSPParameterRecord.value` and the `GAMSVariableRecord.level` methods.

```
...
for (double b : bmultlist)
{
    GAMSJob t5 = ws.addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
    ss=transport.solvestat;", cp);
    t5.run();
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << " Modelstatus: " << t5.outDB().getParameter("ms").findRecord().value() << endl;
    cout << " Solvestatus: " << t5.outDB().getParameter("ss").findRecord().value() << endl;
    cout << " Obj: " << t5.outDB().getVariable("z").findRecord().level() << endl;
}
...

```

Note

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the [model status](#) and the [solve status](#) provide important information for a correct solution interpretation.

7.8.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs we already know from `Transport5` in parallel. We create a `GAMSCheckpoint` `cp` and initialize it by running a `GAMSJob`. Furthermore we introduce a demand multiplier as we did before.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromString(getModelText()).run(cp);
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...

```

Furthermore, we introduce a new object `ioMutex` that will be used to avoid mixed up output from the parallel jobs. For each element `b` from the vector of demand multipliers we create a thread executing the `runScenario` method.

```
...
// run multiple parallel jobs using the created GAMSCheckpoint
mutex ioMutex;
vector<thread> v;
for(double b : bmultlist)
    v.emplace_back([&ws, cp, &ioMutex, b]{runScenario(&ws, cp,&ioMutex,b)});
for (auto& t : v)
    t.join();
...

```

In function `runScenario` a `GAMSJob` is created and run just like in the preceding example of `Transport5`. The output section is also the same except for the fact that it is locked by using a `lock_guard` on the `ioMutex`. That means the threads of `runScenario` are running in parallel but the output block of different threads cannot be executed in parallel since it is locked using the same `ioMutex`.

```
...
void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
    ss=transport.solvestat;", cp);
    t6.run();
    // we need to make the output a critical section to avoid messed up report information
    lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << " Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << " Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << " Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
...
```

While the output in `Transport5` is strictly ordered subject to the order of the elements of `bmultlist`, in `Transport6` the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lock_guard` mechanism.

If you want a further impression of the impact of the `lock_guard`, just rerun `Transport6` but comment out the `lock_guard` as follows and compare the output.

```
...
void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
    ss=transport.solvestat;", cp);
    t6.run();
    // we need to make the output a critical section to avoid messed up report information
    // lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << " Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << " Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << " Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
...
```

7.8.3.16 How to create a `GAMSModelInstance` from a `GAMSCheckpoint` (`Transport7`)

In `Transport7` the usage of `gams::GAMSModelInstance` is demonstrated.

At first we create a checkpoint `cp` as in the preceding examples. Then we create the `GAMSModelInstance` `mi` using the `GAMSCheckpoint.addModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
GAMSJob t7 = ws.addJobFromString(getModelText());
t7.run(cp);
GAMSModelInstance mi = cp.addModelInstance();
...
```

7.8.3.17 How to modify a parameter of a `GAMSModelInstance` using `GAMSModifier` (`Transport7`)

A `GAMSModelInstance` uses a `syncDB` to maintain the data. We define `bmult` as `GAMSPParameter` using the `GAMSDatabase.addParameter` method and specify `cplex` as solver. Afterwards the `GAMSModelInstance` is instantiated with three arguments: the solve statement, the `GAMSOptions` object `opt` and `bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of `GAMSModelInstance` `mi` stay unchanged.

We use the `GAMSPParameter.addRecord` method to assign a value to `bmult` that can be varied afterwards using the `GAMSPParameter.firstRecord` method to reproduce our well-known example with different demand multipliers.

```
...
```

```

GAMSModelInstance mi = cp.addModelInstance();
GAMSParameter bmult = mi.syncDb().addParameter("bmult", 0, "demand multiplier");
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("cplex");
// instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult));
bmult.addRecord().setValue(1.0);
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
for (double b : bmultlist) {
    bmult.firstRecord().setValue(b);
    mi.solve();
    cout << "Scenario bmult=" << b << " " << endl;
    cout << " Modelstatus: " << mi.modelStatusAsString() << endl;
    cout << " Solvestatus: " << mi.solveStatusAsString() << endl;
    cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
}
...

```

7.8.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a GAMSModelInstance and define `x` as GAMSVariable and its upper bound as GAMSParameter `xup`. At the following instantiate method GAMSModifier has three arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GAMSParameter that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```

...
mi = cp.addModelInstance();
GAMSVariable x = mi.syncDb().addVariable("x", 2, GAMSEnum::VarType::Positive, "");
GAMSParameter xup = mi.syncDb().addParameter("xup", 2, "upper bound on x");
// instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare upper bound of X mutable
mi.instantiate("transport use lp min z", GAMSModifier(x, GAMSEnum::SymbolUpdateAction::Upper, xup));
for (GAMSSetRecord i : t7.outDB().getSet("i")) {
    for (GAMSSetRecord j : t7.outDB().getSet("j")) {
        xup.clear();
        xup.addRecord(i.key(0), j.key(0)).setValue(0);
        mi.solve();
        cout << "Scenario link blocked=" << i.key(0) << "-" << j.key(0) << endl;
        cout << " Modelstatus: " << mi.modelStatusAsString() << endl;
        cout << " Solvestatus: " << mi.solveStatusAsString() << endl;
        cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
    }
}
...

```

7.8.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint `cp` from a GAMSJob. Then we define a vector that represents the different values of the demand multiplier. While `ioMutex` is used to avoid messed up output, `vectorMutex` synchronizes the access to the vector. Then we start multiple thread executing the method `scenSolve`. The number of parallel executed threads is specified by `nrThreads`. All threads share the same vector that provides the different values for `bmult`.

```

...
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromString(getModelText()).run(cp);
vector<double> bmultVector = { 1.3, 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6 };
int nrThreads = 2;
std::mutex vectorMutex;
std::mutex ioMutex;
vector<thread> v;
for (int i = 0; i < nrThreads; i++)
    v.emplace_back([&ws, &cp, &bmultVector, &vectorMutex, &ioMutex] {scenSolve(&ws, &cp, &bmultVector, &vectorMutex, &ioMutex);});
for (auto& t : v)
    t.join();
...

```

In `scenSolve` we create and instantiate a `GAMSModelInstance` as in the preceding examples and make `bmult` modifiable. As long as `bmultVector` is not empty, an element is taken and removed from the vector. The value is used for the scalar `bmult`. Note that we chose `cplex` as solver because it is thread safe (`gurobi` would also be possible). Once the vector is empty the loop terminates.

```
void Transport8::scenSolve(GAMSWorkspace* ws, GAMSCheckpoint* cp, vector<double>* bmultVector, std::mutex* vectorMutex,
    std::mutex* ioMutex)
{
    unique_lock<mutex> vectorLock(*vectorMutex);
    GAMSModelInstance mi = cp->addModelInstance();
    vectorLock.unlock();
    GAMSParameter bmult = mi.syncDb().addParameter("bmult", "demand multiplier");
    GAMSOptions opt = ws->addOptions();
    opt.setAllModelTypes("cplex");
    // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult));
    bmult.addRecord().setValue(1.0);
    while (true)
    {
        double b;
        // dynamically get a bmult value from the vector instead of passing it to the different threads at creation time
        vectorLock.lock();
        if (bmultVector->empty())
            return;
        b = bmultVector->back();
        bmultVector->pop_back();
        vectorLock.unlock();
        bmult.firstRecord().setValue(b);
        mi.solve();
        // we need to make the output a critical section to avoid messed up report informations
        unique_lock<mutex> ioLock(*ioMutex);
        cout << "Scenario bmult=" << b << " " << endl;
        cout << " Modelstatus: " << mi.modelStatus() << endl;
        cout << " Solvestatus: " << mi.solveStatus() << endl;
        cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
        ioLock.unlock();
    }
}
```

7.8.3.20 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a `GAMSDatabase`. It can only be run on Windows since it makes use of the Microsoft Access Driver. Furthermore the example makes use of the `Qt SQL module`. Note that you need to have Microsoft Access installed and that its bitness needs to match the bitness of your GAMS version. In the example we call a function `readFromAccess` that finally returns a `GAMSDatabase` as shown below.

```
...
GAMSDatabase db = readFromAccess(ws);
...
```

The data we are going to read can be found in `<GAMS system directory>\apifiles\Data\transport.accdb`. It might be helpful to open this file for a better understanding. The function begins with the creation of an empty `GAMSDatabase`. Afterwards we create a `QSqlDatabase`, specify the connection string and open the connection to the database. If opening the connection was successful, data is read from the database into the `GAMSDatabase` using the methods `readSet` and `readParameter`.

```
GAMSDatabase readFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.addDatabase();
    QSqlDatabase sqlDb = QSqlDatabase::addDatabase("QODBC", "readConnection");
    QString strAccessConn = ("Driver={Microsoft Access Driver (*.mdb, *.accdb)};DSN='';DBQ=" + ws.systemDirectory() \
        + cPathSep + "apifiles" + cPathSep + "Data" + cPathSep + "transport.accdb").c_str();
    sqlDb.setDatabaseName(strAccessConn);
    if(sqlDb.open())
    {
        // read GAMS sets
        readSet(sqlDb, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
        readSet(sqlDb, db, "SELECT Market FROM Market", "j", 1, "markets");
        // read GAMS parameters
        readParameter(sqlDb, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
        readParameter(sqlDb, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
        readParameter(sqlDb, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
        sqlDb.close();
    }
    else
    {
        cout << "Error: Failed to create a database connection. " << sqlDb.lastError().text().toString() << endl;
        exit(1);
    }
}
```

```

    }
    return db;
}

```

The function `readSet` creates a `QSqlQuery` that reads data from a table of the Access database. A `GAMSSet` is created and populated with the data.

```

void readSet(QSqlDatabase sqlDb, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string setExp = "")
{
    QSqlQuery query(sqlDb);
    if (!query.exec(strAccessSelect.c_str()))
    {
        cout << "Error executing query on set '" << setName << "'" << endl;
        cout << query.lastError().text().toString() << endl;
        exit(1);
    }
    if (query.size() && (query.record().count() != setDim))
    {
        cout << "Number of fields in select statement does not match setDim" << endl;
        exit(1);
    }
    GAMSSet i = db.addSet(setName, setDim, setExp);
    vector<string> keys = vector<string>(setDim);
    while (query.next())
    {
        for (int idx = 0; idx < setDim; idx++)
            keys[idx] = query.value(idx).toString().toString();
        i.addRecord(keys);
    }
}

```

Once we read in all the data we can create a `GAMSJob` from the `GAMSDatabase` and run it as usual. Finally the results are written to `transport.accdb`.

7.8.3.21 How to fill a `GAMSDatabase` by reading from MS Excel (`Transport10`)

This example illustrates how to read data from Excel, or to be more specific, from `<GAMS system directory>\apifiles\Data\transport.xlsx`. It can only be run on Windows. Note that you need to have Microsoft Excel installed and that its bitness needs to match the bitness of your GAMS version. The model is given as string without data like in in many examples before. At first we have to add

```

#include <QAxObject>
#include <Windows.h>

```

to be able to use the `QAxObject` class, which serves as a wrapper for COM objects. Furthermore we include `Windows.h` to access the functions `CoInitialize` and `CoUninitialize`. In the main function we open the aforementioned file to get access to its content. Note that we need to call `CoInitialize(0)` first in order to initialize ActiveX. We create an instance of the class `QAxObject` and use the `querySubObject` method multiple times to get to the sheets of the workbook.

```

...
QAxObject* excel = new QAxObject( "Excel.Application", 0 );
QAxObject* workbooks = excel->querySubObject( "Workbooks" );
QAxObject* workbook = workbooks->querySubObject( "Open(const QString&)", fileName );
QAxObject* sheets = workbook->querySubObject( "Worksheets" );
...

```

The method `sheetToParameter` is used in order to transfer data from the workbook into `GAMSPParameter` instances. In order to determine from which sheet the actual data needs to be read, the method takes the `QAxObject` instance referring to the sheets and the actual sheet name. A new `GAMSPParameter` is added to the `GAMSDatabase` object `db` using `set1` and `set2` as domains. The next step is to determine the number of columns and the number of rows used. The for loop reads the actual data, adds the records to the new `GAMSPParameter` and sets their values.

```

...
GAMSPParameter sheetToParameter(QAxObject* sheets, string sheetName, GAMSDatabase db, string paramName, string paramText,
    GAMSSet set1, GAMSSet set2)
{
    QAxObject* sheet = sheets->querySubObject( "Item( string )", sheetName.c_str() );
    vector<GAMSDomain> sets {set1, set2};
    GAMSPParameter param = db.addParameter(paramName, paramText, sets);
    QAxObject* usedrange = sheet->querySubObject( "UsedRange" );
    QAxObject * columns = usedrange->querySubObject("Columns");
    int intCols = columns->property("Count").toInt();
    QAxObject * rows = usedrange->querySubObject("Rows");
    int intRows = rows->property("Count").toInt();
}

```

```

for (int j = 2; j <= intCols; j++) {
    string namej = sheet->querySubObject("Cells( int, int )", 1, j)->dynamicCall("Value()").toString().toStdString();
    for (int i = 2; i <= intRows; ++i) {
        string namei = sheet->querySubObject("Cells( int, int )", i,
1)->dynamicCall("Value()").toString().toStdString();
        GAMSParameterRecord rec = param.addRecord(namei, namej);
        double value = sheet->querySubObject("Cells( int, int )", i, j)->dynamicCall("Value()").toDouble();
        rec.setValue(value);
    }
}
return param;
}
...

```

After all required data was read from the workbook, we need to close it and quit the Excel application.

```

...
workbook->dynamicCall("Close()");
excel->dynamicCall("Quit()");
...

```

Now we can create and run the GAMSJob using the created GAMSDatabase as usual.

```

...
GAMSOptions opt = ws.addOptions();
GAMSJob t10 = ws.addJobFromString(getModelText());
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t10.run(opt, db);
for (GAMSVariableRecord record : t10.outDB().getVariable("x"))
    cout << "x(" << record.key(0) << ", " << record.key(1) << "): level=" << record.level() <<
        " marginal=" << record.marginal() << endl;
...

```

Finally we need to call 'CoUninitialize' in order to close the COM library.

```

...
::CoUninitialize();
...

```

7.8.3.22 How to create and use a save/restart file (Transport11)

In `Transport11` we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a `GAMSCheckpoint`. We start by creating the save/restart file by calling `createSaveRestart`.

```

...
std::string cpName = "tbase";
createSaveRestart(argc, argv, cpName);
...

```

In function `createSaveRestart` we choose the `checkpointName` as relative path to the current directory in order to create a `GAMSWorkspace`. Then we create a `GAMSJob` from a string. Note that the string given via `getBaseModelText()` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a `GAMSOption` to only compile the job without executing it. Then we create a checkpoint `cp` that is initialized by the following run of the `GAMSJob` and stored in the file given as argument to the function. This becomes possible because the `addCheckpoint` method accepts identifiers as well as file names as argument.

```

void createSaveRestart(int argc, char* argv[], const string &checkpointName)
{
    GAMSWorkspaceInfo wsInfo;
    if (argc > 1)
        wsInfo.setSystemDirectory(argv[1]);
    wsInfo.setWorkingDirectory("." + (cPathSep+ checkpointName));
    GAMSWorkspace ws(wsInfo);
    GAMSJob j1 = ws.addJobFromString(getBaseModelText());
    GAMSOptions opt = ws.addOptions();
    opt.setAction(GAMSOptions::EAction::CompileOnly);
    auto checkpoint = ws.workingDirectory() + cPathSep + checkpointName;
    GAMSCheckpoint cp = ws.addCheckpoint(checkpoint);
    j1.run(opt, cp);
}

```

So what you should keep in mind before we return to further explanations of the main function is, that now the file `tbase` in folder `tbase` contains a checkpoint. Now in the main function we define some data using C++ data structures as we already did in `Transport4` before we create another `GAMSWorkspace`.

```

...
GAMSWorkspaceInfo wsInfo;
if (argc > 1)
    wsInfo.setSystemDirectory(argv[1]);
wsInfo.setWorkingDirectory("." + (cPathSep+ cpName));
GAMSWorkspace ws(wsInfo);
...

```

Afterwards we set up the `GAMSDatabase` like we already did in `Transport4`. Once this is done we run a `GAMSJob` using this data plus the checkpoint stored in file `tbase`.

```

...
GAMSCheckpoint cpBase = ws.addCheckpoint("tbase");
GAMSOptions opt = ws.addOptions();
GAMSJob t4 = ws.addJobFromString(getModelText(), cpBase);
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t4.run(opt, db);
for (auto record : t4.outDB().getVariable("x"))
    cout << "x(" << record.key(0) << ", " << record.key(1) << "): level=" << record.level() <<
        " marginal=" << record.marginal() << endl;
...

```

Note that the string from which we create job `t4` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the `GAMSDatabase` correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

7.8.4 How to use the pre configured example projects

Depending on the operating system, the GAMS C++ API comes with example project configurations for different development tools like CMake, qmake and Visual Studio. They provide an easy way of building and running the distributed GAMS C++ examples and are located in `<GAMS system directory>\apifiles\C++`.

7.8.4.1 CMake

Windows:

Create build directory

```

cd <GAMS system directory>\apifiles\C++
mkdir build && cd build

```

Run CMake and build project

```

cmake -G "Visual Studio 16 2019" -config Release -DVSVERSION:STRING=vs2019 ..
msbuild.exe examples.sln /p:Configuration=Release

```

Note

For other Visual Studio versions, the generator-name (-G) needs to be adjusted (see cmake documentation).

All generated executables can now be found in the CMake build directory. The exact path depends on the project name and the config setting. Assuming the solution was build with `-config Release`, a `transport1.exe` executable is located in `<GAMS system directory>\apifiles\C++\build\transport1\Release`. Therefore you can use the following commands to execute the `transport1` example: In order to execute an example (e.g. `transport1`) run the following commands:

```
cd transport1\Release
set PATH=%PATH%;<GAMS system directory>\apifiles\C++\lib\vs2019
transport1.exe
```

Linux:

Create build directory

```
cd <GAMS system directory>/apifiles/C++
mkdir build && cd build
```

Run CMake and build project

```
cmake ..
make
```

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

```
cd transport1
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<GAMS system directory>/apifiles/C++/lib
./transport1
```

Mac OS X:

Create build directory

```
cd <GAMS system directory>/apifiles/C++
mkdir build && cd build
```

Run CMake and build project

```
cmake ..
make
```

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

```
cd transport1
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:<GAMS system directory>/apifiles/C++/lib
./transport1
```

7.8.4.2 qmake

Building the examples can be done by using Qt Creator. Open `<GAMS system directory>\apifiles\C++\examples.pro` with Qt Creator. After the project is loaded, click on **Build > Build All** in order to compile and link the project. After the build process has carried out, select a subproject and click on **Build > Run** in order to execute the chosen example.

Alternatively you can run qmake using the command line.

Windows:

Create build directory

```
cd <GAMS system directory>\apifiles\C++
mkdir build && cd build
```

Run qmake and build project

```
qmake ..\examples.pro VSVERSION=vs2019
nmake
```

Note

For other supported Visual Studio versions change the value of VSVERSION.

All generated executables can now be found in the qmake output directory. In order to execute an example (e.g. `transport1`) run the following commands:

```
cd ..\bin
set PATH=%PATH%;<GAMS system directory>\apifiles\C++\lib\vs2019
transport1.exe
```

Linux and Mac OS X:

In order to run qmake on Linux and Mac OS X refer to the description of using [CMake](#) above and call qmake instead of cmake.

7.8.4.3 Microsoft Visual Studio

The Visual Studio solutions are available for Windows only. Open the solution file that matches the version of your Visual Studio installation (e.g. `<GAMS system directory>\apifiles\C++\examples-vs2017.sln`).

As soon as the solution is loaded, click on **Build > Configuration Manager** and adjust the **Active solution configuration** and the **Active solution platform**. The solution configuration needs to be set to **Release** for using the distributed binaries of the GAMS C++ API. Note that the platform needs to match the version of your GAMS installation.

The examples `Transport9` and `Transport10` require a Qt installation. If you do not have one, you need to disable these projects. Right click on a project in the Solution Explorer and choose **Unload Project** from the context menu.

Click on **Build > Build Solution** in order to compile and link the examples.

Note

In some cases the build might return with xcopy errors. Just build the project again. Make sure that you don't do a rebuild.

In order to run an example, click on **Debug > Start Without Debugging**. This will execute the current StartUp project. Changing the StartUp project can be achieved by right clicking on a project in the Solution Explorer and choosing **Set as StartUp Project**.

7.9 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Java API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known **transportation problem**. These examples introduce several API features step by step.

- [Getting started](#) A quick introduction about how to compile and run a program from command line or an IDE
- [Important Classes of the API](#) Overview of some fundamental classes of the GAMS Java API
- [How to use API](#) An extensive set of examples describing how to use API components

7.9.1 Getting started

A Java program that uses GAMS Java API requires at least Java SE 7 (Since [25.0](#)) to compile and run.

For all platforms, assume GAMS system has been installed at `[PathToGAMS]` directory, called GAMS directory. The directory `[PathToGAMS]` denotes the path setting according to your GAMS installation on targeted platforms. For instance

- on Windows-based platforms with GAMS distribution 38.0 installed, `[PathToGAMS]` denotes `C:\GAMS\win64\38.0`
- on Unix-based platforms with GAMS distribution 38.0 installed, `[PathToGAMS]` denotes `/usr/gams/gams38.0_linux_x64.64_sfx`

All GAMS Java API classes are contained within one single jar file `GAMSJavaAPI.jar` with a namespace `com.gams.api`. The jar file is distributed with the current GAMS distribution and located at

- on Windows-based platforms:
`[PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar`
- on Unix-based platforms:
`[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar`

There are two different approaches of how to use the GAMS Java API. Either the Java source files can be edited with any common editor and compiled from command line or a Java IDE can be used. The following sections give a quick introduction about the different possibilities.

7.9.1.1 Compiling a Program

To compile a Java program, one usually provides the following information to Java compiler:

- the directory(ies) containing all required Java class files
- the directory to place the generated class files
- the name of the Java source file

A Java program that uses GAMS Java API requires class files that are contained in `GAMSJavaAPI.jar` for compilation.

7.9.1.1.1 Compiling a Program from Command Line To compile a Java program that uses GAMS Java API, for instance `HelloAPI.java`, at the command line:

```
javac -cp [CLASSPATH] -d [TARGETDIR] HelloAPI.java
```

where

[CLASSPATH] is 'GAMSJavaAPI.jar' with its location, as it contains classes files that are used by
On Windows-based platform, [CLASSPATH] denotes
 [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar
On Unix-based platforms, [CLASSPATH] denotes
 [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

[TARGETDIR] is the directory to place the generated classe file.

Please note that it is possible to add [CLASSESPATH] to your CLASSPATH environment variable of the operating system as an alternative to specifying `-cp [CLASSESPATH]`. Also note that `-d [TARGETDIR]` is optional. In case `-d [TARGETDIR]` is omitted and the compilation is successful, the class file will be generated and located under the current directory.

To compile other programs, change the arguments accordingly. See also [How to compile and run examples from the GAMS](#)

7.9.1.1.2 Compiling a Program from Java IDE In case of compiling a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), the location of the jar file `GAMSJavaAPI.jar` shall be added into the Java build path of the IDE's project properties.

For an Eclipse user, see [How to import an Eclipse Java Project from the GAMS system directory](#).

7.9.1.2 Running a Program

To run a Java program, one usually provide the following information to Java Virtual Machine:

- the directory(ies) containing all required Java classes
- the directory(ies) containing all required shared libraries
- the name of an entry point class (in most case containing main method)

A Java program that uses GAMS Java API requires a number of shared libraries for establishing a connection with GAMS software components during run time. These shared libraries are platform dependent and they are located at `[PathToGAMS]/apifiles/Java/api` directory.

7.9.1.2.1 Running a Program from Command Line To run a Java program that uses GAMS Java API, for instance `HelloAPI.class` containing in `[TARGETDIR]` directory, at the command line type:

```
java -cp [CLASSPATH] HelloAPI
```

where

`[CLASSPATH]` is the list of two paths, a path of 'GAMSJavaAPI.jar' and a path of targeted directory containing 'HelloAPI.class', separated by path separator on the targeted platform.
 On Windows-based platform, `[CLASSESPATHS]` denotes
`[PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar; [TARGETDIR]`
 On Unix-based platform, `[CLASSESPATHS]` denotes
`[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar: [TARGETDIR]`

`HelloAPI` is the name of an entry point class containing main method

Please note that it is possible to add `[CLASSPATH]` to your `CLASSPATH` environment variable of the operating system as an alternative to specify `-cp [CLASSPATH]`.

Most operations performed by GAMS Java API such as `gdx` or options operations require shared libraries (located in the folder `[PathToGAMS]/apifiles/Java/api` by default) when running a program. In case no `java.library.path` has been specified when running a program, the Java API will determine the path of the shared libraries from the java class path containing `GAMSJavaAPI.jar`.

Note that it is also possible to pass the following argument to Java Virtual Machine:

```
-Djava.library.path=[LIBRARYPATH]
```

where `[LIBRARYPATH]` describes the list of paths containing all required shared libraries (as previously mentioned, it is `[PathToGAMS]/apifiles/Java/api` by default). In such case, the Java API will give priority to the java library path when loading all required JNI libraries during run time. The java API will raise an exception when either the java virtual machine fails to load the required libraries from the specified java library path or there is a version conflict of shared libraries during run time.

To run other programs, change the arguments accordingly. See also [How to compile and run examples from the GAMS system](#)

7.9.1.2.2 Running a Program from Java IDE In case of running a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), it is possible to set the necessary arguments via the properties of the IDE project.

For an Eclipse user, see [How to import an Eclipse Java Project from the GAMS system directory](#).

7.9.1.3 Setting Up Your Environment

Since 24.3, the GAMS system directory can be specified within the program during run time. Therefore the setting up of execution environment before running a program is no longer required (see also [Release Notes 24.3](#)).

Nevertheless, it is still possible to preconfigure the GAMS system directory before running a program and use the default workspace setting within a program. In the default setting, GAMS system directory is not specified by a user within the program. The directory will be searched during run time from environment variable in the following order (depends on the target platform):

- On Windows-based platform: first from PATH environment variable. If not found, from the platform windows registry `gams.location`,
- On Mac-based platform: first from PATH environment variable. If not found, from `DYLD_LIBRARY_PATH`,
- On other Unix-based platform: from PATH environment variable. If not found, from `LD_LIBRARY_PATH`.

The following examples illustrate how to add [PathToGAMS] into the environment variable PATH on different platforms:

- On Windows 2000, XP, Vista, or Windows 7 desktop:

```
> right-click on 'My Computer'
> choose 'Properties' (alternatively, click on 'System' icon in the control panel)
> click on 'Advanced' tab (or 'Advance system settings')
> click on 'Environment Variables'
> edit 'PATH' by adding [PathToGAMS] to the variable using a semi-colon as a separator.
```

- On Window-based platform via command line terminal:

```
set PATH=[PathToGAMS];%PATH%
```

- On Unix-based platform via command line terminal using Bourne shell and its derivatives:

```
export PATH=[PathToGAMS]:${PATH}
```

- On Unix-based platform via command line terminal using C Shell:

```
setenv PATH [PathToGAMS]:${PATH}
```

7.9.1.4 How to compile and run examples from the GAMS system directory

GAMS provides several examples to demonstrate how to use GAMS Java API. These examples are located in the [PathToGAMS]/apifiles/Java directory containing various examples based on the different optimization problems. The following explanations guide you through the compilation and execution process of one example based on the well-known **transportation problem**, assuming that Java Runtime System is already installed on your machine.

For instance, `Transport1.java` under the directory [PathToGAMS]/apifiles/Java/transport demonstrates how to retrieve GAMS transport model from GAMS Model Library, execute the model with various GAMS options, and extract results after execution.

To compile `Transport1.java` at the command line under the directory [PathToGAMS]/apifiles/Java/transport:

```
javac -cp [CLASSPATH] -d [TARGETDIR] Transport1.java
```

where

[CLASSPATH] is a location of 'GAMSJavaAPI.jar', as it contains classes files that are used by 'Transport1.java'.

On Windows-based platform, [CLASSPATH] denotes
[PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;

On Unix-based platforms, [CLASSESPATHS] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

[TARGETDIR] is the destination directory to place the generated classed file.

As Transport1.java is declared under package `com.gams.examples.transport`, the output class file will be located in [TARGETDIR] under the directory structure corresponding to package information. This means the compiled output file `Transport1.class` is located under:

- [TARGETDIR]\com\gams\examples\transport on Windows-based platform, or
- [TARGETDIR]/com/gams/examples/transport on Unix-based platforms.

To run `Transport1.class` from the command line:

```
java -cp [CLASSPATH] com.gams.examples.transport.Transport1
```

where

[CLASSPATH] is the list of two paths, 'GAMSJavaAPI.jar' with its path and a directory containing 'Transport1.class' and (in this case [TARGETDIR] from the compilation step), separated by path separator on the targeted platform.

On Windows-based platform, [CLASSESPATHS] denotes
[PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar; [TARGETDIR]

On Unix-based platforms, [CLASSESPATHS] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar: [TARGETDIR]

Please note that the path [TARGETDIR] can be either absolute or relative path representing the directory that contains `Transport1.class`.

To compile and run other examples under the directory [PathToGAMS]/apifiles/Java, adjust the arguments accordingly.

See [How to use API](#) for detailed explanations on the series of **transportation problem** examples located in the folder [PathToGAMS]/apifiles/Java/transport.

7.9.1.5 How to import an Eclipse Java Project from the GAMS system directory

Since GAMS version 24.2 there is an prepared Java project that can be imported into Eclipse. The project is located in folder `[PathToGAMS]/apifiles/Java/Eclipse` and contains the examples based on the **transportation problem**. The following explanations guide you through the import and preparation process, assuming that the Eclipse Java IDE is already installed on your machine.

To import the project located in folder `[PathToGAMS]/apifiles/Java/Eclipse` into the workspace:

1. open the Eclipse IDE with the chosen workspace location, click on **File** menu and choose **Import**.
2. In the **Import** window, choose **General > Existing Projects into Workspace** then click **Next**.
3. In the next page of **Import** window, click **Browse..** and select the folder with the prepared project (`[PathToGAMS]/apifiles/Java/Eclipse`) as root directory.

We recommend to check for option **Copy projects into workspace**. Click **Finish** to finish the **Import** window.

4. Now the project is imported, and appears in the **Package Explorer** window on the left hand side of of the IDE (shown below with its elements expanded).
5. As every example in the project requires GAMS Java API classes files to compile (all classes are packaged in `GAMSJavaAPI.jar` located in the folder `[PathToGAMS]/apifiles/Java/api`), you need to tell eclipse where to find `GAMSJavaAPI.jar`. To do this, either click on the project then choose **Project > Properties** or right click on the project name and choose **Properties** .

6. The **Properties** window of the proeject appears. Click **Java Build Path** on the left of the window, choose **Libraries** tab, choose **Add External JARs...**

select `GAMSJavaAPI.jar` located in the folder `[PathToGAMS]/apifiles/Java/api` to be opened.

and click **OK** to finish adding `[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar` to **Java Build Path**.

7. Now all the java files should be successfully compiled without errors except for `Transport10` (unsuccessful compilation is denoted with red x mark in front of the file name). This is because `Transport10` requires an additional `jexcelapi` JAR file `jxl.jar` from `jexcelapi`. It can be downloaded and unzipped the downloaded archive into a local directory e.g. `C:\tools`. Then the jar file `C:\tools\jexcelapi\jxl.jar` can be added to the the Java Build Path of the project in a similar way as explained in 6.

8. To run a transport example, for example `Transport1`, you need to create a **Run Configuration**.

To do this, either click **Run** menu and choose **Run Configurations...**

or open the drop down menu next to the run button and click on **Run Configurations...**

Then create a new run configuration by either press the **New** button in the left hand side of the window or right click at **Java Application** in the left hand side of the window and choose **New**.

9. The run configuration for `Transport1` appears.

For each run configuration it is possible to configure the execution of a program, such as the arguments of the virtual machine, class paths, environment variables and so on.

For instance, to specify the `java.library.path` for `Transport1` run configuration, choose **Arguments** tab in the run configuration and specify `-Djava.library.path=[PathToGAMS]/apifiles/Java/api` as one of the **VM arguments**. Then Click **Apply** and **Run**.

Note that the run configuration described in 8. and 9. is needed to be set for every single example. Once this is done you should be able to use the run configuration to repeat the execution of all the transport examples.

For a more detailed explanations on each transport examples see [How to use API](#).

7.9.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of [examples](#). All GAMS Java API classes are contained within one single jar file `GAMSJavaAPI.jar` with a namespace `com.gams.api`. It provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this namespace allow convenient exchange of input data and model results (`GAMSDatabase`) and help to create and run GAMS models (`GAMSJob`), that can be customized by GAMS options (`GAMSOptions`). Furthermore, it introduces a way to solve a sequence of closely related models in the most efficient way (`GAMSModelInstance`).

Other classes are `GAMSWorkspace`, `GAMSOptions`, `GAMSSymbol`, and `GAMSException`.

7.9.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the Java API. `[PathToGAMS]/apifiles/Java/transport` contains multiple examples dealing with the well-known **transportation problem**. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- [How to choose the GAMS system \(Transport1\)](#)
 - [How to export data to GDX \(TransportGDX\)](#)
 - [How to import data from GDX \(TransportGDX\)](#)
 - [How to run a GAMSJob from file \(Transport1\)](#)
 - [How to retrieve a solution from an output database \(Transport1\)](#)
 - [How to specify the solver using GAMSOptions \(Transport1\)](#)
 - [How to run a job with a solver option file and capture its log output \(Transport1\)](#)
 - [How to use include files \(Transport2\)](#)

7.9.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing `Transport1` with `C:/GAMS/win64/38.0` we use the 64-bit version of GAMS 38.0 to run `Transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
if (args.length > 0)
    wsInfo.setSystemDirectory( args[0] );
GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
...
```

Remember that the bitness of the GAMS system has to match the bitness of your Java Runtime Environment.

7.9.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented Java API offers much more than exchanging data between Java and GDX, a common use case is the export and import of GDX files. The central class for this purpose is `GAMSDatabase`. We assume that the data to be exported is available in Java data structures.

```
...
List<String> plants = Arrays.asList("Seattle", "San-Diego");
List<String> markets = Arrays.asList("New-York", "Chicago", "Topeka");
Map<String, Double> capacity = new HashMap<String, Double>();
{
    capacity.put("Seattle", Double.valueOf(350.0));
    capacity.put("San-Diego", Double.valueOf(600.0));
}
Map<String, Double> demand = new HashMap<String, Double>();
{
    demand.put("New-York", Double.valueOf(325.0));
    demand.put("Chicago", Double.valueOf(300.0));
    demand.put("Topeka", Double.valueOf(275.0));
}
Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double>();
{
    distance.put( new Vector<String>( Arrays.asList(new String[] {"Seattle", "New-York"}) ), Double.valueOf(2.5));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"Seattle", "Chicago"}) ), Double.valueOf(1.7));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"Seattle", "Topeka"}) ), Double.valueOf(1.8));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"San-Diego", "New-York"}) ), Double.valueOf(2.5));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"San-Diego", "Chicago"}) ), Double.valueOf(1.8));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"San-Diego", "Topeka"}) ), Double.valueOf(1.4));
}
...
```

Different type of GAMS symbols are represented using different Java data structures. The data for the GAMS sets is represented using List of Strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by Map (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses Vectors for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with Java data structures.

A new `GAMSDatabase` instance can be created using `GAMSWorkspace.addDatabase`.

```
...
// create new GAMSDatabase instance
GAMSDatabase db = ws.addDatabase();
...
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created `GAMSSet` instance `i` using `GAMSSet.addRecord`.

```
...
GAMSSet i = db.addSet("i", 1, "canning plants");
for(String p : plants)
    i.addRecord(p);
...
```

GAMSPParameter instances can be added by using the method `GAMSDatabase.addParameter`. In this example we use the overloaded method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```
...
GAMSPParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (String p : plants)
    a.addRecord(p).setValue( capacity.get(p) );
...
```

As soon as all data is prepared in the `GAMSDatabase`, the method `GAMSDatabase.export` can be used to create a GDX file.

```
...
db.export("data.gdx");
...
```

7.9.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a `GAMSDatabase` instance.

```
...
GAMSDatabase gdxdb = ws.addDatabaseFromGDX("data.gdx");
...
```

Reading the data from the `GAMSSet i` into a List of Strings can be done as follows:

```
...
List<String>.gdxPlants = new ArrayList<String>();
for(GAMSSetRecord rec : gdxdb.getSet("i"))
   .gdxPlants.add(rec.getKey(0));
...
```

A new List `.gdxPlants` is created. `i` is retrieved by calling `GAMSDatabase.getSet` on `gdxdb`. The returned `GAMSSet` object can be iterated using a for-loop to access the records of the set. Each record is of type `GAMSSetRecord` and can be asked for its keys.

You can do the same for `GAMSPParameter`. Instead of creating a List, we want to have the data in the form of a Map. `GAMSPParameterRecord` can not only be asked for its keys, but also for its value. The following code snippet shows how to read the one dimensional parameter `a` into a `Map<String, Double>`.

```
...
Map<String, Double>.gdxCapacity = new HashMap<String, Double>();
for(GAMSPParameterRecord rec : gdxdb.getParameter("a"))
   .gdxCapacity.put(rec.getKey(0), rec.getValue());
...
```

For a key of multi dimensional symbol, we choose `Vector` of `String` instead of `String`.

```
...
Map<Vector<String>, Double>.gdxDistance = new HashMap<Vector<String>, Double>();
for(GAMSPParameterRecord rec : gdxdb.getParameter("d"))
   .gdxDistance.put( new Vector<String>( Arrays.asList(new String[] {rec.getKey(0), rec.getKey(1)} ) ), rec.getValue());
...
```

Scalar can be read into a variable of type `double` by accessing the value of the first and only record.

```
...
double.gdxFreight = gdxdb.getParameter("f").getFirstRecord().getValue();
...
```

7.9.3.4 How to run a GAMSJob from file (Transport1)

At first we create our workspace using `GAMSWorkspace ws = new GAMSWorkspace();`. Afterward we can create a `GAMSJob t1` using the `addJobFromGamsLib` method and run it.

Apparently you can create a `GAMSJob` with any other gms file you might have created on your own as long as it is located in the current working directory. Then the `GAMSJob t1` can be defined using the `GAMSJob.addJobFromFile` method.

```
...
// create GAMSWorkspace "ws" with default working directory
// (the directory named with current date and time under System.getProperty("java.io.tmpdir"))
GAMSWorkspace ws = new GAMSWorkspace();
// create GAMSJob "t1" from "transport" model in GAMS Model Libraries
GAMSJob t1 = ws.addJobFromGamsLib("transport");
// run GAMSJob "t1"
t1.run();
...
```

See also `Transport1.java`.

7.9.3.5 How to retrieve a solution from an output database (Transport1)

The following lines create the solution output and illustrate the usage of the `GAMSJob.OutDB` property to get access to the `GAMSDatabase` created by the `run` method. To retrieve the content of variable `x` we use the `getVariable` method and the `GAMSVariableRecord` class.

```
...
// retrieve GAMSVariable "x" from GAMSJob's output databases
System.out.println("Ran with Default:");
GAMSVariable x = t1.OutDB().getVariable("x");
for (GAMSVariableRecord rec : x)
{
    System.out.print("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + "):");
    System.out.print(", level = " + rec.getLevel());
    System.out.println(", marginal = " + rec.getMarginal());
}
...
```

See also `Transport1.java`.

7.9.3.6 How to specify the solver using GAMSOptions (Transport1)

The solver can be specified via the `GAMSOptions` class and the `GAMSWorkspace.addOptions` method. The `GAMSOptions.setAllModelTypes` property sets `xpress` as default solver for all model types which the solver can handle. Then we run our `GAMSJob t1` with the new `GAMSOptions`.

```
...
// create GAMSOptions "opt1"
GAMSOptions opt1 = ws.addOptions();
// set all model types of "opt1" for "xpress"
opt1.setAllModelTypes("xpress");
// run GAMSJob "t1" with GAMSOptions "opt1"
t1.run(opt1);
...
```

See also `Transport1.java`.

7.9.3.7 How to run a job with a solver option file and capture its log output (Transport1)

At first we create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterward we use a `GAMSOptions` just like in the preceding example and `GAMSOptions.setOptFile` property to 1 to tell the solver to look for a solver option file. We specify the argument `output` in order to stream the log of the `GAMSJob` into the file `transport1_xpress.log`. When the `output` argument is omitted then the log will be written to standard output.

```
...
// write file "xpress.opt" under GAMSWorkspace's working directory
try {
    BufferedWriter optFile = new BufferedWriter(new FileWriter(
        ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "xpress.opt"
    ));
    optFile.write("algorithm=barrier");
    optFile.close();
} catch (IOException e) {
    e.printStackTrace();
    System.exit(-1);
}
// create GAMSOptions "opt2"
GAMSOptions opt2 = ws.addOptions();
// set all model types of "opt2" for "xpress"
opt2.setAllModelTypes("xpress");
// for "opt2", use "xpress.opt" as solver's option file
opt2.setOptFile(1);
try {
    // run GAMSJob "t2" with GAMSOptions "opt2" and capture log into "transport1_xpress.log".
    PrintStream output = new PrintStream(new File(ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR
        + "transport1_xpress.log"));
    t1.run(opt2, output);
} catch (FileNotFoundException e) {
    // run GAMSJob "t2" with GAMSOptions "opt2" and log is written to standard output
    t1.run(opt2);
}
...
```

See also `Transport1.java`.

7.9.3.8 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings data and model are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
...
try {
    BufferedWriter file = new BufferedWriter(new FileWriter(
        ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gms"
    ));
    file.write(data);
    file.close();
} catch(IOException e) {
    e.printStackTrace();
    System.exit(-1);
}
...
```

Afterwards we create a `GAMSJob` using the `GAMSWorkspace.addJobFromString` method. `GAMSOptions.defines` is used like the the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where `incname` is used as name for the include file in the `model` string.

```
...
// create GAMSJob "t2" from the "model"
GAMSJob t2 = ws.addJobFromString(model);
// create GAMSOption "opt" and define "incname" as "tdata"
GAMSOptions opt = ws.addOptions();
opt.defines("incname", "tdata");
// run GAMSJob "t2" with GAMSOptions "opt"
t2.run(opt);
...
```

The string `model` contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

See also `Transport2.java`.

7.9.3.9 How to set a non-default working directory (Transport3)

At first we create a new directory. Once this is done we can use this directory when creating the `GAMSWorkspace` and make it the working directory.

```
...
// create a directory
File workingDirectory = new File(System.getProperty("user.dir"), "Transport3");
workingDirectory.mkdir();
// create a workspace
GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
...
```

See also `Transport3.java`.

7.9.3.10 How to read data from string and export to GDX (Transport3)

We read the data from the string `data`. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding `GAMSJob` a `GAMSDatabase` is created that is available via the `GAMSJob.OutDB` property. We can use the `GAMSDatabase.export` method to write the content of this database to a `gdx` file `tdata.gdx`.

```
...
// Create and run a job from a data file, then explicitly export to a GDX file
GAMSJob t3 = ws.addJobFromString(data);
t3.run();
t3.OutDB().export( ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gdx" );
...
```

See also `Transport3.java`.

7.9.3.11 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in [Transport2 - How to use include files \(Transport2\)](#)

```
...
// run a job using an instance of GAMSOptions that defines the data include file
t3 = ws.addJobFromString(model);
GAMSOptions opt = ws.addOptions();
opt.defines("gdxincname", "tdata");
t3.run(opt);
...
```

Note that there are some minor changes in model due to the usage of a gdx instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

See also [Transport3.java](#).

7.9.3.12 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two **GAMSJobs** **t3a** and **t3b** where the first one contains only the data and the second one contains only the model without data. After running **t3a** the corresponding **OutDB** can be read in directly just like a gdx file. Note that the database needs to be passed to the **GAMSJob.run** method as additional argument.

```
...
GAMSVariable x = t3.OutDB().getVariable("x");
for (GAMSVariableRecord rec : x)
    System.out.println("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + "): level=" + rec.getLevel() + " marginal=" +
        rec.getMarginal());
System.out.println();
// similar to the previous run but without exporting database into a file
GAMSJob t3a = ws.addJobFromString(data);
GAMSJob t3b = ws.addJobFromString(model);
opt = ws.addOptions();
t3a.run();
opt.defines("gdxincname", t3a.OutDB().getName());
t3b.run(opt, t3a.OutDB());
...
```

See also [Transport3.java](#).

7.9.3.13 How to define data using Java data structures (Transport4)

We use the **List<E>** class and the **Map<Key, Value>** to define Java data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
...
// prepare input data
List<String> plants = Arrays.asList("Seattle", "San-Diego");
List<String> markets = Arrays.asList("New-York", "Chicago", "Topeka");
Map<String, Double> capacity = new HashMap<String, Double>();
{
    capacity.put("Seattle", Double.valueOf(350.0));
    capacity.put("San-Diego", Double.valueOf(600.0));
}
Map<String, Double> demand = new HashMap<String, Double>();
{
    demand.put("New-York", Double.valueOf(325.0));
    demand.put("Chicago", Double.valueOf(300.0));
    demand.put("Topeka", Double.valueOf(275.0));
}
Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double>();
{
    distance.put( new Vector<String>( Arrays.asList(new String[] {"Seattle", "New-York"} ) ), Double.valueOf(2.5));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"Seattle", "Chicago"} ) ), Double.valueOf(1.7));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"Seattle", "Topeka"} ) ), Double.valueOf(1.8));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"San-Diego", "New-York"} ) ), Double.valueOf(2.5));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"San-Diego", "Chicago"} ) ), Double.valueOf(1.8));
    distance.put( new Vector<String>( Arrays.asList(new String[] {"San-Diego", "Topeka"} ) ), Double.valueOf(1.4));
}
...
```

See also [Transport4.java](#).

7.9.3.14 How to prepare a GAMSDatabase from Java data structures (Transport4)

At first we create an empty **GAMSDatabase** `db` using the **GAMSWorkspace.addDatabase** method. Afterwards we prepare the database. To add a set to the database we use the **GAMSSet** class and the **GAMSDatabase.addSet** method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Java data structure and add them by using the **GAMSSet.addRecord** method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that scalars can be treated as parameter with dimension 0.

The **GAMSJob** can be run like explained in the preceding example about implicit database communication.

```
...
// add a database and add input data into the database
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "canning plants");
for(String p : plants)
    i.addRecord(p);
GAMSSet j = db.addSet("j", 1, "markets");
for(String m : markets)
    j.addRecord(m);
GAMSParameter a = db.addParameter("a", 1, "capacity of plant i in cases");
for (String p : plants)
    a.addRecord(p).setValue( capacity.get(p) );
GAMSParameter b = db.addParameter("b", 1, "demand at market j in cases");
for(String m : markets)
    b.addRecord(m).setValue( demand.get(m) );
GAMSParameter d = db.addParameter("d", 2, "distance in thousands of miles");
for(Vector<String> vd : distance.keySet())
    d.addRecord(vd).setValue( distance.get(vd).doubleValue() );
GAMSParameter f = db.addParameter("f", 0, "freight in dollars per case per thousand miles");
f.addRecord().setValue( 90 );
// create and run a job from the model and read.gdx include file from the database
GAMSJob t4 = ws.addJobFromString(model);
GAMSOptions opt = ws.addOptions();
opt.defines("gdxincname", db.getName());
t4.run(opt, db);
...
```

See also **Transport4.java**.

7.9.3.15 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following lines of code conduct several operations. While the first line simply creates a **GAMSCheckpoint**, the second one uses the **GAMSWorkspace.addJobFromString** method to create a **GAMSJob** containing the model text and data but no solve statement. Afterwards the run method gets the **GAMSCheckpoint** as argument. That means the **GAMSCheckpoint** `cp` captures the state of the **GAMSJob**.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
GAMSJob t5 = ws.addJobFromString(model);
t5.run(cp);
...
```

See also **Transport5.java**.

7.9.3.16 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function `model` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
...
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
```

```
Scalar ms 'model status', ss 'solve status';
...
```

In **Transport5** we create a list with eight different values for this demand multiplier.

```
...
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

For each entry of that list we create a **GAMSJob** **t5** using the **GAMSWorkspace.addJobFromString** method. Besides another string which resets the demand multiplier **bmult**, specifies the solve statement and assigns values to the scalars **ms** and **ss** we pass the checkpoint **cp** as additional argument. This results in a **GAMSJob** combined from the checkpoint plus the content provided by the string. We run the **GAMSJob** and echo some interesting data from the **OutDB** using the **GAMSDatabase.getParameter** and **GAMSDatabase.getVariable** methods, the **GAMSPParameter.findRecord** and **GAMSVariable.findRecord** methods plus the **GAMSPParameterRecord.getValue** property and the **GAMSVariableRecord.getLevel** method.

```
...
// create a new GAMSJob that is initialized from the GAMSCheckpoint
for(double b : bmultlist)
{
    t5 = ws.addJobFromString(
        "bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;",
        cp
    );
    t5.run();

    System.out.println("Scenario bmult=" + b + ":");
    System.out.println(
        " Modelstatus: " + GAMSGlobals.ModelStat.lookup(
            (int) t5.OutDB().getParameter("ms").findRecord().getValue()
        )
    );
    System.out.println(
        " Solvestatus: " + GAMSGlobals.SolveStat.lookup(
            (int) t5.OutDB().getParameter("ss").findRecord().getValue()
        )
    );
    System.out.println(" Obj: " + t5.OutDB().getVariable("z").findRecord().getLevel());
}
...
```

Note

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the [model status](#) and the [solve status](#) provide important information for a correct solution interpretation.

See also **Transport5.java**.

7.9.3.17 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs known from **Transport5** in parallel. We initialize the **GAMSCheckpoint** **cp** and introduce a demand multiplier as we did before :

```
...
GAMSJob t6 = ws.addJobFromString(model);
t6.run(cp);
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object **lockObject** that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of **bmultlist** and cause a thread to begin execution.

```
...
// run multiple parallel jobs using the created checkpoint
Object lockObject = new Object();
Scenario[] scenarios = new Scenario[bmultlist.length];
for (int i=0; i<bmultlist.length; i++)
{
    scenarios[i] = new Scenario(ws, cp, lockObject, bmultlist[i]);
    scenarios[i].start();
}
```

```

}
...

```

In class `Scenario` a `GAMSJob t6` is created and run just like in the preceding example of `Transport5`. The output section is also the same except for the fact that it is 'locked' by the object `lockObject` which means that the output section cannot be executed simultaneously for multiple demand multipliers.

```

...
static class Scenario extends Thread
{
    GAMSWorkspace workspace;
    GAMSCheckpoint checkpoint;
    Object lockObject;
    double bmult;
    public Scenario(GAMSWorkspace ws, GAMSCheckpoint cp, Object lockObj, double b)
    {
        workspace = ws;
        checkpoint = cp;
        lockObject = lockObj;
        bmult = b;
    }
    public void run()
    {
        GAMSJob t6 = workspace.addJobFromString(
            "bmult=" + bmult + "; solve transport min z use lp; ms=transport.modelstat;ss=transport.solvestat;",
            checkpoint
        );
        t6.run();
        // we need to make the output a critical section to avoid messed up report information
        synchronized (lockObject)
        {
            System.out.println("Scenario bmult=" + bmult + ":");
            System.out.println(
                " Modelstatus: " + GAMSGlobals.ModelStat.lookup(
                    (int) t6.OutDB().getParameter("ms").findRecord().getValue()
                )
            );
            System.out.println(
                " Solvestatus: " + GAMSGlobals.SolveStat.lookup(
                    (int)t6.OutDB().getParameter("ss").findRecord().getValue()
                )
            );
            System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
        }
    }
}
...

```

While the output in `Transport5` is strictly ordered subject to the order of the elements of `bmultlist` in `Transport6` the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lockObject`.

If you want a further impression of the impact of the `lockObject`, just rerun `Transport6` but comment out the lock as follows and compare the output.

```

...
    // synchronized (lockObject)
    // {
        System.out.println("Scenario bmult=" + bmult + ":");
        System.out.println(
            " Modelstatus: " + GAMSGlobals.ModelStat.lookup(
                (int) t6.OutDB().getParameter("ms").findRecord().getValue()
            )
        );
        System.out.println(
            " Solvestatus: " + GAMSGlobals.SolveStat.lookup(
                (int)t6.OutDB().getParameter("ss").findRecord().getValue()
            )
        );
        System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
    // }
...

```

See also `Transport6.java`.

7.9.3.18 How to create a `GAMSModelInstance` from a `GAMSCheckpoint` (`Transport7`)

In `Transport7` the usage of `com::gams::api::GAMSModelInstance` is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Then we create the `GAMSModelInstance` `mi` using the `GAMSCheckpoint.addModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
// initialize a checkpoint by running a job
GAMSJob t7 = ws.addJobFromString(model);
t7.run(cp);
GAMSModelInstance mi = cp.addModelInstance();
...
```

See also `Transport7.java`.

7.9.3.19 How to modify a parameter of a `GAMSModelInstance` using `GAMSModifier` (`Transport7`)

A `GAMSModelInstance` uses a `SyncDB` to maintain the data. We define `bmult` as `GAMSPParameter` using the `GAMSPParameter` method and specify `gurobi` as solver. Afterwards the `GAMSModelInstance` is instantiated with 3 arguments, the solve statement, `GAMSOptions` `opt` and `GAMSModifier` `bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of `ModelInstance` `mi` stay unchanged. We use the `GAMSPParameter.addRecord` method and the `setValue` function to assign a value to `bmult`. That value can be varied afterwards using the `GAMSPParameter.getFirstRecord` method to reproduce our well-known example with different demand multipliers.

```
...
GAMSPParameter bmult = mi.SyncDB().addParameter("bmult", 0, "demand multiplier");
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("gurobi");
// instantiate the ModelInstance and pass a model definition and Modifier to declare bmult mutable
mi.instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
bmult.addRecord().setValue( 1.0 );
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
for (double b : bmultlist)
{
    bmult.getFirstRecord().setValue( b );
    mi.solve();
    System.out.println("Scenario bmult=" + b + " ");
    System.out.println(" Modelstatus: " + mi.getModelStatus());
    System.out.println(" Solvestatus: " + mi.getSolveStatus());
    System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
}
...
```

See also `Transport7.java`.

7.9.3.20 How to modify a variable of a `GAMSModelInstance` using `GAMSModifier` (`Transport7`)

We create a `GAMSModelInstance` just like in the next to last example. We define `x` as `GAMSVariable` and its upper bound as `GAMSPParameter` `xup`. At the following `instantiate` method `GAMSModifier` has 3 arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the `GAMSPParameter` that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
...
mi = cp.addModelInstance();
GAMSVariable x = mi.SyncDB().addVariable("x", 2, GAMSGlobals.VarType.POSITIVE, "");
GAMSPParameter xup = mi.SyncDB().addParameter("xup", 2, "upper bound on x");
// instantiate the ModelInstance and pass a model definition and Modifier to declare upper bound of X mutable
mi.instantiate("transport use lp min z", new GAMSModifier(x, GAMSGlobals.UpdateAction.UPPER, xup));
for (GAMSSetRecord i : t7.OutDB().getSet("i"))
{
    for (GAMSSetRecord j : t7.OutDB().getSet("j"))
    {
```

```

        xup.clear();
        String[] keys = { i.getKeys()[0], j.getKeys()[0] };
        xup.addRecord(keys).setValue(0);
        mi.solve();
        System.out.println("Scenario link blocked: " + i.getKeys()[0] + " - " + j.getKeys()[0]);
        System.out.println(" Modelstatus: " + mi.getModelStatus());
        System.out.println(" Solvestatus: " + mi.getSolveStatus());
        System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
    }
}
...

```

See also `Transport7.java`.

7.9.3.21 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a `GAMSCheckpoint` `cp` from a `GAMSJob`. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out principle. The object `IOLockObject` is used later to avoid messed up output. Then we call `Scenarios` multiple times in parallel. The number of parallel calls is specified by `numberOfWorkers`.

```

...
GAMSJob t8 = ws.addJobFromString(model);
t8.run(cp);
Queue<Double> bmultQueue = new LinkedList<Double>(
    Arrays.asList( Double.valueOf(0.6), Double.valueOf(0.7),
        Double.valueOf(0.8), Double.valueOf(0.9),
        Double.valueOf(1.0), Double.valueOf(1.1),
        Double.valueOf(1.2), Double.valueOf(1.3) )
);
// solve multiple model instances in parallel
Object IOLockObject = new Object();
int numberOfWorkers = 2;
Scenarios[] scenarios = new Scenarios[numberOfWorkers];
for (int i=0; i<numberOfWorkers; i++)
{
    scenarios[i] = new Scenarios( ws, cp, bmultQueue, IOLockObject, i );
    scenarios[i].start();
}
...

```

In class `Scenarios` we create and instantiate a `GAMSModelInstance` as in the preceding examples and make parameter `bmult` modifiable. Note that we chose `cplex` as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```

...
static class Scenarios extends Thread
{
    GAMSSpace workspace;
    GAMSCheckpoint checkpoint;
    Object IOLockObject;
    Queue<Double> bmultQueue;
    int workerNumber;
    public Scenarios(GAMSSpace ws, GAMSCheckpoint cp, Queue<Double> que, Object IOLockObj, int i)
    {
        workspace = ws;
        checkpoint = cp;
        IOLockObject = IOLockObj;
        bmultQueue = que;
        workerNumber = i;
    }
    public void run()
    {
        GAMSModelInstance mi = checkpoint.addModelInstance();
        {
            GAMSParameter bmult = mi.SyncDB().addParameter("bmult", 0, "demand multiplier");
            GAMSOptions opt = workspace.addOptions();
            opt.setAllModelTypes("cplex");
            // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
            mi.instantiate("transport use lp min z", opt, new
                GAMSModifier(bmult));
            bmult.addRecord().setValue( 1.0 );
            while (true)
            {
                double b = 0.0;
                // dynamically get a bmult value from the queue instead of passing it to the different threads at creation
                time
                synchronized (bmultQueue)
                {
                    if (bmultQueue.isEmpty())
                        break;

```

```

        else
            b = bmultQueue.remove();
    }
    bmult.getFirstRecord().setValue(b);
    mi.solve();
    // we need to make the output a critical section to avoid messed up report informations
    synchronized (IOLockObject)
    {
        System.out.println("#"+workerNumber+":Scenario bmult=" + b + ".");
        System.out.println(" Modelstatus: " + mi.getModelStatus());
        System.out.println(" Solvestatus: " + mi.getSolveStatus());
        System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
    }
    }
}
}
...

```

See also `Transport8.java`.

7.9.3.22 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a `GAMSDatabase` (on Windows platform only). There are a few prerequisites required to run `Transport9` successfully.

- Install a Microsoft access driver on your machine (if none is available) as the driver must be loaded at runtime to connect to a data source file.
- To access the data source file go to Control Panel\System and Security\Administrative Tools\Data Sources (ODBC) and set up a data source name (DSN) as "transportdsn", leave out user ID and password, and select [PathToGAMS]/apfiles/Data/transport.accdb as the data source file.
- Note that an architecture mismatch between the Driver and Application might cause problems.

We call a function `readDataFromAccess` that finally returns a `GAMSDatabase` as shown below.

```

...
GAMSDatabase db = readDataFromAccess(ws);
...

```

The function `readDataFromAccess` begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database by specifying the aforementioned data source name (DSN). To finally read in GAMS sets and parameters we call the functions `readSet` and `readParameter`.

```

static GAMSDatabase readDataFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.addDatabase();
    try {
        // loading the jdbc odbc driver
        Class.forName("sun.jdbc.odbc.JdbcOdbcDriver");
        // creating connection to database
        Connection c = DriverManager.getConnection("jdbc:odbc:transportdsn","","");
        // read GAMS sets
        readSet(c, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
        readSet(c, db, "SELECT Market FROM Market", "j", 1, "markets");
        // read GAMS parameters
        readParameter(c, db, "SELECT Plant, Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
        readParameter(c, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
        readParameter(c, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
        c.close();
    } catch (ClassNotFoundException e) {
        System.err.println("Error: Failed to find a driver for the database.");
        e.printStackTrace();
        System.exit(-1);
    } catch (SQLException e) {
        System.err.println("Error: Failed to retrieve data from the database.");
        e.printStackTrace();
        System.exit(-1);
    }
    return db;
}

```

The function `readSet` adds a set to the `GAMSDatabase` that is filled with the data from the MS Access file afterwards. The function `readParameter` works quite similar.

```
static void readSet(Connection c, GAMSDatabase db, String queryString, String setName, int setDimension, String
    setExplanatoryText) throws SQLException
{
    Statement st = c.createStatement();
    ResultSet rs = st.executeQuery(queryString);
    ResultSetMetaData rsmd = rs.getMetaData();
    if (rsmd.getColumnCount() != setDimension)
    {
        System.err.println("Error: Number of fields in select statement does not match setDimension.");
        c.close();
        System.exit(-1);
    }
    GAMSSet set = db.addSet(setName, setDimension, setExplanatoryText);
    String[] keys = new String[setDimension];
    while (rs.next())
    {
        for (int idx=0; idx < setDimension; idx++)
            keys[idx] = rs.getString(idx+1);
        set.addRecord( keys );
    }
    st.close();
}
```

Once we read in all the data we can create a `GAMSJob` from the `GAMSDatabase` and run it as usual.

See also `Transport9.java`.

7.9.3.23 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from `[PathToGAMS]\apifiles\Data\transport`

At first we have to add an additional jar file to the `[CLASSESPATH]` since we use the Java Excel API which can be downloaded from [jexcelapi](#). We unzipped the Java Excel API folder in `C:\tools`. To compile and run on a Windows platform from the command line go to `C:\GAMS\win64\24.1\apifiles\Java\transport` and use:

```
javac -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\api\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar;. .
```

and

```
java -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\api\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar;. c
```

If you are using an IDE like Eclipse add `C:\tools\jexcelapi\jxl.jar` to the class path as explained in the [Compiling a Program from Java IDE](#) and [Running a Program from Java IDE](#) section.

The model is given as string without data like in many examples before and the Excel file `transport.xlsx` is located at `[gamsdir]\apifiles\Data`.

At first we define the input string and create the corresponding input file.

```
...
String input = gamsdir + "apifiles" +
    GAMSGlobal.FILE_SEPARATOR + "Data" + GAMSGlobal.FILE_SEPARATOR + "transport.xlsx";
File inputFile = new File(input);
...
```

The following lines address the different worksheets and read in the contained data.

```
...
int iCount = 0;
int jCount = 0;
String[][] capacityData = null;
String[][] demandData = null;
String[][] distanceData = null;
Workbook w;
```

```

try {
    w = Workbook.getWorkbook(inputFile);
    Sheet capacity = w.getSheet("capacity");
    capacityData = new String[capacity.getRows()][capacity.getColumns()];
    iCount = capacity.getColumns();
    for (int j = 0; j < capacity.getColumns(); j++)
        for (int i = 0; i < capacity.getRows(); i++)
            capacityData[i][j] = capacity.getCell(j, i).getContents();
    Sheet demand = w.getSheet("demand");
    demandData = new String[demand.getRows()][demand.getColumns()];
    jCount = demand.getColumns();
    for (int j = 0; j < demand.getColumns(); j++)
        for (int i = 0; i < demand.getRows(); i++)
            demandData[i][j] = demand.getCell(j, i).getContents();
    Sheet distance = w.getSheet("distance");
    distanceData = new String[distance.getRows()][distance.getColumns()];
    for (int j = 0; j < distance.getColumns(); j++)
        for (int i = 0; i < distance.getRows(); i++)
            distanceData[i][j] = distance.getCell(j, i).getContents();
    w.close();
} catch (IOException e) {
    e.printStackTrace();
} catch (BiffException e) {
    e.printStackTrace();
}
...

```

Now we can create the **GAMSWorkspace** as usual and afterwards create a **GAMSDatabase** and fill it with the workbook data as follows:

```

...
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "Plants");
GAMSSet j = db.addSet("j", 1, "Markets");
GAMSParameter capacityParam = db.addParameter("a", 1, "Capacity");
GAMSParameter demandParam = db.addParameter("b", 1, "Demand");
GAMSParameter distanceParam = db.addParameter("d", 2, "Distance");
for (int ic = 0; ic < iCount; ic++)
{
    i.addRecord( capacityData[0][ic] );
    capacityParam.addRecord( capacityData[0][ic] ).setValue( Double.valueOf(capacityData[1][ic]).doubleValue() );
}
for (int jc = 0; jc < jCount; jc++)
{
    j.addRecord( demandData[0][jc] );
    demandParam.addRecord( demandData[0][jc] ).setValue( Double.valueOf(demandData[1][jc]).doubleValue() );
    String[] data = null;
    for (int ic = 0; ic < iCount; ic++)
    {
        data = new String[] { distanceData[ic+1][0], distanceData[0][jc+1] };
        distanceParam.addRecord( data ).setValue( Double.valueOf(distanceData[ic+1][jc+1]) );
    }
}
}

```

Note that we can name sets and parameters just like in the database but we don't have to. Now we can run our **GAMSJob** as usual.

```

...
GAMSOptions opt = ws.addOptions();
GAMSJob t10 = ws.addJobFromString(model);
opt.defines("gdxincname", db.getName());
opt.setAllModelTypes("xpress");
t10.run(opt, db);
for (GAMSVariableRecord rec : t10.OutDB().getVariable("x"))
    System.out.println("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + "): level=" + rec.getLevel() + " marginal=" +
        rec.getMarginal());
...

```

See also **Transport10.java**.

7.9.3.24 How to create and use a save/restart file (Transport11)

In **Transport11** we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a **GAMSCheckpoint**. From the main function we call the function **CreateSaveRestart** giving it the current working directory and the desired file name as arguments.

```

...
CreateSaveRestart( workingDirectory, "tbase" );
...

```

In function `CreateSaveRestart` create a workspace with the given working directory. Then we create a `GAMSJob` from a string. Note that the string given via `baseModel` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a `GAMSOptions` to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the `GAMSJob` and stored in the file given as argument to the function, in our case `tbase`. This becomes possible because the `addCheckpoint` method accepts identifiers as well as file names as argument.

```
static void CreateSaveRestart(File workingDirectory, String cpFileName)
{
    GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
    wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
    GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
    GAMSJob j1 = ws.addJobFromString(baseModel);
    GAMSOptions opt = ws.addOptions();
    opt.setAction( GAMSOptions.EAction.CompileOnly );
    GAMSCheckpoint cp = ws.addCheckpoint(cpFileName);
    j1.run(opt, cp);
    opt.dispose();
}
```

So what you should keep in mind before we return to further explanations of the main function is, that the file `tbase` is now in the current working directory and contains a checkpoint. Now in the main function we define some data using Java data structures as we already did in `Transport4` before we create the `GAMSWorkspace` and a `GAMSDatabase`.

```
...
GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
GAMSDatabase db = ws.addDatabase();
...
```

Afterwards we set up the `GAMSDatabase` like we already did in `Transport4`. Once this is done we run a `GAMSJob` using this data plus the checkpoint stored in file `tbase`.

```
...
GAMSCheckpoint cpBase = ws.addCheckpoint("tbase");
GAMSOptions opt = ws.addOptions();
GAMSJob t11 = ws.addJobFromString(model, cpBase);
opt.defines("gdxincname", db.getName());
opt.setAllModelTypes("xpress");
t11.run(opt, db);
...
```

Note that the string from which we create job `t11` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the `GAMSDatabase` correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

See also `Transport11.java`.

7.10 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Python API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known [transportation problem](#). These examples introduce several API features step by step.

- [Getting started](#) A quick introduction about how to run a program
- [Important Classes of the API](#) Overview of some fundamental classes of the GAMS Python API
- [How to use the API](#) An extensive set of examples describing how to use API components

7.10.1 Getting started

The object oriented GAMS Python API is built on top of the different expert-level APIs and provides convenient access to GAMS from within Python. Examples using the API are located in `apifiles/Python`. The expert-level APIs can be found in `apifiles/Python/api_36` for Python 3.6, in `apifiles/Python/api_37` for Python 3.7, in `apifiles/Python/api_38` for Python 3.8, in `apifiles/Python/api_39` for Python 3.9, and in `apifiles/Python/api_310` for Python 3.10. The object oriented API is located in `apifiles/Python/gams`. Making your Python installation aware of the modules provided by GAMS can be done in two fundamentally different ways. Which method to choose depends on your preference and your use pattern of GAMS and Python. Note also that the bitness of your Python version has to match the bitness of the GAMS system.

7.10.1.1 Let Python find the GAMS Python files

There are many ways for a Python installation to find locations with additional packages. Here are two:

a) Extend/set the PYTHONPATH environment variable

The environment variable PYTHONPATH (<https://docs.python.org/3/using/cmdline.html#environment-variables>) can be used to let Python find the GAMS API.

macOS/Linux:

```
export PYTHONPATH=/path/to/gams/apifiles/Python/api_38
export PYTHONPATH=/path/to/gams/apifiles/Python/gams:$PYTHONPATH
```

Windows:

```
set PYTHONPATH=C:\path\to\gams\apifiles\Python\api_38
set PYTHONPATH=C:\path\to\gams\apifiles\Python\gams;%PYTHONPATH%
```

b) Use the site package

The `site` package (<https://docs.python.org/3/library/site.html>) can be used to include the GAMS directories. For example, create a file `sitecustomize.py` in your `site-packages` directory with the following content:

```
import sys
sys.path.append(r'C:\path\to\gams\apifiles\Python\api_38')
sys.path.append(r'C:\path\to\gams\apifiles\Python\gams')
```

Change the path separator to / for macOS and Linux. You find out where your `site-packages` directory is located by running `python -m site` and inspecting the output. Method b) is preferred if creating permanent environment variables is difficult (e.g. on macOS).

7.10.1.2 Copy the GAMS Python files to the Python installation

Open a shell/command prompt and make sure your Python interpreter is found. Change directories to your GAMS system directory with the Python 3.X API files and run `python setup.py install`, e.g. on Windows:

```
cd C:\path\to\gams\apifiles\Python\api_38
C:\path\to\my\python\python.exe setup.py install
```

Note

Per default, the `setup.py` script tries to create a `build` directory before installing its content into the `site-packages` directory of the Python interpreter. In case of missing write permissions in the GAMS system directory (e.g. on **macOS**) it is possible to specify an alternative location using the following command:

```
C:\path\to\my\python\python.exe setup.py build -b C:\path\to\build install
```

Note

For the use of the [Embedded Code Facility](#) for Python, certain dependencies might be required (e.g. `ply`). The directory `/path/to/gams/apifiles/Python/thirdparty` contains all the third party modules used by GMSPython. The content of this directory indicates which modules and packages should be installed in addition.

Running the `transport1.py` example:

In order to see that the Python installation is set up correctly to be used with GAMS, a simple test is to run the `transport1.py` example. Note that you have to change the path separator to `/` for macOS and Linux:

```
C:\path\to\my\python\python.exe C:\path\to\gams\apifiles\Python\trnsport1.py
```

7.10.1.3 Working with Python and multiple GAMS Installations

GAMS uses SWIG (<http://www.swig.org/>) to connect Python to GAMS functionality implemented in dynamic link libraries or shared objects (e.g. `gdxdcplib64.dll` to access GDX functionality). GAMS provides all files necessary to access these libraries from Python in the `apifiles/Python/api_3X` directories. Due to changes in the library API, SWIG version, Python version, etc, these files, that you might have copied to your Python installation in case you choose the [copy method](#) from above, are highly GAMS distribution dependent. If you work with a single GAMS installation this is very easy but if you need to work with different GAMS installations connecting your own Python installation can be a challenge. If you are in this situation we highly recommend to work with a Python installation that supports environment management, like Conda. Create for each major GAMS version a new environment and choose the [copy method](#) or the [site customization](#) (see entry `b`) (e.g. via `sitecustomize.py`) to connect GAMS with this environment. Here is a typical session to create two environments, one for GAMS 31 and one for GAMS 32 using Conda:

```
conda create --name gams31 python=3.8
conda activate gams31
cd /path/to/gams31/apifiles/Python/api_38
python setup.py install
conda create --name gams32 --clone gams31
conda activate gams32
cd /path/to/gams32/apifiles/Python/api_38
python setup.py install
```

7.10.1.4 Specifying a GAMS System Directory

There are several ways to specify which system directory should be used. On all platforms, the system directory can be specified in the GamsWorkspace constructor. If no system directory is specified by the user, The API tries to find one automatically:

- Windows: Try to find a system directory in the Windows registry.
- Linux: Try to find a system directory in the PATH first. If none was found, search LD_LIBRARY_PATH.
- OS X: Try to find a system directory in the PATH first. If none was found, search DYLD_LIBRARY_PATH.

The environment variable PATH can be set as follows on Linux and macOS:

```
export PATH=<Path/To/GAMS>:$PATH
```

Note

On Linux and macOS it is recommended to specify the PATH only instead of (DY)LD_LIBRARY_PATH since this might cause problems loading the correct version of certain modules (e.g. gdx).

7.10.1.5 Troubleshooting

AttributeError: module 'gams' has no attribute 'SuffixDLVars':

Since GAMS 31, the Object-oriented Python API is distributed as source code (*.py files) instead of binaries (*.pyd files on Windows, *.so files on Linux and macOS). Installing the API with `python setup.py install` copies the API files into the `site-packages` directory of the Python interpreter, but won't overwrite or delete old *.so/*.pyd files since those are not part of the distribution anymore. This might lead to wrongly loaded files that are not compatible with each other anymore (e.g. `options.py`). In order to resolve the problem it is required to delete the `gams` directory located in the `site-packages` directory of the used Python installation before installing a new version of the API. Executing `python -m site` will reveal the location of the `site-packages` directory.

7.10.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples in the [How to use the API](#) section.

- `gams::workspace::GamsWorkspace` Class
 - `gams::execution::GamsJob` Class
 - `gams::database::GamsDatabase` Class
 - `gams::options::GamsOptions` Class
 - `gams::execution::GamsModelInstance` Class
-

7.10.3 How to use the API

The GAMS distribution provides several examples that illustrate the usage of the Python API. [GAMSDIR]/apifiles/Python contains multiple examples dealing with the well-known **transportation problem**. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- [How to import packages/modules from the GAMS Python API \(transport1.py\)](#)
- [How to choose the GAMS system \(transport1.py\)](#)
- [How to export data to GDX \(transport_gdx.py\)](#)
- [How to import data from GDX \(transport_gdx.py\)](#)

- [How to create and use a save/restart file \(transport11.py\)](#)

7.10.3.1 How to import packages/modules from the GAMS Python API (transport1.py)

If you followed the instructions from the [Getting started](#) section and installed the GAMS Python API there should be a directory [PYTHONDIR]\Lib\site-packages\gams that contains the required packages and modules. We simply import all of them using

```
from gams import *
```

Conventional Python packages/modules can be imported like that:

```
import os
import sys
```

7.10.3.2 How to choose the GAMS system (transport1.py)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. If we type `python transport1.py C:/GAMS/win64/38.0` we use the 64-bit version of GAMS 38.0 to run `transport1.py` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
if len(sys.argv) > 1:
    ws = GamsWorkspace(system_directory = sys.argv[1])
else:
    ws = GamsWorkspace()
...
```

Remember that the bitness of the GAMS system has to match the bitness of your Python version.

7.10.3.3 How to export data to GDX (transport_gdx.py)

Although the Object-oriented Python API offers much more than exchanging data between Python and GDX, a common use case is the export and import of GDX files. The central class for this purpose is `GamsDatabase`. We assume that the data to be exported is available in Python data structures.

```
...
plants = [ "Seattle", "San-Diego" ]
markets = [ "New-York", "Chicago", "Topeka" ]
capacity = { "Seattle": 350.0, "San-Diego": 600.0 }
demand = { "New-York": 325.0, "Chicago": 300.0, "Topeka": 275.0 }
distance = { ("Seattle", "New-York") : 2.5,
             ("Seattle", "Chicago") : 1.7,
             ("Seattle", "Topeka") : 1.8,
             ("San-Diego", "New-York") : 2.5,
             ("San-Diego", "Chicago") : 1.8,
             ("San-Diego", "Topeka") : 1.4
           }
...
```

Different GAMS symbols are represented using different Python data structures. The data for the GAMS sets is represented using Python lists of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by Python dictionaries (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses Python tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with standard Python data structures.

A new `GamsDatabase` instance can be created using `GamsWorkspace.add_database`.

```
...
# create new GamsDatabase instance
db = ws.add_database()
...
```

We start adding GAMS sets using the method `GamsDatabase.add_set` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created `GamsSet` instance `i` using `GamsSet.add_record`.

```
...
# add 1-dimensional set 'i' with explanatory text 'canning plants' to the GamsDatabase
i = db.add_set("i", 1, "canning plants")
for p in plants:
    i.add_record(p)
...
```

`GamsParameter` instances can be added by using the method `GamsDatabase.add_parameter`. It has the same signature as `GamsDatabase.add_set`. Anyhow, in this example we use `GamsDatabase.add_parameter_dc` instead which takes a list of `GamsSet` instances instead of the dimension for creating a parameter with domain information.

```
...
# add parameter 'a' with domain 'i'
a = db.add_parameter_dc("a", [i], "capacity of plant i in cases")
for p in plants:
    a.add_record(p).value = capacity[p]
...
```

As soon as all data is prepared in the `GamsDatabase`, the method `GamsDatabase.export` can be used to create a GDX file.

```
...
# export the GamsDatabase to a GDX file with name 'data.gdx' located in the 'working_directory' of the GamsWorkspace
db.export("data.gdx")
...
```

7.10.3.4 How to import data from GDX (transport_gdx.py)

Data can be imported from a GDX file using `GamsWorkspace.add_database_from_gdx`. The method takes a path to a GDX file and creates a `GamsDatabase` instance.

```
...
# add a new GamsDatabase and initialize it from the GDX file just created
db2 = ws.add_database_from_gdx("data.gdx")
...
```

Reading the data from the `GamsSet` `i` into a list can be done as follows:

```
...
# read data from symbols into Python data structures
i = [ rec.keys[0] for rec in db2["i"] ]
...
```

A Python list is created using list comprehensions. `i` is retrieved by querying the `GamsDatabase` `db2`. The returned `GamsSet` object can be iterated using a for-loop to access the records of the set. Each record is of type `GamsSetRecord` and can be asked for its keys.

You can do the same for `GamsParameters`. Instead of creating a Python list, we want to have the data in the form of a Python dictionary. `GamsParameterRecords` can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a Python dictionary using dict comprehensions.

```
...
a = { rec.keys[0]:rec.value for rec in db2["a"] }
...
```

For multi dimensional symbols, we choose the Python dictionary keys to be tuples instead of string. We access the keys as usual, but do not address a specific key. Instead, we take the whole list of keys and turn it into a tuple.

```
...
d = dict( tuple(rec.keys), rec.value) for rec in db2["d"] )
...
```

Scalars can be read into a Python identifier by accessing the value of the first and only record.

```
...
f = db["f"].first_record().value
...
```

7.10.3.5 How to run a GamsJob from file (transport1.py)

At first we create our workspace using `ws = GamsWorkspace()`. Afterwards we load the `transport` model from the GAMS model library which puts the corresponding gms file in our working directory. Apparently you can create a `GamsJob` with any other gms file you might have created on your own as long as it is located in the current working directory. Then the `GamsJob` `t1` can be defined using the `add_job_from_file` method and afterwards we run the job.

```
...
ws.gamslib("transport")
t1 = ws.add_job_from_file("transport.gms")
t1.run()
...
```

7.10.3.6 How to retrieve a solution from an output database (transport1.py)

The following lines create the solution output and illustrate the usage of the `GamsJob.out_db` property to get access to the `GamsDatabase` created by the run method. To retrieve the content of variable `x` we use squared brackets that internally call the `get_symbol` method.

```
...
for rec in t1.out_db["x"]:
    print "x(" + rec.keys[0] + ", " + rec.keys[1] + "): level=" + str(rec.level) + " marginal=" + str(rec.marginal)
...
```

Note that instead of using the squared brackets we could also use

```
...
for rec in t1.out_db.get_symbol("x"):
...
```

7.10.3.7 How to specify the solver using GamsOptions (transport1.py)

The solver can be specified via the GamsOptions class and the GamsWorkspace.add_options method. The GamsOptions.all_model_types property sets xpress as default solver for all model types that can be handled by the solver. Then we run our GamsJob t1 with the new GamsOption.

```
...
    opt = ws.add_options()
    opt.all_model_types = "xpress"
    t1.run(opt)
...
```

7.10.3.8 How to run a job with a solver option file and capture its log output (transport1.py)

At first we create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterwards we use a GamsOption just like in the preceding example and set GamsOption.optfile property to 1 to tell the solver to look for a solver option file. In addition, we specify the argument `output` in order to write the log of the GamsJob into the file `transport1_xpress.log`. Providing `newline=""` to the `open` function prevents additional newline characters in the log file.

```
...
    file = open(os.path.join(ws.working_directory, "xpress.opt"), "w")
    file.write("algorithm=barrier")
    file.close()
    opt.optfile = 1
    with open("transport1_xpress.log", "w", newline="") as log:
        t1.run(opt, output=log)
...
```

Instead of writing the log output to a file, any object that provides the functions `write` and `flush` can be used. In order to write the log directly to `stdout`, we can use the following code:

```
...
    t1.run(opt, output=sys.stdout)
...
```

7.10.3.9 How to use include files (transport2.py)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings accessed via functions `get_data_text` and `get_model_text` are using GAMS syntax. At first we write an include file `tdata.gms` that contains the data but not the model text and save it in our current working directory.

```
...
    file = open(os.path.join(ws.working_directory, "tdata.gms"), "w")
    file.write(get_data_text())
    file.close()
...
```

Afterwards we create a GamsJob using the GamsWorkspace.add_job_from_string method. GamsOptions.defines is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where `incname` is used as name for the include file in `get_model_text` as shown below.

```
...
    t2 = ws.add_job_from_string(get_model_text())
    opt = ws.add_options()
    opt.defines["incname"] = "tdata"
    t2.run(opt)
...
```

The string `get_model_text` contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

7.10.3.10 How to read data from string and export to GDX (transport3.py)

We read the data from the string accessed via function `get_data_text`. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding GamsJob a GamsDatabase is created that is available via the `GamsJob.out_db` property. We can use the `GamsDatabase.export` method to write the content of this database to a.gdx file `tdata.gdx` in the current working directory.

```
...
t3 = ws.add_job_from_string(get_data_text())
t3.run()
t3.out_db.export(os.path.join(ws.working_directory, "tdata.gdx"))
...
```

7.10.3.11 How to run a job using data from GDX (transport3.py)

This works quite similar to the usage of an include file explained in [How to use include files \(transport2.py\)](#).

```
...
t3 = ws.add_job_from_string(get_model_text())
opt = ws.add_options()
opt.defines["gdxincname"] = "tdata"
opt.all_model_types = "xpress"
t3.run(opt)
...
```

Note that there are some minor changes in `get_model_text` compared to preceding examples due to the usage of a.gdx instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

7.10.3.12 How to run a job using implicit database communication (transport3.py)

This example does basically the same as the two preceding examples together. We create two GamsJobs `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `out_db` can be read in directly just like a.gdx file. Note that the database needs to be passed to the `GamsJob.run` method as additional argument.

```
...
t3a = ws.add_job_from_string(get_data_text())
t3b = ws.add_job_from_string(get_model_text())
t3a.run()
opt.defines["gdxincname"] = t3a.out_db.name
t3b.run(opt, databases=t3a.out_db)
...
```

7.10.3.13 How to define data using Python data structures (transport4.py)

We use squared brackets (Python Lists) to define the sets and curly brackets (Python Dictionaries) for the parameter definition.

```
...
plants = [ "Seattle", "San-Diego" ]
markets = [ "New-York", "Chicago", "Topeka" ]
capacity = { "Seattle": 350.0, "San-Diego": 600.0 }
demand = { "New-York": 325.0, "Chicago": 300.0, "Topeka": 275.0 }
distance = { ("Seattle", "New-York") : 2.5,
             ("Seattle", "Chicago") : 1.7,
             ("Seattle", "Topeka") : 1.8,
             ("San-Diego", "New-York") : 2.5,
             ("San-Diego", "Chicago") : 1.8,
             ("San-Diego", "Topeka") : 1.4
           }
...
```

7.10.3.14 How to prepare a GamsDatabase from Python data structures (transport4.py)

At first we create an empty GamsDatabase db using the GamsWorkspace.add_database method. Afterwards we prepare the database. To add a set to the database we use the GamsSet class and the GamsDatabase.add_set method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Python data structure and add them by using the GamsSet.add_record method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The GamsJob can be run like explained in the preceding example [How to run a job using implicit database communication](#)

```
...
db = ws.add_database()
i = db.add_set("i", 1, "canning plants")
for p in plants:
    i.add_record(p)
j = GamsSet(db, "j", 1, "markets")
for m in markets:
    j.add_record(m)
a = GamsParameter(db, "a", 1, "capacity of plant i in cases")
for p in plants:
    a.add_record(p).value = capacity[p]
b = GamsParameter(db, "b", 1, "demand at market j in cases")
for m in markets:
    b.add_record(m).value = demand[m]
d = GamsParameter(db, "d", 2, "distance in thousands of miles")
for k, v in distance.iteritems():
    d.add_record(k).value = v
f = GamsParameter(db, "f", 0, "freight in dollars per case per thousand miles")
f.add_record().value = 90
t4 = GamsJob(ws, source=get_model_text())
opt = GamsOptions(ws)
opt.defines["gdxincname"] = db.name
opt.all_model_types = "xpress"
t4.run(opt, databases = db)
...
```

7.10.3.15 How to initialize a GamsCheckpoint by running a GamsJob (transport5.py)

The following lines of code conduct several operations. While the first line simply creates a GamsCheckpoint, the second one uses the GamsWorkspace.add_job_from_string method to create a GamsJob containing the model text and data but no solve statement. Afterwards the run method gets the GamsCheckpoint as argument. That means the GamsCheckpoint cp captures the state of the GamsJob.

```
...
cp = ws.add_checkpoint()
t5 = ws.add_job_from_string(get_model_text())
t5.run(checkpoint=cp)
...
```

7.10.3.16 How to initialize a GamsJob from a GamsCheckpoint (transport5.py)

Note that the string returned from function `get_model_text` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
...
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';
...

```

In transport5.py we create a list with eight different values for this demand multiplier.

```
...
bmultlist = [ 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 ]
...

```

For each entry of that list we create a GamsJob t5 using the GamsWorkspace.add_job_from_string method. Besides another string which resets the demand multiplier bmult, specifies the solve statement and assigns

values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a `GamsJob` combined from the checkpoint plus the content provided by the string.

We run the `GamsJob` and print some interesting data from the `out_db`.

```
...
for b in bmultlist:
    t5 = ws.add_job_from_string("bmult=" + str(b) + "; solve transport min z use lp; ms=transport.modelstat;
    ss=transport.solvestat;", cp)
    t5.run()
    print "Scenario bmult=" + str(b) + ":"
    print " Modelstatus: " + str(t5.out_db["ms"].find_record().value)
    print " Solvestatus: " + str(t5.out_db["ss"].find_record().value)
    print " Obj: " + str(t5.out_db["z"].find_record().level)
...
```

NOTE: Some of the demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the [model status](#) and the [solve status](#) provide important information for a correct solution interpretation.

7.10.3.17 How to run multiple GamsJobs in parallel using a GamsCheckpoint (transport6.py)

This example illustrates how to run the jobs known from `transport5.py` in parallel. We initialize the `GamsCheckpoint` `cp` and introduce a demand multiplier as we did before :

```
...
cp = ws.add_checkpoint()
t6 = ws.add_job_from_string(get_model.text())
t6.run(checkpoint=cp)
bmultlist = [ 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 ]
...
```

Furthermore, we introduce a lock object `io_lock` that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of `bmultlist` and cause a thread to begin execution.

```
...
io_lock = threading.Lock()
threads = {}
for b in bmultlist:
    threads[b] = threading.Thread(target=run_scenario, args=(ws, cp, io_lock, b))
    threads[b].start()
for b in bmultlist:
    threads[b].join()
...
```

In function `run_scenario` a `GamsJob` `t6` is created and run just like in the preceding example of `transport5.py`. The output section is also the same except for the fact that it is 'locked' by the object `io_lock` which means that the output section cannot be executed simultaneously for multiple demand multipliers.

```
...
def run_scenario(workspace, checkpoint, io_lock, b):
    t6 = workspace.add_job_from_string("bmult=" + str(b) + "; solve transport min z use lp; ms=transport.modelstat;
    ss=transport.solvestat;", checkpoint)
    t6.run()
    # we need to make the output a critical section to avoid messed up report informations
    io_lock.acquire()
    print "Scenario bmult=" + str(b) + ":"
    print " Modelstatus: " + str(t6.out_db["ms"][(0)].value)
    print " Solvestatus: " + str(t6.out_db["ss"][(0)].value)
    print " Obj: " + str(t6.out_db["z"][(0)].level)
    io_lock.release()
...
```

While the output in `transport5.py` is strictly ordered subject to the order of the elements of `bmultlist` in `transport6.py` the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `io_lock` object.

7.10.3.18 How to create a GamsModelInstance from a GamsCheckpoint (transport7.py)

In transport7.py the usage of GamsModelInstance is demonstrated.

At first checkpoint cp is created as in the preceding examples. Note that the GamsJob t7 again contains no solve statement and the demand multiplier is already included with default value 1. We create the GamsModelInstance mi using the GamsCheckpoint.add_modelinstance method.

```
...
    cp = ws.add_checkpoint()
    t7 = ws.add_job_from_string(get_model_text())
    t7.run(checkpoint=cp)
    mi = cp.add_modelinstance()
...
```

7.10.3.19 How to modify a parameter of a GamsModelInstance using GamsModifier (transport7.py)

A GamsModelInstance uses a sync_db to maintain the data. We define bmult as GamsParameter using the GamsDatabase.add_parameter method and specify gurobi as solver. Afterwards the GamsModelInstance is instantiated with 3 arguments, the solve statement, GamsModifier bmult and GamsOptions opt. The GamsModifier means that bmult is modifiable while all other parameters, variables and equations of GamsModelInstance mi stay unchanged. We use the GamsParameter.add_record method to assign a value to bmult. That value can be varied afterwards using the GamsParameter.first_record method to reproduce our well-known example with different demand multipliers.

```
...
    bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
    opt = ws.add_options()
    opt.all_model_types = "gurobi"
    mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)
    bmult.add_record().value = 1.0
    bmultlist = [ 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 ]
    for b in bmultlist:
        bmult.first_record().value = b
        mi.solve()
        print "Scenario bmult=" + str(b) + ":"
        print " Modelstatus: " + str(mi.model_status)
        print " Solvestatus: " + str(mi.solver_status)
        print " Obj: " + str(mi.sync_db.get_variable("z").find_record().level)
    ...
```

7.10.3.20 How to modify a variable of a GamsModelInstance using GamsModifier (transport7.py)

We create a GamsModelInstance using the GamsCheckpoint.add_modelinstance method. Afterwards we define x as GamsVariable and a GamsParameter xup that will be used as upper bound for x. At the following instantiate method GamsModifier has 3 arguments. The first one says that x is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GamsParameter that holds the new value, in this case xup.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
...
    mi = cp.add_modelinstance()
    x = mi.sync_db.add_variable("x", 2, VarType.Positive)
    xup = mi.sync_db.add_parameter("xup", 2, "upper bound on x")
    mi.instantiate("transport use lp min z", GamsModifier(x, UpdateAction.Upper, xup))
    mi.solve()
    for i in t7.out_db["i"]:
        for j in t7.out_db["j"]:
            xup.clear()
            xup.add_record((i.keys[0], j.keys[0])).value = 0
            mi.solve()
            print "Scenario link blocked: " + i.keys[0] + " - " + j.keys[0]
            print " Modelstatus: " + str(mi.model_status)
            print " Solvestatus: " + str(mi.solver_status)
            print " Obj: " + str(mi.sync_db["z"].find_record().level)
    ...
```

7.10.3.21 How to use a queue to solve multiple GamsModelInstances in parallel (transport8.py)

We initialize a GamsCheckpoint `cp` from a GamsJob. Then we define a list that represents the different values of the demand multiplier. That list will be used like a queue where we extract the last element first. The objects `list_lock` and `io_lock` are used later to avoid multiple reading of one demand multiplier and messed up output. Then we call function `scen.solve` multiple times in parallel. The number of parallel calls is specified by `nr_workers`.

```
...
cp = ws.add_checkpoint()
t8 = ws.add_job_from_string(get_model.text())
t8.run(checkpoint=cp)
bmult_list = [ 1.3, 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6 ]
list_lock = threading.Lock()
io_lock = threading.Lock()
# start 2 threads
nr_workers = 2
threads = {}
for i in range(nr_workers):
    threads[i] = threading.Thread(target=scen.solve, args=(ws, cp, bmult_list, list_lock, io_lock))
    threads[i].start()
for i in range(nr_workers):
    threads[i].join()
```

In function `scen.solve` we create and instantiate a GamsModelInstance as in the preceding examples and make parameter `bmult` modifiable. Note that we choose `cplex` as solver because it is thread safe (gurobi would also be possible).

We have two critical sections that are locked by the objects `list_lock` and `io_lock`. Note that the `pop` method removes and returns the last element from the list and deletes it. Once the list is empty the loop terminates.

```
...
def scen_solve(workspace, checkpoint, bmult_list, list_lock, io_lock):
    mi = checkpoint.add_modelinstance()
    bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
    opt = ws.add_options()
    opt.all_model_types = "cplex"
    # instantiate the GamsModelInstance and pass a model definition and GamsModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)
    bmult.add_record().value = 1.0
    while True:
        # dynamically get a bmult value from the queue instead of passing it to the different threads at creation time
        list_lock.acquire()
        if 0 == len(bmult_list):
            list_lock.release()
            return
        b = bmult_list.pop()
        list_lock.release()
        bmult.first_record().value = b
        mi.solve()
        # we need to make the output a critical section to avoid messed up report informations
        io_lock.acquire()
        print "Scenario bmult=" + str(b) + ":"
        print " Modelstatus: " + str(mi.model_status)
        print " Solvestatus: " + str(mi.solver_status)
        print " Obj: " + str(mi.sync_db.get_variable("z").find_record().level)
        io_lock.release()
    ...
```

7.10.3.22 How to fill a GamsDatabase by reading from MS Access (transport9.py)

This example illustrates how to import data from Microsoft Access to a GamsDatabase. There are a few prerequisites required to run `transport9.py` successfully.

- We import `pyodbc` which can be downloaded from <http://code.google.com/p/pyodbc/>.
- Note that an architecture mismatch might cause problems. The bitness of your MS Access, Python, `pyodbc` and GAMS should be identical.

We call a function `read_data_from_access` that finally returns a `GamsDatabase` as shown below.

```
...
db = read_from_access(ws)
...
```

The function `read_from_access` begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database `transport.accdb` which can be found in `[GAMSDIR]\apifiles\Data`. To finally read in GAMS sets and parameters we call the functions `read_set` and `read_parameter` that are explained down below.

```
...
def read_from_access(ws):
    db = ws.add_database()
    # connect to database
    str_access_conn = 'DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};DBQ=..\Data\transport.accdb'
    try:
        connection = pyodbc.connect(str_access_conn)
    except Exception as ex:
        print "Error: Failed to create a database connection. \n {0}".format(ex)
        sys.exit(1)
    # read GAMS sets
    read_set(connection, db, "SELECT Plant FROM plant", "i", 1, "canning plants")
    read_set(connection, db, "SELECT Market FROM Market", "j", 1, "markets")
    # read GAMS parameters
    read_parameter(connection, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases")
    read_parameter(connection, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases")
    read_parameter(connection, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles")
    connection.close()
    return db
...
```

The function `read_set` adds a set to the `GamsDatabase` that is filled with the data from the MS Access file afterwards. The function `read_parameter` works quite similar.

```
...
def read_set(connection, db, query_string, set_name, set_dim, set_exp=""):
    try:
        cursor = connection.cursor()
        cursor.execute(query_string)
        data = cursor.fetchall()
        if len(data[0]) != set_dim:
            print "Number of fields in select statement does not match setDim"
            sys.exit(1)
        i = db.add_set(set_name, set_dim, set_exp)
        for row in data:
            keys = []
            for key in row:
                keys.append(str(key))
            i.add_record(keys)
    except Exception as ex:
        print "Error: Failed to retrieve the required data from the DataBase.\n{0}".format(ex)
        sys.exit(1)
    finally:
        cursor.close()
...
```

Once we read in all the data we can create a `GamsJob` from the `GamsDatabase` and run it as usual.

7.10.3.23 How to fill a `GamsDatabase` by reading from MS Excel (`transport10.py`)

This example illustrates how to read data from Excel, or to be more specific, from `[GAMSDIR]\apifiles\Data\transport.xlsx`.

At first you have to download an additional package from [pypi](#), e.g. to `C:\Users\[USERNAME]\Downloads`. Unzip the package and run the following code from command line:

```
cd C:\Users\[Username]\Downloads\xlrd-0.9.2 && python setup.py install && cd [GAMSDIR]\apifiles\Python
```

Now you should be able to find the directory `xlrd` in `[PYTHONDIR]\Lib\site-packages` and to run `transport10.py`.

In `transport10.py` the model is given as string without data like in many examples before and the Excel file `transport.xlsx` is located at `[GAMSDIR]\apifiles\Data`. At first we define the workbook to read from and the different sheet names. To ensure to have the same number of markets and plants in all

spreadsheets, we conduct a little test that checks for the number of rows and columns. Our workspace is only created if this test yields no errors.

```
...
wb = open_workbook("../Data\\transport.xlsx")
capacity = wb.sheet_by_name("capacity")
demand = wb.sheet_by_name("demand")
distance = wb.sheet_by_name("distance")
# number of markets/plants have to be the same in all spreadsheets
assert (distance.ncols-1 == demand.ncols) and (distance.nrows-1 == capacity.ncols), \
    "Size of the spreadsheets doesn't match"
...
```

Now we can create a GamsDatabase and read in the data contained in the different worksheets. We iterate over the columns and read in the set names and the corresponding parameter values.

```
...
db = ws.add_database()
i = db.add_set("i", 1, "Plants")
j = db.add_set("j", 1, "Markets")
capacity_param = db.add_parameter("a", 1, "Capacity")
demand_param = db.add_parameter("b", 1, "Demand")
distance_param = db.add_parameter("d", 2, "Distance")
for cx in range(capacity.ncols):
    i.add_record(str(capacity.cell_value(rowx=0, colx=cx)))
    capacity_param.add_record(str(capacity.cell_value(rowx=0, colx=cx))).value = capacity.cell_value(rowx=1, colx=cx)
for cx in range(demand.ncols):
    j.add_record(str(demand.cell_value(rowx=0, colx=cx)))
    demand_param.add_record(str(demand.cell_value(rowx=0, colx=cx))).value = demand.cell_value(rowx=1, colx=cx)
for cx in range(1, distance.ncols):
    for rx in range(1, distance.nrows):
        keys = ( str(distance.cell_value(rowx=rx, colx=0)), str(distance.cell_value(rowx=0, colx=cx)) )
        distance_param.add_record(keys).value = distance.cell_value(rowx=rx, colx=cx)
...
```

Note that we can name sets and parameters just like in the database but we don't have to. Now we can run our GamsJob as usual.

```
...
t10 = ws.add_job_from_string(get_model_text())
opt = ws.add_options()
opt.defines["gdxincname"] = db.name
opt.all_model_types = "xpress"
t10.run(opt, databases=db)
for rec in t10.out_db["x"]:
    print "x(" + rec.keys[0] + ", " + rec.keys[1] + "): level=" + str(rec.level) + " marginal=" + str(rec.marginal)
...
```

7.10.3.24 How to create and use a save/restart file (transport11.py)

In transport11.py we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GamsCheckpoint.

We create a directory `tmp` with internal identifier `w_dir` in the directory we are currently in (usually `[GAMSDIR]\apifiles\Python`). This file will be used as working directory later. From the main function we call the function `create_save_restart` giving it directory `tmp` and the desired name for the save/restart file (`tbase`) as arguments.

```
...
w_dir = os.path.join(".", "tmp")
create_save_restart(os.path.join(w_dir, "tbase"));
...
```

In function `create_save_restart` we create a workspace with the given working directory (`w_dir` refers to `tmp`). Then we create a GamsJob from a string. Note that the string given via `get_base_model_text` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a GamsOption to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the GamsJob and stored in the file given as argument to the function, in our case `tbase`. This becomes possible because the `add_checkpoint` method accepts identifiers as well as file names as argument.

```
...
def create_save_restart(cp_file_name):
    if len(sys.argv) > 1:
        ws = GamsWorkspace(os.path.dirname(cp_file_name), sys.argv[1])
    else:
```

```

        ws = GamsWorkspace(os.path.dirname(cp_file_name))
    j1 = ws.add_job_from_string(get_base_model_text())
    opt = ws.add_options()
    opt.action = Action.CompileOnly
    cp = ws.add_checkpoint(os.path.basename(cp_file_name))
    j1.run(opt, cp)
    del opt
...

```

So what you should keep in mind before we return to further explanations of the main function is, that the file `tbase` is now in the current working directory and contains a checkpoint that will work exactly like a restart file.

In the main function we define some data using Python data structures as we already did in [transport4.py](#) before we create the `GamsWorkspace` and a `GamsDatabase`.

```

...
if len(sys.argv) > 1:
    ws = GamsWorkspace(w_dir, sys.argv[1])
else:
    ws = GamsWorkspace(w_dir)
    db = ws.add_database()
...

```

Afterwards we set up the `GamsDatabase` like we already did in [transport4.py](#). Once this is done we run a `GamsJob` using this data plus the checkpoint stored in file `tbase`.

```

...
cp_base = ws.add_checkpoint("tbase")
t4 = ws.add_job_from_string(get_model_text(), cp_base)
opt = ws.add_options()
opt.defines["gdxincname"] = db.name
opt.all_model_types = "xpress"
t4.run(opt, databases=db)
...

```

Note that the string from which we create job `t11` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the `GamsDatabase` correctly. The entire model definition is delivered by the checkpoint `cp_base` which is equal to the one we saved in `tbase`.

7.11 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Matlab API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known **transportation problem**. These examples introduce several API features step by step.

- [Getting started](#) A quick introduction about how to add the API to the Matlab path
- [Important Classes of the API](#) Overview of some fundamental classes of the GAMS Matlab API
- [How to use the API](#) An extensive set of examples describing how to use API components

7.11.1 Getting started

The object oriented GAMS Matlab API is built on top of the GAMS Java API and provides convenient access to GAMS from within Matlab (2017b or later) and Octave (5.2 or later). Examples using the API are located in `apifiles/Matlab/examples` and `apifiles/Matlab/examples_octave` for Matlab or Octave, respectively. The examples slightly differ for Octave since it does not support the complete Matlab syntax and functionalities - most importantly to note, enumeration classes (see also the note below). The object oriented API is located in `apifiles/Matlab/api`.

For making your Matlab installation aware of the packages provided by GAMS, you need to do the following two steps. First, add the GAMS Java API to the Matlab java class path. This can be done statically or dynamically. The latter is less efficient but more convenient for testing.

- static: Locate the `javaclasspath.txt` and add the path `[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar`. You can find the location with `cd(prefdir)` in Matlab or `which javaclasspath` in Octave. Finally, restart Matlab or Octave.
- dynamic: Call the function `javaaddpath("[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar")`.

Second, add the GAMS Matlab API to the Matlab path by calling `addpath("[PathToGAMS]/apifiles/Matlab/api")`.

Note

Octave does not support enumeration classes (yet). In order to use the GAMS enumerations, please use the alternative integer or string value. For example, instead of using `GAMS.DebugLevel.SHOW_LOG`, use 2, see **DebugLevel**. To tell the GAMS Matlab API to return the alternative values instead of instances of enumeration classes, set the environment variable `GAMS_MATLAB_ENUM_ALT` to `true`, i.e., `setenv("GAMS_MATLAB_ENUM_ALT", "true");`

You can test your setup by creating a **GAMSWorkspaceInfo**:

```
>> wsinfo = GAMS.GAMSWorkspaceInfo()
wsinfo =
  GAMSWorkspaceInfo with properties:
    debugLevel: OFF
    systemDirectory: ''
    workingDirectory: ''
```

Note

In Matlab you can import the GAMS package by `import GAMS.*`. Then, you don't need to call the GAMS classes with the preceding `GAMS..`

7.11.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS package. Their usage is demonstrated by an extensive set of [examples](#). All GAMS Matlab API classes are contained within one single package `GAMS`. It provides objects to interact with the General Algebraic Modeling System (`GAMS`). Objects in this package allow convenient exchange of input data and model results (`GAMSDatabase`) and help to create and run GAMS models (`GAMSJob`), that can be customized by GAMS options (`GAMSOptions`). Furthermore, it introduces a way to solve a sequence of closely related models in the most efficient way (`GAMSModelInstance`).

Other classes are `GAMSWorkspace`, `GAMSOptions` and `GAMSSymbol`.

7.11.3 How to use the API

In the GAMS system directory there are some examples provided that illustrate the usage of the Matlab API. `[PathToGAMS]/apifiles/Matlab/examples` contains multiple examples dealing - among others - with the well-known **transportation problem**. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

7.11.3.1 How to choose the GAMS system (transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing `transport1` with `C:/GAMS/win64/38.0` we use the 64-bit version of GAMS 38.0 to run `transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
wsInfo = GAMS.GAMSWorkspaceInfo();
if nargin > 0
    wsInfo.systemDirectory = varargin{1};
end
ws = GAMS.GAMSWorkspace(wsInfo);
```

Note

The API can detect GAMS automatically from the `PATH` environment variable. Please note that this is not the `MATLABPATH`. You can inspect the `PATH` with `getenv("PATH")`.

7.11.3.2 How to export data to GDX (transport_gdx)

Although the Object-oriented Matlab API offers much more than exchanging data between Matlab and GDX, a common use case is the export and import of GDX files. The central class for this purpose is `GAMSDatabase`. We assume that the data to be exported is available in Matlab data structures.

```
plants = {'Seattle', 'San-Diego'};
markets = {'New-York', 'Chicago', 'Topeka'};
capacity = containers.Map();
capacity('Seattle') = 350;
capacity('San-Diego') = 600;
demand = containers.Map();
demand('New-York') = 325;
demand('Chicago') = 300;
demand('Topeka') = 275;
distance = containers.Map();
distance('Seattle.New-York') = 2.5;
distance('Seattle.Chicago') = 1.7;
distance('Seattle.Topeka') = 1.8;
distance('San-Diego.New-York') = 2.5;
distance('San-Diego.Chicago') = 1.8;
distance('San-Diego.Topeka') = 1.4;
```

Different type of GAMS symbols are represented using different Matlab data structures. The data for the GAMS sets is represented using a cell of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by a `containers.Map` (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses a dot notation for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with Matlab data structures.

A new `GAMSDatabase` instance can be created using `GAMSWorkspace.addDatabase`.

```
db = ws.addDatabase();
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created `GAMSSet` instance `i` using `GAMSSet.addRecord`.

```
i = db.addSet('i', 1, 'canning plants');
for p = plants
    i.addRecord(p{1});
end
```

`GAMSParameter` instances can be added by using the method `GAMSDatabase.addParameter`. In this example we use the overloaded method which takes a list of `GAMSSet` instances instead of the dimension for creating a parameter with domain information.

```
a = db.addParameter('a', 'capacity of plant i in cases', i);
for p = plants
    a.addRecord(p{1}).value = capacity(p{1});
end
```

As soon as all data is prepared in the `GAMSDatabase`, the method `GAMSDatabase.export` can be used to create a GDX file.

```
db.export('data.gdx');
```

7.11.3.3 How to import data from GDX (transport_gdx)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a `GAMSDatabase` instance.

```
gdxdb = ws.addDatabaseFromGDX('data.gdx');
```

Reading the data from the `GAMSSet` `i` into a cell of strings can be done as follows:

```
gdxPlantsRecords = gdxdb.getSet('i').records;
gdxPlants = cell(size(gdxPlantsRecords));
for i = 1:numel(gdxPlants)
    gdxPlants{i} = gdxPlantsRecords{i}.key(1);
end
```

`i` is retrieved by calling `GAMSDatabase.getSet` on `gdxdb`. The returned `GAMSSet` object has an attribute `records` with an cell array of `GAMSSetRecords`. `set`. Each record can be asked for its keys.

You can do the same for `GAMSPParameter`. Instead of creating a cell, we want to have the data in the form of a `containers.Map`. `GAMSPParameterRecord` can not only be asked for its keys, but also for its value. The following code snippet shows how to read the one dimensional parameter `a` into a map.

```
gdxCapacity = containers.Map();
for rec = gdxdb.getParameter('a').records
    gdxCapacity(rec{1}.key(1)) = rec{1}.value;
end
```

For a key of multi dimensional symbol, we choose a dot based concatenation of keys.

```
gdxDistance = containers.Map();
for rec = gdxdb.getParameter('d').records
    gdxCapacity([rec{1}.key(1), '.', rec{1}.key(2)]) = rec{1}.value;
end
```

Scalar can be read into a variable of type double by accessing the value of the first and only record.

```
gdxFreight = gdxdb.getParameter('f').record.value;
```

7.11.3.4 How to run a GAMSJob from file (transport1)

At first we create our workspace using `GAMSWorkspace ws = GAMS.GAMSWorkspace()`; Afterwards, we can create a `GAMSJob t1` using the `addJobFromGamsLib` method and run it.

Apparently you can create a `GAMSJob` with any other gms file you might have created on your own as long as it is located in the current working directory. Then the `GAMSJob t1` can be defined using the `GAMSJob.addJobFromFile` method.

```
% create GAMSWorkspace "ws" with default working directory
ws = GAMS.GAMSWorkspace();
% create GAMSJob "t1" from "trnsport" model in GAMS Model Libraries
t1 = ws.addJobFromGamsLib('trnsport');
% run GAMSJob "t1"
t1.run();
```

7.11.3.5 How to retrieve a solution from an output database (transport1)

The following lines create the solution output and illustrate the usage of the `GAMSJob.outDB` property to get access to the `GAMSDatabase` created by the `run` method. To retrieve the content of variable `x` we use the `getVariable` method and the `GAMSVariableRecord` class.

```
% retrieve GAMSVariable "x" from GAMSJob's output databases
fprintf('Ran with Default:\n');
for x = t1.outDB.getVariable('x').records
    fprintf('x(%s,%s): level=%g marginal=%g\n', x{1}.keys{:}, x{1}.level, x{1}.marginal);
end
```

7.11.3.6 How to specify the solver using GAMSOptions (transport1)

The solver can be specified via the `GAMSOptions` class and the `GAMSWorkspace.addOptions` method. The `GAMSOptions.setAllModelTypes` property sets `xpress` as default solver for all model types which the solver can handle. Then we run our `GAMSJob t1` with the new `GAMSOptions`.

```
% create GAMSOptions 'opt1'
opt1 = ws.addOptions();
% set all model types of 'opt1' for 'xpress'
opt1.setAllModelTypes('xpress');
% run GAMSJob 't1' with GAMSOptions 'opt1'
t1.run(opt1);
```

7.11.3.7 How to run a job with a solver option file and capture its log output (transport1)

At first we create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterward we use a `GAMSOptions` just like in the preceding example and `GAMSOptions.optFile` property to 1 to tell the solver to look for a solver option file. We specify the argument `output` in order to stream the log of the `GAMSJob` into the file `transport1_xpress.log`. When the `output` argument is omitted then the log will be written to standard output.

```
% write file 'xpress.opt' under GAMSWorkspace's working directory
fid = fopen([ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'xpress.opt'], 'w');
fprintf(fid, 'algorithm=barrier');
fclose(fid);
% create GAMSOptions 'opt2'
opt2 = ws.addOptions();
% set all model types of 'opt2' for 'xpress'
opt2.setAllModelTypes('xpress');
% for 'opt2', use 'xpress.opt' as solver's option file
opt2.optFile = 1;
% run GAMSJob 't2' with GAMSOptions 'opt2' and capture log into 'transport1_xpress.log'.
t1.run(opt2, [ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'transport1_xpress.log']);
```

7.11.3.8 How to use include files (transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings `data` and `model` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
% write 'data' into file 'tdata.gms' under GAMSWorkspace's working directory
fid = fopen([ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'tdata.gms'], 'w');
fprintf(fid, data);
fclose(fid);
```

Afterwards we create a `GAMSJob` using the `GAMSWorkspace.addJobFromString` method. `GAMSOptions.defines` is used like the the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where `incname` is used as name for the include file in the `model` string.

```
% create GAMSJob 't2' from the 'model' string variable
t2 = ws.addJobFromString(model);
% create GAMSOption 'opt' and define 'incname' as 'tdata'
opt = ws.addOptions();
opt.defines('incname', 'tdata');
% run GAMSJob 't2' with GAMSOptions 'opt'
t2.run(opt);
```

The string `model` contains the following lines to read in the data.

```
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
```

7.11.3.9 How to set a non-default working directory (transport3)

At first we create a new directory. Once this is done we can use this directory when creating the `GAMSWorkspace` and make it the working directory.

```
% create a directory
workingDirectory = fullfile(pwd, 'transport3');
mkdir(workingDirectory);
% create a workspace
wsInfo = GAMS.GAMSWorkspaceInfo();
wsInfo.workingDirectory = workingDirectory;
ws = GAMS.GAMSWorkspace(wsInfo);
```

7.11.3.10 How to read data from string and export to GDX (transport3)

We read the data from the string `data`. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding `GAMSJob` a `GAMSDatabase` is created that is available via the `GAMSJob.outDB` property. We can use the `GAMSDatabase.export` method to write the content of this database to a gdx file `tdata.gdx`.

```
% create and run a job from a data file, then explicitly export to a GDX file
t3 = ws.addJobFromString(data);
t3.run();
t3.outDB.export([ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'tdata.gdx']);
```

7.11.3.11 How to run a job using data from GDX (transport3)

This works quite similar to the usage of an include file explained in [transport2 - How to use include files \(transport2\)](#)

```
.
% run a job using an instance of GAMSOptions that defines the data include file
t3 = ws.addJobFromString(model);
opt = ws.addOptions();
opt.defines('gdxincname', 'tdata');
t3.run(opt);
```

Note that there are some minor changes in the model due to the usage of a gdx instead of an include file.

```
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
```

7.11.3.12 How to run a job using implicit database communication (transport3)

This example does basically the same as the two preceding examples together. We create two **GAMSJobs** **t3a** and **t3b** where the first one contains only the data and the second one contains only the model without data. After running **t3a** the corresponding **outDB** can be read in directly just like a gdx file.

Note that the database needs to be passed to the **GAMSJob.run** method as additional argument.

```
t3a = ws.addJobFromString(data);
t3b = ws.addJobFromString(model);
opt = ws.addOptions();
t3a.run();
opt.defines('gdxincname', t3a.outDB.name);
t3b.run(opt, t3a.outDB);
```

7.11.3.13 How to define data using Matlab data structures (transport4)

We use cell arrays and `containers.Map` to define Matlab data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
plants = {'Seattle', 'San-Diego'};
markets = {'New-York', 'Chicago', 'Topeka'};
capacity = containers.Map();
capacity('Seattle') = 350;
capacity('San-Diego') = 600;
demand = containers.Map();
demand('New-York') = 325;
demand('Chicago') = 300;
demand('Topeka') = 275;
distance = containers.Map();
distance('Seattle.New-York') = 2.5;
distance('Seattle.Chicago') = 1.7;
distance('Seattle.Topeka') = 1.8;
distance('San-Diego.New-York') = 2.5;
distance('San-Diego.Chicago') = 1.8;
distance('San-Diego.Topeka') = 1.4;
```

7.11.3.14 How to prepare a GAMSDatabase from Matlab data structures (transport4)

At first we create an empty **GAMSDatabase** **db** using the **GAMSWorkspace.addDatabase** method. Afterwards we prepare the database. To add a set to the database we use the **GAMSSet** class and the **GAMSDatabase.addSet** method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Matlab data structure and add them by using the **GAMSSet.addRecord** method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that scalars can be treated as parameter with dimension 0.

The **GAMSJob** can be run like explained in the preceding example about implicit database communication.

```

db = ws.addDatabase();
i = db.addSet('i', 1, 'canning plants');
for p = plants
    i.addRecord(p{1});
end
j = db.addSet('j', 1, 'markets');
for m = markets
    j.addRecord(m{1});
end
a = db.addParameter('a', 'capacity of plant i in cases', i);
for p = plants
    a.addRecord(p{1}).value = capacity(p{1});
end
b = db.addParameter('b', 'demand at market j in cases', j);
for m = markets
    b.addRecord(m{1}).value = demand(m{1});
end
d = db.addParameter('d', 'distance in thousands of miles', i, j);
for p = plants
    for m = markets
        d.addRecord(p{1}, m{1}).value = distance([p{1}, '.', m{1}]);
    end
end
f = db.addParameter('f', 'freight in dollars per case per thousand miles');
f.addRecord().value = 90;
% create and run a job from the model and read.gdx include file from the database
t4 = ws.addJobFromString(model);
opt = ws.addOptions();
opt.defines('gdxincname', db.name);
t4.run(opt, db);

```

7.11.3.15 How to initialize a GAMSCheckpoint by running a GAMSJob (transport5)

The following lines of code conduct several operations. While the first line simply creates a **GAMSCheckpoint**, the second one uses the **GAMSWorkspace.addJobFromString** method to create a **GAMSJob** containing the model text and data but no solve statement. Afterwards the run method gets the **GAMSCheckpoint** as argument. That means the **GAMSCheckpoint** cp captures the state of the **GAMSJob**.

```

cp = ws.addCheckpoint();
t5 = ws.addJobFromString(model);
t5.run(cp);

```

7.11.3.16 How to initialize a GAMSJob from a GAMSCheckpoint (transport5)

Note that the string returned from function `model` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```

Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';

```

In `transport5` we create a list with eight different values for this demand multiplier.

```

bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3];

```

For each entry of that list we create a **GAMSJob** `t5` using the **GAMSWorkspace.addJobFromString** method. Besides another string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a **GAMSJob** combined from the checkpoint plus the content provided by the string. We run the **GAMSJob** and echo some interesting data from the `outDB` using the **GAMSDatabase.getParameter** and **GAMSDatabase.getVariable** methods and the **GAMSSymbol.record** attribute plus the **GAMSParameterRecord.value** and the **GAMSVariableRecord.level** properties.

```

for i = 1:numel(bmultlist)
    job = sprintf('bmult=%f; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;', bmultlist(i));
    t5 = ws.addJobFromString(job, cp);
    t5.run();
    fprintf('Scenario bmult=%f:\n', bmultlist(i));
    fprintf(' Modelstatus: %s\n', GAMS.ModelStat.lookup(t5.outDB.getParameter('ms').record.value));
    fprintf(' Solvestatus: %s\n', GAMS.SolveStat.lookup(t5.outDB.getParameter('ss').record.value));
    fprintf(' Obj: %f\n', t5.outDB.getVariable('z').record.level);
end

```

Note

Some of the demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the `model status` and the `solve status` provide important information for a correct solution interpretation.

7.11.3.17 How to create a GAMSModelInstance from a GAMSCheckpoint (transport7)

In `transport7` the usage of `Matlab::GAMS::GAMSModelInstance` is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Then we create the `GAMSModelInstance` `mi` using the `GAMSCheckpoint.addModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```
cp = ws.addCheckpoint();
% initialize a checkpoint by running a job
t7 = ws.addJobFromString(model);
t7.run(cp);
% create a ModelInstance and solve it multiple times with different scalar bmult
mi = cp.addModelInstance();
```

7.11.3.18 How to modify a parameter of a GAMSModelInstance using GAMSModifier (transport7)

A `GAMSModelInstance` uses a `syncDB` to maintain the data. We define `bmult` as `GAMSParameter` using the `GAMSParameter` method and specify `cplex` as solver. Afterwards the `GAMSModelInstance` is instantiated with 3 arguments, the solve statement, `GAMSOptions` `opt` and `GAMSModifier` `bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of `ModelInstance` `mi` stay unchanged. We use the `GAMSParameter.addRecord` method and the `value` property to assign a value to `bmult`. That value can be varied afterwards using the `GAMSSymbol.record` property to reproduce our well-known example with different demand multipliers.

```
bmult = mi.syncDB.addParameter('bmult', 'demand multiplier');
opt = ws.addOptions();
opt.setAllModelTypes('cplex');
% instantiate the ModelInstance and pass a model definition and Modifier to declare bmult mutable
mi.instantiate('transport use lp min z', opt, GAMS.GAMSModifier(bmult));
bmult.addRecord().value = 1.0;
bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3];
for i = 1:numel(bmultlist)
    bmult.record.value = bmultlist(i);
    mi.solve();
    fprintf('Scenario bmult=%f:\n', bmultlist(i));
    fprintf(' Modelstatus: %s\n', mi.modelStatus);
    fprintf(' Solvestatus: %s\n', mi.solveStatus);
    fprintf(' Obj: %f\n', mi.syncDB.getVariable('z').record.level);
end
```

7.11.3.19 How to modify a variable of a GAMSModelInstance using GAMSModifier (transport7)

We create a `GAMSModelInstance` just like in the next to last example. We define `x` as `GAMSVariable` and its upper bound as `GAMSParameter` `xup`. At the following `instantiate` method `GAMSModifier` has 3 arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the `GAMSParameter` that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
mi = cp.addModelInstance();
x = mi.syncDB.addVariable('x', 2, GAMS.VarType.POSITIVE, '');
xup = mi.syncDB.addParameter('xup', 2, 'upper bound on x');
% instantiate the ModelInstance and pass a model definition and Modifier to declare upper bound of X mutable
mi.instantiate('transport use lp min z', GAMS.GAMSModifier(x, GAMS.UpdateAction.UPPER, xup));
```

```

for i = t7.outDB.getSet('i').records
    for j = t7.outDB.getSet('j').records
        xup.clear();
        keys = {i{1}.key(1), j{1}.key(1)};
        xup.addRecord(keys).value = 0;
        mi.solve();
        fprintf('Scenario link blocked: %s - %s\n', keys{:});
        fprintf(' Modelstatus: %s\n', mi.modelStatus);
        fprintf(' Solvestatus: %s\n', mi.solveStatus);
        fprintf(' Obj: %f\n', mi.syncDB.getVariable('z').record.level);
    end
end
end

```

7.11.3.20 How to create and use a save/restart file (transport11)

In `transport11` we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a **GAMSCheckpoint**. From the main function we call the function `create_save_restart` giving it the current workspace settings and the desired file name as arguments. `create_save_restart(ws.workingDirectory, ws.systemDirectory, ws.debugLevel, 'tbase');`

In function `create_save_restart` we create a workspace with the given workspace settings. Then we create a **GAMSJob** from a string. Note that the string given via `basemodel` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a **GAMSOptions** to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the **GAMSJob** and stored in the file given as argument to the function, in our case `tbase`. This becomes possible because the `addCheckpoint` method accepts identifiers as well as file names as argument.

```

ws = GAMS.GAMSWorkspace(workdir, systemdir, debuglevel);
j1 = ws.addJobFromString(basemodel);
opt = ws.addOptions();
opt.action = GAMS.Action.CompileOnly;
cp = ws.addCheckpoint('tbase');
j1.run(opt, cp);
opt.dispose();
j1.outDB.dispose();

```

So what you should keep in mind before we return to further explanations of the main function is, that the file `tbase` is now in the current working directory and contains a checkpoint. Now in the main function we define some data using Matlab data structures as we already did in `transport4` before we create the **GAMSWorkspace** and a **GAMSDatabase**.

```

ws = GAMS.GAMSWorkspace(wsInfo);
db = ws.addDatabase();

```

Afterwards we set up the **GAMSDatabase** like we already did in `transport4`. Once this is done we run a **GAMSJob** using this data plus the checkpoint stored in file `tbase`.

```

cpBase = ws.addCheckpoint('tbase');
opt = ws.addOptions();
t11 = ws.addJobFromString(model, cpBase);
opt.defines('gdxincname', db.name);
opt.setAllModelTypes('xpress');
t11.run(opt, db);

```

Note that the string from which we create job `t11` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the **GAMSDatabase** correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

7.12 Release Notes

7.12.1 35.1.0

- Fixed `GAMSOptions.Output` parameter being ignored in `GAMSJob.Run()`.

7.12.2 32.1.0

- Automatically finding a GAMS installation from the Windows registry has been changed from using [HKEY_CURRENT_USER\HKEY_CLASSES_ROOT]\gams.location to [HKEY_CURRENT_USER\HKEY_LOCAL_MACHINE]\Software

7.12.3 25.0.1

Changes for `GAMSSymbol` and `GAMSSymbolRecord`: Both classes got the `IEquatable<T>` Interface. As a result the behavior of the `Equals` function as well as the `==` and `!=` operators were modified. For both classes `Equals` and `==` returns now true, if the internal data reference is the same. Here is an example:

```
GAMSVariable x1 = t1.OutDB.GetVariable("x");
GAMSVariable x2 = t1.OutDB.GetVariable("x");
if(x1 == x2)
    Console.WriteLine("x1==x2");
else
    Console.WriteLine("x1!=x2");
if (x1.Equals(x2))
    Console.WriteLine("x1 equals x2");
else
    Console.WriteLine("x1 does not equal x2");
```

In previous versions we got this output:

```
x1!=x2
x1 does not equal x2
```

Now we get:

```
x1==x2
x1 equals x2
```

7.12.4 24.9.1

- New functions `GAMSWorkspace.AddJobFromApiLib`, `GAMSWorkspace.AddJobFromNoaLib` to create `GAMSJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library

7.12.5 24.8.1

- New option `GAMSOptions.ErrorLog`: Max error message lines written to the log for each error

7.12.6 24.7.4

- `GAMSModelInstance.Instantiate`: Skip creation of GDX file, which was unreachable from within the API anyway

7.12.7 24.7.1

- `GAMSWorkspace.AddJobFromFile`: Throw an exception if given file does not exist

7.12.8 24.5.4

- Fixed a bug with the property `GAMSOptions.IDir`
-

7.12.9 24.5.2

- Fixed a bug that lead to a crash on Linux (using Mono) when the GAMS system directory is a symbolic link

7.12.10 24.5.1

- New functions `GAMSWorkspace.ApiLib` and `GAMSWorkspace.NoaLib` that can be used to retrieve models from the GAMS API Library and the Nonlinear Optimization Applications Library

7.12.11 24.4.2

- New property `GAMSSymbol.DomainsAsStrings`: Domains of Symbol, each element is a string
Note: If the domain is an alias in GAMS, this call will return the name of the Alias, not the name of the aliased Set
- Disable unwanted debug output from Couenne when running with `GAMSModelInstance`

7.12.12 24.4.1

- Modified handling of GAMS Aliases:
 - If we ask for the number of `GAMSSymbols` in a `GAMSDatabase`, the Aliases will be excluded
 - If we iterate over all `GAMSSymbols` in a `GAMSDatabase`, Aliases will be skipped
 - If we ask explicitly for an Alias in a `GAMSDatabase` (`GAMSDatabase.GetSet("a")` with a being an Alias) we will get a reference to the `GAMSSet` referenced by the Alias, not the Alias itself
 - Note: Aliases can appear in a `GAMSDatabase` only, if it was initialized by a GDX file containing an Alias.

7.12.13 24.3.2

- Make more GAMS options available through the `GAMSOptions` class:
 - `GAMSOptions.AppendExpand`: Expand file append option
 - `GAMSOptions.AppendOut`: Output file append option
 - `GAMSOptions.DumpOpt`: Writes preprocessed input to the file `input.dmp`
 - `GAMSOptions.DumpParms`: GAMS parameter logging
 - `GAMSOptions.ErrMsg`: Placing of compilation error messages
 - `GAMSOptions.Expand`: Expanded (include) input file name
 - `GAMSOptions.FErr`: Alternative error message file
 - `GAMSOptions.JobTrace`: Job trace string to be written to the trace file at the end of a Gams job
 - `GAMSOptions.LimCol`: Maximum number of columns listed in one variable block
 - `GAMSOptions.LimRow`: Maximum number of rows listed in one equation block
 - `GAMSOptions.LogLine`: Amount of line tracing to the log file
 - `GAMSOptions.On115`: Generate errors for unknown unique element in an equation
-

- GAMSOptions.Output: Output file
- GAMSOptions.PageContr: Output file page control option
- GAMSOptions.PageSize: Output file page size (=0 no paging)
- GAMSOptions.PageWidth: Output file page width
- GAMSOptions.Reference: Symbol reference file
- GAMSOptions.ScriptExit: Program or script to be executed at the end of a GAMS run
- GAMSOptions.Suppress: Compiler listing option
- GAMSOptions.Symbol: Symbol table file
- GAMSOptions.TraceLevel: Solvestat threshold used in conjunction with a=GT

7.12.14 24.3.1

- GAMSJob.Run creates OutDB now even if it throws a GAMSExceptionExecution
- New function GAMSSymbolRecord.Key(int index): Retrieve key of GAMSSymbolRecord on position index
- GAMSModelInstance.Solve also works now for solvers which require a subsolver, e.g. Dicopt
- GAMSDatabase.Export registers real domains in GDX file now if possible, before relaxed domains were registered always
- GAMSSymbol.CopySymbol works for the Universe of a GAMSDatabase (GAMSDatabase.GetSet(" *")) now, when copying into the Universe, a merge will be performed
- Fix default value for systemDirectory argument in GAMSWorkspace constructor when using MONO: If no value is given, first the PATH and then the (DY)LD_LIBRARY_PATH is checked for a valid GAMS system directory

7.12.15 24.2.3

- Fix memory leak in GAMSDatabase

7.12.16 24.2.2

- Fixed a bug regarding the subtype of equations and their default records, when the equation was added to a GamsDatabase from the API
- Fix GAMSEnum.GAMSExitCode
- Make sure that GAMSModelInstance.Instantiate() does not solve the model, but only prepares everything required for the following Solve()

7.12.17 24.2.1

- New version of function GAMSWorkspace.AddOptions creating an instance of GAMSOptions initialized by an existing option file
 - New properties: GAMSWorkspace.APIVersion, GAMSWorkspace.APIMajorRelNumber, GAMSWorkspace.APIMinorRelNumber and GAMSWorkspace.APIGOLDRelNumber
 - New property GAMSWorkspace.MyEPS: Reset value to be stored in and read from GAMSDatabase for Epsilon, default is double.Epsilon
 - New function GAMSOptions.Export: Write GAMSOptions into a parameter file
 - Switching type of property GAMSOptions.NoNewVarEqu from Integer to Enum (ENoNewVarEqu)
 - Renaming of GAMSEnum.ModelStat.NonOptimalIntermed to GAMSEnum.ModelStat.Feasible
-

7.12.18 24.1.1

- **GAMSDatabase:**
 - New function `CheckDomains`: Check for all symbols if all records are within the specified domain of the symbol
 - New function `GetDatabaseDVs`: Return all `GAMSDatabaseDomainViolations`
 - New property `SuppressAutoDomainChecking`: Controls whether domain checking is called in `GAMSDatabase` export
 - New variants of the functions `AddEquation`, `AddParameter`, `AddSet`, `AddVariable`: Allow to specify domain information
 - Function `Compact` becomes obsolete and will be dropped in future
- **GAMSModelInstance:**
 - New function `CopyModelInstance`: Copies a `ModelInstance` to a new `ModelInstance` which gets constructed at this call
 - New function `Interrupt`: Sends interrupt signal to running `GAMSModelInstance`
- **GAMSModifier:**
 - Allow to define `SymbolUpdateType` for each `GAMSModifier` separately
- **GAMSSymbol (`GAMSEquation`, `GAMSPParameter`, `GAMSSet`, `GAMSVariable`):**
 - New function `CheckDomains`: Check if all records are within the specified domain of the symbol
 - New function `CopyToArray`: Copies values of a dense symbol into a dense array
 - New function `CopyToSqdArray`: Copies values of a sparse symbol into a squeezed array
 - New function `CopySparseToDenseArray`: Copies values of a sparse symbol into a dense array
 - New function `CopyFromDenseArray`: Copies values from dense array into a symbol
 - New function `CopySliceFromDenseArray`: Copies values from slice of dense array into a symbol
 - New function `GetSymbolDVs`: Return all `GAMSSymbolDomainViolations`
 - New function `MergeRecord`: Finds record in `GAMSSymbol` if it exists, adds it if not
 - New property `Domains`: Domains of Symbol, each element is either a `GAMSSet` (real domain) or a string (relaxed domain)
- **GAMSWorkspace:**
 - Change the `Debug` parameter from a Boolean flag to an enum type called `DebugLevel`
 - The `Debug` parameter can be overwritten by the system environment variable "GAMSOOAPI-DEBUG" if set to one of the following: `Off`, `KeepFiles`, `ShowLog`, `Verbose`
 - Improve performance significantly for function `AddDatabase(GAMSDatabase)`
 - New functions: `AddJobFromGamsLib`, `AddJobFromTestLib`, `AddJobFromEmpLib`, `AddJobFromDataLib` and `AddJobFromFinLib`
 - New properties: `Version`, `MajorRelNumber`, `MinorRelNumber` and `GOLDRelNumber`
 - New optional parameter `inModelName` for functions `AddDatabaseFromGDX/AddDatabase`: `GAMS` string constant that is used to access this database
- Add new sub class of `GAMSException`: `GAMSExceptionExecution`. This provides additional info about the reason of the failed execution.

7.12.19 24.0.2

- Add new function `GAMSSymbol.CopySymbol` which copys all records from one to another `GAMSSymbol`
 - Label and symbol lookup is now case insensitive
 - Fixed handling of infinite bounds for `GAMSModifiers`
-

7.12.20 24.0.1

- Add function `Interrupt` to `GAMSJob`
- Do not throw an exception when hitting an `Alias` with the `GAMSDatabaseEnumerator` or `GetSymbol` function but return the aliased `GAMSSet`

7.12.21 23.9.3

- Constructor of `GAMSWorkspace` now appends conditionally the GAMS system directory to the `PATH` environment variable. This fixes a problem with applications that create and dispose many `GAMSWorkspace` instances.

7.12.22 23.9.2

- `GAMSModelInstance.Instantiate` is now thread-safe
- Additional flag `createOutDB` for method `GAMSJob.Solve` which allows to switch off automatic `outDB` creation
- Fix a problem with parallel execution of `GAMSModelInstances` in Debug mode
- Add new class `GAMSException`
- Add tighter restriction on adding symbols to `GAMSModelInstance.SyncDB`
- Add new class `GAMSModelInstanceOpt` to customize method `GAMSModelInstance.Solve`
 - `GAMSModelInstanceOpt.Debug`: produces a `gams.gms`, `jacobian.gdx` and `dictmap.gdx` allowing inspection of the model instance solved in the `GAMSModelInstance.Solve` method
 - `GAMSModelInstanceOpt.NoMatchLimit`: controls the maximum number of accepted unmatched scenario records before terminating the solve
 - `GAMSModelInstanceOpt.OptFile`: allows to choose solver option for `GAMSModelInstance.Solve`
 - `GAMSModelInstanceOpt.Solver`: allows to choose solver for `GAMSModelInstance.Solve`
- Add `GAMSWorkspace.ScratchFilePrefix` to prefix all scratch files created by `GAMS.Net`
- `GAMSJob` no longer implements `IDisposable`

7.13 Release Notes

7.13.1 35.1.0

- Fixed `GAMSOptions.setOutput` parameter being ignored in `GAMSJob.run()`.

7.13.2 32.1.0 (July 2020)

- On windows platform, change of window registry configuration used for finding the installed GAMS directory from: `[HKEY_CURRENT_USER|HKEY_CLASSES_ROOT]\gams.location` to: `[HKEY_CURRENT_USER|HKEY_LOCAL_MACHINE]\Software\Classes\gams.location`, effective only when the installed GAMS directory is not found from "PATH" environment variable.
-

7.13.3 29.1.0 (November 2019)

- Increase the minimum version requirement of the Java Runtime Environment to Java SE 8.
- The remove operation `GAMSDatabaseIterator.remove` is no longer supported. The method now throws an instance of `java.lang.UnsupportedOperationException` and performs no other actions. (To remove all records of the current iterating symbol, use the method `GAMSSymbol.clear` instead.)
- Fixed the behavior of the remove operation `GAMSSymbolIterator.remove`. The method now removes all records of the last `GAMSSymbol` element returned by an instance of `GAMSSymbolIterator` and can be called only once per call to `GAMSSymbolIterator.next`. The behavior of an iterator is unspecified if the underlying collection is modified while the iteration is in progress in any way other than by calling the method.

7.13.4 28.2.0 (August 2019)

- Added new method `GAMSSymbolRecord.dispose` for on-demand release of external resources hold by non-java library.

7.13.5 28.1.0 (August 2019)

- Announced a plan to increase the minimum version requirement of the Java Runtime Environment to Java SE 8 with the next major release.

7.13.6 25.1.1 (May 2018)

- Changed the naming scheme of a temporary working directory to be created from 'yyyyM-Mdd_HHmms' to the prefixed 'gams_' (defined by `GAMSGlobals.workingDirectoryPrefix`), in case no working directory has been specified.
 - Fixed the behavior when `GAMSDatabase` is added with the name that already exists, now `GAMSException` will be raised. (see `GAMSWorkspace.addDatabase(String databaseName)` and `GAMSWorkspace.addDatabaseFromGDX(String gdxFileName, String databaseName)`)
 - Calls on `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` are no longer available. As calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommended to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See `GAMSDatabase.dispose`, `GAMSModelInstance.dispose`, and `GAMSOptions.dispose`.
 - All Java native interfaces to [Expert-Level APIs](#) are now included in the distributed `GAMSJavaAPI.jar`, located under the `[Path/To/GAMS]/apifiles/Java/api/` directory.
-

7.13.7 25.0.1 (January 2018)

- The minimum version requirement of Java Runtime Environment for using with GAMS Java API is now Java SE 7.
- New `TransportGDX` example to demonstrate how to import and export GDX files.
- Removed `GAMSSymbol.compact`, deprecated since 24.8.1 (December 2016).
- Changed equivalence behavior of `GAMSSymbol` and `GAMSSymbolRecord` objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
 - Two symbols are equivalent if and only if they have the same internal reference.
 - Two symbol records are equivalent if and only if they have the same internal reference.

The behavior of operator `==` remains unchanged. The following example illustrates the new equivalence behavior:

```
GAMSVariable x1 = db.getVariable("x");
GAMSVariable x2 = db.getVariable("x");
GAMSVariable x3 = x1;
assertTrue(x1.equals(x2)); // true, previously false
assertFalse(x1 == x2); // false, previously false
assertTrue(x1.equals(x3)); // true, previously true
assertTrue(x1 == x3); // true, previously true
```

7.13.8 24.8.1 (December 2016)

- Deprecated `GAMSSymbol.compact` and the method will be removed in the next major release
- an exception or an error thrown by `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` now must be caught or declared to be thrown. Note that an explicit call on one of these two methods is not recommended unless it is necessary to do so.

7.13.9 24.7.4 (September 2016)

- **`GAMSModelInstance.instantiate`**: Skip creation of GDX file, which was unreachable from within the API anyway

7.13.10 24.7.1 (March 2016)

- Fixed a bug with the property `GAMSOPTIONS.defines` : When too many entries were added, all of them were ignored.

7.13.11 24.5.1 (August 2015)

- New examples
 - **Clad** at `[Path/To/GAMS]/apifiles/Java/clad/Clad.java`
 - **SpecialValues** at `[Path/To/GAMS]/apifiles/Java/specialvalues/SpecialValues.java`
- New functions `GAMSWorkspace.addJobFromApiLib` and `GAMSWorkspace.addJobFromNoaLib` that can be used to retrieve models from **GAMS API Library** and **Nonlinear Optimization Applications Library**.

7.13.12 24.4.2 (March 2015)

- New property **GAMSSymbol.getDomainsAsStrings**: get domains of symbol, each element is a string
Note: If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.
- Disable unwanted debug output from Couenne when running with **GAMSModelInstance**
- Change naming scheme of.gdx output scratch file to sequence number.

7.13.13 24.4.1 (December 2014)

- Modify the handling of GAMS Aliases in the object oriented APIs:
 - If we ask for the number of **GAMSSymbol** in a **GAMSDatabase**, the Aliases will be excluded.
 - If we iterate over all **GAMSSymbol** in a **GAMSDatabase**, Aliases will be skipped.
 - If we ask explicitly for an Alias in a **GAMSDatabase** (**GAMSDatabase.getSet("a")** with a being an Alias) we will get a reference to the **GAMSSet** referenced by the Alias, not the Alias itself.
 - Note:
 - * Aliases can appear in a **GAMSDatabase** only, if it was initialized by a GDX file containing an Alias.
 - * The new example **Alias** at [Path/To/GAMS]/apifiles/Java/alias/Alias.java demonstrates this new behavior.

7.13.14 24.3.3 (September 2014)

Fixed

- a location of listing file when creating a job from (full-path) file without giving a job name

7.13.15 24.3.2 (August 2014)

- Make more GAMS options available through the **GAMSOptions** class:
 - **GAMSOptions.EAppendExpand** (**enum**, getter, and setter): Expand file append option
 - **GAMSOptions.EAppendOut** (**enum**, getter, and setter): Output file append option
 - **GAMSOptions.EDumpOpt** (**enum**, getter, and setter): Writes preprocessed input to the file input.dmp
 - **GAMSOptions.EDumpParms** (**enum**, getter, and setter): GAMS parameter logging
 - **GAMSOptions.EErrMsg** (**enum**, getter, and setter): Placing of compilation error messages
 - **GAMSOptions.EAppendExpand** (**getter**, and **setter**): Expanded (include) input file name
 - **GAMSOptions.FErr** (**getter**, and **setter**): Alternative error message file
 - **GAMSOptions.JobTrace** (**getter**, and **setter**): Job trace string to be written to the trace file at the end of a Gams job
 - **GAMSOptions.LimCol** (**getter**, and **setter**): Maximum number of columns listed in one variable block

- `GAMSOptions.LimRow` (**getter**, and **setter**): Maximum number of rows listed in one equation block
- `GAMSOptions.ELogLine` (**enum**, **getter**, and **setter**): Amount of line tracing to the log file
- `GAMSOptions.EOn115` (**enum**, **getter**, and **setter**): Generate errors for unknown unique element in an equation
- `GAMSOptions.Output` (**getter**, and **setter**): Output file
- `GAMSOptions.EPageContr` (**enum**, **getter**, and **setter**): Output file page control option
- `GAMSOptions.PageSize` (**getter**, and **setter**): Output file page size (=0 no paging)
- `GAMSOptions.PageWidth` (**getter**, and **setter**): Output file page width
- `GAMSOptions.Reference` (**getter**, and **setter**): Symbol reference file
- `GAMSOptions.ScriptExit` (**getter**, and **setter**): Program or script to be executed at the end of a GAMS run
- `GAMSOptions.ESuppress` (**enum**, **getter**, and **setter**): Compiler listing option
- `GAMSOptions.Symbol` (**getter**, and **setter**): Symbol table file
- `GAMSOptions.TraceLevel` (**getter**, and **setter**): Solvestat threshold used in conjunction with `a=GT`

7.13.16 24.3.1 (July 2014)

New

- **Transport14** example at `[Path/To/GAMS]/apifiles/Java/transport/Transport14.java`.
- **GAMSSymbolRecord.getKey** method: to retrieve key of **GAMSWorkspace** on specified position index.

Changed

- no longer necessary to set up environment variable before running a program
 - possible to specify the GAMS system directory during run time using **GAMSWorkspaceInfo.setSystemDirectory(String directory)** and **GAMSWorkspace(GAMSWorkspaceInfo info)**
 - no longer necessary to specify `-Djava.library.path` when running a program
 - if `java.library.path` is specified, the shared libraries will be loaded from `java.library.path`
 - otherwise the shared libraries will be loaded from the class path that contains `GAMSJavaAPI.jar`.
 - when exporting a database to GDX: a symbol with real domains from now on will be registered
 - in **GAMSJob.run** : always creates output database `OutDB` even if **GAMSExecutionException** has been raised.
 - in **GAMSSymbol.copySymbol** when copy into the Universe symbol (**GAMS-Database.getSet("*)**) of a **GAMSDatabase** : merge operation will be performed.
 - in **GAMSWorkspace** default constructor: API will apply the default setting, that is, finding GAMS system directory from environment variable in the following order (depends on the target platform):
 - Windows: first from `PATH` environment variable. If not found, from the platform windows registry `gams.location`,
 - Mac OS: first from `PATH` environment variable. If not found, from `DYLD_LIBRARY_PATH`,
-

- Unix: from PATH environment variable. If not found, from LD_LIBRARY_PATH.
- in non-default **GAMSWorkspace** constructor:
 - user can specify a GAMS system directory during run time, API will not search for a GAMS system directory from an environment variable.
 - in case the specified system directory is null or user specify other workspace attributes but a system directory, API will apply the default setting (see changed in **GAMSWorkspace** default constructor above).

Fixed

- API memory leak issue in **GAMSDatabaseIterator**.
- a bug when reading an option file on Unix platform with non-standard locale

Removed

- all deprecated classes and methods since 24.1.

7.13.17 24.2.3 (May 2014)

Fixed

- API memory leak issue in **GAMSDatabase**.
- a bug in **GAMSDatabase.getDatabaseDomainViolations**.

7.13.18 24.2.2 (March 2014)

Changed

- null string is treated as an invalid key for all record operations of **GAMSSymbol**.

Fixed

- a bug when creating **GAMSDatabase** from source database.
 - a bug when initializing a variable type in **GAMSVariable**.
 - a bug in **GAMSSymbol**: methods **getVarType** and **getEquType**.
 - a bug in **GAMSWorkspaceInfo** : method **getSystemDirectory**.
 - exit codes in **GAMSGlobals.ExitCodeMessage**. Improved
 - **GAMSModelInstance.instantiate**: make sure that the method does not solve the model, but only prepares everything required for the following **GAMSModelInstance.solve**.
-

7.13.19 24.2.1 (December 2013)

New

- tutorial: (`GAMS_java_Tutorial.pdf`) under `<Path/To/GAMS>/docs/API`. From the GAMSIDE this document can be accessed at `Help -> Docs -> API`.
- method in `GAMSGlobals.SpecialValues` : `setValue`, to set a GAMS special value
- method in `GAMSOptions`: `export`, to write an option into a parameter file
- methods in `GAMSWorkspace` : `addOptions` to create a `GAMSOptions` object from either another object or an option file
- methods in `GAMSWorkspace`: `getAPIVersion`, `getAPIMajorReleaseNumber`, `getAPIMinorReleaseNumber`, and `getAPIGoldReleaseNumber`, to retrieve API version number

Changed

- default value of `GAMSGlobals.SpecialValues`: `NAN`, `PLUS_INF`, `MINUS_INF`, and `EPS`
- deprecated `GAMSGlobals.ModelStat.NONOPTIMAL_INTERMED`, replaced by `GAMSGlobals.ModelStat.FEASIBLE`
- deprecated `GAMSOptions.PoolFree4`, replaced by `GAMSOptions.EIntVarUp`
- deprecated the type of `GAMSOptions.NoNewVarEqu`, replaced by enum `GAMSOptions.ENoNewVarEqu`

Fixed

- a bug when running a job with an input directory `IDir` added into `GAMSOptions` object.

7.13.20 24.1.3 (July 2013)

Improve data iterator

- New classes:
 - `GAMSDatabaseIterator` implements `java.util.Iterator`
 - `GAMSSymbolIterator` implements `java.util.Iterator`
- Deprecated Interface:
 - `GAMSSymbolIterable`, replaced by `GAMSDatabaseIterator` and `GAMSSymbolIterator`
- Changes in `GAMSDatabase` :
 - `GAMSDatabase` implements `GAMSDatabaseIterator` instead of `GAMSSymbolIterable`
 - deprecated the implemented methods of `GAMSSymbolIterable`: `next()`, `hasnext()`, and `remove()`
- Changes in `GAMSSymbol`:
 - `GAMSSymbol` implements `GAMSSymbolIterator` instead of `GAMSSymbolIterable`
 - deprecated the implemented methods of `GAMSSymbolIterable`: `next()`, `hasnext()`, and `remove()`
- New methods in `GAMSSymbolRecord`:
 - `moveNext`: to iterate to the next record using the current data iterator criterion
 - `movePrevious` : to iterate to the previous record using the current data iterator criterion

Update example:

- `Transport12` at `[Path/To/GAMS]/apifiles/Java/transport/Transport12.java`

7.13.21 24.1.1 (May 2013)

Changes in **GAMSDatabase**:

- deprecates the `compact` method, as it has no effect anymore.

Changes in **GAMSGlobals**:

- the default value of working directory has been changed from `System.getProperty("user.dir")` to `System.getProperty("java.io.tmpdir")`.

Changes in **GAMSMoelInstance** :

- deprecates the `instantiate(GAMSOptions options)`, `instantiate(GAMSModifier[])`, and `instantiate(GAMSOptions, GAMSModifier[])` methods and replaced by `instantiate(String, GAMSModifier ...)` and `instantiate(String, GAMSOptions, GAMSModifier ...)` methods

Changes in **GAMSWorkspace** and **GAMSWorkspaceInfo**:

- deprecates boolean `debug` flag and replaced by a debug level flag (type of a new class **GAMSGlobals.DebugLevel**).
- allows an override of debug level flag from an environment variable `GAMSOOAPIDEBUG`

New methods in **GAMSDatabase**:

- **GAMSDatabase.addEquation**, **addParameter**, **addSet**, and **addVariable**: to add symbols with domain information.
- **checkDomains**: to check whether or not all records of all symbols are within the specified domain of the symbols.
- **getDatabaseDomainViolations**: to retrieve a domain violation information as a list of **GAMSDatabaseDomainViolation** objects.
- **isAutoDomainCheckingSuppressed** and **suppressAutoDomainChecking**: to control whether domain checking will be called when exporting a database.

New class **GAMSDatabaseDomainViolation**:

- contains domain violation information of all symbols (if any) in the database.
- returns call from a new method **GAMSDatabase.getDatabaseDomainViolations**.

New enumeration class **GAMSGlobals.DebugLevel**:

- defines values of different GAMS Debug Levels.

New methods in **GAMSMoelInstance**:

- **copyMoelInstance**: to copy a **GAMSMoelInstance** object.
-

- **interrupt** : to send an interrupt signal to a running **GAMSModelInstance** object.

New enumerated value of **GAMSModelInstance.SymbolUpdateType**:

- **GAMSModelInstance.SymbolUpdateType.INHERIT**: to specify **GAMSModelInstance.SymbolUpdateType** separately for each **GAMSModifier**.

New methods in **GAMSModifier**:

- **constructor**: to specify **SymbolUpdateType** for each **GAMSModifier** object.
- **getUpdateType**: to retrieve **SymbolUpdateType** property of the object.

New methods in **GAMSSymbol**:

- **checkDomains**: to check whether or not all records of the symbol are within the specified domain.
- **getDomains**: to retrieve a list of domains of the symbol, each element is either a **GAMSSet** (real domain) or a **String** (relaxed domain).
- **getSymbolDomainViolations**: to retrieve a domain violation information as a list of **GAMSSymbolDomainViolation** objects.
- **mergeRecord**: to add a new symbol record in case the record does not exist.

New class **GAMSSymbolDomainViolation**:

- contains domain violation information of the symbol (if any).
- returns call from a new method **GAMSSymbol.getSymbolDomainViolations**.

New methods in **GAMSWorkspace**

- **getGAMSVersion**: to retrieve information about GAMS Version.
- **getGoldReleaseNumber**: to retrieve GAMS GOLD Release Number.
- **getMajorReleaseNumber**: to retrieve GAMS Major Release Number.
- **getMinorReleaseNumber**: to retrieve GAMS Minor Release Number.

Fixed a bug when iterating through the records of a **GAMSSymbol**

Changes of location of examples:

- **Bender Examples**: from [Path/To/GAMS]/apifiles/Java/Benders*.java to [Path/To/GAMS]/apifiles/Java/
- **Cutstock**: from [Path/To/GAMS]/apifiles/Java/Cutstock.java to [Path/To/GAMS]/apifiles/Java/cutstock/
- **ConsoleInterrupt**: from [Path/To/GAMS]/apifiles/Java/ConsoleInterrupt.java to [Path/To/GAMS]/apifiles/Java/interrupt/ConsoleInterrupt.java
- **Transport Examples**: from [Path/To/GAMS]/apifiles/Java/Transport*.java to [Path/To/GAMS]/apifiles/Java/transport/Transport*.java
- **Warehouse**: from [Path/To/GAMS]/apifiles/Java/Warehouse.java to [Path/To/GAMS]/apifiles/Java/warehouse/

New examples :

- **SimpleCutstock** at [Path/To/GAMS]/apifiles/Java/cutstock/SimpleCutstock.java
 - **DomainCheck** at [Path/To/GAMS]/apifiles/Java/domain/DomainCheck.java
 - **Transport13** at [Path/To/GAMS]/apifiles/Java/transport/Transport13.java
 - **Tsp** at [Path/To/GAMS]/apifiles/Java/tsp/Tsp.java
-

7.13.22 24.0.2 (February 2013)

New method in `GAMSSymbol`

- added new method `copySymbol`.

7.13.23 24.0.1 (December 2012)

This release contains a beta version of the object-oriented Java API that can be used to control GAMS from a Java program. It allows the seamless integration of GAMS into Java by providing appropriate classes for the interaction with GAMS. GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (`GAMSDatabase`), and to create and run GAMS models (`GAMSJob`) that can be customized by GAMS options (`GAMSOptions`). Furthermore, they introduce a way to solve a sequence of closely related model instances in the more efficient way (`GAMSModelInstance`).

- A Java program that uses object-oriented Java API requires at least Java SE 5 to compile and run.
- All classes are distributed within one single jar file `GAMSJavaAPI.jar` with a namespace `com.gams.api`, located under the `[Path/To/GAMS]/apifiles/Java/api/` directory.
- Java program examples are distributed with namespace `com.gams.examples`, located under `[Path/To/GAMS]/apifiles/Java/` directory.
- Installation and detailed documents can be found in `[Path/To/GAMS]/apifiles/readme.txt` and `[Path/To/GAMS]/docs/API/GAMS_java.pdf`.
- Javadoc for `GAMSJavaAPI.jar` can be found under `[Path/To/GAMS]/apifiles/java/api/javadoc` directory.

7.14 Release Notes

7.14.1 38.1.0

- Added support for Python 3.10.

7.14.2 35.1.0

- Fixed `GamsOptions.output` parameter being ignored in `GamsJob.run()`.

7.14.3 34.1.0

- Added support for Python 3.9.

7.14.4 32.1.0

- Dropped support for Python 2.
 - Automatically finding a GAMS installation from the Windows registry has been changed from using `[HKEY_CURRENT_USER|HKEY_CLASSES_ROOT]\gams.location` to `[HKEY_CURRENT_USER|HKEY_LOCAL_MACHINE]\Software`
-

7.14.5 31.1.0

- The object-oriented GAMS Python API comes now in source code using the MIT open source license.
- For accessing the GAMS API the Python interpreter needs to find files in `<GAMS Systemdirectory>/apifiles/Python/api_XY` and `<GAMS Systemdirectory>/apifiles/Python/gams` where XY corresponds to the Python version X.Y, e.g. 3.7. The `GMSPython` installation is already set up to find all required files. The documentation section [Let Python find the GAMS Python files](#) gives details on how to connect an external Python system with GAMS.
- There is a different directory structure in `<GAMS Systemdirectory>/apifiles/Python`. The content of the `api` directory has been moved to different places:
 - `api_27` for the binary Python 2.7 API files
 - `src` for the files required to build the expert-level API files from source
 - `gams` for source files of the GAMS Python API plus a few extra Python source files for working with indexed EMP syntax, e.g. **`emppython1.gms` : Three Simple EMP Models with Indexed EMP Syntax and Python Parser**
 - `thirdparty` for the Python package `ply` for processing of indexed EMP syntax
- Option `pySetup` has been removed from the class `GamsOptions`.
- Removed GAMS return code 116 ("Could not find GMSPython").
- Fixed a memory leak with `GamsModelInstance.solve`.

7.14.6 30.1.0

- Dropped support for Python 3.4.
- Added support for Python 3.8.

7.14.7 29.1.0

- Added support for Python 3.7.

7.14.8 28.1.0

- Dropped support for Python 2.6.

7.14.9 25.0.1

- Added implementation of `__eq__()` and `__ne__()` to classes `_GamsSymbol` and `_GamsSymbolRecord` and its derived classes. As a result the behavior of the operators `==` and `!=` has changed. `==` returns now `True`, if the internal data reference is the same. The behavior of `is` remains unchanged.
 - New example `transport_gdx.py` that shows how to import and export GDX files.
 - Added description of example `transport_gdx.py` to the tutorial.
-

7.14.10 24.9.2

- Fixed a bug in the setup script that prevented files from being installed in the correct location in certain cases.

7.14.11 24.9.1

- New functions `GamsWorkspace.add_job_from_apilib`, `GamsWorkspace.add_job_from_noalib` to create `GamsJob` from models from the GAMS API Library and the Nonlinear Optimization Applications Library
- Added a version check for the `setup.py` scripts to avoid unintentional installation of wrong versions

7.14.12 24.8.4

- Added support for Python 3.6
- Fixed a bug in `GamsJob.run()` that prevented the underlying GAMS model from terminating, if executables spawned by GAMS generate log output that is not captured.

7.14.13 24.8.1

- The option `GamsOptions._errorlog` was renamed as `GamsOptions.errorlog` in order to indicate it as public. The option sets the maximum error message lines written to the log for each error

7.14.14 24.7.4

- Added support for Python 3.4 on Mac OS X
- Skip creation of a GDX file in `GamsModelInstance.instantiate` that was unreachable from within the API.
- Fixed a problems with Exceptions in `GamsWorkspace`.

7.14.15 24.7.2

- Fixed a minor bug regarding the names of `GamsJob` listing files.

7.14.16 24.7.1

- Fixed a bug with the property `GamsOptions.defines`: When too many entries were added, all of them were ignored
- Fixed a memory leak in `GamsDatabase`

7.14.17 24.6.1

- New Python example `transport8a.py`
-

7.14.18 24.5.2

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. The property `GamsWorkspace.system_directory` now always returns the canonical path with all symbolic links resolved.

7.14.19 24.5.1

- Added support for Python 3.4 (Windows and Linux only)
 - The examples have been changed to be compatible with all supported Python versions
- New Python example `special_values.py`.
- New Python example `clad.py`.
- New functions `GamsWorkspace.noalib` and `GamsWorkspace.apilib` that can be used to retrieve models from the NOALIB and the APILIB

7.14.20 24.4.2

- Fixed a bug in the constructor of all subclasses of `_GamsSymbol` that occurred when the explanatory text was omitted.
- Disable unwanted debug output from Couenne when running with `GamsModelInstance`
- New property `_GamsSymbol.domains_as_strings`: Domains of Symbol, each element is a string. Note: If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set
- Fixed potential problem with `GamsModelInstance` used with BARON.

7.14.21 24.4.1

- Fixed a bug in `GamsDatabase.merge_record` that prevented the function from creating a record if none was found.
 - We changed the handling of GAMS Aliases in the object oriented APIs:
 - If we ask for the number of `GamsSymbols` in a `GamsDatabase`, the Aliases will be excluded.
 - If we iterate over all `GamsSymbols` in a `GamsDatabase`, Aliases will be skipped.
 - If we ask explicitly for an Alias in a `GamsDatabase` (`GamsDatabase.get_set("a")` with `a` being an Alias) we will get a reference to the `GamsSet` referenced by the Alias, not the Alias itself.
 - Note: Aliases can appear in a `GamsDatabase` only, if it was initialized by a GDX file containing an Alias.
 - The new Python example `alias.py` demonstrates this new behavior.
-

7.14.22 24.3.2

- Make more GAMS options available through the GamsOptions class (Removed leading underscores of property identifiers):
 - GamsOptions.appendexpand: Expand file append option
 - GamsOptions.appendout: Output file append option
 - GamsOptions.dumpopt: Writes preprocessed input to the file input.dmp
 - GamsOptions.dumpparms: GAMS parameter logging
 - GamsOptions.errmsg: Placing of compilation error messages
 - GamsOptions.expand: Expanded (include) input file name
 - GamsOptions.ferr: Alternative error message file
 - GamsOptions.jobtrace: Job trace string to be written to the trace file at the end of a Gams job
 - GamsOptions.limcol: Maximum number of columns listed in one variable block
 - GamsOptions.limrow: Maximum number of rows listed in one equation block
 - GamsOptions.logline: Amount of line tracing to the log file
 - GamsOptions.on115: Generate errors for unknown unique element in an equation
 - GamsOptions.output: Output file
 - GamsOptions.pagecontr: Output file page control option
 - GamsOptions.pagesize: Output file page size (=0 no paging)
 - GamsOptions.pagewidth: Output file page width
 - GamsOptions.reference: Symbol reference file
 - GamsOptions.scriptexit: Program or script to be executed at the end of a GAMS run
 - GamsOptions.suppress: Compiler listing option
 - GamsOptions.symbol: Symbol table file
 - GamsOptions.tracelevel: Solvestat threshold used in conjunction with a=GT

7.14.23 24.3.1

- On Linux and OS X: LD_LIBRARY_PATH and DYLD_LIBRARY_PATH do not need to contain a GAMS system directory anymore. Anyway, if no system directory is specified in the GamsWorkspace constructor, PATH and LD_LIBRARY_PATH/DYLD_LIBRARY_PATH is used to find a GAMS system directory. The order is as follows:
 - Linux: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check LD_LIBRARY_PATH
 - OS X: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check DYLD_LIBRARY_PATH
 - Windows: If no system directory is specified in the GamsWorkspace constructor, check registry.
 - GamsJob.run creates out_db now even if it throws a GamsExceptionExecution
 - New example transport14
 - New function _GamsSymbolRecord.key(int index): Retrieve key of GamsSymbolRecord on position index
 - GamsModelInstance.solve now also works for solvers which require a subsolver, e.g. Dicopt
-

7.14.24 24.2.3

- Fix memory leak in GamsDatabase

7.14.25 24.2.2

- Fixed a bug regarding the subtype of equations and their default records, when the equation was added to a GamsDatabase from the API.
- Fixed a bug in GamsSymbol.delete_record.
- Fixed GamsExitCode.
- Make sure that GamsModelInstance.instantiate() does not solve the model, but only prepares everything required for the following solve()

7.14.26 24.2.1

- Add tutorial (GAMS_python_Tutorial.pdf) to <Path/To/GAMS>/docs/API. From the GAMSIDE this document can be accessed at Help -> Docs -> API
- New parameter opt_file in function GamsWorkspace.add_options allows to create an instance of GamsOptions that is initialized by an existing option file
- New function GamsOptions.export: Write GamsOptions into a parameter file
- New properties: GamsWorkspace.api_version, GamsWorkspace.api_major_rel_number, GamsWorkspace.api_minor_rel_number and GamsWorkspace.api_gold_rel_number
- New property GamsWorkspace.my_eps: Reset value to be stored in and read from GamsDatabase for Epsilon.
- New class NoNewVarEqu providing static fields to set option nonewvarequ
- Renaming of GamsOptions.PoolFree4 to GamsOptions.IntVarUp and property poolfree4 to intvarup
- Renaming of ModelStat.NonOptimalIntermed to ModelStat.Feasible
- Fixed a bug in _GamsSymbol.add_record() that occurred when using empty strings as keys
- Fixed a bug in GamsModelInstance.solve() that affected the logging behavior
- The following functions throw an exception, when a wrong data type is passed for the keys/slice parameter: delete_record, find_record, add_record, merge_record, first_record, last_record. Valid data types are str, list, tuple and their subclasses

7.14.27 24.1.1

- New examples: markowitz.py, tsp.py, transport13.py, simple_cutstock.py, domain_checking.py
 - New facility for GamsSymbols with domain information:
 - GamsDatabase:
 - * New functions add_parameter_dc, add_variable_dc, add_equation_dc and add_set_dc: Create GamsSymbols with domain information
 - * New function check_domains: Check for all symbols if all records are within the specified domain of the symbol
-

- * New function `get_database_dvs`: Return all `GamsDatabaseDomainViolations`
- * New property `suppress_auto_domain_checking`: Controls whether domain checking is called in `GamsDatabase` export
- `_GamsSymbol` and its derived classes:
 - * New function `check_domains`: Check if all records are within the specified domain of the symbol
 - * New function `get_symbol_dvs`: Return all `GamsDatabaseDomainViolations`
 - * New property `domains`: Domains of `Symbol`, each element is either a `GamsSet` (real domain) or a string (relaxed domain)
- New classes `GamsDatabaseDomainViolation` and `GamsSymbolDomainViolation` that are returned by `GamsDatabase.get_database_dvs` and `_GamsSymbol.get_symbol_dvs`
- New functions in `GamsModelInstance`:
 - `copy_modelinstance`: Copies a `GamsModelInstance` to a new `GamsModelInstance` which gets constructed at this call
 - `interrupt`: Sends interrupt signal to running `GamsModelInstance`
- New function in `_GamsSymbol` and its derived classes: `merge_record` finds a record if it exists and adds it if not
- New functions in `GamsWorkspace`: `add_job_from_gamslib`, `add_job_from_testlib`, `add_job_from_emplib`, `add_job_from_datailib` and `add_job_from_finlib`
- New properties in `GamsWorkspace`: `version`, `major_rel_number`, `minor_rel_number`, `gold_rel_number`
- New optional parameter `in_model_name` for functions `add_database_from_gdx/add_database` in `GamsWorkspace`: GAMS string constant that is used to access this database
- Changed the debug argument passed to the `GamsWorkspace` constructor. Use members of class `DebugLevel`: `Off`, `KeepFiles`, `ShowLog` and `Verbose` instead of `True` and `False`
- New sub class of `GamsException`: `GamsExceptionExecution`, which provides additional info about the reason of the failed execution
- Allow to define `SymbolUpdateType` for each `GamsModifier` separately
- Significant performance improvement for function `GamsWorkspace.add_database` when creating from an already existing database
- Changed the unicode settings on Linux from `UCS2` to `UCS4`
- The `Debug` parameter of `GamsWorkspace` can be overwritten by the system environment variable `"GAMSOAPIDEBUG"` if set to one of the following: `Off`, `KeepFiles`, `ShowLog`, `Verbose`
- The compact method of `GamsDatabase` is obsolete and has no effect anymore. It will be removed in the future.
- Fixed a bug in `GamsModelInstance.solve()`
- Fixed a bug in `GamsDatabase`, where the special value for undefined was set to 0 instead of 1.0E300 (`SV_UNDEF`)
- Fixed a bug when iterating through the records of a `GamsSymbol`

7.14.28 24.0.2

- Added new function `_GamsSymbol.copy_symbol` which copys all records from one to another `GamsSymbol`
 - Label and symbol lookup is now case insensitive
 - Fixed handling of infinite bounds for `GamsModifiers`
-

7.14.29 24.0.1

This release contains a beta version of the object-oriented Python API that can be used to control GAMS from within Python 2.7. It allows the seamless integration of GAMS into Python by providing appropriate classes for the interaction with GAMS. The GamsDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GamsJob class and by using the GamsModelInstance class a sequence of closely related model instances can be solved in an efficient way. To use this API see the [Getting started](#) section.

7.15 GAMS Environment Object Options

Option	Description	Default
AlgFileType	File type of scratch files	1
Cheat	optCheat solver default Range: $[-\infty, \infty]$	0
CurSolver	Solver id of the last gevallsolver	0
CutOff	CutOff solver default Range: $[-\infty, \infty]$	0
DomLim	Domain violation limit solver default	0
FDDelta	Step size for finite differences Range: $[1e-9, 1]$	1e-5
FDOpt	Options for finite differences Range: $[0, 14]$	0
GamsVersion	GAMS CMEX Version	999
GenSolver	Indicator for generic solver executable	0
HeapLimit	Maximum Heap size allowed	1e20
IDEFlag	IDE Flag 0 unknown environment 1 runs under GAMS IDE	0
Integer1	Range: $[-\infty, \infty]$	0
Integer2	Range: $[-\infty, \infty]$	0
Integer3	Range: $[-\infty, \infty]$	0
Integer4	Range: $[-\infty, \infty]$	0
Integer5	Range: $[-\infty, \infty]$	0
IterLim	Iteration limit solver default	2000000000
Keep	Keep scratch directory Range: $[0, 1]$	0
License1	License line 1	
License2	License line 2	
License3	License line 3	
License4	License line 4	

Option	Description	Default
License5	License line 5	
LogOption	Log option 0 no log output 1 log output to screen (console) 2 log output to logfile 3 log output to standard output 4 log output to logfile and standard output	1
NameCtrFile	Control file name	
NameCurDir	Current directory	
NameExtFFile	External Function file name	
NameGamsDate	GAMS Date	
NameGamsTime	GAMS Time	
NameInstr	Instruction file name	
NameLogFile	Log file name	
NameMatrix	Matrix file name	
NameParams	Parameter file name	
NameScenFile	Scenario file name	
NameScrDir	Scratch directory	
NameScrExt	Scratch extension	dat
NameStaFile	Status file name	
NameSysDir	System directory	
NameWrkDir	Working directory	
NodeLim	Node limit solver default	0
OptCA	optAbsolute Optimality criterion solver default	0
OptCR	optRelative Optimality criterion solver default	0.1
PageSize	Output file page size	78
PageWidth	Output file page width	123
Real1	Range: $[-\infty, \infty]$	0
Real2	Range: $[-\infty, \infty]$	0
Real3	Range: $[-\infty, \infty]$	0
Real4	Range: $[-\infty, \infty]$	0
Real5	Range: $[-\infty, \infty]$	0
Reform	Reform option	100
ResLim	Resource (CPU) solver default limit	1000

Option	Description	Default
SysOut	Solver Status file reporting option Range: [0, 1]	0
ThreadsRaw	Range: $[-\infty, \infty]$	1
TryInt	TryInt solver default	0
UseCheat	UseCheat solver default	0
UseCutOff	UseCutOff solver default	0
WorkFactor	Work space multiplier for some solvers	1
WorkSpace	Work space for some solvers	0

7.16 GAMS Modeling Object Design

This document gives a brief introduction to GAMS' new model-solver API, including a description of its design goals and philosophy. This document is not intended to be used as a user's manual but rather to give a picture of what the new API can do and a description of some of the conceptual underpinnings for the new API.

Further material: [Presentation at ICS 2011](#)

7.16.1 Introduction

Historically, there have been a number of different GAMS solver interface libraries, i.e. libraries that enabled a solver to get all required information from a GAMS model, compute the solution, and return the solution, status information, and other information (e.g. solver log messages, nonlinear function evaluation error messages, node counts, time used) to GAMS. Each library was unique in some way, e.g. in the computer language or subset of GAMS model types it supported. Each library had its own advantages and disadvantages, but all of them were feature-poor and supported a limited scheme of operation: GAMS/Base would write *scratch files* containing the model to be solved, the GAMS solver link executable would use one of the solver interface libraries to read the model from scratch file and write a solution file, and GAMS/Base would read this solution file. While this scheme worked for many years it was inconvenient for the library user, difficult to maintain, slow, and a barrier to further development.

To address these issues and others, GAMS developed a new model-solver interface library, called GMO (GAMS Model Object), and a companion library called GEV (GAMS Environment Object). The two libraries are distinct and help to separate the purely model-specific tasks and information handled by GMO from the computing and solver environment that the model will be solved in, handled by GEV. The two libraries are typically used together and we will sometimes refer to them as simply GMO. For legacy reasons the new libraries support the old file-based scheme to communicate a model through scratch files.

In what follows, we first describe the basic structure, organization, and usage of GMO ([Basic organization](#)). Client applications can be split into two types: those defining or updating the model ([Modeler Access to GMO](#)) and those passing the model to a solver ([Solver Access to GMO](#)). We next describe some ways to update a model in [Updating a GMO instance](#).

7.16.2 Basic organization

In this section we outline the basic organization of GMO. GMO is implemented as a shared library that interfaces to different languages via language-specific header files and interface code. The header files and code are included in source form with the GAMS distribution. Since the interface code employs dynamic loading, each GMO session begins with a call to initialize the required shared library (i.e. load it and all its symbols) and return an empty model object.

The next step is to load a model into the model object. This is typically done with a single wrapper call, as in the case of loading a model from model scratch files prior to solving in one of the GAMS solver links. It is also possible build up a model from scratch with a sequence of calls to provide the model column-wise or row-wise. If the model is built up column-wise or row-wise, additional information (e.g. about nonlinearities) may be passed to the object after the basic structure is built up. Once the model is complete, a finalization routine is called. This routine prepares the model object for efficient access by the user. Typically the model does not change after this point. There are exceptions to this (see [Updating a GMO instance](#)), but they usually involve small modifications to the existing model (like adding alternative bounds) or the addition of constraints and variables that require the *re-finalization* of the model.

When a model is fully loaded, the GMO client can start accessing the model. Typically the GMO client doing this will be a solver, but other clients (e.g. the CONVERT *solver*, the Examiner utility, or a model structure browser) exist also. In addition to querying the model, the client can also request that the model be presented or viewed in various different ways. For example, GMO can be requested to use an objective function or an objective variable. Most types of information are available immediately when the model is loaded, but some type of queries (e.g. Hessians, alternative QP forms) are less common and relatively expensive in time and/or space: these require that an initialization routine be called before the information is requested. Once the client has completed its work it reports on the solution found, if any. Typically, the model object is destroyed at this point. Model access by a client, especially solvers, is an important topic that is discussed in [Solver Access to GMO](#).

The variety of data that go into the interface library when a model is defined and that a solver can request during solution is large, but the data can be divided into two types - data defining the model (e.g. number of rows and columns, coefficients, nonlinear functions) and data defining the solver environment (e.g. available and default GAMS solvers, license info, algorithm tolerances and limits). It is sometimes useful to separate these two types of data, so that it is possible to define and work with a model without specifying anything about the environment it exists in. The environment can be specified separately, and multiple models can make use of the same basic environment. To facilitate this, the solver interface is in two parts: the GMO interface deals with model-specific information and the GEV interface with information about the environment. The two environments are linked, since they are typically used together, with one (or multiple) models existing in one environment, but the separation makes it possible to define a model without defining its environment, etc. Since the bulk of the information and the code lies with GMO, we usually speak of the two libraries as one, called GMO, but it is worth remembering that GEV is a separate object.

7.16.3 Solver Access to GMO

One of the primary purposes of GMO is to provide convenient, efficient access to the model. GAMS links to many solvers, each solver link using GMO to access the model in different ways, so there is a wide array of possible methods to access the model in GMO. We describe them in this section.

There are multiple but equivalent views possible for the same model. For example, the model can be formulated with an objective function or with an objective variable. Free rows can be removed or left in, and the rows and/or columns can be permuted. Prior to accessing the model, the solver link can choose what view it would like to use. The view can be changed later, but since this can obviate the data obtained previously, the choice of view is usually made early on and left unchanged. Moreover, a view can be stored and restored in case multiple users access the same model.

All solvers will need to get basic information about a model - simple things like row and column counts, nonzero counts, etc. These are available via simple access routines. Since the model is essentially fixed (assuming the view does not change), basic information is pre-computed when the model takes its final form and is available at essentially no cost. Information about the rows and columns (e.g. variable level values, marginal values, variable priorities, row types) is also available, either for single rows/cols or in an array for all rows/cols at once.

For linear models, the only information left to get is the matrix of coefficients. This is available in a number of different forms e.g. column-wise or row-wise, either as a complete matrix returned with one call or as separate rows or columns returned via many calls. For nonlinear models, there are more variants on this theme: calls to return the function value or the function value and derivatives, calls for constraints and calls for the objective function. You can request that the nonlinear model be treated as its linearization around a certain point. There are also routines to do interval evaluations of functions and gradients. The GMO library prepares the model object to handle all these calls efficiently when the model takes its final form.

Nonlinear models present several additional challenges. When NL functions are evaluated, mathematical errors can occur (e.g. $\sqrt{-1}$). GMO supports different ways to log and handle these errors. Some algorithms will require or want 2nd-order information. Since this can be relatively expensive to compute, the solver must first call an initialization routine specifying what is desired (e.g. only Hessian-vector products, Lagrangian Hessian, single-row Hessians) and potentially a limit on the memory dedicated to computing Hessians. After this initialization, 2nd-order information is available.

Once the solver finishes, the solution (if any) and related status values must be reported back to GMO. There are a number of convenience routines included in GMO for this purpose.

A convenient interface was and is an important design goal for GMO, especially in the area of solver access to the model. Convenience takes many forms: a number of ways to get the same model data in order to support a variety of different solver libraries, self-contained calls with minimal requirements on previous setup for correct behavior, and a modern interface adhering to design principles like information hiding, encapsulation, and an object model. By keeping these goals at the fore when designing GMO we have made accessing the model convenient and efficient, which greatly simplifies the task of building a correctly-functioning solver link.

In addition to providing convenient access to the model, a solver link needs to expose a particular API to be recognized by the GAMS system. This is not directly connected to the GMO API itself but knowledge about the expected solver link library API is required so we include it here.

GAMS calls a solver through the GEV API function `gevCallSolver` which eventually results in a sequence of calls to functions in the solver link library. GAMS loads solver link libraries dynamically at run time. The name of the library is specified in the [configuration file](#) together with the three letter audit code, e.g., `cpx` for CPLEX. All functions in the solver link library are prefixed by this audit code (we use `xyz` in this example). The following functions are recognized:

- `void xyzInitialize(void)` (optional): Function called when loading the solver link library.
- `void xyzFinalize(void)` (optional): Function called when unloading the solver link library.
- `int xyzCreate(void** handle, char* msg, int sizeBuf)`: Function to create a solver link *object*. Returns 0 and stores a non-NULL pointer to the object in `handle` on success, otherwise an error message should be stored in `msg`.
- `void xyzFree(void** handle)`: Function to destroy a solver link object.

Depending on the *solver interface type* (again communicated as part of the [configuration file](#)) different functions need to be in the API. For solver interface type 1 we have:

- `int xyzReadyAPI(void* handle, void* gmoHandle)`: Function to set up the model instance in the solver space. Returns 0 on success.
-

- `int xyzCallSolver(void* handle)`: Function to do the actual solve and solution reporting. Returns 0 on success.
- `int xyzModifyProblem(void* handle)` (optional): Function to modify the problem. Returns 0 on success.

For solver interface type 2 we only have a single call:

- `int xyzCallSolver(void* handle, void* gmoHandle)`: Function to setup and solve. Returns 0 on success.

Usually, a *solve* in GAMS triggers the following sequence of function: `xyzCreate`, `xyzReadyAPI`, `xyzCallSolver`, `xyzFree` (interface type 1) or `xyzCreate`, `xyzCallSolver`, `xyzFree` (interface type 2) and the separation of `xyzReadyAPI` and `xyzCallSolver` seems unnecessary.

With [Gather-Update-Solve-Scatter \(GUSS\)](#) and the `GAMSModelInstance` class in various APIs we repeatedly solve a model with the same rim but different data (bounds, rhs, matrix coefficients). In this case the sequence of solves results in a sequence of function calls. Without the presence of `xyzModifyProblem` the following sequences will be called: `xyzCreate`, `xyzReadyAPI`, `xyzCallSolver`, `xyzReadyAPI`, `xyzCallSolver`, `xyzReadyAPI`, `xyzCallSolver`, ..., `xyzFree` (interface type 1) or `xyzCreate`, `xyzCallSolver`, `xyzCallSolver`, `xyzCallSolver`, ..., `xyzFree` (interface type 2). So, again there is little point (but possible) to split the link work in `xyzReadyAPI` and `xyzCallSolver` without the presence of `xyzModifyProblem`. If `xyzModifyProblem` is present (only with flavor 1) the following sequences will be called: `xyzCreate`, `xyzReadyAPI`, `xyzCallSolver`, `xyzModifyProblem`, `xyzCallSolver`, `xyzModifyProblem`, `xyzCallSolver`, ..., `xyzFree`.

7.16.4 Modeler Access to GMO

In normal operation the modeler creates a model in GAMS source form and the GAMS/Base module handles all the details necessary to build up model instances in GMO. However, there are cases (e.g. solving a model many times over with different scenario data) where it is useful to access and modify a GMO instance outside of GAMS/Base. GMO provides routines to support this, specifically routines to update the model (see [Updating a GMO instance](#)), solve the model with one of the GAMS solvers available as part of the GAMS environment and GEV, and retrieve the solution.

Access to a GMO instance is usually done using integer indices, [1..m] for the rows and [1..n] for the columns. However, it is also possible to reference rows and columns using the notation from the original GAMS model, e.g. `x('seattle', 'topeka')` or `demand('chicago')`. This is more convenient when specifying what data should be updated to define a new scenario. In order to update a model instance in this case, it is useful to have a convenient, efficient way to translate row and column indices from one form to the other. This translation is done by the *model dictionary* interface DCT.

The DCT API provides information about the variables, equations, and sets used to define the GMO model instance. In addition, given a row or column index, it will translate this index into the equation or variable name and the list of set labels that correspond to this index. It will also do the inverse operation, translating an equation/variable name and list of labels into a row or column index. GAMS builds models in a way that makes this translation very efficient.

This organization is also useful when updating models to create new scenarios. Models are organized so that:

- There is one ordered universe of all labels appearing in the variables and equations of a given model. The order for the labeling does not change from symbol to symbol within a model.

- All of the columns in a model corresponding to a given variable are contiguous. (Ditto for rows and equations)
- The columns corresponding to a given variable are sorted by their index labels, using the universal order, with the left-most index varying slowest. (Ditto for rows and equations)
- GDX data is sorted in the same way: sorted by index label order, left-most index varying slowest. This can be very useful, *provided the model and the GDX data use the same label ordering.*

Using the various GAMS component libraries, it is possible to create a model updating interface that is both convenient for the user (by using the symbolic names referenced in the GAMS source) and efficient in updating the model data.

7.16.5 Updating a GMO instance

There are several possible ways to modify a model contained in a GMO instance. By updating, we mean an actual model change, rather than a change in the view that doesn't alter the set of solutions.

In perhaps the simplest case, the user can specify alternate variable bounds, as is useful when implementing a branch and bound code. The original bounds are retained in this case, so that the model can be reverted to the original bounds with a single call.

It is possible to linearize a model around a given point. This requires no information from the point to linearize around and can be undone easily. This is almost a change in view but since the solutions of the original and linearized models may be quite different we can also consider this a model update.

Many algorithms (e.g. outer approximation, Benders decomposition, Danzig-Wolfe decomposition) involve the addition of rows, and columns incident on these rows, to a core model. Such algorithms can be implemented effectively using GMO by taking advantage of GMO facilities to add rows and columns. There will be only a small amount of work required to prepare the GMO instance for use after each round of additional rows and columns. Note that all the changes to the model in this case are *additions*: the existing structure and data are left as is.

Finally, there are facilities in GMO to update variable bounds (as mentioned before), variable types (e.g. to relax single discrete variables), and the right-hand-side of constraints. The user cannot directly modify matrix coefficients. There is a much better way to safely update exogenous data in a model: GAMS can provide a model instance in which GAMS parameters are visible and can be updated. A reevaluation of the expressions in the models provides the updated matrix elements. The underlying concept is also used in [Gather-Update-Solve-Scatter \(GUSS\)](#) and described in more detail in [this paper](#). This is a powerful tool to efficiently do e.g. Monte-Carlo simulation without the need for GAMS to regenerate the entire model over and over.
