To give an example, imagine you are solving a model with 400 variables and you set the partition attribute to -1 for variables 0-99, 0 for variables 100-199, 1 for variables 200-299, and 2 for variables 300-399. The heuristic would solve two sub-MIP models: sub-MIP 1 would fix variables 0-99 and 300-399 to their values in the incumbent and solve for the rest, while sub-MIP 2 would fix variables 0-99 and 200-299.

The parameter `PartitionPlace` controls the use of the heuristic. The partition numbers are specified through the option `.partition`. The syntax for `dot options` is explained in the Introduction chapter of the Solver Manual.

Default: 0

partitionplace (*integer*): Controls when the partition heuristic runs ↔

This option works in combination with the `Partition` number for variables. Setting this option and providing some partitions enables the partitioning heuristic, which uses large-neighborhood search to try to improve the current incumbent solution.

This parameter determines where that heuristic runs. Options are:

- Before the root relaxation is solved (16)
- At the start of the root cut loop (8)
- At the end of the root cut loop (4)
- At the nodes of the branch-and-cut search (2)
- When the branch-and-cut search terminates (1)

The parameter value is a bit vector, where each bit turns the heuristic on or off at that place. The numerical values next to the options listed above indicate which bit controls the corresponding option. Thus, for example, to enable the heuristic at the beginning and end of the root cut loop (and nowhere else), you would set the 8 bit and the 4 bit to 1, which would correspond to a parameter value of 12.

The recommended value is 15 which indicates that every option except the first one listed above is enabled.

Default: 15

perturbvalue (*real*): Simplex perturbation magnitude ↔

Range: $[0, \infty]$

Default: 0.0002

poolgap (*real*): Relative gap for solutions in pool ↔

Determines how large a gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (relative) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of `PoolGap=0.2` would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: `maxdouble`

poolgapabs (*real*): Absolute gap for solutions in pool ↔

Determines how large a (absolute) gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (absolute) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of `PoolGapAbs=20` would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: `maxdouble`

poolsearchmode (*integer*): Choose the approach used to find additional solutions ↔

With the default setting (`PoolSearchMode=0`), the MIP solver tries to find an optimal solution to the model. It keeps other solutions found along the way, but those are incidental. By setting this parameter to a non-default value, the MIP search will continue after the optimal solution has been found in order to find additional, high-quality solutions. With a setting of 2, it will find the n best solutions, where n is determined by the value of the `PoolSolutions` parameter. With a setting of 1, it will try to find additional solutions, but with no guarantees about the quality of those solutions. The cost of the solve will increase with increasing values of this parameter.

Once optimization is complete, the `PoolObjBound` attribute (printed to the log) can be used to evaluate the quality of the solutions that were found. For example, a value of `PoolObjBound=100` indicates that there are no other solutions with objective better 100, and thus that any known solutions with objective better than 100 are better than any as-yet undiscovered solutions.

Default: 0

poolsolutions (*integer*): Number of solutions to keep in pool ↔

Determines how many MIP solutions are stored. For the default value of `PoolSearchMode`, these are just the solutions that are found along the way in the process of exploring the MIP search tree. For other values of `PoolSearchMode`, this parameter sets a target for how many solutions to find, so larger values will impact performance.

Default: 10

precrush (*boolean*): Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model ↔

Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model. This parameter is turned on when you use BCH with Gurobi.

Default: 0

predeprop (*integer*): Presolve dependent row reduction ↔

Controls the presolve dependent row reduction, which eliminates linearly dependent constraints from the constraint matrix. The default setting (-1) applies the reduction to continuous models but not to MIP models. Setting 0 turns the reduction off for all models. Setting 1 turns it on for all models.

Default: -1

predual (*integer*): Presolve dualization ↔

Depending on the structure of the model, solving the dual can reduce overall solution time. The default setting uses a heuristic to decide. Setting 0 forbids presolve from forming the dual, while setting 1 forces it to take the dual. Setting 2 employs a more expensive heuristic that forms both the presolved primal and dual models (on two threads), and heuristically chooses one of them.

Default: -1

premiqcpform (*integer*): Format of presolved MIQCP model ↔

Option 0 leaves the model in MIQCP form, so the branch-and-cut algorithm will operate on a model with arbitrary quadratic constraints. Option 1 always transforms the model into MISOCP form; quadratic constraints are transformed into second-order cone constraints. Option 2 always transforms the model into disaggregated MISOCP form; quadratic constraints are transformed into rotated cone constraints, where each rotated cone contains two terms and involves only three variables.

Default: -1

value	meaning
-1	Auto
0	Always leaves the model in MIQCP form
1	Always transforms the model into MISOCP form
2	Always transforms the model into disaggregated MISOCP form

prepasses (*integer*): Presolve pass limit ↔

Limits the number of passes performed by presolve. The default setting (-1) chooses the number of passes automatically.

Default: -1

prelinearize (*integer*): Presolve Q matrix linearization ↔

Options 1 and 2 attempt to linearize quadratic constraints or a quadratic objective, potentially transforming an MIQP or MIQCP model into an MILP. Option 1 focuses on getting a strong LP relaxation. Option 2 aims for a compact relaxation. Option 0 always leaves Q matrices unmodified. The default setting (-1) chooses automatically.

Default: -1

value	meaning
-1	Auto
0	Linearization off
1	Force Linearization and get strong LP relaxation
2	Force Linearization and get compact relaxation

Presolve (*integer*): Presolve level [↔](#)

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

presos1bigm (*real*): Controls largest coefficient in SOS1 reformulation [↔](#)

Controls the automatic reformulation of SOS1 constraints into binary form. SOS1 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS1 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of -1 chooses a threshold automatically. You should set the parameter to 0 to shut off SOS1 reformulation entirely, or a large value to force reformulation.

Range: [-1, 1e+10]

Default: -1

presos1encoding (*integer*): Controls SOS1 reformulation [↔](#)

Controls the automatic reformulation of SOS1 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several different ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS1 constraint using a formulation whose size is linear in the number of SOS members. Option 0 uses a so-called multiple choice model. It usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model. It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS1 using a formulation of logarithmic size. They both only apply when all the variables in the SOS1 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS1 is equal to 1. Logarithmic formulations are often advantageous when the SOS1 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS1 constraint automatically.

Note that the reformulation of SOS1 constraints is also influenced by the [PreSOS1BigM](#) parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: -1

presos2bigm (*real*): Controls largest coefficient in SOS2 reformulation [↔](#)

Controls the automatic reformulation of SOS2 constraints into binary form. SOS2 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS2 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of 0 disables the reformulation. You can set the parameter to -1 to choose an automatic approach, or a large value to force reformulation.

Range: [-1, 1e+10]

Default: -1

presos2encoding (*integer*): Controls SOS2 reformulation [↔](#)

Controls the automatic reformulation of SOS2 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several different ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS2 constraint using a formulation whose size is linear in the the number of SOS members. Option 0 uses a so-called multiple choice model. It usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model. It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS2 using a formulation of logarithmic size. They both only apply when all the variables in the SOS2 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS2 is equal to 1. Logarithmic formulations are often advantageous when the SOS2 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS2 constraint automatically.

Note that the reformulation of SOS2 constraints is also influenced by the [PreSOS2BigM](#) parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: -1

presparsify (*integer*): Presolve sparsify reduction [↔](#)

This reduction can sometimes significantly reduce the number of nonzero values in the presolved model.

Default: -1

value	meaning
-1	Auto
0	Disable the presolve sparsify reduction
1	Enable the presolve sparsify reduction

printoptions (*boolean*): List values of all options to GAMS listing file [↔](#)

Default: 0

value	meaning
0	Do not list option values to GAMS listing file
1	List option values to GAMS listing file

.prior (*real*): Branching priorities [↔](#)

GAMS allows to specify priorities for discrete variables only. Gurobi can detect that continuous variables are implied discrete variables and can utilize priorities. Such priorities can be specified through a GAMS/Gurobi solver option file. The syntax for [dot options](#) is explained in the Introduction chapter of the Solver Manual. The priorities are only passed on to Gurobi if the model attribute `priorOpt` is turned on.

Default: 1

projimpliedcuts (*integer*): Projected implied bound cut generation [↔](#)

Default: -1

value	meaning
-1	Auto
0	Off
1	Moderate
2	Aggressive

psdcuts (*integer*): PSD cut generation [↔](#)

Default: -1

value	meaning
-1	Auto
0	Off
1	Moderate
2	Aggressive

psdtol (*real*): Positive semi-definite tolerance [↔](#)

Positive semi-definite tolerance (for QP/MIQP). Sets a limit on the amount of diagonal perturbation that the optimizer is allowed to automatically perform on the Q matrix in order to correct minor PSD violations. If a larger perturbation is required, the optimizer will terminate stating the problem is not PSD.

Range: $[0, \infty]$

Default: $1e-06$

pumppasses (*integer*): Feasibility pump heuristic control [↔](#)

Note that this heuristic is only applied at the end of the MIP root.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: -1

qcpdual (*boolean*): Compute dual variables for QCP models [↔](#)

Determines whether dual variable values are computed for QCP models. Computing them can add significant time to the optimization, so you should turn this parameter to 0 if you do not need them.

Default: 1

value	meaning
0	Do not compute dual for QCP problem
1	Compute dual for QCP problem

qextractalg (*integer*): quadratic extraction algorithm in GAMS interface [↔](#)

Default: 0

value	meaning
0	Automatic
1	ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.
2	DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.

quad (*integer*): Quad precision computation in simplex [↔](#)

Enables or disables quad precision computation in simplex. The -1 default setting allows the algorithm to decide.

Default: -1

readparams (*string*): Read Gurobi parameter file [↔](#)

relaxliftcuts (*integer*): Relax-and-lift cut generation [↔](#)

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

rerun (*integer*): Resolve without presolve in case of unbounded or infeasible [↔](#)

In case Gurobi reports *Model was proven to be either infeasible or unbounded*, this option decides about a resolve without presolve which will determine the exact model status. If the option is set to *auto*, which is the default, and the model fits into demo limits, the problems is resolved.

Default: 0

value	meaning
-1	No
0	Auto
1	Yes

rins (*integer*): RINS heuristic ↔

Default value (-1) chooses automatically. A value of 0 shuts off RINS. A positive value n applies RINS at every n -th node of the MIP search tree.

Default: -1

rltcuts (*integer*): RLT cut generation ↔

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

rngrestart (*string*): Write GAMS readable ranging information file ↔

If the extension specified is `gdx`, a GDX file is exported, and a GAMS file otherwise.

scaleflag (*integer*): Model scaling ↔

Controls model scaling. By default, the rows and columns of the model are scaled in order to improve the numerical properties of the constraint matrix. The scaling is removed before the final solution is returned. Scaling typically reduces solution times, but it may lead to larger constraint violations in the original, unscaled model. Turning off scaling `ScaleFlag=0` can sometimes produce smaller constraint violations. Choosing a more aggressive scaling option `ScaleFlag=2` can sometimes improve performance for particularly numerically difficult models.

Default: -1

seed (*integer*): Modify the random number seed ↔

Modifies the random number seed. This acts as a small perturbation to the solver, and typically leads to different solution paths.

Default: 0

sensitivity (*boolean*): Provide sensitivity information ↔

Default: 0

value	meaning
0	Do not provide sensitivity information
1	Provide sensitivity information

sifting (*integer*): Sifting within dual simplex ↔

Enables or disables sifting within dual simplex. Sifting is often useful for LP models where the number of variables is many times larger than the number of constraints. With a *Moderate* setting, sifting will be applied to LP models and to the root node for MIP models. With an *Aggressive* setting, sifting will be also applied to the nodes of a MIP. Note that this parameter has no effect if you aren't using dual simplex. Note also that sifting will be skipped in cases where it is obviously a worse choice, even when sifting has been selected.

Default: -1

value	meaning
-1	Auto
0	Off
1	Moderate
2	Agressive

siftmethod (*integer*): LP method used to solve sifting sub-problems ↔

Note that this parameter only has an effect when you are using dual simplex and sifting has been selected (either by the automatic method, or through the [Sifting](#) parameter).

Default: -1

value	meaning
-1	Auto
0	Primal Simplex
1	Dual Simplex
2	Barrier

simplexpricing (*integer*): Simplex variable pricing strategy ↔

Default: -1

value	meaning
-1	Auto
0	Partial Pricing
1	Steepest Edge
2	Devex
3	Quick-Start Steepest Edge

solfiles (*string*): Location to store intermediate solution files ↔

During the MIP solution process, multiple incumbent solutions are typically found on the path to finding a proven optimal solution. Setting this parameter to a non-empty string causes these solutions to be written to files (in .sol format) as they are found. The MIP solver will append `_n.sol` to the value of the parameter to form the name of the file that contains solution number `n`. For example, setting the parameter to value `solutions/mymodel` will create files `mymodel_0.sol`, `mymodel_1.sol`, etc., in directory `solutions`.

solnpool (*string*): Controls export of alternate MIP solutions ↔

The GDX file specified by this option will contain a set call `index` that contains the names of GDX files with the individual solutions. For details see example model `dumpsol` in the GAMS Test Library. The option [PoolSolutions](#), [PoolSearchModel](#), and [PoolGap](#) control the search for alternative solutions. Please also refer to the section [Solution Pool](#).

solnpoolmerge (*string*): Controls export of alternate MIP solutions for merged GDX solution file ↔

Similar to [SolnPool](#) this option stores multiple alternative solutions to a MIP problem, but in a single GDX file. The GDX file specified by this option will contain all variables with an additional first index (determined through [SolnPoolPrefix](#)) as parameters. The option [PoolSolutions](#), [PoolSearchModel](#), and [PoolGap](#) control the search for alternative solutions. Please also refer to the section [Solution Pool](#).

solnpoolnumsym (*integer*): Maximum number of variable symbols when writing merged GDX solution file ↔

Default: 10

solnpoolprefix (*string*): First dimension of variables for merged GDX solution file or file name prefix for GDX solution files ↔

Default: soln

solutionlimit (*integer*): MIP feasible solution limit ↔

Default: maxint

solvefixed (*boolean*): Indicator for solving the fixed problem for a MIP to get a dual solution ↔

Default: 1

value	meaning
0	Do not solve the fixed problem
1	Solve the fixed problem

startnodelimit (*integer*): Node limit for MIP start sub-MIP ↔

This parameter limits the number of branch-and-bound nodes explored when completing a partial MIP start. The default value of -1 uses the value of the [SubMIPNodes](#) parameter. A value of -2 means to only check full MIP starts for feasibility and to ignore partial MIP starts. A value of -3 shuts off MIP start processing entirely. Non-negative values are node limits.

Default: -1

strongcgcuts (*integer*): Strong-CG cut generation ↔

Controls Strong Chvátal-Gomory (Strong-CG) cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the [Cuts](#) parameter.

Default: -1

submipcuts (*integer*): Sub-MIP cut generation ↔

See the description of the global [Cuts](#) parameter for further information.

Default: -1

submipnodes (*integer*): Nodes explored by sub-MIP heuristics ↔

Limits the number of nodes explored by the heuristics, like RINS. Exploring more nodes can produce better solutions, but it generally takes longer.

Default: 500

symmetry (*integer*): Symmetry detection ↔

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

threads (*integer*): Number of parallel threads to use ↔

Default number of parallel threads allowed for any solution method. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

Default: GAMS threads

timelimit (*real*): Time limit ↔

Default: GAMS reslim

tunecleanup (*real*): Enables a tuning cleanup phase ↔

Enables a cleanup phase at the end of tuning. The parameter indicates the percentage of total tuning time to devote to this phase, with a goal of reducing the number of parameter changes required to achieve the best tuning result.

Default: 0

tunecriterion (*integer*): Specify tuning criterion ↔

Modifies the tuning criterion for the tuning tool. The primary tuning criterion is always to minimize the runtime required to find a proven optimal solution. However, for MIP models that don't solve to optimality within the specified time limit, a secondary criterion is needed. Set this parameter to 1 to use the optimality gap as the secondary criterion. Choose a value of 2 to use the objective of the best feasible solution found. Choose a value of 3 to use the best objective bound. Choose 0 to ignore the secondary criterion and focus entirely on minimizing the time to find a proven optimal solution. The default value of -1 chooses automatically.

Default: -1

tunejobs (*integer*): Enables distributed tuning ↔

Enables distributed parallel tuning, which can significantly increase the performance of the tuning tool. A value of n causes the tuning tool to distribute tuning work among n parallel jobs. These jobs are distributed among a set of workers. Use the [WorkerPool](#) parameter to provide a list of available workers.

Note that distributed tuning is most effective when the workers have similar performance. Distributed tuning doesn't attempt to normalize performance by worker, so it can incorrectly attribute a boost in performance to a parameter change when the associated setting is tried on a worker that is significantly faster than the others.

Default: 0

tunemetric (*integer*): Metric to aggregate results into a single measure ↔

A single tuning run typically produces multiple timing results for each candidate parameter set, either as a result of performing multiple trials, or tuning multiple models, or both. This parameter controls how these results are aggregated into a single measure. The default setting (-1) chooses the aggregation automatically; setting 0 computes the average of all individual results; setting 1 takes the maximum.

Default: -1

tuneoutput (*integer*): Tuning output level ↔

Default: 2

value	meaning
0	No output
1	Summary output only when a new best parameter set is found
2	Summary output for each parameter set that is tried
3	Summary output, plus detailed solver output, for each parameter set tried

tunerresults (*integer*): Number of improved parameter sets returned ↔

The tuning tool often finds multiple parameter sets that produce better results than the baseline settings. This parameter controls how many of these sets should be retained when tuning is complete. The default value retains the best results that were found for each count of changed parameters. In other words, it retains the best result for one changed parameter, for two changed parameter, etc. Results that aren't on the efficient frontier are discard.

Default: -1

tunetargetmipgap (*real*): A target gap to be reached ↔

A target gap to be reached. As soon as the tuner has found parameter settings that allow Gurobi to reach the target gap for the given model(s), it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see [TuneCleanup](#) parameter).

Default: 0

tunetargettime (*real*): A target runtime in seconds to be reached ↔

A target runtime in seconds to be reached. As soon as the tuner has found parameter settings that allow Gurobi to solve the model(s) within the target runtime, it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see [TuneCleanup](#) parameter).

Default: 0.005

tunetimelimit (*real*): Time limit for tuning ↔

Limits total tuning runtime (in seconds). The default setting (-1) chooses a time limit automatically.

Default: -1

tunetrials (*integer*): Perform multiple runs on each parameter set to limit the effect of random noise ↔

Performance on a MIP model can sometimes experience significant variations due to random effects. As a result, the tuning tool may return parameter sets that improve on the baseline only due to randomness. This parameter allows you to perform multiple solves for each parameter set, using different Seed values for each, in order to reduce the influence of randomness on the results. The default value of 0 indicates an automatic choice that depends on model characteristics.

Note: Only affects mixed integer programming (MIP) models

Default: 0

Tuning (*string*): Parameter Tuning ↔

Invokes the Gurobi parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Gurobi option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in MPS, REW, LP, RLP, and ILP format created by the [WriteProb](#) option. Gurobi will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Gurobi option file name without considering the problem provided by GAMS. The result of such a run is the updated GAMS/Gurobi option file with a tuned set of parameters. In case the option [TuneResults](#) is larger than 1, GAMS/Gurobi will create a sequence of GAMS/Gurobi option files. The solver and model status returned to GAMS will be `NORMAL COMPLETION` and `NO SOLUTION`. Tuning is incompatible with advanced features like [FeasOpt](#) of GAMS/Gurobi.

usebasis (*integer*): Use basis from GAMS [↔](#)

If `UseBasis` is not specified, GAMS (via option `BRatio`) decides if the starting basis or a primal/dual solution is given to Gurobi. If `UseBasis` is explicitly set in an option file then the basis or a primal/dual solution is passed to Gurobi independent of the GAMS option `BRatio`. Please note, if Gurobi uses a starting basis presolve will be skipped.

Default: GAMS `bratio`

value	meaning
0	No basis
1	Supply basis if basis is full otherwise provide primal dual solution
2	Supply basis iff basis is full
3	Supply primal dual solution

varbranch (*integer*): Branch variable selection strategy [↔](#)

Default: -1

value	meaning
-1	Auto
0	Pseudo Reduced Cost Branching
1	Pseudo Shadow Price Branching
2	Maximum Infeasibility Branching
3	Strong Branching

varhint (*boolean*): Guide heuristics and branching through variable hints [↔](#)

If you know that a variable is likely to take a particular value in high quality solutions of a MIP model, you can provide this information as a hint. If `VarHint` option is active, GAMS/Gurobi will pass variable levels rounded to the nearest integer as hints to Gurobi if their level is within `TryInt` of an integer. The closer the level is to the rounded integer the higher your level of confidence in this hint. Internally this is recalculated into a Gurobi variable hint priority:
$$\frac{1}{\max(10^{-6}, |x.l - [x.l]|)}$$

The Gurobi MIP solver will use these variable hints in a number of different ways. Hints will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree. In general, high quality hints should produce high quality MIP solutions faster. In contrast, low quality hints will lead to some wasted effort, but shouldn't lead to dramatic performance degradations.

Variables hints and [MIP starts](#) are similar in concept, but they behave in very different ways. If you specify a MIP start, the Gurobi MIP solver will try to build a single feasible solution from the provided set of variable values. If you know a solution, you should use a MIP start to provide it to the solver. In contrast, variable hints provide guidance to the MIP solver that affects the entire solution process. If you have a general sense of the likely values for variables, you should provide them through variable hints.

Default: 0

workerpassword (*string*): Password for distributed worker cluster ↔

When using a distributed algorithm (the distributed concurrent MIP solver or distributed tuning), this parameter allows you to specify the password for the workers listed in the [WorkerPool](#) parameter.

workerpool (*string*): Distributed worker cluster ↔

When using a distributed algorithm (distributed MIP, distributed concurrent, or distributed tuning), this parameter allows you to specify a Remote Services cluster that will provide distributed workers. You should also specify the access password for that cluster, if there is one, in the [WorkerPassword](#) parameter.

You can provide a comma-separated list of machines for added robustness. If the first node in the list is unavailable, the client will attempt to contact the second node, etc.

To give an example, if you have a Remote Services cluster that uses port 61000 on a pair of machines named `server1` and `server2`, you could set `WorkerPool` to `server1:61000,server2:61000`.

worklimit (*real*): Work limit ↔

Limits the total work expended (in work units).

In contrast to the [TimeLimit](#), work limits are deterministic. This means that on the same hardware and with the same parameter and attribute settings, a work limit will stop the optimization of a given model at the exact same point every time. One work unit corresponds very roughly to one second on a single thread, but this greatly depends on the hardware on which Gurobi is running and the model that is being solved.

Note that optimization may not stop immediately upon hitting the work limit. It will stop when the optimization is next in a deterministic state, and it will then perform the required additional computations of the attributes associated with the terminated optimization. As a result, the Work attribute may be larger than the specified `WorkLimit` upon completion, and repeating the optimization with a `WorkLimit` set to the Work attribute of the stopped optimization may result in additional computations and a larger attribute value.

Default: `maxdouble`

writeparams (*string*): Write Gurobi parameter file ↔

writeprob (*string*): Save the problem instance ↔

zerohalfcuts (*integer*): Zero-half cut generation ↔

See the description of the global [Cuts](#) parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

zeroobjnodes (*integer*): Zero objective heuristic control ↔

Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: -1

5.19.8 Setting up a GAMS/Gurobi-Link license

The GAMS/Gurobi-Link requires two licenses:

- A GAMS license with components GAMS/GUROBI-Link and GAMS/BASE (to generate models beyond the demo limits)
- A Gurobi license which you need to get directly from Gurobi

An attempt to use the GAMS/Gurobi solver with a GAMS/Gurobi-Link license but without a properly set up Gurobi license will result in a licensing error with a message describing the problem. For example, the following message is sent to the log when attempting to solve a model with dimensions beyond the [community limits](#):

```
--- Executing GUROBI (SolveLink=2): elapsed 0:00:00.047[LST:85]

Gurobi          32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window

Gurobi link license.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)
```

Starting with GAMS distribution 24.7, even [demo sized](#) models require a license from Gurobi. An attempt to solve a demo sized model without a Gurobi license installed results in:

```
--- Executing GUROBI (SolveLink=2): elapsed 0:00:00.016[LST:208]

Gurobi          32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window

*** This solver runs with a demo license. No commercial use.
GAMS/Gurobi demo/community requires a Gurobi license from Gurobi Optimization.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)
```

To make the GAMS/Gurobi-Link work you do **not** need to download or install the Gurobi software but only your Gurobi license. GAMS will use it's own Gurobi DLL/shared library, so the **Gurobi license has to be valid for the Gurobi version GAMS uses**. You can download your Gurobi license from www.gurobi.com. Log in to your Gurobi account and go to Download & Licenses -> Your Gurobi licenses.

Now click on the license you want to download and click on `Get License Details`. On the license detail page, copy the `grbgetkey` command on the bottom.

Paste the `grbgetkey` command to a command/terminal prompt. Your GAMS system directory contains the `grbgetkey` program, so to make sure it is found you should open the terminal via [GAMS Studio](#) or add your GAMS system directory to the path variable. After running the `grbgetkey` command, you will be asked where you would like to save your Gurobi license.

```
$ ./grbgetkey [...]
info : grbgetkey version 9.0.3, build v9.0.3rc0
info : Contacting Gurobi key server...
info : Key for license ID [...] was successfully retrieved
info : License expires at the end of the day on 2021-08-31
info : Saving license key...
```

```
In which directory would you like to store the Gurobi license key file?
[hit Enter to store it in /opt/gurobi]: /home/nb/gurobilic
```

```
info : License [...] written to file /home/nb/gurobilic/gurobi.lic
info : You may have saved the license key to a non-default location
info : You need to set the environment variable GRB_LICENSE_FILE before you can use this license key
info : GRB_LICENSE_FILE=/home/nb/gurobilic/gurobi.lic
```

Once you have saved your `gurobi.lic` file, you need to make GAMS/Gurobi aware of that license via environment variable `GRB_LICENSE_FILE`. The `environmentVariables` section in the [GAMS configuration file](#) (available as of GAMS version 31.1.0) is a convenient way to set the `GRB_LICENSE_FILE` environment variable. This can either be done by manually opening and editing the `gamsconfig.yaml` file which can be found in one of the [standard locations](#) or via the corresponding [GAMS Configuration Editor in GAMS Studio](#). As a result, the configuration file should contain an entry for environment variable `GRB_LICENSE_FILE` that points to the Gurobi license, e.g.

```
[...]
environmentVariables:
  [...]
  - GRB_LICENSE_FILE:
    value: /home/nb/gurobilic/gurobi.lic
[...]
```

As an alternative you could also set `GRB_LICENSE_FILE` via the usual OS-specific ways to set environment variables.

To test whether the license setup has been successful, you can solve a model from the GAMS Model library, e.g. `[INDUS89]`, where you should get the following output.

```
$ gamslib indus89
Copy ASCII : indus89.gms
$ gams indus89 lp gurobi
--- Job indus89 Start 09/01/20 12:41:41 32.2.0 rc62c018 LEX-LEG x86 64bit/Linux
[...]
```

Gurobi 32.2.0 rc62c018 Released Aug 26, 2020 LEG x86 64bit/Linux

Gurobi link license.

Gurobi library version 9.0.3

[...]

User-callback calls 3040, time in user-callback 0.00 sec

LP status(2): Model was solved to optimality (subject to tolerances).

--- Reading solution for model wsisn

*** Status: Normal completion

--- Job indus89.gms Stop 09/01/20 12:29:49 elapsed 0:00:00.835

Note

To install a Gurobi license key as described above, the `grbgetkey` program needs to be able to communicate with the Gurobi website. If it fails to work, the `grbprobe` program which can also be found in your GAMS system directory may be used to retrieve the required hardware information which then needs to be manually submitted to the Gurobi Website (detailed instructions can be found [here](#)).

5.20 Gather-Update-Solve-Scatter (GUSS)

5.20.1 Introduction

The purpose of this chapter is to detail an extension of the GAMS modeling system that allows collections of models (parameterized exogenously by a set of samples or indices) to be described, instantiated, and solved efficiently.

As a specific example, we consider the parametric optimization problem $\mathcal{P}(s)$ defined by:

$$\min_{x \in X(s)} f(x; s) \text{ s.t. } g(x; s) \leq 0 \quad (5.11)$$

where $s \in S = \{1, \dots, K\}$. Note that each scenario s represents a different problem for which the optimization variable is x . The form of the constraint set as given above is simply for concreteness; equality constraints and range and bound constraints are trivial extensions of the above framework. Clearly the problems $\mathcal{P}(s)$ are interlinked. We intend to show how such problems can be easily specified within GAMS, and detail one type of algorithmic extension that can exploit the nature of the linkage. Other extensions of GAMS allow solves to be executed in parallel or by using grid computing resources. Note that in our description we will use the terms indexed, parameterized, and scenario somewhat interchangeably. An extended version of this chapter containing several examples is available as a paper at <http://www.gams.com/modlib/adddocs/gusspaper.pdf>.

5.20.2 Design Methodology

One of the most important functions of GAMS is to build a model instance from the collection of equations (i.e. an optimization model defined by the GAMS keyword `MODEL`) and corresponding data (consisting of the content of GAMS (sub)sets and parameters). Such a model instance is constructed or generated when the GAMS execution system executes a `SOLVE` statement. The generated model instance is passed to a solver which searches for a solution of this model instance and returns status information, statistics, and a (primal and dual) solution of the model instance. After the solver terminates, GAMS brings the solution back into the GAMS database, i.e. it updates the level (.L) and marginal (.M) fields of variable and equation symbols used in the model instance. Hence, the `SOLVE` statement can be interpreted as a complex operator against the GAMS database. The model instance generated by a `SOLVE` statement only lives during the execution of this one statement, and hence has no representation within the GAMS language. Moreover, its structure does fit the relational data model of GAMS. A model instance consists of vectors of bounds and right hand sides, a sparse matrix representation of the Jacobian, a representation of the non-linear expressions that allow the efficient calculation of gradient vectors and Hessian matrices, and so on.

This chapter is concerned with solving collections of models that have similar structure but modified data. As an example, consider a linear program of the form:

$$\min c^T x \text{ s.t. } Ax \geq b, \ell \leq x \leq u.$$

The data in this problem is (A, b, c, ℓ, u) . Omitting some details, the following code could be used within GAMS to solve a collection of such linear programs in which each member of the collection has a different A matrix and lower bound ℓ :

```

Set      i / ... /, j / ... /;
Parameter A(i,j), b(i);
Variable x(j), z, ...;
Equation e(i), ...;
e(i).. sum(j, A(i,j)*x(j)) =g= b(i);
...
model mymodel /all/;

Set s / s1*s10 /
Parameter
    A_s(s,i,j) 'Scenario data'
    xlo_s(s,j) 'Scenario lower bound for variable x'
    xl_s(s,j)  'Scenario solution for x.l'
    em_s(s,i)  'Scenario solution for e.m';
Loop(s,
    A(i,j) = A_s(s,i,j);
    x.lo(j)= xlo_s(s,j);
    solve mymodel min z using lp;
    xl_s(s,j) = x.l(j);
    em_s(s,i) = e.m(i);
);

```

Summarizing, we solve one particular model (`mymodel`) in a loop over `s` with an unchanged model rim (i.e. the same individual variables and equations) but with different model data and different bounds for the variables. The change in model data for a subsequent solve statement does not depend on the previous model solutions in the loop.

The purpose of this new Gather-Update-Solve-Scatter (GUSS) manager is to provide syntax at the GAMS modeling level that makes an instance of a problem that provides limited access to treat that instance as an object, and allows the modeler to update portions of it iteratively. Specifically, we provide syntax that gives a list of data changes to an instance, and allows these changes to be applied sequentially to

the instance (which is then solved without returning to GAMS). Thus, we can simulate a limited set of actions to be applied to the model instance object and retrieve portions of the solution of these changed instances back in the modeling environment. Such changes can be done to any model type in GAMS, including nonlinear problems and mixed integer models. However, the only changes we allow are to named parameters appearing in the equations and lower and upper bounds used in the model definition.

Thus, in the above example GUSS allows us to replace lines 15-21 by

```
Set dict / s.  scenario.  ''
      A.  param.   A_s
      x.  lower.   xlo_s
      x.  level.   xl_s
      e.  marginal. em_s  /;
solve mymodel min z using lp scenario dict;
```

The three dimensional `set dict` (you can freely choose the name of this symbol) contains mapping information between symbols in the model (in the first position) and symbols that supply required update data or store solution information (in the third position), and the type of update/storing (in the second position). An exception to this rule is the tuple with label `scenario` in the second position. This tuple determines the symbol (in the first position) that is used as the scenario index. This scenario symbol can be a multidimensional set. A tuple in this set represents a single scenario. The remaining tuples in the `set dict` can be grouped into input and output tuples. Input tuples determine the modifications of the model instance prior to solving, while output tuples determine which part of the solution gets saved away. The following keywords can be used in the second position of the `set dict`:

Type	Keywords	Description
Input:	<code>param</code>	Supplies scenario data for a parameter used in the model
	<code>lower</code>	Supplies scenario lower bounds for a variable
	<code>upper</code>	Supplies scenario upper bounds for a variable
	<code>fixed</code>	Supplies scenario fixed bounds for a variable
Output:	<code>level</code>	Stores the levels of a scenario solution of variable or equation
	<code>marginal</code>	Stores the marginals of a scenario solution of variable or equation

Sets in the model cannot be updated. GUSS works as follows: GAMS generates the model instance for the original data. As with regular `SOLVE` statements, all the model data (e.g. parameter `A`) needs to be defined at this time. The model instance with the original data is also called the *base case*. The solution of the base case is reported back to GAMS in the regular way and is accessible via the regular `.L` and `.M` fields after the `SOLVE` statement. After solving the base case, the update data for the first scenario is applied to the model. The tuples with `lower`, `upper`, `fixed` update the bounds of the variables, whereas the tuples with `param` update the parameters in the model.

The scenario index `s` needs to be the first index in the parameters mapped in the `set dict`. The update of the model parameters goes far beyond updating the coefficients of the constraint matrix/objective function or the right hand side of an equation, as one can do with some other systems. GAMS stores all the necessary expressions of the constraints with the model instance, so the change in the constraint matrix coefficient is the result of an expression evaluation. For example, consider a term in the calculation of the cost for shipping a variable amount of goods $x(i,j)$ between cities i and j . The expression for shipping cost is $d(i,j)*f*x(i,j)$, i.e. the distance between the cities times a freight rate f times the variable amount of goods. In order to find out the sensitivity of the solution with respect to the freight rate f , one can solve the same model with different values for f . In a matrix representation of the model one would need to calculate the coefficient of $x(i,j)$ which is $d(i,j)*f$, but with GUSS it is sufficient to supply different values for f that potentially result in many modified coefficients on the matrix level. GUSS evaluates the shipping cost term and communicates the resulting matrix coefficient to the solver reliably behind the scenes.

After the variable bound and the model parameter updates have been applied and the resulting updates to the model instance data structures (e.g. constraint matrix) has been determined, the modified model instance is passed to the solver. Some solvers (e.g. Cplex, Gurobi, SoPlex, and Xpress) allow modifying a model instance. In these cases GUSS only communicates the changes from the previous model instance to the solver. This reduces the amount of data communicated to the solver and also, in the case of an LP model, allows the solver to restart from an advanced basis and its factorization. In the case of an NLP model, this provides initial values. After the solver determines the solution of a model instance, GUSS stores the part of the solution requested by the output tuples of `dict` to some GAMS parameters and continues with the next scenario. GUSS emphasizes on speed and only works with solver that allow to communicate the model instance through memory, Hence, the following solvers cannot be used as subsolvers of GUSS: ALPHAIECP, BARON, CONVERT, DECISC, DECISM, DICOPT, EXAMINER, GAMSCHK, JAMS, KESTREL, LOGMIP, MILES, MPSGE, MSNLP, NLPEC, PATHNLP, SBB, and XA.

5.20.3 GUSS Options

The execution of GUSS can be parameterized using some options. Options are not passed through a solver option file but via another tuple in the `dict` set. The keyword in the second position of this tuple is `opt`. A one dimensional parameter is expected in the first position (or the label `''`). This parameter may contain some of the following labels with values:

Options	Description
<code>OptfileInit:</code>	Option file number for the first solve (default from GAMS OptFile setting)
<code>Optfile:</code>	Option file number for subsequent solves (default 0)
<code>LogOption:</code>	Determines amount of log output: 0 - Moderate log (default) 1 - Minimal log 2 - Detailed log
<code>NoHotStart:</code>	Disable hot start capability in solver that supports hot starts (default 0)
<code>NoMatchLimit:</code>	Limit of unmatched scenario records (default 0)
<code>RestartType::</code>	Determines restart point for the scenarios 0 - Restart from last solution (default) 1 - Restart from solution of base case 2 - Restart from input point
<code>SkipBaseCase:</code>	Switch for solving the base case (0 solves the base case)
<code>ReportLastScen:</code>	Switch for reporting the solution of the last scenario rather than solution of the base case (default 0)
<code>SolveEmpty:</code>	Limit of solved empty scenarios, afterwards empty scenarios will be skipped (default 0)
<code>UpdateType:</code>	Scenario update mechanism: 0 - Set everything to zero and apply changes (default) 1 - Reestablish base case and apply changes 2 - Build on top of last scenario and apply changes

For the example model above the `UpdateType` setting would mean:

```
UpdateType=0: loop(s, A(i,j) = A_s(s,i,j))
UpdateType=1: loop(s, A(i,j) = A_base(i,j);
               A(i,j) $= A_s(s,i,j))
UpdateType=2: loop(s, A(i,j) $= A_s(s,i,j))
```

The option `SkipBaseCase=1` allows the user to skip the base case. This means only the scenarios are solved and there is no solution reported back to GAMS in the traditional way. The third position in the `opt`-tuple can contain a parameter for storing the scenario solution attribute information, e.g. model and solve status, or needs to have the label `''`. The labels to store solution status information must be known to GAMS, so one needs to declare a set with such labels. A convenient way to enter these attributes is via `System.GUSSModelAttributes`:

```
Set ma 'GUSS Model Attributes' / System.GUSSModelAttributes /; display ma;
```

```
----      1 SET ma  GUSS Model Attributes

ModelStat,   SolveStat,   NumInfes ,   SumInfes ,   IterUsd
ResUsd   ,   ObjVal   ,   NodUsd   ,   ObjEst   ,   DomUsd
RObj     ,   MaxInfes ,   MeanInfes
```

The following example shows how to use some of the GUSS options and the use of a parameter to store some solution status information:

```
Set h solution headers / System.GUSSModelAttributes /;
Parameter
  o / SkipBaseCase 1, UpdateType 1, Optfile 1 /
  r_s(s,h) Solution status report;
Set dict / s.  scenario. ''
           o.  opt.      r_s
           a.  param.   a_s
           x.  lower.   xlo_s
           x.  level.   xl_s
           e.  marginal. em_s /;
solve mymodel min z using lp scenario dict;
```

Please note that the domain set of the solution status report attributes (here `h`) must only contain model attributes known to GUSS. If this domain (unless the domain in `*`) contains a label unknown to GUSS, a compilation error is triggered.

5.20.4 Implementation Details

This section describes some technical details that may provide useful insight in case of unexpected behavior.

Because GUSS changes all model parameters mentioned in the `dict` set to variables, a linear model can produce some non-linear instructions (e.g. `d(i,j)*f*x(i,j)` becomes a non-linear expression since `f` becomes a variable in the model instance given to GUSS). This also explains why some models compile without complaint, but if the model is used in the context of GUSS, the compile time check of the model will fail because a parameter that is turned into a variable can no longer be used in that way. For example, suppose the model contains a constraint `e(i).. sum(j$A(i,j), ...)`. If `A(i,j)` is a parameter in the regular model, the compiler will not complain, but if `A` becomes a parameter that shows up in the first position of a `param` tuple in the `dict` set, the GAMS compiler will turn `A` into a variable and complain that an endogenous variable cannot be used in a `$`-condition.

The sparsity pattern of a model can be greatly affected by GUSS. In a regular model instance GAMS will only generate and pass on non-zero matrix elements of a constraint `e(i).. sum(j, A(i,j)*x(j)) ...`, so the sparsity of `A` determines the sparsity of the generated model instance. GUSS allows to use this constraint with different values for `A` hence GUSS cannot exclude any of the pairs `(i,j)` and generate a dense matrix. The user can enforce some sparsity by explicitly restricting the `(i,j)` pairs: `e(i).. sum(ij(i,j), A(i,j)*x(j)) ...`

Attention

While GUSS is available for many model types quadratic models require special attention. Linear solvers that have been extended to cover (convex) quadratic models, e.g. Cplex, Gurobi, Mosek, Xpress, do not work properly if the modifying parameter affects the left hand side of linear equations or any modifications of quadratic equations. Bound updates as well as changes of the right hand side of linear constraints are okay (see the example of the quadratic support vector machine below). Unfortunately, detecting if a quadratic model is okay or not for a given solver is at the moment difficult to detect, so use caution with quadratic models in combination with such (linear) solvers.

The actual change of the GAMS language required for the implementation of GUSS is minimal. The only true change is the extension of the SOLVE statement with the term SCENARIO dict. Existing language elements have been used to store symbol mapping information, options, and model result statistics. Some parts of the GUSS presentation look somewhat unnatural, e.g. since dict is a three dimensional set the specification the scenario set using keyword scenario requires a third dummy label ''. However, this approach gives maximum flexibility for future extension, allows reliable consistency checks at compile and execution time, and allows the user to delay the commitment for significant and permanent syntax changes of a developing method to handle model instances at a GAMS language level.

5.20.5 Applications

5.20.5.1 Cross Validation in GAMS via GUSS

Cross validation is a statistical/machine learning technique that aims to evaluate the generalizability of a classifier (or other decision) process. It does this by setting aside a portion of the data for testing, and uses the remaining data entries to produce the classifier. The testing data is subsequently used to evaluate how well the classifier works. Cross validation performs this whole process a number of times in order to estimate the true power of the classifier.

Ten-fold cross validation is a special case, where the original data is split into ten pieces, and cross validation is performed using each of these ten pieces as the testing set. Thus, the training process is performed ten times, each of which uses the data obtained by deleting the testing set from the whole dataset. We show below how to carry this out using the Gather-Update-Solve-Scatter (GUSS) facility in GAMS.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available [here](#).

5.20.5.1.1 GUSS formulation in GAMS The following example compares the two formulations for a feature-selection model under cross-validation using data files [a_data.inc](#) and [b_data.inc](#). The actual source code for both of these GAMS formulations is available [here](#).

Original GAMS formulation (without the GAMS/DEA interface):

```
$title Ten-fold cross validation example
$eolcom !

$setglobal num_folds 10

  slb.fx(b) = 0; slb.up(b)$b_test(p,b) = inf;
  solve train using mip minimizing c;
  train.optfile = 1; ! use mipstart for the second run
  rep(p,'modelstat') = train.modelstat;
  rep(p,'solvestat') = train.solvestat;
  rep(p,'objval') = train.objval;
);
display rep;

```

Options file for the original formulation: xpress.opt

```
loadmipsol=1
```

The `batinclude` file `gentestset.inc` . gives instructions for generating the testing sets. It produces `a_test` and `b_test` that detail which equations are left out on solve `p`.

The actual model is set up to include all the data points in the equations `a_def` and `b_def`. To delete the equations that correspond to the test set, we introduce nonnegative slack variables into all the equations. We then set the upper bounds of the slack variables to zero in equations corresponding to the training set, and to infinity in equations corresponding to the testing set. At the same time we fix the error measures `a_err` and `b_err` belonging to the testing set by setting their upper bounds to zero. Thus the testing set equations are always satisfiable by choice of the slack variables alone - essentially they are discarded from the model as required. An alternative formulation could "include" the data equations that you need in each scenario, but the update from one scenario to the next in the defining data is much larger.

Cross validation formulated using GUSS: This model essentially mimics what the standard model does, but the implementation of the solver loop behind the scenes is much more efficient, and the consequences are that are clear to see if you execute both model runs. The changes are in the last 40 lines of the GAMS code.

```

  gamma.level.    gval /

$echo loadmipsol=1 > xpress.opt

Parameter aupper(p,a), bupper(p,b), afree(p,a), bfree(p,b);

aupper(p,a)$(not a_test(p,a)) = inf;
bupper(p,b)$(not b_test(p,b)) = inf;

afree(p,a)$a_test(p,a) = inf;
bfree(p,b)$b_test(p,b) = inf;

option mip=xpress, optcr=0, optca=0;
solve train using mip minimizing c scenario dict;
display scenrep, gval;

```

Firstly, parameters `aupper`, `bupper`, `afree` and `bfree` are used to set the bounds on the error and slack variables in the testing set equations respectively. The setting of the upper bounds are governed by the syntax shown in the controlling set `dict`. Furthermore, the output of the classifier (`w`, `gamma`) for each fold of the cross validation uses the `dict` set to place results into the parameters `wval` and `gval` respectively. Finally, the GUSS options are used to guarantee that the subsequent solves are instructed to process solver options (`Optfile 1`) which instruct the solver to use the previous solution to start the branch-and-cut process (`loadmipsol=1`).

The complete data and model files for this example are found in ([galaxy zip archive](#)). The data and model for a second instance based on the Wisconsin Diagnostic Breast Cancer Database is downloadable as ([wdbc zip archive](#)).

5.20.5.1.2 Quadratic Programs GUSS is not limited to linear programs, but can be used more generally. Simple (indexed) quadratic models can be solved using GUSS. The following example illustrates the use of GUSS for quadratic programs. In this example, a support vector machine is used to determine a linear classifier that separates data into two categories. We use the following model:

$$\begin{aligned}
 & \text{Min}_{w,g,z} && (1/2)\|w\|^2 + Ce^T z \\
 & \text{subject to} && D(Aw - g) + z \geq 1 \\
 & && z \geq 0
 \end{aligned} \tag{5.12}$$

Here, A is a matrix containing the training data (patients by features) and D is a diagonal matrix with values $+1$ or -1 (each denoting one of the two classes). C is a parameter weighting the importance of

maximizing the margin between the classes ($2/\|w\|_2$) versus minimizing the misclassification error (z). The solution w and g are used to define a separating hyperplane $\{x|w^T x = g\}$ to classify (unseen) data points.

As given, the standard linear support vector machine is not a slice model per se. It becomes a slice model under cross-validation training, where it is solved multiple times on different pieces of data. In this case, only the data A and D vary between solves, appropriately fitting the definition of a slice model.

The data for this example comes from the Wisconsin Diagnosis Breast Cancer Database, and is available [here](#). The data was converted to the GAMS file `wdbc.gms`, which defines A and D . The actual source code for the following GAMS formulation is available [here](#).

The GUSS formulation for quadratic svm:

```

$title Ten-fold cross validation example using GUSS
$eolcom !

$setglobal num_folds 10

set p /1*%num_folds%/; ! folds to perform

! Read in data
$include "wdbc.gms"

set test(p,i); ! testing set

! Define problem
parameter C /1/;
positive variables z(i);
variables obj, w(k), gamma, slack(i);

equations obj_def, sep_def(i);

obj_def.. obj =e= 1/2*sum(k, sqr(w(k))) + C*sum(i, z(i));
sep_def(i)..
    D(i)*(sum(k, A(i,k)*w(k)) - gamma) + z(i) + slack(i) =g= 1;

model train /all/;

! Generate testing sets (to be deleted in each problem)
loop(p,
$batinclude gentestset2.inc "p,i"
);

set headers report / modelstat, solvestat, objval /;
parameter
    scenrep(p,headers)
    scopt / SkipBaseCase 1, LogOption 2 /;

set dict / p. scenario.'
    scopt.opt. scenrep
    z. upper. iupper
    slack.upper. ifree /;

Parameter iupper(p,i), ifree(p,i);
iupper(p,i)$not test(p,i) = inf;
ifree(p,i)$test(p,i) = inf;

```

```
option qcp=conopt, optcr=0, optca=0;
solve train using qcp minimizing obj scenario dict;
display scenrep;
```

Because the problem is quadratic, we must use a quadratic program solver. The variable values for weight and gamma could be saved for later testing using the same method as detailed above for the linear case.

The batinclude file `gentestset2.inc` is very similar to `gentestset.inc` from the earlier cross-validation examples. In `gentestset2.inc`, though, only one set is being dealt with rather than two. The complete source GAMS code for this formulation is available in this [zip archive](#).

5.20.5.2 DEA Modeling in GAMS via GUSS

Data Envelopment Analysis (DEA) models can be solved most efficiently in GAMS using the Gather-Update-Solve-Scatter (GUSS) facility. This is the preferred method since release 23.7 of GAMS and hence the GAMS/DEA solver is no longer available.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available [here](#).

5.20.5.2.1 Introduction The basic (CCR) DEA model is a collection of models indexed by k and defined by

$$\begin{array}{llll}
 \max_{u,v} & u^T Y_{*,k} & & \text{(objective slice)} \\
 \text{subject to} & v^T X_{*,k} = 1 & & \text{(slice constraint)} \\
 & u^T Y \leq v^T X & & \text{(core constraint)} \\
 & u, v \geq 0 & & \text{(core constraint)}
 \end{array} \tag{5.13}$$

where X, Y are data matrices.

Without using GUSS in GAMS, a model would be defined and solved in a loop over k , requiring the model to be generated multiple times with different instances for each value of k . GUSS is an alternative (and more efficient) way to define the individual programs and pass them to any underlying GAMS solver. In this way, individual programs are not re-generated, but are instead defined as data modifications of each other. This reduces overall model generation time. Further, previous solutions can be used as starting points in later solves to speed up overall processing time.

Some DEA examples compare the two formulations. The actual source code for both of these formulations is available [here](#).

5.20.5.2.2 DEA Examples Original GAMS formulation (without GUSS): In all these models the model setup and data are given at the top of the file and the code of interest is in the last 10 or so lines. In this setting we loop over the set k and change the data in the objective function and the first constraint of the model explicitly before each solve. We only output a minimal summary of the solution.

```
$title Data Envelopment Analysis - DEA
```

```
$ontext
```

```
Data Envelopment Analysis (DEA) is a technique for measuring the relative
performance of organizational units where presence of multiple inputs and
outputs makes comparison difficult.
```

```
efficiency = weighted sum of output / weighted sum of input
```

Find weights that maximize the efficiency for one unit while ensuring that no other units has an efficiency < 1 using these weights. A primal and dual formulation is presented.

Dyson, Thanassoulis, and Boussofiane, A DEA Tutorial.

solve dea using lp max eff scenario dict;
display scenrep,eff_k;

```

In the GUSS version we indicate the collection of models to be solved using the set `dict`. The first element of `dict` determines the set to be used for the scenario (collection) index, in this case k . The second element of `dict` then details that in each scenario k , the parameter `slice` is instantiated using a slice of the parameter data. Essentially, this corresponds to the GAMS statement:

$$\text{slice}(j) = \text{data}(k,j)$$

Note the scenario index k must appear as the first index of the parameter data. The third element of `dict` allows the modeler to collect information from each solve and store it into a GAMS parameter. Essentially, the third element of `dict` corresponds to the GAMS statement:

$$\text{eff.k}(k) = \text{eff.l}$$

that gets executed immediately after the solve of scenario k .

More complex scenario models can also be formulated using GUSS, including multiple equations being updated. This is shown by the dual of the basic DEA model, given by

$$\begin{array}{lll}
 \min_{z,\lambda} & z & \text{(objective)} \\
 \text{subject to} & X^*\lambda \leq zX_{*,k} & \text{(slice constraint)} \\
 & Y^*\lambda \geq Y_{*,k} & \text{(slice constraint)} \\
 & \lambda \geq 0 & \text{(core constraint)}
 \end{array} \tag{5.14}$$

The next example compares the two formulations for this model. The actual source code for both of these formulations is available [here](#).

Original GAMS formulation (without GUSS):

```

Extensions of these models to formulations with weighted outputs or variable returns to scale are easy to formulate with the scenario solver within GAMS. This extended model can be downloaded [here](#).

The **DEA model** in the model library is similar to the extended model, but does not make use of GUSS.

5.21 IPOPT and IPOPTH

COIN-OR IPOPT (Interior Point Optimizer) is an open-source solver for large-scale nonlinear programming (NLP). The code has been written primarily by Andreas Wächter.

IPOPT implements an interior point line search filter method for nonlinear programming models which functions can be nonconvex, but should be twice continuously differentiable. For more information on the algorithm we refer to [195] [255] [254] [256] [253] and the [IPOPT documentation](#). Most of the IPOPT documentation in the section was taken from the IPOPT manual [139].

5.21.1 Available linear solvers

The performance and robustness of IPOPT on larger models heavily relies on the used solver for sparse symmetric indefinite linear systems.

GAMS/IPOPT includes the sparse solver **MUMPS** [14] [15] (currently the default), and MKL PARDISO [224] [225]. In the commercially licensed GAMS/IPOPTH version, also the Harwell Subroutine Library (HSL) solvers MA27, MA57, HSL_MA86, and HSL_MA97 are available and MA27 is used by default.

MUMPS, MA57, HSL_MA86, and HSL_MA97 use **METIS** for matrix ordering [138], see also the [METIS manual](#). METIS is copyrighted by the regents of the University of Minnesota.

IPOPT and IPOPTH can exploit parallelization of the linear solvers MKL Pardiso, HSL MA86, and HSL MA97 and the linear algebra routines (see next section).

The linear solver is chosen by the [linear_solver](#) option. Benchmarks have shown that MA57 and HSL_MA97 are often able to outperform MA27 on larger instances. Further, PARDISO often allows for performance that is better than MUMPS and similar to the HSL solvers. If IPOPT fails to solve an instance with PARDISO, it's worth to try changing the options [pardisomkl_order](#) and [pardisomkl_max_iterative_refinement_steps](#).

It is also possible to use the linear solver PARDISO from the [PARDISO Solver Project](#) or the [HSL routines](#) with GAMS/IPOPT if a user provides libraries that can be loaded at runtime. PARDISO from the PARDISO Solver Project can provide performance that exceeds the one of PARDISO from Intel MKL. To build the HSL routines, COIN-OR project [ThirdParty-HSL](#) may be useful. See also options [linear_solver](#), [linear_system_scaling](#), [nlp_scaling_method](#), [pardisolib](#), and [hslilib](#). Note that it is your responsibility to ensure that you are entitled to download and use these routines!

5.21.2 The linear algebra library

The IPOPT library distributed by GAMS and most of the linear solvers used by IPOPT use the [Intel oneAPI Math Kernel Library \(MKL\)](#), which provides a fast and parallel implementation of linear algebra routines (BLAS/LAPACK) and the linear solver PARDISO. MKL chooses an internal code path that provides the best possible performance for the used CPU type. As a consequence, results can be different when changing from one CPU to another. By setting an environment variable, the code path to use can be set by the user. See the Intel MKL documentation regarding [Conditional Numerical Reproducibility](#) for more details.

Intel MKL has been optimized for use with Intel CPUs. On CPUs from other vendors, MKL may not use an internal code path that could provide a better performance on that CPU. For example, it may not use AVX2 instructions on an AMD CPU that provides AVX2.

To gain more insight into the use of MKL in GAMS/IPOPT, one may [set the environment variable MKL_VERBOSE to 1](#). This will print out information about the MKL library used, functions being called, time spend there, etc.

5.21.3 Usage

The following statement can be used inside your GAMS program to specify using IPOPT

```
Option NLP = IPOPT;      { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

The above statement should appear before the Solve statement. If IPOPT was specified as the default solver during GAMS installation, the above statement is not necessary.

To use IPOPTH, the statement should be

```
Option NLP = IPOPTH;    { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

5.21.3.1 Specification of Options

IPOPT has many options that can be adjusted for the algorithm (see Section [List of IPOPT Options](#)). Options are all identified by a string name, and their values can be of one of three types: Number (real), Integer, or String. Number options are used for things like tolerances, integer options are used for things like maximum number of iterations, and string options are used for setting algorithm details, like the NLP scaling method. Options can be set by creating a `ipopt.opt` file in the directory you are executing IPOPT.

The `ipopt.opt` file is read line by line and each line should contain the option name, followed by whitespace, and then the value. Comments can be included with the `#` symbol. For example, the following is a valid `ipopt.opt` file:

```
# This is a comment

# Turn off the NLP scaling
nlp_scaling_method none

# Change the initial barrier parameter
mu_init 1e-2

# Set the max number of iterations
max_iter 500
```

GAMS/IPOPT understands currently the following GAMS parameters: [reslim](#) (time limit), [iterlim](#) (iteration limit), [domlim](#) (domain violation limit). Further the option [threads](#) can be used to control the number of threads used in the [linear algebra routines and the linear solver](#).

5.21.3.2 Warmstarting IPOPT

As an interior point solver, it is difficult to warm start IPOPT. By default, only the level values of the variables are passed as starting point to IPOPT. Setting the IPOPT option `warm_start_init_point` to `yes` enables that also dual values for variables and constraints are passed to IPOPT.

However, the expected behavior that IPOPT finishes within one iteration if optimal primal and dual values are passed is not reached this way, yet. This is, because IPOPT by default moves any initial value that is close to a bound into the interior. The amount on how much the initial point is moved can be controlled by various `bound_push` and `bound_frac` options. To make IPOPT accept an optimal primal/dual solution within one iteration, it should be sufficient to set the following options:

```
warm_start_init_point      yes
warm_start_bound_push     1e-9
warm_start_bound_frac     1e-9
warm_start_slack_bound_frac 1e-9
warm_start_slack_bound_push 1e-9
warm_start_mult_bound_push 1e-9
```

Further, it can be useful to specify that IPOPT can use a less central path in its first iterations by reducing the value of option `mu_init`. This option is only used if option `mu_strategy` is set to "monotone", so the option file entries would be

```
mu_strategy monotone
mu_init      0.0001
```

Finally, IPOPT by default checks whether it should scale the problem. The computed scaling depends on the starting point, which can be undesired when warmstarting. Thus, it may be useful to turn off scaling via option `nlp_scaling_method`:

```
nlp_scaling_method none
```

If a modified but structurally equivalent problem instance is solved, e.g., via `GUSS`, option `warm_start_init_point` is automatically set to "yes" for every solve following the first one. If this is not desired, `warm_start_init_point` should explicitly be set to "no" in an IPOPT options file.

5.21.4 Output

This section describes the standard IPOPT console output. The output is designed to provide a quick summary of each iteration as IPOPT solves the problem.

Before IPOPT starts to solve the problem, it displays the problem statistics (number of nonzero-elements in the matrices, number of variables, etc.). Note that if you have fixed variables (both upper and lower bounds are equal), IPOPT may remove these variables from the problem internally and not include them in the problem statistics.

Following the problem statistics, IPOPT will begin to solve the problem and you will see output resembling the following,

```
iter   objective   inf_pr   inf_du lg(mu)  ||d||  lg(rg) alpha_du alpha_pr  ls
  0   1.6109693e+01  1.12e+01  5.28e-01  0.0  0.00e+00   -  0.00e+00  0.00e+00  0
  1   1.8029749e+01  9.90e-01  6.62e+01  0.1  2.05e+00   -  2.14e-01  1.00e+00f  1
  2   1.8719906e+01  1.25e-02  9.04e+00 -2.2  5.94e-02  2.0  8.04e-01  1.00e+00h  1
```

and the columns of output are defined as

item

The current iteration count. This includes regular iterations and iterations while in restoration phase. If the algorithm is in the restoration phase, the letter **r** will be appended to the iteration number.

objective

The unscaled objective value at the current point. During the restoration phase, this value remains the unscaled objective value for the original problem.

inf_pr

The unscaled constraint violation at the current point. This quantity is the infinity-norm (max) of the (unscaled) constraint violation. During the restoration phase, this value remains the constraint violation of the original problem at the current point. The option `inf_pr_output` can be used to switch to the printing of a different quantity. During the restoration phase, this value is the primal infeasibility of the original problem at the current point.

inf_du

The scaled dual infeasibility at the current point. This quantity measure the infinity-norm (max) of the internal dual infeasibility (Eq. (4a) in [256]), including inequality constraints reformulated using slack variables and problem scaling. During the restoration phase, this is the value of the dual infeasibility for the restoration phase problem.

lg(mu)

\log_{10} of the value of the barrier parameter μ .

||d||

The infinity norm (max) of the primal step (for the original variables \mathbf{x} and the internal slack variables \mathbf{s}). During the restoration phase, this value includes the values of additional variables, \mathbf{p} and \mathbf{n} in Eq. (10) of [256].

lg(rg)

\log_{10} of the value of the regularization term for the Hessian of the Lagrangian in the augmented system (δ_w in Eq. (26) of [256]). A dash (-) indicates that no regularization was done.

alpha_du

The stepsize for the dual variables (α_k^z in Eq. (14c) of [256]).

alpha_pr

The stepsize for the primal variables (α_k in Eq. (14a) of [256]). The number is usually followed by a character for additional diagnostic information regarding the step acceptance criterion:

- **f**: f-type iteration in the filter method w/o second order correction
 - **F**: f-type iteration in the filter method w/ second order correction
 - **h**: h-type iteration in the filter method w/o second order correction
 - **H**: h-type iteration in the filter method w/ second order correction
 - **k**: penalty value unchanged in merit function method w/o second order correction
-

- K: penalty value unchanged in merit function method w/ second order correction
- n: penalty value updated in merit function method w/o second order correction
- N: penalty value updated in merit function method w/ second order correction
- R: Restoration phase just started
- w: in watchdog procedure
- s: step accepted in soft restoration phase
- t/T: tiny step accepted without line search
- r: some previous iterate restored

ls

The number of backtracking line search steps (does not include second-order correction steps).

Note that the step acceptance mechanisms in IPOPT consider the barrier objective function (Eq. (3a) in [256]) which is usually different from the value reported in the `objective` column. Similarly, for the purposes of the step acceptance, the constraint violation is measured for the internal problem formulation, which includes slack variables for inequality constraints and potentially scaling of the constraint functions. This value, too, is usually different from the value reported in `inf_pr`. As a consequence, a new iterate might have worse values both for the objective function and the constraint violation as reported in the iteration output, seemingly contradicting globalization procedure.

When the algorithm terminates, IPOPT will output a message to the screen. The following is a list of the possible output messages and a brief description.

Optimal Solution Found.

This message indicates that IPOPT found a (locally) optimal point within the desired tolerances.

Solved To Acceptable Level.

This indicates that the algorithm did not converge to the "desired" tolerances, but that it was able to obtain a point satisfying the "acceptable" tolerance level as specified by `acceptable-*` options. This may happen if the desired tolerances are too small for the current problem.

Feasible point for square problem found.

This message is printed if the problem is "square" (i.e., it has as many equality constraints as free variables) and IPOPT found a point that is feasible w.r.t. `constr_viol_tol`. It may, however, not be feasible w.r.t. `tol`.

Converged to a point of local infeasibility. Problem may be infeasible.

The restoration phase converged to a point that is a minimizer for the constraint violation (in the ℓ_1 -norm), but is not feasible for the original problem. This indicates that the problem may be infeasible (or at least that the algorithm is stuck at a locally infeasible point). The returned point (the minimizer of the constraint violation) might help you to find which constraint is causing the problem. If you believe that the NLP is feasible, it might help to start the optimization from a different point.

Search Direction is becoming Too Small.

This indicates that IPOPT is calculating very small step sizes and making very little progress. This could happen if the problem has been solved to the best numerical accuracy possible given the current scaling.

Iterates diverging; problem might be unbounded.

This message is printed if the max-norm of the iterates becomes larger than the value of the option [diverging_iterates_tol](#). This can happen if the problem is unbounded below and the iterates are diverging.

Stopping optimization at current point as requested by user.

This message is printed if either an interrupt signal was received (e.g., Ctrl+C was pressed) or the domain violation limit is reached.

Maximum Number of Iterations Exceeded.

This indicates that IPOPT has exceeded the maximum number of iterations as specified by the IPOPT option [max_iter](#) or the GAMS option [iterlim](#).

Maximum wallclock time exceeded.

This indicates that IPOPT has exceeded the maximum number of wallclock seconds as specified by the IPOPT option [max_wall_time](#) or the GAMS option [reslim](#).

Maximum CPU time exceeded.

This indicates that IPOPT has exceeded the maximum number of CPU seconds as specified by the IPOPT option [max_cpu_time](#).

Restoration Failed!

This indicates that the restoration phase failed to find a feasible point that was acceptable to the filter line search for the original problem. This could happen if the problem is highly degenerate, does not satisfy the constraint qualification, or if an external or extrinsic function in GAMS provides incorrect derivative information.

Error in step computation!

This message is printed if IPOPT is unable to compute a step towards a new iterate and the current iterate is not acceptable for the specified tolerances.

A possible reason is that a search direction could not be computed despite several attempts to modify the iteration matrix. Usually, the value of the regularization parameter then becomes too large.

Another reason is that the feasibility restoration phase could not be activated because the current iterate is not infeasible. Reasons for this again include that the problem is highly degenerate, badly scaled, or does not satisfy the constraint qualification. Before IPOPT 3.14, this resulted in a `Restoration_Failed` status code with message "Restoration phase is called at almost feasible point...".

Problem has too few degrees of freedom.

This indicates that your problem, as specified, has too few degrees of freedom. This can happen if you have too many equality constraints, or if you fix too many variables (IPOPT removes fixed variables by default, see also the option [fixed_variable_treatment](#)).

Not enough memory.

An error occurred while trying to allocate memory. The problem may be too large for your current memory and swap configuration. Sometimes it can help to choose a different [linear solver](#).

INTERNAL ERROR: Unknown SolverReturn value - Notify IPOPT Authors.

An unknown internal error has occurred. Please notify the authors of the GAMS/IPOPT link or IPOPT (refer to support@gams.com).

5.21.4.1 Diagnostic Tags for IPOPT

To print additional diagnostic tags for each iteration of IPOPT, set the options `print_info_string` to `yes`. With this, a tag will appear at the end of an iteration line with the following diagnostic meaning that are useful to flag difficulties for a particular IPOPT run. The following is a list of possible strings:

- **!**: Tighten resto tolerance if only slightly infeasible, see Sec. 3.3 in [256]
 - **A**: Current iteration is acceptable (alternate termination)
 - **a**: Perturbation for PD Singularity can't be done, assume singular, see Sec. 3.1 in [256]
 - **C**: Second Order Correction taken, see Sec. 2.4 in [256]
 - **Dh**: Hessian degenerate based on multiple iterations, see Sec. 3.1 in [256]
 - **Dhj**: Hessian/Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [256]
 - **Dj**: Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [256]
 - **dx**: δ_x perturbation too large, see Sec. 3.1 in [256]
 - **e**: Cutting back α due to evaluation error (in backtracking line search)
 - **F-**: Filter should be reset, but maximal resets exceeded, see Sec. 2.3 in [256]
 - **F+**: Resetting filter due to last few rejections of filter, see Sec. 2.3 in [256]
 - **L**: Degenerate Jacobian, δ_c already perturbed, see Sec. 3.1 in [256]
 - **l**: Degenerate Jacobian, δ_c perturbed, see Sec. 3.1 in [256]
 - **M**: Magic step taken for slack variables (in backtracking line search)
 - **Nh**: Hessian not yet degenerate, see Sec. 3.1 in [256]
 - **Nhj**: Hessian/Jacobian not yet degenerate, see Sec. 3.1 in [256]
 - **Nj**: Jacobian not yet degenerate, see Sec. 3.1 in [256]
 - **NW**: Warm start initialization failed (in Warm Start Initialization)
 - **q**: PD system possibly singular, attempt to improve solution quality, see Sec. 3.1 in [256]
 - **R**: Solution of restoration phase, see Sec. 3.3 in [256]
 - **S**: PD system possibly singular, accept current solution, see Sec. 3.1 in [256]
 - **s**: PD system singular, see Sec. 3.1 in [256]
 - **s**: Square Problem. Set multipliers to zero (default initialization routine)
 - **Tmax**: Trial θ is larger than θ_{\max} (filter parameter, Eq. (21) in [256])
 - **W**: Watchdog line search procedure successful, see Sec. 3.2 in [256]
 - **w**: Watchdog line search procedure unsuccessful, stopped, see Sec. 3.2 in [256]
 - **Wb**: Undoing most recent SR1 update, see Sec. 5.4.1 in [38]
 - **We**: Skip Limited-Memory Update in restoration phase, see Sec. 5.4.1 in [38]
 - **Wp**: Safeguard $B^0 = \sigma I$ for Limited-Memory Update, see Sec. 5.4.1 in [38]
 - **Wr**: Resetting Limited-Memory Update, see Sec. 5.4.1 in [38]
 - **Ws**: Skip Limited-Memory Update since $s^T y$ is not positive, see Sec. 5.4.1 in [38]
 - **WS**: Skip Limited-Memory Update since Δx is too small, see Sec. 5.4.1 in [38]
 - **y**: Dual infeasibility, use least square multiplier update (during IPOPT algorithm)
 - **z**: Apply correction to bound multiplier if too large (during IPOPT algorithm)
-

5.21.5 List of IPOPT Options

5.21.5.1 Termination

Option	Description	Default
acceptable_compl_inf_tol	"Acceptance" threshold for the complementarity conditions.	0.01
acceptable_constr_viol_tol	"Acceptance" threshold for the constraint violation.	0.01
acceptable_dual_inf_tol	"Acceptance" threshold for the dual infeasibility.	1e+10
acceptable_iter	Number of "acceptable" iterates before triggering termination.	0
acceptable_obj_change_tol	"Acceptance" stopping criterion based on objective function change.	1e+20
acceptable_tol	"Acceptable" convergence tolerance (relative).	1e-06
compl_inf_tol	Desired threshold for the complementarity conditions.	0.0001
constr_viol_tol	Desired threshold for the constraint and variable bound violation.	1e-06
diverging_iterates_tol	Threshold for maximal value of primal iterates.	1e+20
dual_inf_tol	Desired threshold for the dual infeasibility.	1
max_cpu_time	Maximum number of CPU seconds.	1e+20
max_iter	Maximum number of iterations.	GAMS iterlim
max_wall_time	Maximum number of walltime clock seconds.	GAMS reslim
mu_target	Desired value of complementarity.	0
tol	Desired convergence tolerance (relative).	1e-08
Options for expert users		
s_max	Scaling threshold for the NLP error.	100

5.21.5.2 Output

Option	Description	Default
inf_pr_output	Determines what value is printed in the "inf_pr" output column.	original
print_eval_error	Switch to enable printing information about function evaluation errors into the GAMS listing file.	yes
print_frequency_iter	Determines at which iteration frequency the summarizing iteration output line should be printed.	1
print_frequency_time	Determines at which time frequency the summarizing iteration output line should be printed.	0
print_info_string	Enables printing of additional info string at end of iteration output.	no
print_level	Output verbosity level.	5
print_options_mode	format in which to print options documentation	text
print_timing_statistics	Switch to print timing statistics.	no

Option	Description	Default
report_mininfeas_solution	Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible.	no
Options for expert users		
print_advanced_options	whether to print also advanced options	no

5.21.5.3 NLP

Option	Description	Default
bound_relax_factor	Factor for initial relaxation of the bounds.	1e-10
check_derivatives_for_naninf	Indicates whether it is desired to check for Nan/Inf in derivative matrices	no
fixed_variable_treatment	Determines how fixed variables should be handled.	make_parameter
honor_original_bounds	Indicates whether final points should be projected into original bounds.	no
jac_c_constant	Indicates whether to assume that all equality constraints are linear	no
jac_d_constant	Indicates whether to assume that all inequality constraints are linear	no
Options for expert users		
dependency_detection_with_rhs	Indicates if the right hand sides of the constraints should be considered in addition to gradients during dependency detection	no
dependency_detector	Indicates which linear solver should be used to detect linearly dependent equality constraints.	none
kappa_d	Weight for linear damping term (to handle one-sided bounds).	1e-05

5.21.5.4 NLP Scaling

Option	Description	Default
nlp_scaling_max_gradient	Maximum gradient after NLP scaling.	100
nlp_scaling_method	Select the technique used for scaling the NLP.	gradient-based if GAMS scaleopt is not set, otherwise none
nlp_scaling_min_value	Minimum value of gradient-based scaling values.	1e-08
Options for expert users		
nlp_scaling_constr_target_gradient	Target value for constraint function gradient size.	0
nlp_scaling_obj_target_gradient	Target value for objective function gradient size.	0

5.21.5.5 Initialization

Option	Description	Default
bound_frac	Desired minimum relative distance from the initial point to bound.	0.01
bound_mult_init_method	Initialization method for bound multipliers	constant
bound_mult_init_val	Initial value for the bound multipliers.	1
bound_push	Desired minimum absolute distance from the initial point to bound.	0.01
constr_mult_init_max	Maximum allowed least-square guess of constraint multipliers.	1000
least_square_init_duals	Least square initialization of all dual variables	no
least_square_init_primal	Least square initialization of the primal variables	no
slack_bound_frac	Desired minimum relative distance from the initial slack to bound.	0.01
slack_bound_push	Desired minimum absolute distance from the initial slack to bound.	0.01

5.21.5.6 Warm Start

Option	Description	Default
warm_start_bound_frac	same as bound_frac for the regular initializer	0.001
warm_start_bound_push	same as bound_push for the regular initializer	0.001
warm_start_init_point	Warm-start for initial point	yes, if run on modified model instance (e.g., from GUSS), otherwise no
warm_start_mult_bound_push	same as mult_bound_push for the regular initializer	0.001
warm_start_mult_init_max	Maximum initial value for the equality multipliers.	1e+06
warm_start_slack_bound_frac	same as slack_bound_frac for the regular initializer	0.001
warm_start_slack_bound_push	same as slack_bound_push for the regular initializer	0.001
Options for expert users		
warm_start_target_mu		0

5.21.5.7 Miscellaneous

Option	Description	Default
timing_statistics	Indicates whether to measure time spend in components of Ipopt and NLP evaluation	no
Options for expert users		
replace_bounds	Whether all variable bounds should be replaced by inequality constraints	no

5.21.5.8 Barrier Parameter Update

Option	Description	Default
adaptive_mu_globalization	Globalization strategy for the adaptive mu selection mode.	obj-constr-filter
barrier_tol_factor	Factor for mu in barrier stop test.	10
fixed_mu_oracle	Oracle for the barrier parameter when switching to fixed mode.	average_compl
mu_init	Initial value for the barrier parameter.	0.1
mu_linear_decrease_factor	Determines linear decrease rate of barrier parameter.	0.2
mu_max	Maximum value for barrier parameter.	100000
mu_max_fact	Factor for initialization of maximum value for barrier parameter.	1000
mu_min	Minimum value for barrier parameter.	1e-11
mu_oracle	Oracle for a new barrier parameter in the adaptive strategy.	quality-function
mu_strategy	Update strategy for barrier parameter.	adaptive
mu_superlinear_decrease_power	Determines superlinear decrease rate of barrier parameter.	1.5
quality_function_max_section_steps	Maximum number of search steps during direct search procedure determining the optimal centering parameter.	8
Options for expert users		
adaptive_mu_kkt_norm_type	Norm used for the KKT error in the adaptive mu globalization strategies.	2-norm-squared
adaptive_mu_kkterror_red_fact	Sufficient decrease factor for "kkt-error" globalization strategy.	0.9999
adaptive_mu_kkterror_red_iters	Maximum number of iterations requiring sufficient progress.	4
adaptive_mu_monotone_init_factor	Determines the initial value of the barrier parameter when switching to the monotone mode.	0.8
adaptive_mu_restore_previous_iterate	Indicates if the previous accepted iterate should be restored if the monotone mode is entered.	no
filter_margin_fact	Factor determining width of margin for obj-constr-filter adaptive globalization strategy.	1e-05
filter_max_margin	Maximum width of margin in obj-constr-filter adaptive globalization strategy.	1
mu_allow_fast_monotone_decrease	Allow skipping of barrier problem if barrier test is already met.	yes
quality_function_balancing_term	The balancing term included in the quality function for centrality.	none
quality_function_centrality	The penalty term for centrality that is included in quality function.	none
quality_function_norm_type	Norm used for components of the quality function.	2-norm-squared
quality_function_section_qf_tol	Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space).	0

Option	Description	Default
<code>quality_function_section_sigma_tol</code>	Tolerance for the section search procedure determining the optimal centering parameter (in sigma space).	0.01
<code>sigma_max</code>	Maximum value of the centering parameter.	100
<code>sigma_min</code>	Minimum value of the centering parameter.	1e-06
<code>tau_min</code>	Lower bound on fraction-to-the-boundary parameter tau.	0.99

5.21.5.9 Line Search

Option	Description	Default
<code>accept_every_trial_step</code>	Always accept the first trial step.	no
<code>alpha_for_y</code>	Method to determine the step size for constraint multipliers (alpha.y) .	primal
<code>alpha_for_y_tol</code>	Tolerance for switching to full equality multiplier steps.	10
<code>max_soc</code>	Maximum number of second order correction trial steps at each iteration.	4
<code>recalc_y</code>	Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates.	no
<code>recalc_y_feas_tol</code>	Feasibility threshold for recomputation of multipliers.	1e-06
<code>soc_method</code>	Ways to apply second order correction	0
<code>watchdog_shortened_iter_trigger</code>	Number of shortened iterations that trigger the watchdog.	10
<code>watchdog_trial_iter_max</code>	Maximum number of watchdog iterations.	3
Options for expert users		
<code>accept_after_max_steps</code>	Accept a trial point after maximal this number of steps even if it does not satisfy line search conditions.	-1
<code>alpha_min_frac</code>	Safety factor for the minimal step size (before switching to restoration phase).	0.05
<code>alpha_red_factor</code>	Fractional reduction of the trial step size in the backtracking line search.	0.5
<code>constraint_violation_norm_type</code>	Norm to be used for the constraint violation in the line search.	1-norm
<code>corrector_compl_avrg_red_fact</code>	Complementarity tolerance factor for accepting corrector step.	1
<code>corrector_type</code>	The type of corrector steps that should be taken.	none
<code>delta</code>	Multiplier for constraint violation in the switching rule.	1
<code>eta_phi</code>	Relaxation factor in the Armijo condition.	1e-08
<code>filter_reset_trigger</code>	Number of iterations that trigger the filter reset.	5
<code>gamma_phi</code>	Relaxation factor in the filter margin for the barrier function.	1e-08
<code>gamma_theta</code>	Relaxation factor in the filter margin for the constraint violation.	1e-05

Option	Description	Default
kappa_sigma	Factor limiting the deviation of dual variables from primal estimates.	1e+10
kappa_soc	Factor in the sufficient reduction rule for second order correction.	0.99
line_search_method	Globalization method used in backtracking line search	filter
max_filter_resets	Maximal allowed number of filter resets	5
nu_inc	Increment of the penalty parameter.	0.0001
nu_init	Initial value of the penalty parameter.	1e-06
obj_max_inc	Determines the upper bound on the acceptable increase of barrier objective function.	5
rho	Value in penalty parameter update formula.	0.1
s_phi	Exponent for linear barrier function model in the switching rule.	2.3
s_theta	Exponent for current constraint violation in the switching rule.	1.1
skip_corr_if_neg_curv	Whether to skip the corrector step in negative curvature iteration.	yes
skip_corr_in_monotone_mode	Whether to skip the corrector step during monotone barrier parameter mode.	yes
slack_move	Correction size for very small slacks.	1.81899e-12
theta_max_fact	Determines upper bound for constraint violation in the filter.	10000
theta_min_fact	Determines constraint violation threshold in the switching rule.	0.0001
tiny_step_tol	Tolerance for detecting numerically insignificant steps.	2.22045e-15
tiny_step_y_tol	Tolerance for quitting because of numerically insignificant steps.	0.01

5.21.5.10 Linear Solver

Option	Description	Default
hslslib	Name of library containing HSL routines for load at runtime	libhsl.so (Linux), libhsl.dylib (macOS), libhsl.dll (Windows)
linear_scaling_on_demand	Flag indicating that linear scaling is only done if it seems required.	yes
linear_solver	Linear solver used for step computations.	ma27, if IpoptH, otherwise mumps
linear_system_scaling	Method for scaling the linear system.	mc19, if IpoptH, otherwise none
pardisolib	Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime	libpardiso.so (Linux), libpardiso.dylib (macOS), libpardiso.dll (Windows)

5.21.5.11 Step Calculation

Option	Description	Default
<code>fast_step_computation</code>	Indicates if the linear system should be solved quickly.	no
<code>first_hessian_perturbation</code>	Size of first x-s perturbation tried.	0.0001
<code>jacobian_regularization_value</code>	Size of the regularization for rank-deficient constraint Jacobians.	1e-08
<code>max_hessian_perturbation</code>	Maximum value of regularization parameter for handling negative curvature.	1e+20
<code>max_refinement_steps</code>	Maximum number of iterative refinement steps per linear system solve.	10
<code>mehrotra_algorithm</code>	Indicates whether to do Mehrotra's predictor-corrector algorithm.	no
<code>min_hessian_perturbation</code>	Smallest perturbation of the Hessian block.	1e-20
<code>min_refinement_steps</code>	Minimum number of iterative refinement steps per linear system solve.	1
<code>neg_curv_test_reg</code>	Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).	yes
<code>neg_curv_test_tol</code>	Tolerance for heuristic to ignore wrong inertia.	0
<code>perturb_dec_fact</code>	Decrease factor for x-s perturbation.	0.333333
<code>perturb_inc_fact</code>	Increase factor for x-s perturbation.	8
<code>perturb_inc_fact_first</code>	Increase factor for x-s perturbation for very first perturbation.	100
Options for expert users		
<code>jacobian_regularization_exponent</code>	Exponent for mu in the regularization for rank-deficient constraint Jacobians.	0.25
<code>perturb_always_cd</code>	Active permanent perturbation of constraint linearization.	no
<code>residual_improvement_factor</code>	Minimal required reduction of residual test ratio in iterative refinement.	1
<code>residual_ratio_max</code>	Iterative refinement tolerance	1e-10
<code>residual_ratio_singular</code>	Threshold for declaring linear system singular after failed iterative refinement.	1e-05

5.21.5.12 Restoration Phase

Option	Description	Default
<code>bound_mult_reset_threshold</code>	Threshold for resetting bound multipliers after the restoration phase.	1000
<code>constr_mult_reset_threshold</code>	Threshold for resetting equality and inequality multipliers after restoration phase.	0
<code>evaluate_orig_obj_at_resto_trial</code>	Determines if the original objective function should be evaluated at restoration phase trial points.	yes
<code>expect_infeasible_problem</code>	Enable heuristics to quickly detect an infeasible problem.	no
<code>expect_infeasible_problem_ctol</code>	Threshold for disabling "expect_infeasible_problem" option.	0.001
<code>expect_infeasible_problem_ytol</code>	Multiplier threshold for activating "expect_infeasible_problem" option.	1e+08
<code>required_infeasibility_reduction</code>	Required reduction of infeasibility before leaving restoration phase.	0.9

Option	Description	Default
soft_resto_pderror_reduction_factor	Required reduction in primal-dual error in the soft restoration phase.	0.9999
start_with_resto	Whether to switch to restoration phase in first iteration.	no
Options for expert users		
max_resto_iter	Maximum number of successive iterations in restoration phase.	3000000
max_soft_resto_iters	Maximum number of iterations performed successively in soft restoration phase.	10
resto_failure_feasibility_threshold	Threshold for primal infeasibility to declare failure of restoration phase.	0
resto_penalty_parameter	Penalty parameter in the restoration phase objective function.	1000
resto_proximity_weight	Weighting factor for the proximity term in restoration phase objective.	1

5.21.5.13 Hessian Approximation

Option	Description	Default
hessian_approximation	Indicates what Hessian information is to be used.	exact
limited_memory_init_val	Value for B0 in low-rank update.	1
limited_memory_init_val_max	Upper bound on value for B0 in low-rank update.	1e+08
limited_memory_init_val_min	Lower bound on value for B0 in low-rank update.	1e-08
limited_memory_initialization	Initialization strategy for the limited memory quasi-Newton approximation.	scalar1
limited_memory_max_history	Maximum size of the history for the limited quasi-Newton Hessian approximation.	6
limited_memory_max_skipping	Threshold for successive iterations where update is skipped.	2
limited_memory_special_for_resto	Determines if the quasi-Newton updates should be special during the restoration phase.	no
limited_memory_update_type	Quasi-Newton update formula for the limited memory quasi-Newton approximation.	bfgs
Options for expert users		
hessian_approximation_space	Indicates in which subspace the Hessian information is to be approximated.	nonlinear-variables
limited_memory_aug_solver	Strategy for solving the augmented system for low-rank Hessian.	sherman-morrison

5.21.5.14 MA27 Linear Solver

Option	Description	Default
ma27_la_init_factor	Real workspace memory for MA27.	5
ma27_liw_init_factor	Integer workspace memory for MA27.	5

Option	Description	Default
ma27_meminc_factor	Increment factor for workspace size for MA27.	2
ma27_pivotl	Pivot tolerance for the linear solver MA27.	1e-08
ma27_pivotlmax	Maximum pivot tolerance for the linear solver MA27.	0.0001
Options for expert users		
ma27_ignore_singularity	Whether to use MA27's ability to solve a linear system even if the matrix is singular.	no
ma27_skip_inertia_check	Whether to always pretend that inertia is correct.	no

5.21.5.15 MA57 Linear Solver

Option	Description	Default
ma57_automatic_scaling	Controls whether to enable automatic scaling in MA57	no
ma57_block_size	Controls block size used by Level 3 BLAS in MA57BD	16
ma57_node_amalgamation	Node amalgamation parameter	16
ma57_pivot_order	Controls pivot order in MA57	5
ma57_pivotl	Pivot tolerance for the linear solver MA57.	1e-08
ma57_pivotlmax	Maximum pivot tolerance for the linear solver MA57.	0.0001
ma57_pre_alloc	Safety factor for work space memory allocation for the linear solver MA57.	1.05
ma57_small_pivot_flag	Handling of small pivots	0

5.21.5.16 MA77 Linear Solver

Option	Description	Default
ma77_buffer_lpage	Number of scalars per MA77 in-core buffer page in the out-of-core solver MA77	4096
ma77_buffer_npage	Number of pages that make up MA77 buffer	1600
ma77_file_size	Target size of each temporary file for MA77, scalars per type	2097152
ma77_maxstore	Maximum storage size for MA77 in-core mode	0
ma77_nemin	Node Amalgamation parameter	8
ma77_order	Controls type of ordering used by MA77	metis
ma77_print_level	Debug printing level for the linear solver MA77	-1
ma77_small	Zero Pivot Threshold	1e-20
ma77_static	Static Pivoting Threshold	0
ma77_u	Pivoting Threshold	1e-08
ma77_umax	Maximum Pivoting Threshold	0.0001

5.21.5.17 MA86 Linear Solver

Option	Description	Default
ma86_nemin	Node Amalgamation parameter	32
ma86_order	Controls type of ordering	auto
ma86_print_level	Debug printing level	-1
ma86_scaling	Controls scaling of matrix	mc64
ma86_small	Zero Pivot Threshold	1e-20
ma86_static	Static Pivoting Threshold	0
ma86_u	Pivoting Threshold	1e-08
ma86_umax	Maximum Pivoting Threshold	0.0001

5.21.5.18 MA97 Linear Solver

Option	Description	Default
ma97_nemin	Node Amalgamation parameter	8
ma97_order	Controls type of ordering	auto
ma97_print_level	Debug printing level	-1
ma97_scaling	Specifies strategy for scaling	dynamic
ma97_small	Zero Pivot Threshold	1e-20
ma97_u	Pivoting Threshold	1e-08
ma97_umax	Maximum Pivoting Threshold	0.0001
Options for expert users		
ma97_scaling1	First scaling.	mc64
ma97_scaling2	Second scaling.	mc64
ma97_scaling3	Third scaling.	mc64
ma97_solve_blas3	Controls if blas2 or blas3 routines are used for solve	no
ma97_switch1	First switch, determine when ma97_scaling1 is enabled.	od_hd_reuse
ma97_switch2	Second switch, determine when ma97_scaling2 is enabled.	never
ma97_switch3	Third switch, determine when ma97_scaling3 is enabled.	never

5.21.5.19 Pardiso (pardiso-project.org) Linear Solver

Option	Description	Default
pardiso_matching_strategy	Matching strategy to be used by Pardiso	complete+2x2
pardiso_max_iterative_refinement_steps	Limit on number of iterative refinement steps.	0

Option	Description	Default
pardiso_msglvl	Pardiso message level	0
pardiso_order	Controls the fill-in reduction ordering algorithm for the input matrix.	metis
Options for expert users		
pardiso_iter_coarse_size	Maximum Size of Coarse Grid Matrix	5000
pardiso_iter_dropping_factor	dropping value for incomplete factor	0.5
pardiso_iter_dropping_schur	dropping value for sparsify schur complement factor	0.1
pardiso_iter_inverse_norm_factor		5e+06
pardiso_iter_max_levels	Maximum Size of Grid Levels	10
pardiso_iter_max_row_fill	max fill for each row	10000000
pardiso_iter_relative_tol	Relative Residual Convergence	1e-06
pardiso_iterative	Switch for iterative solver in Pardiso library	no
pardiso_max_droptol_corrections	Maximal number of decreases of drop tolerance during one solve.	4
pardiso_max_iter	Maximum number of Krylov-Subspace Iteration	500
pardiso_redo_symbolic_fact_only_if_inertia_wrong	Toggle for handling case when elements were perturbed by Pardiso.	no
pardiso_repeated_perturbation_means_singular	Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization.	no
pardiso_skip_inertia_check	Whether to pretend that inertia is correct.	no

5.21.5.20 Pardiso (MKL) Linear Solver

Option	Description	Default
pardisomkl_matching_strategy	Matching strategy to be used by Pardiso	complete+2x2
pardisomkl_max_iterative_refinement_steps	Limit on number of iterative refinement steps.	1
pardisomkl_msglvl	Pardiso message level	0
pardisomkl_order	Controls the fill-in reduction ordering algorithm for the input matrix.	metis
Options for expert users		
pardisomkl_redo_symbolic_fact_only_if_inertia_wrong	Toggle for handling case when elements were perturbed by Pardiso.	no
pardisomkl_repeated_perturbation_means_singular	Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization.	no
pardisomkl_skip_inertia_check	Whether to pretend that inertia is correct.	no

5.21.5.21 Mumps Linear Solver

Option	Description	Default
mumps_mem_percent	Percentage increase in the estimated working space for MUMPS.	1000
mumps_permuting_scaling	Controls permuting and scaling in MUMPS	7
mumps_pivot_order	Controls pivot order in MUMPS	7
mumps_pivtol	Pivot tolerance for the linear solver MUMPS.	1e-06
mumps_pivtolmax	Maximum pivot tolerance for the linear solver MUMPS.	0.1
mumps_scaling	Controls scaling in MUMPS	77
Options for expert users		
mumps_dep_tol	Threshold to consider a pivot at zero in detection of linearly dependent constraints with MUMPS.	0

5.21.6 Detailed Options Description

accept_after_max_steps (*advanced*): Accept a trial point after maximal this number of steps even if it does not satisfy line search conditions. [↔](#)

Setting this to -1 disables this option.

Range: $\{-1, \dots, \infty\}$

Default: -1

accept_every_trial_step: Always accept the first trial step. [↔](#)

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Range: yes, no

Default: no

acceptable_compl_inf_tol: "Acceptance" threshold for the complementarity conditions. [↔](#)

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also `acceptable_tol`.

Range: $(0, \infty]$

Default: 0.01

acceptable_constr_viol_tol: "Acceptance" threshold for the constraint violation. [↔](#)

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also `acceptable_tol`.

Range: $(0, \infty]$

Default: 0.01

acceptable_dual_inf_tol: "Acceptance" threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also `acceptable_tol`.

Range: $(0, \infty]$

Default: `1e+10`

acceptable_iter: Number of "acceptable" iterates before triggering termination. [↔](#)

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Range: $\{0, \dots, \infty\}$

Default: `0`

acceptable_obj_change_tol: "Acceptance" stopping criterion based on objective function change. [↔](#)

If the relative change of the objective function (scaled by $\text{Max}(1, |f(x)|)$) is less than this value, this part of the acceptable tolerance termination is satisfied; see also `acceptable_tol`. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Range: $[0, \infty]$

Default: `1e+20`

acceptable_tol: "Acceptable" convergence tolerance (relative). [↔](#)

Determines which (scaled) overall optimality error is considered to be "acceptable". There are two levels of termination criteria. If the usual "desired" tolerances (see `tol`, `dual_inf_tol` etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Range: $(0, \infty]$

Default: `1e-06`

adaptive_mu_globalization: Globalization strategy for the adaptive mu selection mode. [↔](#)

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive".)

value	meaning
kkt-error	nonmonotone decrease of kkt-error
obj-constr-filter	2-dim filter for objective and constraint violation
never-monotone-mode	disables globalization

Default: `obj-constr-filter`

adaptive_mu_kkt_norm_type (*advanced*): Norm used for the KKT error in the adaptive mu globalization strategies. [↔](#)

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this option is also used in the QualityFunctionMuOracle.

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)
2-norm	use 2-norm

Default: 2-norm-squared

adaptive_mu_kkterror_red_fact (*advanced*): Sufficient decrease factor for "kkt-error" globalization strategy. [↔](#)

For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: (0, 1)

Default: 0.9999

adaptive_mu_kkterror_red_iters (*advanced*): Maximum number of iterations requiring sufficient progress. [↔](#)

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkterror_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Range: {0, ..., ∞}

Default: 4

adaptive_mu_monotone_init_factor (*advanced*): Determines the initial value of the barrier parameter when switching to the monotone mode. [↔](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Range: (0, ∞]

Default: 0.8

adaptive_mu_restore_previous_iterate (*advanced*): Indicates if the previous accepted iterate should be restored if the monotone mode is entered. [↔](#)

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Range: yes, no

Default: no

alpha_for_y: Method to determine the step size for constraint multipliers (alpha_y) . [↔](#)

value	meaning
primal	use primal step size
bound-mult	use step size for the bound multipliers (good for LPs)
min	use the min of primal and bound multipliers
max	use the max of primal and bound multipliers
full	take a full step of size one
min-dual-infeas	choose step size minimizing new dual infeasibility
safer-min-dual-infeas	like "min_dual_infeas", but safeguarded by "min" and "max"
primal-and-full	use the primal step size, and full step if $\delta_x \leq \alpha_{\text{for_y_tol}}$
dual-and-full	use the dual step size, and full step if $\delta_x \leq \alpha_{\text{for_y_tol}}$
acceptor	Call LSacceptor to get step size for y

Default: primal

alpha_for_y_tol: Tolerance for switching to full equality multiplier steps. \leftrightarrow

This is only relevant if "alpha_for_y" is chosen "primal-and-full" or "dual-and-full". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Range: $[0, \infty]$

Default: 10

alpha_min_frac (*advanced*): Safety factor for the minimal step size (before switching to restoration phase). \leftrightarrow

This is γ_{alpha} in Eqn. (20) in the implementation paper.

Range: $(0, 1)$

Default: 0.05

alpha_red_factor (*advanced*): Fractional reduction of the trial step size in the backtracking line search. \leftrightarrow

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: $(0, 1)$

Default: 0.5

barrier_tol_factor: Factor for μ in barrier stop test. \leftrightarrow

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "barrier_tol_factor". This option is also used in the adaptive μ strategy during the monotone mode. This is κ_{epsilon} in implementation paper.

Range: $(0, \infty]$

Default: 10

bound_frac: Desired minimum relative distance from the initial point to bound. \leftrightarrow

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_push"). (This is κ_2 in Section 3.6 of implementation paper.)

Range: $(0, 0.5]$

Default: 0.01

bound_mult_init_method: Initialization method for bound multipliers \leftrightarrow

This option defines how the iterates for the bound multipliers are initialized. If "constant" is chosen, then all bound multipliers are initialized to the value of "bound_mult_init_val". If "mu-based" is chosen, the each value is initialized to the the value of "mu_init" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.

value	meaning
constant	set all bound multipliers to the value of bound_mult_init_val
mu-based	initialize to mu_init/x_slack

Default: constant

bound_mult_init_val: Initial value for the bound multipliers. [↔](#)

All dual variables corresponding to bound constraints are initialized to this value.

Range: $(0, \infty]$

Default: 1

bound_mult_reset_threshold: Threshold for resetting bound multipliers after the restoration phase. [↔](#)

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Range: $[0, \infty]$

Default: 1000

bound_push: Desired minimum absolute distance from the initial point to bound. [↔](#)

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Range: $(0, \infty]$

Default: 0.01

bound_relax_factor: Factor for initial relaxation of the bounds. [↔](#)

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. Additionally, the constraint violation tolerance constr_viol_tol is used to bound the relaxation by an absolute value. If it is set to zero, then the bounds relaxation is disabled. See Eqn.(35) in implementation paper. Note that the constraint violation reported by Ipopt at the end of the solution process does not include violations of the original (non-relaxed) variable bounds. See also option honor_original_bounds.

Range: $[0, \infty]$

Default: 1e-10

check_derivatives_for_naninf: Indicates whether it is desired to check for Nan/Inf in derivative matrices [↔](#)

Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an invalid number is detected, the matrix is written to output with `print_level` corresponding to `J_MORE_DETAILED`; so beware of large output!

Range: yes, no

Default: no

compl_inf_tol: Desired threshold for the complementarity conditions. [↔](#)

Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Range: $(0, \infty]$

Default: 0.0001

constr_mult_init_max: Maximum allowed least-square guess of constraint multipliers. [↔](#)

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint multipliers are set to zero. This options is also used when initializing the restoration phase. By default, "resto.constr_mult_init_max" (the one used in `RestoIterateInitializer`) is set to zero.

Range: $[0, \infty]$

Default: 1000

constr_mult_reset_threshold: Threshold for resetting equality and inequality multipliers after restoration phase. [↔](#)

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Range: $[0, \infty]$

Default: 0

constr_viol_tol: Desired threshold for the constraint and variable bound violation. [↔](#)

Absolute tolerance on the constraint and variable bound violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold. If option `bound_relax_factor` is not zero 0, then Ipopt relaxes given variable bounds. The value of `constr_viol_tol` is used to restrict the absolute amount of this bound relaxation.

Range: $(0, \infty]$

Default: 1e-06

constraint_violation_norm_type (*advanced*): Norm to be used for the constraint violation in the line search. [↔](#)

Determines which norm should be used when the algorithm computes the constraint violation in the line search.

value	meaning
1-norm	use the 1-norm
2-norm	use the 2-norm
max-norm	use the infinity norm

Default: 1-norm

corrector_compl_avrg_red_fact (*advanced*): Complementarity tolerance factor for accepting corrector step. [↔](#)

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Range: $(0, \infty]$

Default: 1

corrector_type (*advanced*): The type of corrector steps that should be taken. [↔](#)

If "mu_strategy" is "adaptive", this option determines what kind of corrector steps should be tried. Changing this option is experimental.

value	meaning
none	no corrector
affine	corrector step towards mu=0
primal-dual	corrector step towards current mu

Default: none

delta (*advanced*): Multiplier for constraint violation in the switching rule. [↔](#)

See Eqn. (19) in the implementation paper.

Range: $(0, \infty]$

Default: 1

dependency_detection_with_rhs (*advanced*): Indicates if the right hand sides of the constraints should be considered in addition to gradients during dependency detection [↔](#)

Range: yes, no

Default: no

dependency_detector (*advanced*): Indicates which linear solver should be used to detect linearly dependent equality constraints. [↔](#)

This is experimental and does not work well.

value	meaning
none	don't check; no extra work at beginning
mumps	use MUMPS

Default: none

diverging_iterates_tol: Threshold for maximal value of primal iterates. [↔](#)

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Range: $(0, \infty]$

Default: 1e+20

dual_inf_tol: Desired threshold for the dual infeasibility. [↔](#)

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Range: $(0, \infty]$

Default: 1

eta_phi (*advanced*): Relaxation factor in the Armijo condition. [↔](#)

See Eqn. (20) in the implementation paper.

Range: $(0, 0.5)$

Default: 1e-08

evaluate_orig_obj_at_resto_trial: Determines if the original objective function should be evaluated at restoration phase trial points. [↔](#)

Enabling this option makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Range: yes, no

Default: yes

expect_infeasible_problem: Enable heuristics to quickly detect an infeasible problem. [↔](#)

This options is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Range: yes, no

Default: no

expect_infeasible_problem_ctol: Threshold for disabling "expect_infeasible_problem" option. [↔](#)

If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this options is set to 0.

Range: $[0, \infty]$

Default: 0.001

expect_infeasible_problem_ytol: Multiplier threshold for activating "expect_infeasible_problem" option. [↔](#)

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Range: $(0, \infty]$

Default: 1e+08

fast_step_computation: Indicates if the linear system should be solved quickly. [↔](#)

If enabled, the algorithm assumes that the linear system that is solved to obtain the search direction is solved sufficiently well. In that case, no residuals are computed to verify the solution and the computation of the search direction is a little faster.

Range: yes, no

Default: no

filter_margin_fact (*advanced*): Factor determining width of margin for obj-constr-filter adaptive globalization strategy. [↔](#)

When using the adaptive globalization strategy, "obj-constr-filter", sufficient progress for a filter entry is defined as follows: $(\text{new obj}) < (\text{filter obj}) - \text{filter_margin_fact} * (\text{new constr-viol})$ OR $(\text{new constr-viol}) < (\text{filter constr-viol}) - \text{filter_margin_fact} * (\text{new constr-viol})$. For the description of the "kkt-error-filter" option see "filter_max_margin".

Range: $(0, 1)$

Default: 1e-05

filter_max_margin (*advanced*): Maximum width of margin in obj-constr-filter adaptive globalization strategy. [↔](#)

Range: $(0, \infty]$

Default: 1

filter_reset_trigger (*advanced*): Number of iterations that trigger the filter reset. [↔](#)

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: $\{1, \dots, \infty\}$

Default: 5

first_hessian_perturbation: Size of first x-s perturbation tried. [↔](#)

The first value tried for the x-s perturbation in the inertia correction scheme. This is delta_0 in the implementation paper.

Range: $(0, \infty]$

Default: 0.0001

fixed_mu_oracle: Oracle for the barrier parameter when switching to fixed mode. [↔](#)

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if "adaptive" is selected for option "mu_strategy".)

value	meaning
probing	Mehrotra's probing heuristic
loqo	LOQO's centrality rule
quality-function	minimize a quality function
average_compl	base on current average complementarity

Default: average_compl

fixed_variable_treatment: Determines how fixed variables should be handled. [↔](#)

The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter(_nodual)" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to "bound_relax_factor"). For all but "make_parameter_nodual", bound multipliers are computed for the fixed variables.

value	meaning
make_parameter	Remove fixed variable from optimization variables
make_parameter_nodual	Remove fixed variable from optimization variables and do not compute bound multipliers for fixed variables
make_constraint	Add equality constraints fixing variables
relax_bounds	Relax fixing bound constraints

Default: make_parameter

gamma_phi (*advanced*): Relaxation factor in the filter margin for the barrier function. [↔](#)

See Eqn. (18a) in the implementation paper.

Range: (0, 1)

Default: 1e-08

gamma_theta (*advanced*): Relaxation factor in the filter margin for the constraint violation. [↔](#)

See Eqn. (18b) in the implementation paper.

Range: (0, 1)

Default: 1e-05

hessian_approximation: Indicates what Hessian information is to be used. [↔](#)

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

value	meaning
exact	Use second derivatives provided by the NLP.
limited-memory	Perform a limited-memory quasi-Newton approximation

Default: exact

hessian_approximation_space (*advanced*): Indicates in which subspace the Hessian information is to be approximated. ↩

value	meaning
nonlinear-variables	only in space of nonlinear variables.
all-variables	in space of all variables (without slacks)

Default: nonlinear-variables

honor_original_bounds: Indicates whether final points should be projected into original bounds. ↩

Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provide original bounds after the optimization. Note that violations of constraints and complementarity reported by Ipopt at the end of the solution process are for the non-projected point.

Range: yes, no

Default: no

hllib: Name of library containing HSL routines for load at runtime ↩

Range: string

Default: libhsl.so (Linux), libhsl.dylib (macOS), libhsl.dll (Windows)

inf_pr_output: Determines what value is printed in the "inf_pr" output column. ↩

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

value	meaning
internal	max-norm of violation of internal equality constraints
original	maximal constraint violation in original NLP

Default: original

jac_c_constant: Indicates whether to assume that all equality constraints are linear ↩

Activating this option will cause Ipopt to ask for the Jacobian of the equality constraints only once from the NLP and reuse this information later.

Range: yes, no

Default: no

jac_d_constant: Indicates whether to assume that all inequality constraints are linear ↩

Activating this option will cause Ipopt to ask for the Jacobian of the inequality constraints only once from the NLP and reuse this information later.

Range: yes, no

Default: no

jacobian_regularization_exponent (*advanced*): Exponent for mu in the regularization for rank-deficient constraint Jacobians. [↔](#)

This is kappa_c in the implementation paper.

Range: $[0, \infty]$

Default: 0.25

jacobian_regularization_value: Size of the regularization for rank-deficient constraint Jacobians. [↔](#)

This is bar delta_c in the implementation paper.

Range: $[0, \infty]$

Default: 1e-08

kappa_d (*advanced*): Weight for linear damping term (to handle one-sided bounds). [↔](#)

See Section 3.7 in implementation paper.

Range: $[0, \infty]$

Default: 1e-05

kappa_sigma (*advanced*): Factor limiting the deviation of dual variables from primal estimates. [↔](#)

If the dual variables deviate from their primal estimates, a correction is performed. See Eqn. (16) in the implementation paper. Setting the value to less than 1 disables the correction.

Range: $(0, \infty]$

Default: 1e+10

kappa_soc (*advanced*): Factor in the sufficient reduction rule for second order correction. [↔](#)

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. See Step A-5.9 of Algorithm A in the implementation paper.

Range: $(0, \infty]$

Default: 0.99

least_square_init_duals: Least square initialization of all dual variables [↔](#)

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least bound_mult_init_val. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP. This overwrites option "bound_mult_init_method".

value	meaning
no	use bound_mult_init_val and least-square equality constraint multipliers
yes	overwrite user-provided point with least-square estimates

Default: no

least_square_init_primal: Least square initialization of the primal variables [↔](#)

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s) to fit the linearized equality and inequality constraints. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP.

value	meaning
no	take user-provided point
yes	overwrite user-provided point with least-square estimates

Default: no

limited_memory_aug_solver (*advanced*): Strategy for solving the augmented system for low-rank Hessian. [↔](#)

value	meaning
sherman-morrison	use Sherman-Morrison formula
extended	use an extended augmented system

Default: sherman-morrison

limited_memory_init_val: Value for B0 in low-rank update. [↔](#)

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: $(0, \infty]$

Default: 1

limited_memory_init_val_max: Upper bound on value for B0 in low-rank update. [↔](#)

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: $(0, \infty]$

Default: 1e+08

limited_memory_init_val_min: Lower bound on value for B0 in low-rank update. [↔](#)

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: $(0, \infty]$

Default: 1e-08

limited_memory_initialization: Initialization strategy for the limited memory quasi-Newton approximation. [↔](#)

Determines how the diagonal Matrix B.0 as the first term in the limited memory approximation should be computed.

value	meaning
scalar1	$\sigma = s^T y / s^T s$
scalar2	$\sigma = y^T y / s^T y$
scalar3	arithmetic average of scalar1 and scalar2
scalar4	geometric average of scalar1 and scalar2
constant	$\sigma = \text{limited_memory_init_val}$

Default: scalar1

limited_memory_max_history: Maximum size of the history for the limited quasi-Newton Hessian approximation. [↔](#)

This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Range: $\{0, \dots, \infty\}$

Default: 6

limited_memory_max_skipping: Threshold for successive iterations where update is skipped. [↔](#)

If the update is skipped more than this number of successive iterations, the quasi-Newton approximation is reset.

Range: $\{1, \dots, \infty\}$

Default: 2

limited_memory_special_for_resto: Determines if the quasi-Newton updates should be special during the restoration phase. [↔](#)

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Range: yes, no

Default: no

limited_memory_update_type: Quasi-Newton update formula for the limited memory quasi-Newton approximation. [↔](#)

value	meaning
bfgs	BFGS update (with skipping)
sr1	SR1 (not working well)

Default: bfgs

line_search_method (*advanced*): Globalization method used in backtracking line search [↔](#)

Only the "filter" choice is officially supported. But sometimes, good results might be obtained with the other choices.

value	meaning
filter	Filter method
cg-penalty	Chen-Goldfarb penalty function
penalty	Standard penalty function

Default: filter

linear_scaling_on_demand: Flag indicating that linear scaling is only done if it seems required. ↔

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Range: yes, no

Default: yes

linear_solver: Linear solver used for step computations. ↔

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, that MA27, MA57, MA86, and MA97 are included with a commercially supported GAMS/IpoptH license only. To use MA27, MA57, MA86, or MA97 with GAMS/Ipopt, or to use HSL_MA77, a HSL library needs to be provided by the user. To use Pardiso from pardiso-project.org, a Pardiso library needs to be provided by the user. **ATTENTION:** Before Ipopt 3.14 (GAMS 36), value *pardiso* specified to use Pardiso from Intel MKL. With GAMS 36, this value has been renamed to *pardisomkl*.

value	meaning
ma27	IpoptH: use the Harwell routine MA27; Ipopt: load the Harwell routine MA27 from user-provided library
ma57	IpoptH: use the Harwell routine MA57; Ipopt: load the Harwell routine MA57 from user-provided library
ma77	load the Harwell routine HSL_MA77 from user-provided library
ma86	IpoptH: use the Harwell routine HSL_MA86; Ipopt: load the Harwell routine HSL_MA86 from user-provided library
ma97	IpoptH: use the Harwell routine HSL_MA97; Ipopt: load the Harwell routine HSL_MA97 from user-provided library
pardiso	load the Pardiso package from pardiso-project.org from user-provided library at runtime
pardisomkl	use the Pardiso package from Intel MKL
mumps	use the Mumps package

Default: ma27, if IpoptH, otherwise mumps

linear_system_scaling: Method for scaling the linear system. ↔

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. Note, that MC19 is included with a commercially supported GAMS/IpoptH license only. To use MC19 with GAMS/Ipopt, a HSL library needs to be provided by the user.

value	meaning
none	no scaling will be performed
mc19	IpoptH: use the Harwell routine MC19; Ipopt: load the Harwell routine MC19 from user-provided library
slack-based	use the slack values

Default: mc19, if IpoptH, otherwise none

ma27_ignore_singularity (*advanced*): Whether to use MA27's ability to solve a linear system even if the matrix is singular. [↔](#)

Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Range: yes, no

Default: no

ma27_la_init_factor: Real workspace memory for MA27. [↔](#)

The initial real workspace memory = la_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]

Default: 5

ma27_liw_init_factor: Integer workspace memory for MA27. [↔](#)

The initial integer workspace memory = liw_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]

Default: 5

ma27_meminc_factor: Increment factor for workspace size for MA27. [↔](#)

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor.

Range: [1, ∞]

Default: 2

ma27_pivtol: Pivot tolerance for the linear solver MA27. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: (0, 1)

Default: 1e-08

ma27_pivtolmax: Maximum pivot tolerance for the linear solver MA27. [↔](#)

Ippopt may increase pivtol as high as ma27_pivtolmax to get a more accurate solution to the linear system.

Range: (0, 1)

Default: 0.0001

ma27_skip_inertia_check (*advanced*): Whether to always pretend that inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

ma57_automatic_scaling: Controls whether to enable automatic scaling in MA57 [↔](#)

For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Range: yes, no

Default: no

ma57_block_size: Controls block size used by Level 3 BLAS in MA57BD [↔](#)

This is ICNTL(11) in MA57.

Range: {1, ..., ∞ }

Default: 16

ma57_node_amalgamation: Node amalgamation parameter [↔](#)

This is ICNTL(12) in MA57.

Range: {1, ..., ∞ }

Default: 16

ma57_pivot_order: Controls pivot order in MA57 [↔](#)

This is ICNTL(6) in MA57.

Range: {0, ..., 5}

Default: 5

ma57_pivtol: Pivot tolerance for the linear solver MA57. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: (0, 1)

Default: 1e-08

ma57_pivtolmax: Maximum pivot tolerance for the linear solver MA57. [↔](#)

Ipoprt may increase pivtol as high as `ma57_pivtolmax` to get a more accurate solution to the linear system.

Range: (0, 1)

Default: 0.0001

ma57_pre_alloc: Safety factor for work space memory allocation for the linear solver MA57. [↔](#)

If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice.

Range: [1, ∞]

Default: 1.05

ma57_small_pivot_flag: Handling of small pivots [↔](#)

If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient. This is ICNTL(16) in MA57.

Range: {0, ..., 1}

Default: 0

ma77_buffer_lpage: Number of scalars per MA77 in-core buffer page in the out-of-core solver MA77 [↔](#)

Must be at most `ma77_file_size`.

Range: {1, ..., ∞ }

Default: 4096

ma77_buffer_npage: Number of pages that make up MA77 buffer [↔](#)

Number of pages of size `buffer_lpage` that exist in-core for the out-of-core solver MA77.

Range: {1, ..., ∞ }

Default: 1600

ma77_file_size: Target size of each temporary file for MA77, scalars per type [↔](#)

MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.

Range: {1, ..., ∞ }

Default: 2097152

ma77_maxstore: Maximum storage size for MA77 in-core mode [↔](#)

If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.

Range: {0, ..., ∞ }

Default: 0

ma77_nemin: Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than `ma77_nemin` variables.

Range: {1, ..., ∞ }

Default: 8

ma77_order: Controls type of ordering used by MA77 [↔](#)

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm (if available)

Default: metis

ma77_print_level: Debug printing level for the linear solver MA77 [↔](#)

<0: no printing; 0: Error and warning messages only; 1: Limited diagnostic printing; >1 Additional diagnostic printing.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

ma77_small: Zero Pivot Threshold [↔](#)

Any pivot less than ma77_small is treated as zero.

Range: $[0, \infty]$

Default: 1e-20

ma77_static: Static Pivoting Threshold [↔](#)

See MA77 documentation. Either `ma77_static=0.0` or `ma77_static>ma77_small`. `ma77_static=0.0` disables static pivoting.

Range: $[0, \infty]$

Default: 0

ma77_u: Pivoting Threshold [↔](#)

See MA77 documentation.

Range: $[0, 0.5]$

Default: 1e-08

ma77_umax: Maximum Pivoting Threshold [↔](#)

Maximum value to which u will be increased to improve quality.

Range: $[0, 0.5]$

Default: 0.0001

ma86_nemin: Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than ma86_nemin variables.

Range: $\{1, \dots, \infty\}$

Default: 32

ma86_order: Controls type of ordering [↔](#)

value	meaning
auto	Try both AMD and MeTiS, pick best
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm (if available)

Default: auto

ma86_print_level: Debug printing level [↔](#)

<0: no printing; 0: Error and warning messages only; 1: Limited diagnostic printing; >1 Additional diagnostic printing.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

ma86_scaling: Controls scaling of matrix [↔](#)

value	meaning
none	Do not scale the linear system matrix
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma86_small: Zero Pivot Threshold [↔](#)

Any pivot less than ma86_small is treated as zero.

Range: $[0, \infty]$

Default: 1e-20

ma86_static: Static Pivoting Threshold [↔](#)

See MA86 documentation. Either `ma86_static=0.0` or `ma86_static>ma86_small`. `ma86_static=0.0` disables static pivoting.

Range: $[0, \infty]$

Default: 0

ma86_u: Pivoting Threshold [↔](#)

See MA86 documentation.

Range: $[0, 0.5]$

Default: 1e-08

ma86_umax: Maximum Pivoting Threshold [↔](#)

Maximum value to which u will be increased to improve quality.

Range: $[0, 0.5]$

Default: 0.0001

ma97_nemin: Node Amalgamation parameter [↔](#)

Two nodes in elimination tree are merged if result has fewer than ma97_nemin variables.

Range: $\{1, \dots, \infty\}$

Default: 8

ma97_order: Controls type of ordering [↔](#)

value	meaning
auto	Use HSL_MA97 heuristic to guess best of AMD and METIS
best	Try both AMD and MeTiS, pick best
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm
matched-auto	Use the HSL_MC80 matching with heuristic choice of AMD or METIS
matched-metis	Use the HSL_MC80 matching based ordering with METIS
matched-amd	Use the HSL_MC80 matching based ordering with AMD

Default: auto

ma97_print_level: Debug printing level [↔](#)

<0: no printing; 0: Error and warning messages only; 1: Limited diagnostic printing; >1 Additional diagnostic printing.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

ma97_scaling: Specifies strategy for scaling [↔](#)

value	meaning
none	Do not scale the linear system matrix
mc30	Scale all linear system matrices using MC30
mc64	Scale all linear system matrices using MC64
mc77	Scale all linear system matrices using MC77 [1,3,0]
dynamic	Dynamically select scaling according to rules specified by ma97_scalingX and ma97_switchX options.

Default: dynamic

ma97_scaling1 (*advanced*): First scaling. [↔](#)

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch1. If ma97_switch2 is triggered it is disabled.

value	meaning
none	No scaling
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma97_scaling2 (*advanced*): Second scaling. [↔](#)

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch2. If ma97_switch3 is triggered it is disabled.

value	meaning
none	No scaling
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma97_scaling3 (*advanced*): Third scaling. [↔](#)

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch3.

value	meaning
none	No scaling
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma97_small: Zero Pivot Threshold [↔](#)

Any pivot less than ma97_small is treated as zero.

Range: $[0, \infty]$

Default: 1e-20

ma97_solve_blas3 (*advanced*): Controls if blas2 or blas3 routines are used for solve [↔](#)

value	meaning
no	Use BLAS2 (faster, some implementations bit incompatible)
yes	Use BLAS3 (slower)

Default: no

ma97_switch1 (*advanced*): First switch, determine when ma97_scaling1 is enabled. [↔](#)

If ma97_scaling=dynamic, ma97_scaling1 is enabled according to this condition. If ma97_switch2 occurs this option is henceforth ignored.

value	meaning
never	Scaling is never enabled.
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr
high_delay	Scaling to be used after more than $0.05*n$ delays are present

value	meaning
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05*n additional delays, otherwise reuse scaling from previous itr
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse

Default: od_hd_reuse

ma97_switch2 (*advanced*): Second switch, determine when ma97_scaling2 is enabled. [↔](#)

If ma97_scaling=dynamic, ma97_scaling2 is enabled according to this condition. If ma97_switch3 occurs this option is henceforth ignored.

value	meaning
never	Scaling is never enabled.
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr
high_delay	Scaling to be used after more than 0.05*n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05*n additional delays, otherwise reuse scaling from previous itr
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse

Default: never

ma97_switch3 (*advanced*): Third switch, determine when ma97_scaling3 is enabled. [↔](#)

If ma97_scaling=dynamic, ma97_scaling3 is enabled according to this condition.

value	meaning
never	Scaling is never enabled.
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr
high_delay	Scaling to be used after more than 0.05*n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05*n additional delays, otherwise reuse scaling from previous itr
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse

Default: never

ma97_u: Pivoting Threshold [↔](#)

See MA97 documentation.

Range: $[0, 0.5]$

Default: 1e-08

ma97_umax: Maximum Pivoting Threshold [↔](#)

See MA97 documentation.

Range: $[0, 0.5]$

Default: 0.0001

max_cpu_time: Maximum number of CPU seconds. [↔](#)

A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: $(0, \infty]$

Default: 1e+20

max_filter_resets (*advanced*): Maximal allowed number of filter resets [↔](#)

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determine the maximal number of resets that are allowed to take place.

Range: $\{0, \dots, \infty\}$

Default: 5

max_hessian_perturbation: Maximum value of regularization parameter for handling negative curvature. [↔](#)

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. This is δ_w^{\max} in the implementation paper.

Range: $(0, \infty]$

Default: 1e+20

max_iter: Maximum number of iterations. [↔](#)

The algorithm terminates with a message if the number of iterations exceeded this number.

Range: $\{0, \dots, \infty\}$

Default: GAMS iterlim

max_refinement_steps: Maximum number of iterative refinement steps per linear system solve. [↔](#)

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Range: $\{0, \dots, \infty\}$

Default: 10

max_resto_iter (*advanced*): Maximum number of successive iterations in restoration phase. [↔](#)

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Range: $\{0, \dots, \infty\}$

Default: 3000000

max_soc: Maximum number of second order correction trial steps at each iteration. [↔](#)

Choosing 0 disables the second order corrections. This is $p^{\{\max\}}$ of Step A-5.9 of Algorithm A in the implementation paper.

Range: $\{0, \dots, \infty\}$

Default: 4

max_soft_resto_iters (*advanced*): Maximum number of iterations performed successively in soft restoration phase. [↔](#)

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Range: $\{0, \dots, \infty\}$

Default: 10

max_wall_time: Maximum number of walltime clock seconds. [↔](#)

A limit on walltime clock seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: $(0, \infty]$

Default: GAMS reslim

mehrotra_algorithm: Indicates whether to do Mehrotra's predictor-corrector algorithm. [↔](#)

If enabled, line search is disabled and the (unglobalized) adaptive mu strategy is chosen with the "probing" oracle, and "corrector_type=affine" is used without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult". The Mehrotra's predictor-corrector algorithm works usually very well for LPs and convex QPs.

Range: yes, no

Default: no

min_hessian_perturbation: Smallest perturbation of the Hessian block. [↔](#)

The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. This is $\delta_{w^{\min}}$ in implementation paper.

Range: $[0, \infty]$

Default: 1e-20

min_refinement_steps: Minimum number of iterative refinement steps per linear system solve. [↔](#)

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Range: $\{0, \dots, \infty\}$

Default: 1

mu_allow_fast_monotone_decrease (*advanced*): Allow skipping of barrier problem if barrier test is already met. [↔](#)

value	meaning
no	Take at least one iteration per barrier problem even if the barrier test is already met for the updated barrier parameter
yes	Allow fast decrease of mu if barrier test it met

Default: yes

mu_init: Initial value for the barrier parameter. [↔](#)

This option determines the initial value for the barrier parameter (μ). It is only relevant in the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as "monotone")

Range: $(0, \infty]$

Default: 0.1

mu_linear_decrease_factor: Determines linear decrease rate of barrier parameter. [↔](#)

For the Fiacco-McCormick update procedure the new barrier parameter μ is obtained by taking the minimum of $\mu * \text{mu_linear_decrease_factor}$ and $\mu^{\text{superlinear_decrease_power}}$. This is κ_{μ} in implementation paper. This option is also used in the adaptive μ strategy during the monotone mode.

Range: $(0, 1)$

Default: 0.2

mu_max: Maximum value for barrier parameter. [↔](#)

This option specifies an upper bound on the barrier parameter in the adaptive μ selection mode. If this option is set, it overwrites the effect of mu_max_fact. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: $(0, \infty]$

Default: 100000

mu_max_fact: Factor for initialization of maximum value for barrier parameter. [↔](#)

This option determines the upper bound on the barrier parameter. This upper bound is computed as the average complementarity at the initial point times the value of this option. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: $(0, \infty]$

Default: 1000

mu_min: Minimum value for barrier parameter. [↔](#)

This option specifies the lower bound on the barrier parameter in the adaptive μ selection mode. By default, it is set to the minimum of $1e-11$ and $\min(\text{"tol"}, \text{"compl_inf_tol"}) / (\text{"barrier_tol_factor"} + 1)$, which should be a reasonable value. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: $(0, \infty]$

Default: $1e-11$

mu_oracle: Oracle for a new barrier parameter in the adaptive strategy. [↔](#)

Determines how a new barrier parameter is computed in each "free-mode" iteration of the adaptive barrier parameter strategy. (Only considered if "adaptive" is selected for option "mu_strategy").

value	meaning
probing	Mehrotra's probing heuristic
loqo	LOQO's centrality rule
quality-function	minimize a quality function

Default: quality-function

mu_strategy: Update strategy for barrier parameter. [↔](#)

Determines which barrier parameter update strategy is to be used.

value	meaning
monotone	use the monotone (Fiacco-McCormick) strategy
adaptive	use the adaptive update strategy

Default: adaptive

mu_superlinear_decrease_power: Determines superlinear decrease rate of barrier parameter. [↔](#)

For the Fiacco-McCormick update procedure the new barrier parameter μ is obtained by taking the minimum of $\mu * \text{mu_linear_decrease_factor}$ and $\mu^{\text{superlinear_decrease_power}}$. This is θ_μ in implementation paper. This option is also used in the adaptive μ strategy during the monotone mode.

Range: (1, 2)

Default: 1.5

mu_target: Desired value of complementarity. [↔](#)

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of "mu_target" specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Range: $[0, \infty]$

Default: 0

mumps_dep_tol (*advanced*): Threshold to consider a pivot at zero in detection of linearly dependent constraints with MUMPS. [↔](#)

This is CNTL(3) in MUMPS.

Range: real

Default: 0

mumps_mem_percent: Percentage increase in the estimated working space for MUMPS. [↔](#)

When significant extra fill-in is caused by numerical pivoting, larger values of `mumps_mem_percent` may help use the workspace more efficiently. On the other hand, if memory requirements are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Range: $\{0, \dots, \infty\}$

Default: 1000

mumps_permuting_scaling: Controls permuting and scaling in MUMPS [↔](#)

This is ICNTL(6) in MUMPS.

Range: $\{0, \dots, 7\}$

Default: 7

mumps_pivot_order: Controls pivot order in MUMPS [↔](#)

This is ICNTL(7) in MUMPS.

Range: $\{0, \dots, 7\}$

Default: 7

mumps_pivtol: Pivot tolerance for the linear solver MUMPS. [↔](#)

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: $[0, 1]$

Default: 1e-06

mumps_pivtolmax: Maximum pivot tolerance for the linear solver MUMPS. [↔](#)

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system.

Range: $[0, 1]$

Default: 0.1

mumps_scaling: Controls scaling in MUMPS [↔](#)

This is ICNTL(8) in MUMPS.

Range: $\{-2, \dots, 77\}$

Default: 77

neg_curv_test_reg: Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014). [↔](#)

value	meaning
yes	use primal regularization with the inertia-free curvature test
no	use original IPOPT approach, in which the primal regularization is ignored

Default: yes

neg_curv_test_tol: Tolerance for heuristic to ignore wrong inertia. [↔](#)

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is `alpha_n` in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of $[1e-12, 1e-11]$ is recommended.

Range: $[0, \infty]$

Default: 0

nlp_scaling_constr_target_gradient (*advanced*): Target value for constraint function gradient size. [↔](#)

If a positive number is chosen, the scaling factors for the constraint functions are computed so that the gradient has the max norm of the given size at the starting point. This overrides `nlp_scaling_max_gradient` for the constraint functions.

Range: $[0, \infty]$

Default: 0

nlp_scaling_max_gradient: Maximum gradient after NLP scaling. [↔](#)

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is `g_max` in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: $(0, \infty]$

Default: 100

nlp_scaling_method: Select the technique used for scaling the NLP. [↔](#)

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP.

value	meaning
none	no problem scaling will be performed
gradient-based	scale the problem so the maximum gradient at the starting point is <code>nlp_scaling_max_gradient</code>
equilibration-based	scale the problem so that first derivatives are of order 1 at random points (GAMS/Ipopt: requires user-provided library with HSL routine MC19)

Default: gradient-based if GAMS `scaleopt` is not set, otherwise none

nlp_scaling_min_value: Minimum value of gradient-based scaling values. [↔](#)

This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: $[0, \infty]$

Default: 1e-08

nlp_scaling_obj_target_gradient (*advanced*): Target value for objective function gradient size. [↔](#)

If a positive number is chosen, the scaling factor for the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides `nlp_scaling_max_gradient` for the objective function.

Range: $[0, \infty]$

Default: 0

nu_inc (*advanced*): Increment of the penalty parameter. [↔](#)

Range: $(0, \infty]$

Default: 0.0001

nu_init (*advanced*): Initial value of the penalty parameter. [↔](#)

Range: $(0, \infty]$

Default: 1e-06

obj_max_inc (*advanced*): Determines the upper bound on the acceptable increase of barrier objective function. [↔](#)

Trial points are rejected if they lead to an increase in the barrier objective function by more than `obj_max_inc` orders of magnitude.

Range: $(1, \infty]$

Default: 5

pardiso_iter_coarse_size (*advanced*): Maximum Size of Coarse Grid Matrix [↔](#)

DPARM(3)

Range: $\{1, \dots, \infty\}$

Default: 5000

pardiso_iter_dropping_factor (*advanced*): dropping value for incomplete factor [↔](#)

DPARM(5)

Range: $(0, 1)$

Default: 0.5

pardiso_iter_dropping_schur (*advanced*): dropping value for sparsify schur complement factor [↔](#)

DPARM(6)

Range: $(0, 1)$

Default: 0.1

pardiso_iter_inverse_norm_factor (*advanced*): [↔](#)

DPARAM(8)

Range: $(1, \infty]$

Default: $5e+06$

pardiso_iter_max_levels (*advanced*): Maximum Size of Grid Levels [↔](#)

DPARAM(4)

Range: $\{1, \dots, \infty\}$

Default: 10

pardiso_iter_max_row_fill (*advanced*): max fill for each row [↔](#)

DPARAM(7)

Range: $\{1, \dots, \infty\}$

Default: 10000000

pardiso_iter_relative_tol (*advanced*): Relative Residual Convergence [↔](#)

DPARAM(2)

Range: $(0, 1)$

Default: $1e-06$

pardiso_iterative (*advanced*): Switch for iterative solver in Pardiso library [↔](#)

Range: yes, no

Default: no

pardiso_matching_strategy: Matching strategy to be used by Pardiso [↔](#)

This is IPAR(13) in Pardiso manual.

value	meaning
complete	Match complete (IPAR(13)=1)
complete+2x2	Match complete+2x2 (IPAR(13)=2)
constraints	Match constraints (IPAR(13)=3)

Default: complete+2x2

pardiso_max_droptol_corrections (*advanced*): Maximal number of decreases of drop tolerance during one solve. [↔](#)

This is relevant only for iterative Pardiso options.

Range: $\{1, \dots, \infty\}$

Default: 4

pardiso_max_iter (*advanced*): Maximum number of Krylov-Subspace Iteration [↔](#)

DPARAM(1)

Range: {1, ..., ∞ }

Default: 500

pardiso_max_iterative_refinement_steps: Limit on number of iterative refinement steps. [↔](#)

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: { $-\infty$, ..., ∞ }

Default: 0

pardiso_msglvl: Pardiso message level [↔](#)

This is MSGLVL in the Pardiso manual.

Range: {0, ..., ∞ }

Default: 0

pardiso_order: Controls the fill-in reduction ordering algorithm for the input matrix. [↔](#)

value	meaning
amd	minimum degree algorithm
one	
metis	MeTiS nested dissection algorithm
pmetis	parallel (OpenMP) version of MeTiS nested dissection algorithm
four	
five	

Default: metis

pardiso_redo_symbolic_fact_only_if_inertia_wrong (*advanced*): Toggle for handling case when elements were perturbed by Pardiso. [↔](#)

value	meaning
no	Always redo symbolic factorization when elements were perturbed
yes	Only redo symbolic factorization when elements were perturbed if also the inertia was wrong

Default: no

pardiso_repeated_perturbation_means_singular (*advanced*): Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization. [↔](#)

Range: yes, no

Default: no

pardiso_skip_inertia_check (*advanced*): Whether to pretend that inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

pardisolib: Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime [↔](#)

Range: string

Default: libpardiso.so (Linux), libpardiso.dylib (macOS), libpardiso.dll (Windows)

pardisomkl_matching_strategy: Matching strategy to be used by Pardiso [↔](#)

This is IPAR(13) in Pardiso manual.

value	meaning
complete	Match complete (IPAR(13)=1)
complete+2x2	Match complete+2x2 (IPAR(13)=2)
constraints	Match constraints (IPAR(13)=3)

Default: complete+2x2

pardisomkl_max_iterative_refinement_steps: Limit on number of iterative refinement steps. [↔](#)

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: $\{-\infty, \dots, \infty\}$

Default: 1

pardisomkl_msglvl: Pardiso message level [↔](#)

This is MSGLVL in the Pardiso manual.

Range: $\{0, \dots, \infty\}$

Default: 0

pardisomkl_order: Controls the fill-in reduction ordering algorithm for the input matrix. [↔](#)

value	meaning
amd	minimum degree algorithm
one	undocumented
metis	MeTiS nested dissection algorithm
pmetis	parallel (OpenMP) version of MeTiS nested dissection algorithm

Default: metis

pardisomkl_redo_symbolic_fact_only_if_inertia_wrong (*advanced*): Toggle for handling case when elements were perturbed by Pardiso. [↔](#)

value	meaning
no	Always redo symbolic factorization when elements were perturbed
yes	Only redo symbolic factorization when elements were perturbed if also the inertia was wrong

Default: no

pardisomkl_repeated_perturbation_means_singular (*advanced*): Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization. [↔](#)

Range: yes, no

Default: no

pardisomkl_skip_inertia_check (*advanced*): Whether to pretend that inertia is correct. [↔](#)

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

perturb_always_cd (*advanced*): Active permanent perturbation of constraint linearization. [↔](#)

Enabling this option leads to using the delta_c and delta_d perturbation for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Range: yes, no

Default: no

perturb_dec_fact: Decrease factor for x-s perturbation. [↔](#)

The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. This is κ_w^- in the implementation paper.

Range: (0, 1)

Default: 0.333333

perturb_inc_fact: Increase factor for x-s perturbation. [↔](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. This is κ_w^+ in the implementation paper.

Range: (1, ∞]

Default: 8

perturb_inc_fact_first: Increase factor for x-s perturbation for very first perturbation. [↔](#)

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for the first perturbation than that used for the remaining perturbations. This is $\bar{\kappa}_w^+$ in the implementation paper.

Range: $(1, \infty]$

Default: 100

print_advanced_options (*advanced*): whether to print also advanced options [↔](#)

Range: yes, no

Default: no

print_eval_error: Switch to enable printing information about function evaluation errors into the GAMS listing file. [↔](#)

Range: no, yes

Default: yes

print_frequency_iter: Determines at which iteration frequency the summarizing iteration output line should be printed. [↔](#)

Summarizing iteration output is printed every `print_frequency_iter` iterations, if at least `print_frequency_time` seconds have passed since last output.

Range: $\{1, \dots, \infty\}$

Default: 1

print_frequency_time: Determines at which time frequency the summarizing iteration output line should be printed. [↔](#)

Summarizing iteration output is printed if at least `print_frequency_time` seconds have passed since last output and the iteration number is a multiple of `print_frequency_iter`.

Range: $[0, \infty]$

Default: 0

print_info_string: Enables printing of additional info string at end of iteration output. [↔](#)

This string contains some insider information about the current iteration. For details, look for "Diagnostic Tags" in the Ipopth documentation.

Range: yes, no

Default: no

print_level: Output verbosity level. [↔](#)

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: $\{0, \dots, 12\}$

Default: 5

print_options_mode: format in which to print options documentation [↔](#)

value	meaning
text	Ordinary text
latex	LaTeX formatted
doxygen	Doxygen (markdown) formatted

Default: text

print_timing_statistics: Switch to print timing statistics. [↔](#)

If selected, the program will print the time spend for selected tasks. This implies `timing_statistics=yes`.

Range: yes, no

Default: no

quality_function_balancing_term (*advanced*): The balancing term included in the quality function for centrality. [↔](#)

This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. Only used if option "mu_oracle" is set to "quality-function".

value	meaning
none	no balancing term is added
cubic	$\text{Max}(0, \text{Max}(\text{dual_inf}, \text{primal_inf}) - \text{compl})^3$

Default: none

quality_function_centrality (*advanced*): The penalty term for centrality that is included in quality function. [↔](#)

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the xi in the Loqo update rule. Only used if option "mu_oracle" is set to "quality-function".

value	meaning
none	no penalty term is added
log	complementarity * the log of the centrality measure
reciprocal	complementarity * the reciprocal of the centrality measure
cubed-reciprocal	complementarity * the reciprocal of the centrality measure cubed

Default: none

quality_function_max_section_steps: Maximum number of search steps during direct search procedure determining the optimal centering parameter. [↔](#)

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: {0, ..., ∞ }

Default: 8

quality_function_norm_type (*advanced*): Norm used for components of the quality function. [↔](#)

Only used if option "mu_oracle" is set to "quality-function".

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)
2-norm	use 2-norm

Default: 2-norm-squared

quality_function_section_qf_tol (*advanced*): Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space). [↔](#)

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: [0, 1)

Default: 0

quality_function_section_sigma_tol (*advanced*): Tolerance for the section search procedure determining the optimal centering parameter (in sigma space). [↔](#)

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: [0, 1)

Default: 0.01

recalc_y: Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates. [↔](#)

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than `recalc_y_feas_tol`. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.

value	meaning
no	use the Newton step to update the multipliers
yes	use least-square multiplier estimates

Default: no

recalc_y_feas_tol: Feasibility threshold for recomputation of multipliers. [↔](#)

If `recalc_y` is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Range: (0, ∞]

Default: 1e-06

replace_bounds (*advanced*): Whether all variable bounds should be replaced by inequality constraints
↔

This option must be set for the inexact algorithm.

Range: yes, no

Default: no

report_mininfeas_solution: Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible. ↔

This option allows to obtain the most feasible solution found by Ipopt during the iteration process, if it stops at a (locally) infeasible solution, due to a limit (time, iterations, ...), or with a failure in the restoration phase.

Range: no, yes

Default: no

required_infeasibility_reduction: Required reduction of infeasibility before leaving restoration phase.
↔

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: [0, 1)

Default: 0.9

residual_improvement_factor (*advanced*): Minimal required reduction of residual test ratio in iterative refinement. ↔

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Range: (0, ∞]

Default: 1

residual_ratio_max (*advanced*): Iterative refinement tolerance ↔

Iterative refinement is performed until the residual test ratio is less than this tolerance (or until "max_refinement_steps" refinement steps are performed).

Range: (0, ∞]

Default: 1e-10

residual_ratio_singular (*advanced*): Threshold for declaring linear system singular after failed iterative refinement. ↔

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Range: (0, ∞]

Default: 1e-05

resto_failure_feasibility_threshold (*advanced*): Threshold for primal infeasibility to declare failure of restoration phase. [↔](#)

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is actually $1e2 * tol$, where tol is the general termination tolerance.

Range: $[0, \infty]$

Default: 0

resto_penalty_parameter (*advanced*): Penalty parameter in the restoration phase objective function. [↔](#)

This is the parameter ρ in equation (31a) in the Ipopt implementation paper.

Range: $(0, \infty]$

Default: 1000

resto_proximity_weight (*advanced*): Weighting factor for the proximity term in restoration phase objective. [↔](#)

This determines how the parameter ζ in equation (29a) in the implementation paper is computed. ζ here is $resto_proximity_weight * \sqrt{\mu}$, where μ is the current barrier parameter.

Range: $[0, \infty]$

Default: 1

rho (*advanced*): Value in penalty parameter update formula. [↔](#)

Range: $(0, 1)$

Default: 0.1

s_max (*advanced*): Scaling threshold for the NLP error. [↔](#)

See paragraph after Eqn. (6) in the implementation paper.

Range: $(0, \infty]$

Default: 100

s_phi (*advanced*): Exponent for linear barrier function model in the switching rule. [↔](#)

See Eqn. (19) in the implementation paper.

Range: $(1, \infty]$

Default: 2.3

s_theta (*advanced*): Exponent for current constraint violation in the switching rule. [↔](#)

See Eqn. (19) in the implementation paper.

Range: $(1, \infty]$

Default: 1.1

sigma_max (*advanced*): Maximum value of the centering parameter. [↔](#)

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: $(0, \infty]$

Default: 100

sigma_min (*advanced*): Minimum value of the centering parameter. [↔](#)

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: $[0, \infty]$

Default: 1e-06

skip_corr_if_neg_curv (*advanced*): Whether to skip the corrector step in negative curvature iteration. [↔](#)

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no

Default: yes

skip_corr_in_monotone_mode (*advanced*): Whether to skip the corrector step during monotone barrier parameter mode. [↔](#)

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier_strategy"). This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no

Default: yes

slack_bound_frac: Desired minimum relative distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: $(0, 0.5]$

Default: 0.01

slack_bound_push: Desired minimum absolute distance from the initial slack to bound. [↔](#)

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Range: $(0, \infty]$

Default: 0.01

slack_move (*advanced*): Correction size for very small slacks. [↔](#)

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is $\text{mach_eps}^{\{3/4\}}$. See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.

Range: $[0, \infty]$

Default: 1.81899e-12

soc_method: Ways to apply second order correction [↔](#)

This option determines the way to apply second order correction, 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of x and s rows.

Range: $\{0, \dots, 1\}$

Default: 0

soft_resto_pderror_reduction_factor: Required reduction in primal-dual error in the soft restoration phase. [↔](#)

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing "0" here disables the soft restoration phase.

Range: $[0, \infty]$

Default: 0.9999

start_with_resto: Whether to switch to restoration phase in first iteration. [↔](#)

Setting this option to "yes" forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.

Range: yes, no

Default: no

tau_min (*advanced*): Lower bound on fraction-to-the-boundary parameter tau. [↔](#)

This is tau_min in the implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: $(0, 1)$

Default: 0.99

theta_max_fact (*advanced*): Determines upper bound for constraint violation in the filter. [↔](#)

The algorithmic parameter theta_max is determined as theta_max_fact times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than theta_max is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Range: $(0, \infty]$

Default: 10000

theta_min_fact (*advanced*): Determines constraint violation threshold in the switching rule. [↔](#)

The algorithmic parameter `theta_min` is determined as `theta_min_fact` times the maximum of 1 and the constraint violation at initial point. The switching rules treats an iteration as an h-type iteration whenever the current constraint violation is larger than `theta_min` (see paragraph before Eqn. (19) in the implementation paper).

Range: $(0, \infty]$

Default: 0.0001

timing_statistics: Indicates whether to measure time spend in components of Ipopt and NLP evaluation [↔](#)

The overall algorithm time is unaffected by this option.

Range: yes, no

Default: no

tiny_step_tol (*advanced*): Tolerance for detecting numerically insignificant steps. [↔](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Range: $[0, \infty]$

Default: 2.22045e-15

tiny_step_y_tol (*advanced*): Tolerance for quitting because of numerically insignificant steps. [↔](#)

If the search direction in the primal variables (x and s) is, in relative terms for each component, repeatedly less than `tiny_step_tol`, and the step in the y variables is smaller than this threshold, the algorithm will terminate.

Range: $[0, \infty]$

Default: 0.01

tol: Desired convergence tolerance (relative). [↔](#)

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. This is `epsilon_tol` in Eqn. (6) in implementation paper. See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Range: $(0, \infty]$

Default: 1e-08

warm_start_bound_frac: same as `bound_frac` for the regular initializer [↔](#)

Range: $(0, 0.5]$

Default: 0.001

warm_start_bound_push: same as `bound_push` for the regular initializer [↔](#)

Range: $(0, \infty]$

Default: 0.001

warm_start_init_point: Warm-start for initial point [↔](#)

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

value	meaning
no	do not use the warm start initialization
yes	use the warm start initialization

Default: yes, if run on modified model instance (e.g., from GUSS), otherwise no

warm_start_mult_bound_push: same as mult_bound_push for the regular initializer [↔](#)

Range: $(0, \infty]$

Default: 0.001

warm_start_mult_init_max: Maximum initial value for the equality multipliers. [↔](#)

Range: real

Default: $1e+06$

warm_start_slack_bound_frac: same as slack_bound_frac for the regular initializer [↔](#)

Range: $(0, 0.5]$

Default: 0.001

warm_start_slack_bound_push: same as slack_bound_push for the regular initializer [↔](#)

Range: $(0, \infty]$

Default: 0.001

warm_start_target_mu (*advanced*): [↔](#)

Experimental!

Range: real

Default: 0

watchdog_shortened_iter_trigger: Number of shortened iterations that trigger the watchdog. [↔](#)

If the number of successive iterations in which the backtracking line search did not accept the first trial point exceeds this number, the watchdog procedure is activated. Choosing "0" here disables the watchdog procedure.

Range: $\{0, \dots, \infty\}$

Default: 10

watchdog_trial_iter_max: Maximum number of watchdog iterations. [↔](#)

This option determines the number of trial iterations allowed before the watchdog procedure is aborted and the algorithm returns to the stored point.

Range: $\{1, \dots, \infty\}$

Default: 3

5.22 JAMS and LogMIP

5.22.1 Introduction

EMP (Extended Mathematical Programming) is not a solver but an (experimental) framework for automated mathematical programming reformulations. The idea behind EMP is that new upcoming types of models which currently cannot be solved reliably are reformulated into models of established math programming classes in order to use mature solver technology. At this stage, EMP supports the modeling of Bilevel Programs, Variational Inequalities, Disjunctive Programs, Extended Nonlinear Programs and Embedded Complementarity Systems.

Extended mathematical programs are collections of functions and variables joined together using specific optimization and complementarity primitives. EMP annotates the existing relationships within a model to facilitate higher level structure identification. A specific implementation of this framework is outlined that reformulates the original GAMS model automatically using directives contained in an "empinfo" file into an equivalent model that can be solved using existing GAMS solvers.

The reformulation is done by the solver JAMS which currently is the only solver that is capable of handling EMP models. Examples showing how to use the EMP framework and the solver JAMS are made available through the GAMS EMP Library which is included in the GAMS Distribution. In order to generate a copy of an EMPLIB model, one can use the library facility of the GAMS IDE, or execute the command line directive `emplib <modelname>`, where `modelname` is the (stem of the) file containing the model.

EMP has been developed jointly by Michael Ferris of UW-Madison, Ignacio Grossmann of Carnegie Mellon University, and GAMS Development Corporation. EMP and JAMS come free of charge with any licensed GAMS system but require a subsolver to solve the generated models.

5.22.2 JAMS: a reformulation tool

EMP models are currently processed by the JAMS solver. The solver JAMS creates a scalar version of the given GAMS model. This scalar version of the model is then solved by an appropriate subsolver. By default, there are no reformulations carried out, so the model generated is simply a GAMS scalar form of the model the actual subsolver will process. The subsolver used is by default the currently specified solver for the given model type.

5.22.2.1 The JAMS Option File

As with any GAMS solver, JAMS has an option file, typically called `jams.opt`. A JAMS option `subsolver` is available to change the subsolver used for the reformulated model, along with an option to utilize a subsolver option file (`subsolveropt`).

The actual scalar version of the model can also be seen by the modeler using the option `filename`. For example, the option file

```
subsolver path
subsolveropt 1
filename mcpmo.d.gms
```

when applied to an EMP model that is a complementarity problem will create a file called `mcpmod.gms` in the current directory and solve that model using the solver PATH utilizing any options for PATH that are specified in `path.opt`. The scalarized model is not particularly useful to look at since all of the original variables have been renamed into a scalar form. The mapping between original variables and the ones used in the scalar version of the model is given in a dictionary file that can also be seen by the modeler using the `dict` option. If a user simply wants to generate this scalar model, then the option `terminate` will not solve the generated model.

After the scalar version of the model is solved, the solution values are mapped back into the original namespace and returned to the modeler as usual in the listing file. The JAMS option `margtol` allows the modeler to suppress reporting marginals that have (absolute) values smaller than this tolerance.

Obviously, all of the above functionality is not of much value: the key part of JAMS is to interpret additional directives to take the original model and produce a *reformulated* scalar model. This is carried out using an "empinfo" file. The syntax and use of this file is the content of the remaining sections of this document.

The option `EMPIInfoFile` allows the user to specify the path and name of a file containing additional EMP information. The syntax of this file is described by examples elsewhere in this document and in section [Empinfo file details](#). There is a subtlety that should be mentioned when a user writes this file in the default location in the GAMS scratch directory of the current run specified in the `gams` file using:

```
file empinfo / '%emp.info%' /;
```

wherein certain additional formatting instructions are given. If instead, the file handle is given by:

```
file empinfo / 'empinfo.txt' /;
```

for example, then to produce the same file the following lines must be added to the `gams` source file:

```
empinfo.pc = 8;
empinfo.pw = 255;
```

The following tables list all available options.

5.22.2.2 Reformulation Options

Option	Description	Default
KeepObj	Keep original objective function and variables in generated MCP model. This option is only valid for reformulations into complementarity systems. If KeepObj is set the generated MCP program will incorporate the original objective function and the Karush-Kuhn-Tucker condition of the original objective variable.	0
MargTol	Only report marginals with an absolute value above the tolerance	1e-6
ObjVarName	Name of objective variable in generated model.	objvar

5.22.2.3 General Options

Option	Description	Default
CompModel	Complementarity model (MCP or VI) to generate for equilibrium problems.	mcp
Dict	Generate a dictionary file that maps original variable and equation names to the ones of the scalar JAMS model.	dict.txt
DisjBinRelax	Relax requirement that disjunction variables are binary.	0
EMPInfoFile	Path and name of file containing additional EMP information as disjunctions, perpendiculars, bilevel characterization etc. By default, the file is expected to exist in the GAMS scratch directory of the current run (<code>gams.scrdir</code>). If this option is used, EMP searches for the file based on the provided relative or absolute path. In case of a given relative path, it is assumed to be relative to the working directory.	
FileName	Filename of generated scalar reformulated GAMS model.	emp.gms
ImplVarModel	Reformulation model to generate for implicit variables. Replication: Shared variables are replicated for each agent Substitution: Shared multipliers are substituted out: assumes implicit function Switching: Switch function-variable matching to avoid replication	switching
NLConsToFunc	Stick nonlinear constraints into functional part when generating a VI model for equilibrium problems	0
SharedEqu	Allow shared equations in equilibrium problems	0
SubSolvePar	User defined GAMS parameters for subsolve	
SubSolver	Subsolver used to solve the reformulated model. The subsolver chosen has to be suitable for the chosen reformulation type. The user can also provide a solver related option file, see SubSolverOpt .	
SubSolverOpt	Optfile value to pass to the subsolver Range: {1, ..., 999}	1
Terminate	Generate the GAMS source code of the reformulated model in a file and terminate without solving the model.	0
UserPFFile	Filename of extra GAMS options when running the reformulated GAMS model.	
ZipDebug	Zip-file name to create if the internal GAMS model fails	none

5.22.3 Forming Optimality Conditions: NLP2MCP

The first nontrivial use of the JAMS solver is to automatically generate the first order conditions of a linear or nonlinear program; essentially we *reformulate* the optimization problem as a mixed complementarity problem (MCP). The "empinfo" file to do this simply contains the following line:

```
modeltype mcp
```

Behind the scenes, JAMS forms the Lagrangian of the nonlinear program and then forms its Karush-Kuhn-Tucker optimality conditions. To be clear, given the original nonlinear program

$$\min_x f(x) \text{ s.t. } g(x) \leq 0, h(x) = 0, \quad (\text{NLP})$$

the Lagrangian is:

$$\mathcal{L}(x, \lambda, \mu) = f(x) - \langle \lambda, g(x) \rangle - \langle \mu, h(x) \rangle.$$

The first order conditions are the following MCP:

$$\begin{aligned} 0 &= \nabla_x \mathcal{L}(x, \lambda, \mu) && \perp & x \text{ free} \\ 0 &\geq -\nabla_\lambda \mathcal{L}(x, \lambda, \mu) && \perp & \lambda \leq 0 \\ 0 &= -\nabla_\mu \mathcal{L}(x, \lambda, \mu) && \perp & \mu \text{ free} \end{aligned}$$

A specific example is:

$$\begin{aligned} \min_{x,y,z} \quad & -3x + y \\ \text{s.t.} \quad & x + y \leq 1, \quad x + y - z = 2, \quad x, y \geq 0 \end{aligned}$$

which is found in the EMPLIB model **nlp2mcp**:

```
Positive Variables x, y;
Variables f, z;
Equations g, h, defobj;
g..      x + y      =l= 1;
h..      x + y - z =e= 2;
defobj.. f          =e= -3*x + y;
model comp / defobj, g, h /;
file info / '%emp.info%' /;
putclose info / 'modeltype mcp';
solve comp using emp minimizing f;
```

The putclose line writes out the default "empinfo" file whose location is provided in the system string %emp.info%. Armed with this additional information, the EMP tool automatically creates the following MCP:

$$\begin{aligned} 0 &\leq -3 - \lambda - \mu && \perp & x \geq 0 \\ 0 &\leq 1 - \lambda - \mu && \perp & y \geq 0 \\ 0 &= \mu && \perp & z \text{ free} \\ 0 &\geq x + y - 1 && \perp & \lambda \leq 0 \\ 0 &= x + y - z - 2 && \perp & \mu \text{ free.} \end{aligned}$$

5.22.4 Soft Constraints

In many cases, we wish to relax certain constraints in a model during solution (to help identify feasibility issues for example). As an example, consider the problem

$$\begin{aligned} \min_{x_1, x_2, x_3} \quad & \exp(x_1) \\ \text{s.t.} \quad & \log(x_1) = 1, \\ & x_2^2 \leq 2, \\ & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, \quad x_1 \geq 0, \quad x_2 \geq 0, \end{aligned}$$

which can be formulated in GAMS as

```
$title simple example of ENLP
Variables obj, x1, x2, x3;
Equations f0, f1, f2, f3, f4;
f0.. obj      =e= exp(x1);
f1.. log(x1)  =e= 1;
f2.. sqrt(x2) =g= 2;
f3.. x1/x2    =e= log(x3);
f4.. 3*x1 + x2 =l= 5;
x1.lo = 0; x2.lo = 0;
model enlpemp /all/;
x1.l = 1; x2.l = 1; x3.l = 1;
solve enlpemp using nlp min obj;
```

5.22.4.1 Reformulation as a classical NLP

Soft constraints allow us to treat certain equations in the model as "soft" by removing the constraints and adding a penalty term to the objective function. Explicitly, we replace the above problem by:

$$\begin{aligned} \min_{x_1, x_2, x_3} \quad & \exp(x_1) + 5 \|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

In this problem, we still force $x_1/x_2 = \log(x_3)$, but apply a least squares penalty to $\log(x_1) - 1$ and a smaller one-sided penalization to $x_2^2 - 2$.

The above formulation is nonsmooth due to the "max" term in the objective function; in practice we would replace this by:

$$\begin{aligned} \min_{x_1, x_2, x_3, w} \quad & \exp(x_1) + 5(\log(x_1) - 1)^2 + 2w \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\ & w \geq x_2^2 - 2, w \geq 0 \end{aligned}$$

and recover a standard form NLP.

The "empinfo" file:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 maxx 2
```

coupled with replacing the last line with

```
solve enlpemp using emp min obj;
```

achieves this goal. The parameter values provide the penalty coefficients above.

5.22.4.2 Reformulation as an MCP

As an alternative, we can rewrite the problem as an MCP, also dealing explicitly with the nonsmoothness. The "empinfo" file is given by:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 maxx 2
```

and this generates the following MCP:

$$\begin{array}{ll} 0 = \log(x_1) - 1 + y_1/10 & \perp \quad y_1 \text{ free,} \\ 0 \leq x_2^2 - 2 & \perp \quad y_2 \geq 0, \\ 0 = x_1/x_2 - \log(x_3) & \perp \quad y_3 \text{ free,} \\ 0 \geq 3x_1 + x_2 - 5 & \perp \quad y_4 \leq 0, \\ 0 \leq \exp(x_1) - y_1/x_1 - y_3/x_2 - 3y_4 & \perp \quad x_1 \geq 0, \\ 0 \leq -2y_2x_2 + x_1y_3/x_2^2 - y_4 & \perp \quad x_2 \geq 0, \\ 0 = y_3/x_3 & \perp \quad x_3 \text{ free,} \end{array}$$

where y represent the multipliers.

A complete description of the process to derive this MCP will be given later in section [Extended Nonlinear Programs](#).

5.22.5 Bilevel Programs

Mathematical programs with optimization problems in their constraints have a long history in operations research including [28] [48] [99]. New codes are being developed that exploit this structure, at least for simple hierarchies, and attempt to define and implement algorithms for their solution.

The simplest case is that of bilevel programming, where an upper level problem depends on the solution of a lower level optimization. For example:

$$\begin{aligned} \min_{x,y} f(x,y) \\ \text{s.t. } g(x,y) \leq 0, \\ y \text{ solves } \min_y v(x,y) \text{ s.t. } h(x,y) \geq 0. \end{aligned}$$

Often, the upper level is referred to as the "leader", while the lower level is the "follower".

This problem can be reformulated as a Mathematical Program with Complementarity Constraints (MPCC) by replacing the lower level optimization problem by its first order optimality conditions:

$$\begin{aligned} \min_{x,y} f(x,y) \\ \text{s.t. } g(x,y) \leq 0, \\ 0 = \nabla_y v(x,y) - \lambda^T \nabla_y h(x,y) \perp x \text{ free} \\ 0 \leq h(x,y) \perp \lambda \geq 0. \end{aligned}$$

We find a solution of the MPCC, not of the bilevel program. This approach allows the MPCC to be solved using the NLPEC code, for example. Note that this reformulation is potentially problematic. First order conditions require theoretical assumptions to be necessary and sufficient for *local optimality*. There may be cases where the lower level problem has multiple local solutions, but the modeler really was interested in the *global* solution. The approach here may not produce this solution, even if a global solver is used within NLPEC.

The following example is Example 5.1.1, page 197 from [28]. Mathematically, the problem is

$$\begin{aligned} \min_{x,y} x - 4y \\ \text{s.t. } y \text{ solves } \min_y \\ \text{s.t. } x + y \geq 3 \\ 2x - y \geq 0 \\ -2x - y \geq -12 \\ -3x + 2y \geq -4 \end{aligned}$$

and the EMPLIB model **bard511** contains the following code:

```
Positive variables x, y;
Variables objout, objin;
equations defout, defin, e1, e2, e3, e4;
defout.. objout =e= x - 4*y;
defin.. objin =e= y;
e1.. x + y =g= 3;
e2.. 2*x - y =g= 0;
e3.. -2*x - y =g= -12;
e4.. -3*x + 2*y =g= -4;
model bard / all /;
$echo bilevel x min objin y defin e1 e2 e3 e4 > "%emp.info%"
solve bard using emp minimizing objout;
```

Note that first the functions that form the objectives and constraints of the model are defined and the model is assembled. The `$echo` line writes the "empinfo" file and states that the lower level problem

involves the objective `objin` which is to be minimized by choice of variables `y` subject to the constraints specified in (`defin`), `e1`, `e2`, `e3`, and `e4`.

Note that the variables `x` are declared to be variables of the upper level problem and this example has no upper level constraints `g`. Having written the problem in this way, the MPCC is generated automatically, and passed on to a solver. In the case where that solver is NLPEC, a further reformulation of the model is carried out to convert the MPCC into an equivalent NLP or a parametric sequence of NLP's.

Further examples of bilevel models in **EMPLIB** are named: `bard*`, `ccmg74`, `ccmg153`, `flds*`, `jointc1`, `jointc2`, `mirrlees`, `transbp`.

The EMP model type allows multiple lower level problems to be specified within the bilevel format. An example of this is given in EMPLIB as **ccmg71**. The equations and objectives are specified in the normal manner; the only change is the definition of the "empinfo" file, shown below:

```
...
defh1.. h1 =e= sqrt(u1-x1) + sqrt(u2-x2) + sqrt(u3-x3) + sqrt(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$onecho > "%emp.info%"
bilevel x1 x2 x3 x4
min h1 u1 u2 u3 u4 defh1 e1
min h2 v1 v2 v3 v4 defh2 e2
$offecho
```

This corresponds to a bilevel program with two followers, both solving minimization problems. The first follower minimizes the objective function `h1` (defined in `defh1`) over the variables `u1`, `u2`, `u3`, and `u4` subject to the constraint given in `e1`. The second followers problem is defined analogously next. Note that `h1` involves the variables `x1`, `x2`, `x3`, and `x4` that are optimization variables of the leader. The constraint in `e1` could also include these variables, and also the variables `v1`, `v2`, `v3`, or `v4` of the second follower, but all of these would be treated as parameters by the first follower.

The actual model (**ccmg71**) in EMPLIB uses a shortcut notation:

```
...
defh1.. h1 =e= sqrt(u1-x1) + sqrt(u2-x2) + sqrt(u3-x3) + sqrt(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$onecho > "%emp.info%"
bilevel x1 x2 x3 x4
min h1 * defh1 e1
min h2 * defh2 e2
$offecho
```

In the followers problem, the '*' notation indicates that this agent will optimize over all the variables used in `defh1` and `e1` that are not under the control of any other follower or the leader. In this case, this means `u1`, `u2`, `u3`, and `u4`. To avoid confusion, it is recommended that the modeler explicitly names all the variables in each followers problem as shown before.

5.22.6 Variational Inequalities

A variational inequality $VI(F, X)$ is to find $x \in X$:

$$\langle F(x), (z - x) \rangle \geq 0, \text{ for all } z \in X.$$

Here X is a closed (frequently assumed convex) set, defined for example as

$$X = \{x \mid x \geq 0, h(x) \geq 0\}.$$

Note that the first-order (minimum principle) conditions of a nonlinear program

$$\min_{z \in X} f(z)$$

are precisely of this form with $F(x) = \nabla f(x)$.

It is well known that such problems can be reformulated as complementarity problems when the set X has the representation $\{x \mid x \geq 0, h(x) \geq 0\}$ by introducing multipliers λ on the constraints $h(x) \geq 0$:

$$\begin{array}{rcl} 0 \leq F(x) - \langle \lambda, \nabla h(x) \rangle & \perp & x \geq 0 \\ 0 \leq h(x) & \perp & \lambda \geq 0. \end{array}$$

If X has a different representation, this construction would be modified appropriately.

A simple two dimensional example may be useful to improve understanding. Let

$$F(x) = \begin{bmatrix} x_1 + 2 \\ x_1 + x_2 - 3 \end{bmatrix}, \quad X = \{x \geq 0 \mid x_1 + x_2 \leq 1\},$$

so that F is an affine function, but F is not the gradient of any function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$. For this particular data, $VI(F, X)$ has a unique solution $x = (0, 1)$.

```
Set J / 1, 2 /;
Positive Variable x(J) 'vars, perp to f(J)';
Equations F(J), h;
F(J).. (x('1') + 2)$sameas(J,'1') + (x('1') + x('2') - 3)$sameas(J,'2') =n= 0 ;
h.. x('1') + x('2') =l= 1;
model simpleVI / F, h/;
file fx /"%emp.info%"/;
putclose fx 'vi F x h';
solve simpleVI using emp;
```

Note that the first lines of this file define the F and h using standard GAMS syntax and include the defining equations in the model `simpleVI`. The extension is the annotation "empinfo" file that indicates certain equations are to be treated differently by the EMP tool. The annotation simply says that the model is a VI (vi) that pairs F with x and that the remaining (unpaired) equations form the constraint set X . (Alternative notation allows the keyword `vi` to be replaced by `vifunc`.) Thus, model equations F define a function F that is to be part of a variational inequality, while the equations h define constraints of X . It is also acceptable in this setting to use the "empinfo" file defined by:

```
putclose fx 'vi F x';
```

In this case, by default, any equations that are given in the model statement but not included as a pair in the `vi` statement are automatically used to form X . An alternative way to write this model without using `sameas` is given in EMPLIB as `affinevi`.

Some subtleties related to VI's are demonstrated in the EMPLIB model `zerofunc`. In this model, the set X is defined using variables y and z , for which z does not appear in the definition of $F \equiv F_y$. In this case, the variable z is then matched with a "0" function. The "empinfo" file can be written in a number of different ways:

```
putclose fx 'vi F_y y';
```

or

```
putclose fx 'vi z F_y y';
```

or

```
putclose fx 'vi z F_y y gCons';
```

or

```
putclose fx 'vi F_z z F_y y gCons';
```

where `F_z` simply defines the zero function. To some extent, our preferred notation is the one listed third: it explicitly includes all the variables and constraints that are present in the model and does not require the modeler to define `F_z` at all.

Further example models in EMPLIB are `simplevi`, `simplevi2`, `simplevi3`, `target`, `traffic`, `traffic2`, and `transvi`.

Note also that the lower level problems of a bilevel program could be VI's instead of optimization problems - these problems are called Mathematical Programs with Equilibrium Constraints (MPEC) in the literature. Note that since MPCC is a special case of MPEC, the GAMS model type MPEC covers both. An example demonstrating this setup is given in EMPLIB as `multmpcc`. The actual model to solve is:

$$\begin{aligned} & \min_{u,v,w,z} z \\ & \text{s.t. } \exp(z) + w = 2, z \geq 1 \\ & \quad (u, v) \text{ solves VI}([v + w + z - 1; u - \log(v)], \{(u, v) \mid u \geq 0, v \geq 0\}) \\ & \quad w \text{ solves VI}(w + z + 3, \{w \mid w \text{ free}\}) \end{aligned}$$

Note that the two VI's (due to the definitional sets) correspond respectively to a complementarity problem:

$$\begin{aligned} 0 \leq v + w + z - 1 & \quad \perp \quad u \geq 0 \\ 0 \leq u - \log(v) & \quad \perp \quad v \geq 0 \end{aligned}$$

and a linear equation:

$$w + z + 3 = 0$$

The actual GAMS code is as follows:

```
Positive Variable u;
Variables v, w, z;
Equations f1, f2, f3, h;
f1.. v + w + z =n= 1;
f2.. u =n= log(v);
f3.. w + z =n= -3;
h.. exp(z) + w =e= 2;
v.lo = 0; v.l = 1; z.lo = 1;
model mpecmod /all/;
$onecho > %emp.info%
bilevel
  vi f1 u
  f2 v
  vi f3 w
$offecho
solve mpecmod using emp min z;
```

The initial level value for `v` (`v.l = 1`) is needed to protect the evaluation of `log(v)`. The two complementarity problems are specified in the `empinfo` file (it is not really necessary to split these VI's apart, but it may give information to a solver that can be exploited). It is of course possible to write the MPCC directly in GAMS using the model type MPEC instead of EMP.

5.22.7 Embedded Complementarity Systems

A different type of embedded optimization model that arises frequently in applications is:

$$\begin{aligned} \max_x \quad & f(x, y) \\ \text{s.t.} \quad & g(x, y) \leq 0 \quad (\perp p \geq 0) \\ & H(x, y, p) = 0 \quad (\perp y \text{ free}) \end{aligned}$$

Note the difference here: the optimization problem is over the variable x , and is parameterized by the variable y . The choice of y is fixed by the (auxiliary) complementarity relationships depicted here by H . Note that the H equations are not part of the optimization problem, but are essentially auxiliary constraints to tie down remaining variables in the model.

A specific example is:

$$\begin{aligned} \max_x \quad & x \\ \text{s.t.} \quad & x + y \leq 1 \\ & -3x + y = 0.5 \quad (\perp y \text{ free}) \end{aligned}$$

which is found in the EMPLIB model **simpequil2**:

```
Variables y;
Positive variables x;
Equations optcons, vicons;
optcons.. x + y =1= 1;
vicons.. -3*x + y =e= 0.5;
model comp / optcons, vicons /;
file info / '%emp.info%' /;
put info / 'equilibrium';
put      / 'max x optcons';
putclose / 'vi vicons y';
solve comp using emp;
```

In order that this model can be processed correctly as an EMP, the modeler provides additional annotations to the model defining equations in an "empinfo" file. Specifically, first it is indicated that the problem is an equilibrium problem involving one or more agent problems. Next, the first agent is defined as an optimizer (over x). Finally, the second agent is defined as solving a VI in y . Armed with this additional information, the EMP tool automatically creates the following MCP:

$$\begin{aligned} 0 &\leq -1 + p && \perp x \geq 0 \\ 0 &\leq 1 - x - y && \perp p \geq 0 \\ 0 &= -3x + y - 0.5 && \perp y \text{ free,} \end{aligned}$$

(which is formed by the steps we outline below). EMP explicitly enforces the rule that every variable and constraint is under the control of exactly one agent. Thus a constraint or a variable cannot appear in both the max problem and the VI problem.

The above example is slightly simpler than the general form described above in which H is a function of x , y , and p , the multiplier on the constraint of the optimization problem. The problem is that we do not have that variable around in the model code if we only specify the optimization problem there. This occurs for example in the classical PIES Model due to Hogan. In this setting, the problem is described by a linear program

$$\begin{aligned} \min_x \quad & c^T x \\ \text{s.t.} \quad & Ax = q(p) \\ & Bx = b \\ & x \geq 0 \end{aligned}$$

in which the quantity q is a function of p , which is a multiplier on one of the LP constraints. To do this in EMP, we simply add the annotation:

```
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo / '%emp.info%' /;
put myinfo 'equilibrium';
put 'min obj c o ct ot lt ht defobj dembal cmbal ombal lmbal hmbal ruse';
putclose 'dualvar p dembal';
solve piesemp using emp;
```

where `dembal` is the name of the constraint for which `p` needs to be the multiplier. The full model is found in the EMPLIB model `pies`. Two final points: the `dualvar` directive identifies the variable `p` with the multiplier on the `dembal` constraint, and all variables and constraints must be owned by a single agent. In this case, since there is only one agent (the minimizer), all constraints of the model are explicitly claimed, along with all variables except for `p`. However, next, `p` is identified with the `dembal` constraint, which is owned by the min agent, and hence `p` is also owned by that agent.

There are several shorthands possible here. The first is that the explicit statement of variables can be replaced by the '*' form:

```
model pie Kemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'%emp.info%'/;
put myinfo 'equilibrium ';
put 'min obj * defobj dembal cmbal ombal lmbal hmbal ruse ';
```

Alternatively, an even shorter version is possible since there is only one agent present in this model, namely:

```
model pie Kemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'%emp.info%'/;
putclose myinfo 'dualvar p dembal';
solve pie Kemp using emp minimizing obj;
```

Note that in this form, all the variables and constraints of the original model are included in the (single) agent's problem, and the original variable `p` is identified in the constructed MCP with the multiplier on the `dembal` constraint.

In the general case where the "empinfo" file contains all three lines:

```
min x optcons
vi vicons y
dualvar p optcons
```

namely that the function H that is defined in `vicons` is complementary to the variable y (and hence the variable y is a parameter to the optimization problem), and furthermore that the dual variable associated with the equation `optcons` in the optimization problem is one and the same as the variable `p` used to define H , the EMP tool automatically creates the following MCP:

$$\begin{aligned} 0 &= \nabla_x \mathcal{L}(x, y, p) && \perp & x \text{ free} \\ 0 &\geq -\nabla_p \mathcal{L}(x, y, p) && \perp & p \leq 0 \\ 0 &= H(x, y, p) && \perp & y \text{ free,} \end{aligned}$$

where the Lagrangian is defined as

$$\mathcal{L}(x, y, p) = f(x, y) - \langle p, g(x, y) \rangle.$$

Essentially, this MCP consists of the first order optimality conditions of the optimization problem, coupled with the VI that is the second agent's problem. An example that does both of these things together is provided in EMPLIB as `scarfemp-primal`.

Note that since the PIES model has no y variables, this is a special case of the general form in which the second agent's (VI) problem is simply not present.

Example models are `ferris43`, `flipper pies`, `scarfemp-dual`, `simpequill`, `transecs`, and `transeql`.

5.22.8 MOPECs

MOPECs (Multiple Optimization Problems with Equilibrium Constraints) are a simple conceptual extension of the aforementioned embedded complementarity system. Instead of having a single optimizing agent and a variational inequality, one instead allows multiple optimizing agents coupled with an equilibrium constraint (the variational inequality).

Perhaps the most popular use of this formulation is where competition is allowed between agents. A standard method to deal with such cases is via the concept of Nash Games. In this setting x^* is a Nash Equilibrium if

$$x_i^* \in \arg \min_{x_i \in X_i} \ell_i(x_i, x_{-i}^*, q), \forall i \in \mathcal{I},$$

where x_{-i} are other players decisions and the quantities q are given exogenously, or via complementarity:

$$0 \leq H(x, q) \quad \perp \quad q \geq 0.$$

This mechanism is extremely popular in economics, and Nash famously won the Nobel Prize for his contributions to this literature.

This format is again an EMP, more general than the example given above in two respects. Firstly, there is more than one optimization problem specified in the embedded complementarity system. Secondly, the parameters in each optimization problem consist of two types. Firstly, there are the variables q that are tied down by the auxiliary complementarity condition and hence are treated as parameters by the i th Nash player. Also there are the variables x_{-i} that are treated as parameters by the i th Nash player, but are treated as variables by a different player j .

While we do not specify the syntax here for these issues, **EMPLIB** provides examples that outline how to carry out this matching within GAMS. Finally, two points of note: first it is clear that the resulting model is a complementarity problem and can be solved using PATH, for example. Secondly, performing the conversion from an embedded complementarity system or a Nash Game automatically is a critical step in making such models practically useful.

We note that there is a large literature on discrete-time finite-state stochastic games: this has become a central tool in analysis of strategic interactions among forward-looking players in dynamic environments. The model of dynamic competition in an oligopolistic industry given in [77] is exactly in the format described above, and has been used extensively in applications such as advertising, collusion, mergers, technology adoption, international trade and finance. Ongoing work aims to use the EMP format to model these problems.

5.22.9 Extended Nonlinear Programs

Optimization models have traditionally been of the form (NLP). Specialized codes have allowed certain problem structures to be exploited algorithmically, for example simple bounds on variables. However, for the most part, assumptions of smoothness of f , g and h are required for many solvers to process these problems effectively. In a series of papers, Rockafellar and colleagues [208] [209] [210] have introduced the notion of extended nonlinear programming, where the (primal) problem has the form:

$$\min_{x \in X} f(x) + \theta(g_1(x), \dots, g_m(x)). \quad (\text{ENLP})$$

In this setting, X is assumed to be a nonempty polyhedral set, and the functions f, g_1, \dots, g_m are smooth. The function θ can be thought of as a generalized penalty function that may well be nonsmooth. However, when θ has the form

$$\theta(u) = \sup_{y \in Y} \{\langle y, u \rangle - k(y)\}, \quad (\theta \text{ conj})$$

a computationally exploitable and theoretically powerful framework can be developed based on conjugate duality. A key point for computation and modeling is that the function θ can be fully described by defining the set Y and the function k . Furthermore, from a modeling perspective, an extended nonlinear program can be specified simply by defining the functions f, g_1, \dots, g_m in the manner already provided by the modeling system, with the additional issue of simply defining Y and k . Conceptually, this is not much harder than what is carried out already, but leads to significant enhancements to the types of models that are available. Once a modeler determines which constraints are treated via which choice of k and Y , the EMP model interface automatically forms an equivalent variational inequality or complementarity problem. As we show later, there may be alternative formulations that are computationally more appealing; such reformulations can be generated using different options to JAMS.

5.22.9.1 Forms of theta

The EMP model type makes the problem format (ENLP) available to users in GAMS. As special cases, we can model piecewise linear penalties, least squares, and L_1 approximation problems, as well as the notion of soft and hard constraints.

For ease of exposition, we now describe a subset of the types of functions θ that can be generated by particular choices of Y and k . In many cases, the function θ is separable, that is

$$\theta(u) = \sum_{i=1}^m \theta_i(u_i),$$

so we can either specify θ_i or θ itself.

Extended nonlinear programs include the classical nonlinear programming form (NLP) as a special case. This follows from the observation that if K is a closed convex cone, and we let ψ_K denote the "indicator function" of K defined by:

$$\psi_K(u) = \begin{cases} 0 & \text{if } u \in K, \\ \infty & \text{else,} \end{cases}$$

then (NLP) can be rewritten as:

$$\min_x f(x) + \psi_K((g(x), h(x))), \quad K = \mathbf{R}_-^m \times \{0\}^p,$$

where m and p are the dimensions of g and h respectively and $\mathbf{R}_-^m = \{u \in \mathbf{R}^m \mid u \leq 0\}$. An elementary calculation shows that

$$\psi_K(u) = \sup_{v \in K^\circ} \langle u, v \rangle,$$

where $K^\circ = \{u \mid \langle u, v \rangle \leq 0, \forall v \in K\}$ is the polar cone of the given cone K . Thus, when $\theta(u) = \psi_K(u)$ we simply take $k \equiv 0$ and $Y = K^\circ$. In our example, $K^\circ = \mathbf{R}_+^m \times \mathbf{R}^p$. To some extent, this is just a formalism that allows us to claim the classical case as a specialization; however when we take the cone K to be more general than the polyhedral cone used above, we can generate conic programs for example.

The second example involves a piecewise linear function θ : Formally, for $u \in \mathbf{R}$,

$$\theta(u) = \begin{cases} \rho u & \text{if } u \geq 0, \\ \sigma u & \text{else.} \end{cases}$$

In this case, simple calculations prove that θ has the form (θ conj) for the choices

$$k \equiv 0 \text{ and } Y = [\sigma, \rho].$$

The special case where $\sigma = -\rho$ results in

$$\theta(u) = \rho |u|.$$

This allows us to model nonsmooth L_1 approximation problems. Another special case results from the choice of $\sigma = -\gamma, \rho = 0$, whereby

$$\theta(u) = \gamma \max\{-u, 0\}.$$

This formulation corresponds to a soft penalization on an inequality constraint, namely if $\theta(-g_1(x))$ is used then nothing is added to the objective function if $g_1(x) \leq 0$, but $\gamma g_1(x)$ is added if the constraint $g_1(x) \leq 0$ is violated. Contrast this to the classical setting above, where ∞ is added to the objective if the inequality constraint is violated. It is interesting to see that truncating the set Y , which amounts to bounding the multipliers, results in replacing the classical constraint by a linearized penalty.

The third example involves a more interesting choice of k . If we wish to replace the "absolute value" penalization given above by a quadratic penalization (as in classical least squares analysis), that is

$$\theta(u) = \gamma u^2$$

then a simple calculation shows that we should take

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = \mathbf{R}.$$

By simply specifying this different choice of k and Y we can generate such models easily and quickly within the modeling system. Note, however, that the reformulation we would use in $\theta(u) = \rho |u|$ and $\theta(u) = \gamma u^2$ are very different as we shall explain in the simple example below. Furthermore, in many applications it has become popular to penalize violations using a quadratic penalty only within a certain interval, afterwards switching to a linear penalty (chosen to make the penalty function θ continuously differentiable - see [131]). That is:

$$\theta(u) = \begin{cases} \gamma u - \frac{1}{2}\gamma^2 & \text{if } u \geq \gamma \\ \frac{1}{2}u^2 & \text{if } u \in [-\gamma, \gamma] \\ -\gamma u - \frac{1}{2}\gamma^2 & \text{else.} \end{cases}$$

Such functions arise from quadratic k and simple bound sets Y . In particular, the somewhat more general function

$$\theta(u) = \begin{cases} \gamma\beta^2 + \rho(u - \beta) & \text{if } u \geq \beta \\ \gamma u^2 & \text{if } u \in [\alpha, \beta] \\ \gamma\alpha^2 + \sigma(u - \alpha) & \text{else} \end{cases}$$

arises from the choice of

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = [\sigma, \rho],$$

with $\alpha = \frac{\sigma}{2\gamma}$ and $\beta = \frac{\rho}{2\gamma}$.

The final example that we give is that of L_∞ penalization. This example is different to the examples given above in that θ is not separable. However, straightforward calculation can be used to show

$$\theta(u) = \max_{i=1, \dots, m} u_i$$

results from the choice of

$$k \equiv 0 \text{ and } Y = \left\{ y \in \mathbf{R}^m \mid y \geq 0, \sum_{i=1}^m y_i = 1 \right\},$$

that is, Y is the unit simplex.

5.22.9.2 Underlying theory

The underlying structure of θ leads to a set of extended optimality conditions and an elegant duality theory. This is based on an extended form of the Lagrangian:

$$\mathcal{L}(x, y) = f(x) + \sum_{i=1}^m y_i g_i(x) - k(y)$$

$$x \in X, y \in Y$$

Note that the Lagrangian \mathcal{L} is smooth - all the nonsmoothness is captured in the θ function. The theory is an elegant combination of calculus arguments related to g_i and its derivatives, and variational analysis for features related to θ .

It is shown in [209] that under a standard constraint qualification, the first-order conditions of (ENLP) are precisely in the form of the following variational inequality:

$$\text{VI} \left(\begin{bmatrix} \nabla_x \mathcal{L}(x, y) \\ -\nabla_y \mathcal{L}(x, y) \end{bmatrix}, X \times Y \right). \quad (\text{ENLP VI})$$

When X and Y are simple bound sets, this is simply a complementarity problem.

Note that EMP exploits this result. In particular, if an extended nonlinear program of the form (ENLP) is given to EMP, then the optimality conditions (ENLP VI) are formed as a variational inequality problem and can be processed as outlined above. For a specific example, we cite the fact that if we use the (classical) choice $k \equiv 0$ and $Y = K^\circ$, then the optimality conditions of (ENLP) are precisely the standard complementarity problem given as (ENLP VI). While this is of interest, we believe that other choices of k and Y may be more useful and lead to models that have more practical significance.

Under appropriate convexity assumptions on this Lagrangian, it can be shown that a solution of the VI (ENLP VI) is a saddle point for the Lagrangian on $X \times Y$. Furthermore, in this setting, the saddle point generates solutions to the primal problem (ENLP) and its dual problem:

$$\max_{y \in Y} d(y), \quad \text{where } d(y) = \inf_{x \in X} \mathcal{L}(x, y),$$

with no duality gap.

Unfortunately, the perturbations y in Rockafellar's theory are precisely the negative of those used throughout the GAMS system. Thus, we need to replace y by $-y$ throughout in the above to recover the same multipliers as those GAMS uses.

5.22.9.3 A simple example

As an example, consider the problem

$$\begin{aligned} \min_{x_1, x_2, x_3} \quad & \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2 \max(x_2^2 - 2, 0) \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

In this problem, we would take

$$X = \{x \in \mathbf{R}^3 \mid 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0\}.$$

The function θ essentially treats 3 separable pieces:

$$\begin{aligned} g_1(x) &= \log(x_1) - 1, \\ g_2(x) &= x_2^2 - 2, \\ g_3(x) &= x_1/x_2 - \log(x_3). \end{aligned}$$

A classical problem would force $g_1(x) = 0$, $g_2(x) \leq 0$, and $g_3(x) = 0$, while minimizing $f(x) = \exp(x_1)$. In our problem, we still force $g_3(x) = 0$, but apply a (soft) least squares penalty on $g_1(x)$ and a smaller

one-sided penalization on $g_2(x)$. The above formulation is nonsmooth due to the "max" term in the objective function; in practice we could replace this by:

$$\begin{aligned} \min_{x_1, x_2, x_3, w} \quad & \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2w \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\ & w \geq x_2^2 - 2, w \geq 0 \end{aligned}$$

and recover a standard form NLP. If the penalty on $g_1(x)$ would be replaced by a one-norm penalization (instead of least squares), we would have to play a similar game, moving the function $g_1(x)$ into the constraints and adding additional variable(s). To some extent, this seems unnatural - a modeler should be able to interchange the penalization without having to reformulate the problem from scratch. The proposed extended NLP would not be reformulated at all by the modeler, but allows all these "generalized constraints" to be treated in a similar manner within the modeling system. The actual formulation would take:

$$\theta(u) = \theta_1(u_1) + \theta_2(u_2) + \theta_3(u_3)$$

where

$$\begin{aligned} \theta_1(u_1) &= 5u_1^2, \\ \theta_2(u_2) &= 2 \max(u_2, 0), \\ \theta_3(u_3) &= \psi_{\{0\}}(u_3). \end{aligned}$$

The discussion above allows us to see that

$$\begin{aligned} Y &= -(\mathbf{R} \times [0, 2] \times \mathbf{R}), \\ k(y) &= \frac{1}{20}y_1^2 + 0 + 0. \end{aligned}$$

The corresponding Lagrangian is the smooth function:

$$\mathcal{L}(x, y) = f(x) - \sum_{i=1}^3 y_i g_i(x) - k(y).$$

The corresponding VI ([ENLP VI](#)) can almost be formulated in GAMS (except that the linear constraint in X cannot be handled currently except by introducing a $\theta_4(x)$). Thus

$$g_4(x) = 3x_1 + x_2 - 5, \theta_4(u) = \psi_{\mathbf{R}_-}$$

resulting in the following choices for Y and k :

$$\begin{aligned} Y &= -(\mathbf{R} \times [0, 2] \times \mathbf{R} \times \mathbf{R}_+), \\ k(y) &= \frac{1}{20}y_1^2 + 0 + 0 + 0. \end{aligned}$$

Since X and Y are now simple bound sets, ([ENLP VI](#)) is now a complementarity problem and can be solved for example using PATH. A simple "empinfo" file details the choices of Y and k from the implemented library:

```
Adjustequ
e1 sqr 5
e2 MaxZ 2
```

5.22.9.4 Reformulation as a classical NLP

Suppose

$$\theta(u) = \sup_{y \in Y} \{ \langle u, y \rangle - \frac{1}{2} \langle y, Qy \rangle \}$$

for a polyhedral set $Y \in \mathbf{R}^m$ and a symmetric positive semidefinite $Q \in \mathbf{R}^{m \times m}$ (possibly $Q = 0$).

Suppose further that

$$\begin{aligned} X &= \{x \mid Rx \leq r\}, Y = \{y \mid S^T y \leq s\}, \\ Q &= DJ^{-1}D^T, F(x) = (g_1(x), \dots, g_m(x)), \end{aligned}$$

where J is symmetric and positive definite (for instance $J = I$). Then, as outlined by [210], the optimal solutions \bar{x} of (ENLP) are the \bar{x} components of the optimal solutions $(\bar{x}, \bar{z}, \bar{w})$ to

$$\begin{aligned} \min \quad & f(x) + \langle s, z \rangle + \frac{1}{2} \langle w, Jw \rangle \\ \text{s.t.} \quad & Rx \leq r, z \geq 0, F(x) - Sz - Dw = 0. \end{aligned}$$

The multiplier on the equality constraint in the usual sense is the multiplier associated with \bar{x} in the extended Lagrangian for (ENLP). (Note that a Cholesky factorization may be needed to determine D .)

It may be better to solve this reformulated NLP than to solve the VI (ENLP VI). However, it is important that we can convey all types of nonsmooth optimization problems to a solver as smooth optimization problems, and hence it is important to communicate the appropriate structure to the solver interface. We believe that specifying Y and k is a theoretically sound way to do this.

5.22.10 Disjunctive Programs (LogMIP)

There are many ways that the EMP model type can be used for further extensions to the modeling capabilities of a given system. In particular, the procedures outlined in [248] [101] for disjunctive programming extensions are also implemented within the EMP model type.

The disjunctive programming procedures are also known as the LogMIP 2.0 solver for solving linear and nonlinear disjunctive programming problems involving binary variables and disjunction definitions for modeling discrete choices. While the modeling and solution of these disjunctive optimization problems has not yet reached the stage of maturity and reliability as LP, MIP and NLP modeling, these problems have a rich area of applications.

LogMIP 2.0 has been developed by Dr. Aldo Vecchietti from INGAR (Santa Fe, Argentina) and Professor Ignacio E. Grossmann from Carnegie Mellon University (Pittsburgh, USA), and supersedes its previous version, LogMIP 1.0 (GAMS releases 22.6 (December 2007) to 23.6 (December 2010)). Changes in version 2.0 are at the level of language, where now the EMP syntax and modeltype is used, and at the level of solvers, where Big-M and convex-hull relaxations are combined. For more information see the website <http://www.logmip.ceride.gov.ar/> and the documentation <http://www.logmip.ceride.gov.ar/files/pdfs/newUserManual.pdf>.

One simple example to highlight the disjunctive programming feature is the notion of an ordering of tasks, namely that either job i completes before job j starts or the converse, i.e., that the jobs cannot overlap. Such a disjunction can be specified using an empinfo file containing lines:

```
disjunction * seq(i,j) else seq(j,i)
```

In such an example, one can implement a Big-M method, employ indicator constraints, or utilize a convex hull reformulation. The convex hull reformulation is the default strategy; to utilize the Big-M formulation, the additional option

```
default bigm 1000
```

would add binary variables and constraints to impose the disjunction using a Big-M value of 1000. Alternatively, the option setting

```
default indic
```

writes out a model and an option file that implements a reformulation using indicator constraints, which can be handled by the solvers CPLEX, SCIP, and XPRESS. The EMPLIB model **sequence** is sequencing model that implements all of these options.

More complicated (nonlinear) examples make the utility of this approach clearer. The design of a multiproduct batch plan with intermediate storage described in [247] and a synthesis problem involving 8 processes from [244] are also included in the EMP model library. As a final example, the gasoline emission model outlined in [100] is precisely in the form that could exploit the features of EMP related to (nonlinear) disjunctive programming.

5.22.11 Empinfo file details

We have explained above many of the standard vectorized ways to write an "empinfo" file. The "empinfo" file has a vectorized format and a more powerful (but more complex) scalar version. We describe some of the features of the scalar version in this section.

An example of the use of the scalar syntax is given below

```
file info / '%emp.info%' /;
put info / 'equilibrium';
loop(h,
  put / 'min' obj(h) /;
  loop(j, put x(h,j)); put /;
  loop(k, put z(h,k));
  put / costdef(h) /;
  loop(i, put nodebal(h,i)); put /;
);
loop(a, put 'vi',flowdef(a),f(a) /);
```

This is an example of a MOPEC in which the optimization agents are indexed by h and each of these agents control variables x_{hj} and z_{hk} . The objective function for each h is defined in `costdef`, the constraints of each minimization problem are defined in `nodebal`, and the equilibrium constraints that link all the optimization problems are a VI defined by variables f_a and functions within `flowdef`. Sometimes it is necessary to use syntax that generates the "tl" fields of sets, but this seems only necessary when abnormal side conditions are needed.

The format of the empinfo file is given below:

```
Disjunction [chull [big eps] | bigM [big eps threshold] | indic]
            [NOT] var[* [NOT] {equ} {ELSEIF [NOT] var[* [NOT] {equ}}] [ELSE [NOT] {equ}]]

Default [chull [big eps] | bigM [big eps threshold] | indic]

ParallelStep1 {equ|*}

AdjustEqu equ abs|sqr|maxz|... {weight}
```

```
ModelType MCP|NLP|MIP|...
```

```
BiLevel {var} {MAX|MIN obj {var|*} {[ -] equ}} {VI {var|*} {[ -] equ var} {[ -] equ}}
        {DualVar {var [-] equ}}
```

```
Equilibrium {Implicit {var equ}} {VIsol {equ}}
            {MAX|MIN obj {var|*} {[ -] equ}} {VI {var|*} {[ -] equ var} {[ -] equ}}
            {DualVar {var [-] equ}}
```

```
VI {var|*} {[ -] equ var} {[ -] equ}
```

```
DualEqu {[ -] equ var}
```

```
DualVar {var [-] equ}
```

```
-----
```

```
[ ] optional      | exclusive      { } can be repeated
```

5.23 KESTREL - Remote Solver Execution on NEOS Servers

5.23.1 Background

The Kestrel client/server is a way of sending your GAMS solve job to be solved via the NEOS Server from within your usual GAMS modeling environment and receiving results that can be processed as with any local solver. Starting with distribution 23.7 the Kestrel solver is part of the GAMS distribution. The solve statement using the GAMS/KESTREL solver invokes a client program that sends your problem to a solver running on one of the NEOS Server's remote computers. The results from the NEOS Server are eventually returned through Kestrel to GAMS, where you can view and manipulate them locally in the usual way. The introduction below covers everything you need to know to start using GAMS/KESTREL. Further information about more advanced features and other uses of Kestrel can be found at the [Kestrel page on the NEOS Server](#). Please also make you familiar with the [NEOS optimization service terms of use](#) before submitting jobs via GAMS/KESTREL.

5.23.1.1 Kestrel and IBM DOcloud

With GAMS 24.6 the GAMS/Kestrel client has been adjusted to work with IBM's cloud service [Decision Optimization on Cloud \(DOcloud\)](#). When the Kestrel option `docloudurl` is set, the generated model instance will be automatically translated into an MPS format and send to DOcloud and solved by Cplex in IBM's cloud. So no GAMS/Cplex license is required on your local machine. You as a user need to register with IBM on the web page mentioned about and pay IBM for the solution time spend in IBM's cloud. IBM provides details how to [get started](#) with DOcloud.

5.23.2 Using GAMS/KESTREL

The Kestrel solver can be used to solve a GAMS model remotely. For example, consider the **trnsport model**. It can be solved locally in GAMS through the following statements,

```
model transport /all/;
solve transport using lp minimizing z;
```

which specify the `transport` model and solve it with the default linear programming solver. We can add an option statement to the code to explicitly specify the solver. For example, if we change the linear programming solver to GAMS/MINOS, the code becomes

```
model transport /all/;
option lp=minos;
solve transport using lp minimizing z;
```

To solve the same problem remotely through the NEOS Server, we simply change the linear programming solver to Kestrel. In addition we have to provide an email address. This can be specified either in an option file or by setting the environment variable `NEOS_EMAIL`. In order to set this permanently, it is recommended to add `NEOS_EMAIL` to your [gamsconfig.yaml](#) file.

Without an option file Kestrel will submit the model instance to the NEOS server and use the default LP solver on NEOS.

```
option lp=kestrel;
solve transport using lp minimizing z;
```

We can support a Kestrel option file and determine the solver on the NEOS server:

```
transport.optfile=1;
option lp=kestrel;
solve transport using lp minimizing z;
$echo email jdoe@jeangreyhigh.edu > kestrel.opt
$echo kestrel_solver minos >> kestrel.opt
```

The statement `transport.optfile=1` specifies that an options file, called `kestrel.opt`, will be used. The options file contains the email address, the remote solver name as well as any options for the remote solver. We instruct the Kestrel solver to use GAMS/MINOS as the remote solver by writing the following `kestrel.opt` file:

```
email jdoe@jeangreyhigh.edu
kestrel_solver minos
```

If you do not know what solvers are available via GAMS/KESTREL on NEOS, submitting a job with a nonexistent solver set will return a list of enabled solvers. If you want to change the URL of the server, you can specify the option `neos_server`. The complete format of the parameter is `protocol://host:port`.

A subsequent run of the code through the GAMS interpreter results in the `transport` model being solved through the NEOS Server with the GAMS/MINOS solver. Once the job is submitted to the NEOS Server, a job number, password, and Web address are displayed to the screen, which provide information on accessing the job and viewing the intermediate output, for example,

```
--- Executing KESTREL
Job has been submitted to Kestrel
Kestrel/NEOS Job number      : 93478
Kestrel/NEOS Job password   : utiwtxTK
Check the following URL for progress report :
      https://neos-server.org/neos/cgi-bin/nph-neos-solver.cgi?admin=results&jobnumber=93478&pass=uti
```

To look at the solver's output while it is running, point your browser at the URL given in the Kestrel output as shown above, and click on **View Intermediate Results** in the web page that appears. This will take you to another page that shows all of the output produced by the solver for your problem so far. To track the solver's progress, simply update this page periodically.

If the NEOS Server or the network becomes unavailable after the submission, a particular job can be retrieved by setting both the `kestrel_job` and `kestrel_password` in the options file.

```
kestrel_solver minos
kestrel_job 93478
kestrel_password utiwtxTK
```

Re-issuing the command `gams transport` with this options file will retrieve the results for the specified job number.

By specifying `neos_username` and `neos_user_password` in the option file, you can submit an authenticated job using your NEOS user account. Authenticated jobs will appear in your user account on the NEOS website.

```
neos_username username
neos_user_password password
```

5.23.2.1 Using GAMS/KESTREL with IBM DOcloud

In order to use GAMS/Kestrel to solve model instances with Cplex on IBM's DOcloud, the only thing that needs to be done is to provide a different option file. The option `docloud_url` triggers the submission to IBM's DOcloud rather than NEOS. You need an account on DOcloud (and pay IBM for the Cplex solution time in their cloud). Some additional account information needs to be specified in the Kestrel option `docloud_key`. The use of Cplex in DOcloud is limited to solve a model instance, special options that are available in the GAMS/Cplex system, like [IIS](#) or [FeasOpt](#) cannot be used (yet) through Kestrel/DOcloud. Moreover, for problems with discrete variables, only the primal solution is returned. If you want to specify Cplex options this needs to be done with a Cplex parameter file which is quite different from the GAMS/Cplex option file. You can use a GAMS/Cplex option file and have the additional option [WriteParam](#) to produce such a Cplex parameter file. The Cplex parameter file might have a few more options compared to the GAMS/Cplex option file because some [GAMS options](#) set Cplex parameters. Please note that you can produce the Cplex parameter file with GAMS/Cplex even if you do not have a license for GAMS/Cplex as long as you run a demo sized model (e.g. from the GAMS Model Library) to produce the Cplex parameter file. The following GAMS/Cplex optfile

```
lpmethod 4
advind 0
eprhs 1e-4
scaind 1
writeparam cplex.prm
```

produces the Cplex parameter file `cplex.prm` which can be submitted to Kestrel/DOcloud via the option `docloud_prmfile`:

```
CPLEX Parameter File Version 12.6.3.0
CPX_PARAM_ADVIND          0
CPX_PARAM_EPRHS          1.0000000000000000e-04
CPX_PARAM_SIMDISPLAY      2
CPX_PARAM_SCAIND          1
CPX_PARAM_TILIM           1.0000000000000000e+03
CPX_PARAM_LPMETHOD      4
CPX_PARAM_THREADS         1
CPX_PARAM_PARALLELMODE    1
```

Users of GAMS/Kestrel on platforms other than Windows, Linux, or macOS have to manually provide a Python 3 installation that has access to the following modules:

- [GAMS Python API](#)
- IBM DOcloud [Python package](#).

5.24 KNITRO

5.24.1 Introduction

Artelys Knitro is a software package for finding local solutions of both continuous (i.e. smooth) optimization problems, with or without constraints, and discrete optimization problems with integer or binary variables. Even though Knitro has been designed for solving large-scale general problems, it is efficient for solving all of the following classes of optimization problems:

- unconstrained,
- bound constrained,
- equality constrained,
- systems of nonlinear equations,
- least squares problems,
- linear programming problems (LPs),
- quadratic programming problems (QPs),
- general (inequality) constrained problems,
- (convex) mixed integer nonlinear programs (MINLP) of moderate size.

The Knitro package provides the following features:

- Efficient and robust solution of small or large problems,
- Solvers for both continuous and discrete problems,
- Derivative-free, 1st derivative and 2nd derivative options,
- Both interior-point (barrier) and active-set optimizers,
- Both feasible and infeasible versions,
- Both iterative and direct approaches for computing steps,

The problems solved by Knitro have the form

$$\begin{array}{lll}
 \text{minimize} & f(x) & (1a) \\
 \text{subject to} & c^L \leq c(x) \leq c^U & (1b) \\
 & b^L \leq x \leq b^U, & (1c)
 \end{array}$$

where the variables x can be continuous, binary, or integer. This allows many forms of constraints, including bounds on the variables. Knitro requires that the functions $f(x)$ and $c(x)$ be smooth functions.

Knitro implements both state-of-the-art interior-point and active-set methods for solving nonlinear optimization problems. In the interior method (also known as a barrier method), the nonlinear programming problem is replaced by a series of barrier sub-problems controlled by a barrier parameter μ . The algorithm uses trust regions and a merit function to promote convergence. The algorithm performs one or more minimization steps on each barrier problem, then decreases the barrier parameter, and repeats the process until the original problem (1) has been solved to the desired accuracy.

Knitro provides two procedures for computing the steps within the interior point approach. In the version known as **Interior/CG** each step is computed using a projected conjugate gradient iteration. This approach differs from most interior methods proposed in the literature in that it does not compute each step by solving a linear system involving the KKT (or primal-dual) matrix. Instead, it factors a projection matrix, and uses the conjugate gradient method, to approximately minimize a quadratic model of the barrier problem.

The second procedure for computing the steps, which we call **Interior/Direct**, always attempts to compute a new iterate by solving the primal-dual KKT matrix using direct linear algebra. In the case when this step cannot be guaranteed to be of good quality, or if negative curvature is detected, then the new iterate is computed by the **Interior/CG** procedure.

Knitro also implements an active-set sequential linear-quadratic programming (SLQP) algorithm which we call **Active**. This method is similar in nature to a sequential quadratic programming method but uses linear programming sub-problems to estimate the active-set at each iteration. This active-set code may be preferable when a good initial point can be provided, for example, when solving a sequence of related problems.

For problems with discrete variables, Knitro provides two variants of the branch and bound algorithm. The first is a standard implementation, while the second is specialized for convex, mixed-integer nonlinear problems.

We encourage the user to try all algorithmic options to determine which one is more suitable for the application at hand. For guidance on choosing the best algorithm see section [Algorithm Options](#).

For a detailed description of the algorithm implemented in **Interior/CG** see [49] and for the global convergence theory see [50]. The method implemented in **Interior/Direct** is described in [257]. The **Active** algorithm is described in [52] and the global convergence theory for this algorithm is in [53]. An important component of Knitro is the HSL routine MA27 [122] which is used to solve the linear systems arising at every iteration of the algorithm. In addition, the **Active Set** algorithm in Knitro may make use of the COIN-OR Clp linear programming solver module. The version used in Knitro may be downloaded from <http://www.artelys.com/tools/clp/>.

5.24.2 Usage

Basic details of solver usage, including how to choose Knitro as the solver and how to use a solver-specific option file, are part of Chapter [Solver Usage](#).

As an NLP solver, Knitro can also be used to solve linear programs (LP), and both convex and nonconvex quadratic programs (QCP).

5.24.3 GAMS Options

The following [GAMS options](#) are used by the GAMS/Knitro link:

- Option ResLim = x;
Sets the time limit in seconds. If this limit is exceeded the solver will terminate and pass on the current solution to GAMS. See also [reslim](#) in section [GAMS options](#) .
- Option SysOut = On;
This option sends additional Knitro messages to the GAMS listing file. It is useful in case of a solver failure or to get algorithmic details. See also [sysout](#) in section [GAMS options](#)
- *ModelName*.optCA = x;
Absolute gap stop criterion for a discrete problem. The Knitro option [mip_opt_gap_abs](#) takes its default from this value. See also [optca](#) in section [GAMS options](#).
- *ModelName*.optCR = x;
Relative gap stop criterion for a discrete problem. The Knitro option [mip_opt_gap_rel](#) takes its default from this value. See also [optcr](#) in section [GAMS options](#).

5.24.4 Summary of Knitro Options

The Knitro options file `knitro.opt` allows the user to easily set options controlling Knitro's behavior. Options are set by specifying a keyword and a corresponding value on a line in the `knitro.opt` file. Lines that begin with a `#` character are treated as comments and blank lines are ignored. For example, to set the maximum allowable number of iterations to 500, one could use the following options file:

```
maxit 500
```

5.24.4.1 General options

Option	Description	Default
algorithm	Indicates which algorithm to use to solve the problem	0
blasoption	Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations	1
blasoptionlib	Specifies a dynamic library name that contains object code for BLAS/LAPACK functions	
bndrange	Specifies max limits on the magnitude of constraint and variable bounds	1e+20
cg_maxit	Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration	-1
cg_pmem	Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner	10
cg_precond	Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms	0

Option	Description	Default
<code>cg_stoptol</code>	Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves	0.01
<code>convex</code>	Declare the problem as convex by setting to 1 or non-convex by setting to 0	-1
<code>cpuplatform</code>	This option can be used to specify the target instruction set architecture for the machine on which Knitro is running	-1
<code>datacheck</code>	Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure)	0
<code>delta</code>	Specifies the initial trust region radius scaling factor used to determine the initial trust region size	1
<code>honorbnds</code>	Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization	-1
<code>initpenalty</code>	Specifies the initial penalty parameter used in the Knitro merit functions	10
<code>linesearch</code>	Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate	0
<code>linesearch_maxtrials</code>	Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step	3
<code>linsolver</code>	Indicates which linear solver to use to solve linear systems arising in Knitro algorithms	0
<code>linsolver_maxitref</code>	Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro	2
<code>linsolver_ooc</code>	Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when <code>linsolver = mklpardiso</code>	0
<code>linsolver_pivottol</code>	Specifies the initial pivot threshold used in factorization routines	1e-08
<code>names</code>	Enable to pass variable and equation names to Knitro	0
<code>ncvx_qcqp_init</code>	Specifies the initialization strategy used for non-convex QPs and QCQPs	-1
<code>newpoint</code>	Specifies additional action to take after every iteration in a solve of a continuous problem	0
<code>objrange</code>	Specifies the extreme limits of the objective function for purposes of determining unboundedness	1e+20
<code>option_file</code>	additional option file name - read only by KNITRO solver lib	
<code>output_time</code>	print output on where time is used	0
<code>presolve</code>	Determine whether or not to use the Knitro presolver to try to simplify the model by removing variables or constraints	1
<code>presolveop_tighten</code>	Determine whether or not to enable the Knitro presolve operation to tighten variable bounds	-1
<code>presolve_initpt</code>	Control whether the Knitro presolver can shift a user-supplied initial point	-1
<code>presolve_level</code>	Set the level of presolve operations to enable through the Knitro presolver	-1
<code>presolve_passes</code>	Set a maximum limit on the number of passes through the Knitro presolve operations	10
<code>presolve_tol</code>	Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model	1e-06
<code>qextractalg</code>	quadratic extraction algorithm in GAMS interface	0

Option	Description	Default
<code>restarts</code>	Specifies whether or not to enable automatic restarts in Knitro	-1
<code>restarts_maxit</code>	When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart	0
<code>scale</code>	Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables	1
<code>soc</code>	Specifies whether or not to try second order corrections (SOC)	1
<code>strat_warm_start</code>	Specifies whether or not to invoke a warm-start strategy	0

5.24.4.2 Derivative options

Option	Description	Default
<code>bfgs_scaling</code>	Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation	0
<code>findiff_relstepsize</code>	Specifies the relative stepsize used for finite-difference gradients	0
<code>findiff_terminate</code>	This option specifies the termination criteria when using finite-difference gradients	1
<code>gradopt</code>	Specifies how to compute the gradients of the objective and constraint functions	1
<code>hessopt</code>	Specifies how to compute the (approximate) Hessian of the Lagrangian	0
<code>lmsize</code>	Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option	10

5.24.4.3 Termination options

Option	Description	Default
<code>feastol</code>	Specifies the final relative stopping tolerance for the feasibility error	1e-06
<code>feastolabs</code>	Specifies the final absolute stopping tolerance for the feasibility error	0.001
<code>fstopval</code>	Used to implement a custom stopping condition based on the objective function value	maxdouble
<code>ftol</code>	The optimization process will terminate if the relative change in the objective function is less than <code>ftol</code> for <code>ftol_iters</code> consecutive feasible iterations	1e-15
<code>ftol_iters</code>	The optimization process will terminate if the relative change in the objective function is less than <code>ftol</code> for <code>ftol_iters</code> consecutive feasible iterations	5
<code>infeastol</code>	Specifies the (relative) tolerance used for declaring infeasibility of a model	1e-08
<code>infeastol_iters</code>	The optimization process will terminate if the relative change in the feasibility error is less than <code>infeastol</code> for <code>infeastol_iters</code> consecutive infeasible iterations	50
<code>maxfevals</code>	Specifies the maximum number of function evaluations before termination	-1
<code>maxit</code>	Specifies the maximum number of iterations before termination	GAMS iterlim
<code>maxtime_cpu</code>	Specifies, in seconds, the maximum allowable CPU time before termination	100000000

Option	Description	Default
maxtime_real	Specifies, in seconds, the maximum allowable real time before termination	GAMS <code>reslim</code>
opttol	Specifies the final relative stopping tolerance for the KKT (optimality) error	1e-06
opttolabs	Specifies the final absolute stopping tolerance for the KKT (optimality) error	0.001
xtol	The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol.iters	1e-12
xtol.iters	The optimization process will terminate if the relative change in the solution estimate is less than xtol for xtol.iters consecutive iterations	0

5.24.4.4 Barrier options

Option	Description	Default
bar_conic_enable	Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm)	-1
bar_directinterval	Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra	-1
bar_feasible	Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms	0
bar_feasmodetol	Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible	0.0001
bar_initmu	Specifies the initial value for the barrier parameter μ used with the barrier algorithms	-1
bar_initpi_mpec	Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms	0
bar_initpt	Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm	0
bar_linsys	Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps	-1
bar_linsys_storage	Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps	-1
bar_maxcorrectors	Specifies the maximum number of corrector steps allowed for primal-dual steps	-1
bar_maxcrossit	Specifies the maximum number of crossover iterations before termination	0
bar_maxrefactor	Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step	-1
bar_murule	Indicates which strategy to use for modifying the barrier parameter mu in the barrier algorithms	0
bar_penaltycons	Indicates whether a penalty approach is applied to the constraints	-1
bar_penaltyrule	Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate	0
bar_refinement	Specifies whether to try to refine the barrier solution for better precision	0
bar_relaxcons	Indicates whether a relaxation approach is applied to the constraints	2

Option	Description	Default
bar_slackboundpush	Specifies the amount by which the barrier slack variables are initially pushed inside the bounds	-1
bar_switchobj	Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase	1
bar_switchrule	Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase	-1
bar_watchdog	Specifies whether to enable watchdog heuristic for barrier algorithms	0

5.24.4.5 Active-set options

Option	Description	Default
act_lpfcastol	Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms	1e-08
act_lppenalty	Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms	1
act_lppresolve	Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms	0
act_parametric	Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms	1
act_qpalg	Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms	0
act_qppenalty	Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm	-1

5.24.4.6 MIP options

Option	Description	Default
mip_branchrule	Specifies which branching rule to use for MIP branch and bound procedure	0
mip_clique	Specifies rules for adding clique cuts	0
mip_cutfactor	This value specifies a limit on the number of cuts added to a node subproblem	1
mip_cutoff	This value specifies the objective cutoff value for MIP	maxdouble
mip_cutting_plane	Specifies when to apply the cutting plane procedure	0
mip_gub_branch	Specifies whether or not to branch on generalized upper bounds (GUBs)	0
mip_heuristic_diving	Specifies whether or not to enable the MIP diving heuristic	-1
mip_heuristic_feaspump	Specifies whether or not to enable the MIP feasibility pump heuristic	-1
mip_heuristic_lns	Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics	-1
mip_heuristic_maxit	Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled	100
mip_heuristic_mpec	Specifies whether or not to enable the MIP MPEC heuristic	-1

Option	Description	Default
mip_heuristic_strategy	Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point	-1
mip_heuristic_terminate	Specifies the condition for terminating the MIP heuristic	1
mip_implications	Specifies whether or not to add constraints to the MIP derived from logical implications	1
mip_integer_tol	This value specifies the threshold for deciding whether or not a variable is determined to be an integer	1e-08
mip_intvar_strategy	Specifies how to handle integer variables	0
mip_knapsack	Specifies rules for adding MIP knapsack cuts	1
mip_liftproject	Specifies rules for adding lift and project cuts	0
mip_lpalg	Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch and bound procedure	0
mip_maxnodes	Specifies the maximum number of nodes explored (0 means no limit)	GAMS nodlim
mip_maxsolves	Specifies the maximum number of subproblem solves allowed (0 means no limit)	0
mip_maxtime_cpu	Specifies the maximum allowable CPU time in seconds for the complete MIP solution	100000000
mip_maxtime_real	Specifies the maximum allowable real time in seconds for the complete MIP solution	GAMS reslim
mip_method	Specifies which MIP method to use	0
mip_mir	Specifies rules for adding mixed integer rounding cuts	-1
mip_multistart	Use to enable MIP multi-start at the branch-and-bound level	0
mip_nodealg	Specifies which algorithm to use for standard node subproblem solves in MIP (same options as algorithm user option)	0
mip_numthreads	Specify the number of threads to use for MIP branch and bound (when mip_method = 1)	0
mip_opt_gap_abs	The absolute optimality gap stop tolerance for MIP	GAMS optca
mip_opt_gap_rel	The relative optimality gap stop tolerance for MIP	GAMS optcr
mip_outinterval	Specifies node printing interval for mip_outlevel when mip_outlevel > 0	0
mip_outlevel	Specifies how much MIP information to print	2
mip_pseudoinit	Specifies the method used to initialize pseudo-costs corresponding to variables that have not yet been branched on in the MIP method	0
mip_relaxable	Specifies Whether integer variables are relaxable	1
mip_rootalg	Specifies which algorithm to use for the root node solve in MIP (same options as algorithm user option)	0
mip_rounding	Specifies the MIP rounding rule to apply	-1
mip_selectdir	Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch and bound tree	0

Option	Description	Default
mip_selectrule	Specifies the MIP select rule for choosing the next node in the branch and bound tree	0
mip_strong_candlim	Specifies the maximum number of candidates to explore for MIP strong branching	128
mip_strong_level	Specifies the maximum number of tree levels on which to perform MIP strong branching	10
mip_strong_maxit	Specifies the maximum number of iterations to allow for MIP strong branching solves	1000
mip_terminate	Specifies conditions for terminating the MIP algorithm	0
mip_zerohalf	Specifies rules for adding zero-half cuts	0

5.24.4.7 Multi-algorithm options

Option	Description	Default
ma_maxtime_cpu	Specifies, in seconds, the maximum allowable CPU time before termination for the multi-algorithm ("MA") procedure (algorithm=5)	100000000
ma_maxtime_real	Specifies, in seconds, the maximum allowable real time before termination for the multi-algorithm ("MA") procedure (algorithm=5)	100000000
ma_outsub	Enable writing algorithm output to files for the multi-algorithm (algorithm=5) procedure	0
ma_terminate	Define the termination condition for the multi-algorithm (algorithm=5) procedure	1

5.24.4.8 Multi-start options

Option	Description	Default
ms_deterministic	Indicates whether Knitro multi-start procedure will be deterministic (when ms_terminate = 0)	1
ms_enable	Indicates whether Knitro will solve from multiple start points to find a better local minimum	0
ms_maxbndrange	Specifies the maximum range that an unbounded variable can take when determining new start points	1000
ms_maxsolves	Specifies how many start points to try in multi-start	0
ms_maxtime_cpu	Specifies, in seconds, the maximum allowable CPU time before termination	100000000
ms_maxtime_real	Specifies, in seconds, the maximum allowable real time before termination	100000000
ms_numthreads	Specify the number of threads to use for multi-start (when ms_enable = 1)	0
ms_num_to_save	Specifies the number of distinct feasible points to save in a file named <code>knitro_mspoints</code>	0
ms_outsub	Enable writing algorithm output to files for the parallel multi-start procedure	0
ms_savetol	Specifies the tolerance for deciding if two feasible points are distinct	1e-06
ms_seed	Seed value used to generate random initial points in multi-start; should be a non-negative integer	0

Option	Description	Default
ms_startprange	Specifies the maximum range that each variable can take when determining new start points	1e+20
ms_terminate	Specifies the condition for terminating multi-start	0

5.24.4.9 Parallelism options

Option	Description	Default
blas_numthreads	Specify the number of threads to use for BLAS operations when blasoption = 1	0
linsolver_numthreads	Specify the number of threads to use for linear system solve operations when linsolver = 6	0
threads	default thread count	GAMS threads

5.24.4.10 Output options

Option	Description	Default
outappend	Specifies whether output should be started in a new file, or appended to existing files	0
outdir	Specifies a single directory as the location to write all output files	
outlev	Controls the level of output produced by Knitro	2
outmode	Specifies where to direct the output from Knitro	0
outname	Use to specify a custom filename when output is written to a file using outmode	
out_csvinfo	Controls whether or not to generate a file <code>knitro_solve</code>	0
out_csvname	Use to specify a custom csv filename when using out_csvinfo	
out_hints	Specifies whether to print diagnostic hints (e.g. about user option settings) after solving	1

5.24.4.11 Tuner options

Option	Description	Default
tuner	Indicates whether to invoke the Knitro-Tuner	0
tuner_maxtime_cpu	Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner	100000000
tuner_maxtime_real	Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner	100000000
tuner_optionsfile	Can be used to specify the location of a Tuner options file	
tuner_outsub	Enable writing additional Tuner subproblem solve output to files for the Knitro-Tuner procedure (tuner =1)	0
tuner_terminate	Define the termination condition for the Knitro-Tuner procedure (tuner =1)	0

5.24.5 Detailed Descriptions of Knitro Options

act_lpfistol (*real*): Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms ↔

Range: $[0, \infty]$

Default: `1e-08`

act_lppenalty (*integer*): Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms ↔

Default: `1`

value	meaning
1	(all) penalize all constraints.
2	(nonlinear) penalize only nonlinear constraints.
3	(dynamic) dynamically choose which constraints to penalize.

act_lppresolve (*boolean*): Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms ↔

Default: `0`

value	meaning
0	(off) presolve turned off for LP subproblems.
1	(on) presolve turned on for LP subproblems.

act_parametric (*integer*): Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms ↔

Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms. A parametric approach will solve a sequence of closely related LPs instead of one LP. It may increase the cost of an active-set iteration, but perhaps lead to convergence in fewer iterations.

Default: `1`

value	meaning
0	(no) do not use a parametric solve (i.e. solve a single LP).
1	(maybe) use a parametric solve sometimes.
2	(yes) always try a parametric solve.

act_qpalg (*integer*): Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms ↔

Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms. This option has no effect on the Interior/Direct and Interior/CG algorithms.

Default: `0`

value	meaning
0	(auto) let Knitro automatically choose an algorithm, based on the problem characteristics.
1	(direct) use the Interior/Direct algorithm.
2	(cg) use the Interior/CG algorithm.
3	(active) use the Active Set algorithm.

act_qp_penalty (*integer*): Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm ↔

Default: -1

value	meaning
-1	(auto) let Knitro automatically decide.
0	(none) do not penalize constraints in QP subproblems.
1	(all) penalize all constraints in QP subproblems.

algorithm (*integer*): Indicates which algorithm to use to solve the problem ↔

Default: 0

value	meaning
0	(auto) let Knitro automatically choose an algorithm, based on the problem characteristics.
1	(direct) use the Interior/Direct algorithm.
2	(cg) use the Interior/CG algorithm.
3	(active) use the Active Set algorithm.
4	(sqp) use the SQP algorithm.
5	(multi) run all algorithms, perhaps in parallel (see Algorithms).

bar_conic_enable (*integer*): Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm) ↔

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the strategy.
0	(none) Do not apply any special treatment for conic constraints.
1	(soc) Apply special treatments for any Second Order Cone (SOC) constraints identified in the model.

bar_directinterval (*integer*): Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra ↔

Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra. This option is only valid for the Interior/Direct algorithm and may be useful on problems where Knitro appears to be taking lots of conjugate gradient steps. Setting **bar_directinterval** to 0 will try to enforce that only direct steps are taken which may produce better results on some problems.

Range: $\{-1, \dots, \infty\}$

Default: -1

bar_feasible (*integer*): Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms \leftrightarrow

Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms. Note This option can only be used with the Interior/Direct and Interior/CG algorithms. If **bar_feasible** = stay or **bar_feasible** = get_stay, this will activate the feasible version of Knitro. The feasible version of Knitro will force iterates to strictly satisfy inequalities, but does not require satisfaction of equality constraints at intermediate iterates. This option and the honorbnds option may be useful in applications where functions are undefined outside the region defined by inequalities. The initial point must satisfy inequalities to a sufficient degree; if not, Knitro may generate infeasible iterates and does not switch to the feasible version until a sufficiently feasible point is found. Sufficient satisfaction occurs at a point x if it is true for all inequalities that $cl + tol \leq c(x) \leq cu - tol$ The constant tol is determined by the option **bar_feasmodetol**. If **bar_feasible** = get or **bar_feasible** = get_stay, Knitro will place special emphasis on first trying to get feasible before trying to optimize.

Default: 0

value	meaning
0	(no) No special emphasis on feasibility.
1	(stay) Iterates must satisfy inequality constraints once they become sufficiently feasible.
2	(get) Special emphasis is placed on getting feasible before trying to optimize.
3	(get_stay) Implement both options 1 and 2 above.

bar_feasmodetol (*real*): Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible \leftrightarrow

Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible. The tolerance applies to all inequality constraints in the problem. This option only has an effect if option **bar_feasible** = stay or **bar_feasible** = get_stay.

Range: $[0, \infty]$

Default: 0.0001

bar_initmu (*real*): Specifies the initial value for the barrier parameter μ used with the barrier algorithms \leftrightarrow

Specifies the initial value for the barrier parameter μ used with the barrier algorithms. This option has no effect on the Active Set algorithm.

Range: $[-\infty, \infty]$

Default: -1

bar_initpi_mpec (*real*): Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms \leftrightarrow

Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms. If this value is non-positive, then Knitro uses an internal formula to initialize the MPEC penalty parameter.

Range: $[0, \infty]$

Default: 0

bar_initpt (*integer*): Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm ↵

Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm. Note, this option only alters the initial x values if the user does not specify an initial x. This option has no effect on the Active Set algorithm.

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the strategy.
1	(convex) Initialization designed for convex models.
2	(nearbnd) Initialization strategy that stays closer to the bounds.
3	(central) Initialization strategy that is more central on double-bounded variables.

bar_linsys (*integer*): Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps ↵

Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps. Eliminating more elements results in a smaller dimensional linear system (but also one that is, perhaps, less numerically stable). The bounds option may be preferable for very large problems with many bounded variables. The ineq option may generate significant speedups on models where the number of variables is small, but the number of inequality constraints is large.

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the linear system form.
0	(full) Use the full linear system.
1	(slacks) Eliminate the slack variables.
2	(bounds) Eliminate the slack variables and bounds.
3	(ineqs) Eliminate the slack variables, bounds, and some inequalities.

bar_linsys_storage (*integer*): Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps ↵

Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps. The lowmem option uses one storage location for multiple linear systems. As a result it may use much less memory, but also may be less efficient when the Interior/Direct algorithm takes a lot of CG steps. The normal option uses separate storage for different linear systems.

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the linear system storage approach.
1	(lowmem) Use common storage for multiple linear systems.
2	(normal) Use separate storage for different linear systems.

bar_maxcorrectors (*integer*): Specifies the maximum number of corrector steps allowed for primal-dual steps ↔

Specifies the maximum number of corrector steps allowed for primal-dual steps. If the value is positive and the algorithm used is Interior/Direct, then Knitro may add at most **bar_maxcorrectors** corrector steps to the primal-dual step to try to stay closer to the central path. This may speedup convergence on some models (although it may make the cost per iteration a little more expensive). If the value is negative, Knitro automatically determines the maximum number of corrector steps to apply.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

bar_maxcrossit (*integer*): Specifies the maximum number of crossover iterations before termination ↔

Specifies the maximum number of crossover iterations before termination. If the value is positive and the algorithm in operation is Interior/Direct or Interior/CG, then Knitro will crossover to the Active Set algorithm near the solution. The Active Set algorithm will then perform at most **bar_maxcrossit** iterations to get a more exact solution. If the value is 0, no Active Set crossover occurs and the interior-point solution is the final result. If Active Set crossover is unable to improve the approximate interior-point solution, then Knitro will restore the interior-point solution. In some cases (especially on large-scale problems or difficult degenerate problems) the cost of the crossover procedure may be significant – for this reason, crossover is disabled by default. Enabling crossover generally provides a more accurate solution than Interior/Direct or Interior/CG.

Range: $\{0, \dots, \infty\}$

Default: 0

bar_maxrefactor (*integer*): Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step ↔

Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step. If this value is set to -1, it will use a dynamic strategy. These refactorizations are performed if negative curvature is detected in the model. Rather than reverting to a CG step, the Hessian matrix is modified in an attempt to make the subproblem convex and then the KKT system is refactorized. Increasing this value will make the Interior/Direct algorithm less likely to take CG steps. If the Interior/Direct algorithm is taking a large number of CG steps (as indicated by a positive value for "CGits" in the output), this may improve performance. This option has no effect on the Active Set algorithm.

Range: $\{-1, \dots, \infty\}$

Default: -1

bar_murule (*integer*): Indicates which strategy to use for modifying the barrier parameter μ in the barrier algorithms ↔

Indicates which strategy to use for modifying the barrier parameter μ in the barrier algorithms. Not all strategies are available for both barrier algorithms, as described below. This option has no effect on the Active Set algorithm.

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the strategy.
1	(monotone) Monotonically decrease the barrier parameter. Available for both barrier algorithms.
2	(adaptive) Use an adaptive rule based on the complementarity gap to determine the value of the barrier parameter. Available for both barrier algorithms.
3	(probing) Use a probing (affine-scaling) step to dynamically determine the barrier parameter. Available only for the Interior/Direct algorithm.
4	(dampmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, with safeguards on the corrector step. Available only for the Interior/Direct algorithm.
5	(fullmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, without safeguards on the corrector step. Available only for the Interior/Direct algorithm.
6	(quality) Minimize a quality function at each iteration to determine the barrier parameter. Available only for the Interior/Direct algorithm.

bar_penaltycons (*integer*): Indicates whether a penalty approach is applied to the constraints \leftrightarrow

Indicates whether a penalty approach is applied to the constraints. Using a penalty approach may be helpful when the problem has degenerate or difficult constraints. It may also help to more quickly identify infeasible problems, or achieve feasibility in problems with difficult constraints. This option has no effect on the Active Set algorithm.

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the strategy.
0	(none) No constraints are penalized.
2	(all) A penalty approach is applied to all general constraints.
3	(equalities) Apply a penalty approach to equality constraints only.

bar_penaltyrule (*integer*): Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate \leftrightarrow

Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate. This option has no effect on the Active Set algorithm.

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the strategy.
1	(single) Use a single penalty parameter in the merit function to weight feasibility versus optimality.
2	(flex) Use a more tolerant and flexible step acceptance procedure based on a range of penalty parameter values.

bar_refinement (*boolean*): Specifies whether to try to refine the barrier solution for better precision \leftrightarrow

Specifies whether to try to refine the barrier solution for better precision. If enabled, once the optimality conditions are satisfied, Knitro will apply an additional refinement/postsolve

phase to try to obtain more precision in the barrier solution. The effect is similar to the effect of enabling `bar_maxcrossit`, but it is usually much more efficient since it does not involve switching to the Active Set algorithm.

Default: 0

bar_relaxcons (*integer*): Indicates whether a relaxation approach is applied to the constraints ↔

Indicates whether a relaxation approach is applied to the constraints. Using a relaxation approach may be helpful when the problem has degenerate or difficult constraints. This option has no effect on the Active Set algorithm.

Default: 2

value	meaning
0	(none) No constraints are relaxed.
1	(eqs) A relaxation approach is applied to general equality constraints.
2	(ineqs) A relaxation approach is applied to general inequality constraints.
3	(all) A relaxation approach is applied to all general constraints.

bar_slackboundpush (*real*): Specifies the amount by which the barrier slack variables are initially pushed inside the bounds ↔

Specifies the amount by which the barrier slack variables are initially pushed inside the bounds. A smaller value may be preferable when warm-starting from a point close to the solution.

Range: $[-\infty, \infty]$

Default: -1

bar_switchobj (*integer*): Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase ↔

Default: 1

value	meaning
0	(none) No (or zero) objective.
1	(scalarprox) Proximal point objective with scalar weighting.
2	(diagprox) Proximal point objective with diagonal weighting.

bar_switchrule (*integer*): Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase ↔

Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase. This option has no effect on the Active Set algorithm.

Default: -1

value	meaning
-1	(auto) Let Knitro determine the switching procedure.
0	(never) Never switch to feasibility phase.
2	(moderate) Allow switches to feasibility phase.
3	(aggressive) Use a more aggressive switching rule.

bar_watchdog (*boolean*): Specifies whether to enable watchdog heuristic for barrier algorithms ↔

Specifies whether to enable watchdog heuristic for barrier algorithms. In general, enabling the watchdog heuristic makes the barrier algorithms more likely to accept trial points. Specifically, the watchdog heuristic may occasionally accept trial points that increase the merit function, provided that subsequent iterates decrease the merit function.

Default: 0

bfgs_scaling (*integer*): Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation ↔

Default: 0

value	meaning
0	(dynamic) Dynamically choose which scaling to use.
1	(invhess) The scaling approximates the scale of the inverse Hessian.
2	(hess) The scaling approximates the scale of the Hessian.

blasoption (*integer*): Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations ↔

Default: 1

value	meaning
0	(knitro) Use Knitro built-in functions.
1	(intel) Use Intel Math Kernel Library (MKL) functions on available platforms.
2	(dynamic) Use the dynamic library specified with option blasoptionlib.
3	(blis) Use BLIS functions on available platforms (currently not available on Windows OS).

blasoptionlib (*string*): Specifies a dynamic library name that contains object code for BLAS/LAPACK functions ↔

Specifies a dynamic library name that contains object code for BLAS/LAPACK functions. The library must implement all the functions declared in the file include/blas.lapack.h.

blas_numthreads (*integer*): Specify the number of threads to use for BLAS operations when **blasoption** = 1 ↔

Range: {0, ..., ∞}

Default: 0

bndrange (*real*): Specifies max limits on the magnitude of constraint and variable bounds ↔

Specifies max limits on the magnitude of constraint and variable bounds. Any constraint or variable bounds whose magnitude is greater than or equal to **bndrange** will be treated as infinite by Knitro. Using very large, finite bounds is discouraged (and is generally an indication of a poorly scaled model).

Range: [0, ∞]

Default: 1e+20

cg_maxit (*integer*): Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration ↔

Default: -1

value	meaning
-1	Let Knitro automatically determine a value.
0	Knitro will set a maximum value based on the problem size.
n	At most n>0 CG iterations may be performed during one minor iteration of Knitro.

cg_pmem (*integer*): Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner ↔

Default: 10

value	meaning
n	At most n>0 nonzero elements per column.

cg_precond (*boolean*): Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms ↔

Default: 0

value	meaning
0	(no) Not applied.
1	(chol) Preconditioner is applied.

cg_stoptol (*real*): Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves ↔

Range: $[0, \infty]$

Default: 0.01

convex (*integer*): Declare the problem as convex by setting to 1 or non-convex by setting to 0 ↔

Declare the problem as convex by setting to 1 or non-convex by setting to 0. Otherwise, Knitro will try to determine this automatically, but may only be able to do so for simple model forms such as QPs or QCQPs. If your model is specified as (or automatically determined to be) convex, this will cause Knitro to apply specializations and tunings that are often beneficial for convex models to speed up the solution. Currently this option is only active for the Interior/Direct algorithm, but may be applied to other algorithms in the future.

Range: $\{-1, \dots, 1\}$

Default: -1

cpuplatform (*integer*): This option can be used to specify the target instruction set architecture for the machine on which Knitro is running ↔

This option can be used to specify the target instruction set architecture for the machine on which Knitro is running. This can be used, for example, to try to produce more consistent Knitro performance across various architectures (at the expense of, perhaps, slower performance on some platforms). This option is currently only used for the Intel Math Kernel Library (MKL) functions used inside Knitro.

Range: $\{-1, \dots, 5\}$

Default: -1

datacheck (*boolean*): Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure) ↔

Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure). The datacheck may have a non-trivial cost for large problems.

Default: 0

delta (*real*): Specifies the initial trust region radius scaling factor used to determine the initial trust region size ↔

Range: [1e-14, ∞]

Default: 1

feastol (*real*): Specifies the final relative stopping tolerance for the feasibility error ↔

Specifies the final relative stopping tolerance for the feasibility error. Smaller values of feastol result in a higher degree of accuracy in the solution with respect to feasibility.

Range: [0, ∞]

Default: 1e-06

feastolabs (*real*): Specifies the final absolute stopping tolerance for the feasibility error ↔

Synonym: feastol_abs

Specifies the final absolute stopping tolerance for the feasibility error. Smaller values of feastol_abs result in a higher degree of accuracy in the solution with respect to feasibility.

Range: [0, ∞]

Default: 0.001

findiff_relstepsize (*real*): Specifies the relative stepsize used for finite-difference gradients ↔

Specifies the relative stepsize used for finite-difference gradients. This option sets the stepsize for all variables.

Range: [-∞, ∞]

Default: 0

findiff_terminate (*boolean*): This option specifies the termination criteria when using finite-difference gradients ↔

This option specifies the termination criteria when using finite-difference gradients. The optimality (or KKT) conditions for nonlinear optimization depend on gradient values of the nonlinear objective and constraint functions. When using finite-difference gradients (e.g. `gradopt` > 1), there will typically be small errors in the computed gradients that will limit the precision in the solution (and the ability to satisfy the optimality conditions). By default, Knitro will try to estimate these finite-difference gradient errors and terminate when it seems that no more accuracy in the solution is possible. The solution will be treated as optimal as long as it is feasible and the optimality conditions are satisfied either by the optimality tolerances (`opttol` and `opttolabs`) or the error estimates. On some problems, the error estimates may result in extra function evaluations on some iterations, but will often prevent extra iterations that produce no significant improvement in the solution. This special termination can be disabled by setting `findiff_terminate` = 0 (none).

Default: 1

value	meaning
0	(none) No special criteria; use the standard stopping conditions.
1	(errest) Allow termination based on estimates of the finite-difference error (when no more significant progress is likely).

fstopval (*real*): Used to implement a custom stopping condition based on the objective function value ↔

Used to implement a custom stopping condition based on the objective function value. Knitro will stop and declare that a satisfactory solution was found if a feasible objective function value at least as good as the value specified by **fstopval** is achieved. This stopping condition is only active when the absolute value of **fstopval** is less than **objrange**.

Range: $[-\infty, \infty]$

Default: `maxdouble`

ftol (*real*): The optimization process will terminate if the relative change in the objective function is less than **ftol** for **ftol_iters** consecutive feasible iterations ↔

Range: $[0, \infty]$

Default: `1e-15`

ftol_iters (*integer*): The optimization process will terminate if the relative change in the objective function is less than **ftol** for **ftol_iters** consecutive feasible iterations ↔

Range: $\{1, \dots, \infty\}$

Default: `5`

gradopt (*integer*): Specifies how to compute the gradients of the objective and constraint functions ↔

Default: `1`

value	meaning
1	(exact) User provides a routine for computing the exact gradients.
2	(forward) Knitro computes gradients by forward finite differences.
3	(central) Knitro computes gradients by central finite differences.

hessopt (*integer*): Specifies how to compute the (approximate) Hessian of the Lagrangian ↔

Default: `0`

value	meaning
0	(auto)
1	(exact) User provides a routine for computing the exact Hessian.
2	(bfgs) Knitro computes a (dense) quasi-Newton BFGS Hessian.
3	(sr1) Knitro computes a (dense) quasi-Newton SR1 Hessian.
4	(product_findiff) Knitro computes Hessian-vector products using finite-differences.
5	(product) User provides a routine to compute the Hessian-vector products.
6	(lbfgs) Knitro computes a limited-memory quasi-Newton BFGS Hessian (its size is determined by the option <code>lmsize</code>).

value	meaning
7	(gauss_newton) Knitro computes a Gauss-Newton approximation of the hessian (available for least-squares only, and default value for least-squares)

honorbnds (*integer*): Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization ↔

Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization. This option and the [bar_feasible](#) option may be useful in applications where functions are undefined outside the region defined by inequalities.

Default: -1

value	meaning
-1	(auto) Knitro automatically determine the best setting.
0	(no) Knitro does not require that the bounds on the variables be satisfied at intermediate iterates.
1	(always) Knitro enforces that the initial point and all subsequent solution estimates satisfy the bounds on the variables.
2	(initpt) Knitro enforces that the initial point satisfies the bounds on the variables.

infeastol (*real*): Specifies the (relative) tolerance used for declaring infeasibility of a model ↔

Specifies the (relative) tolerance used for declaring infeasibility of a model. Smaller values of [infeastol](#) make it more difficult to satisfy the conditions Knitro uses for detecting infeasible models. If you believe Knitro incorrectly declares a model to be infeasible, then you should try a smaller value for [infeastol](#).

Range: $[0, \infty]$

Default: $1e-08$

infeastol_iters (*integer*): The optimization process will terminate if the relative change in the feasibility error is less than [infeastol](#) for [infeastol_iters](#) consecutive infeasible iterations ↔

Range: $\{1, \dots, \infty\}$

Default: 50

initpenalty (*real*): Specifies the initial penalty parameter used in the Knitro merit functions ↔

Specifies the initial penalty parameter used in the Knitro merit functions. The Knitro merit functions are used to balance improvements in the objective function versus improvements in feasibility. A larger initial penalty value places more weight initially on feasibility in the merit function.

Range: $[0, \infty]$

Default: 10

linesearch (*integer*): Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate ↔

Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate. This option has no effect on the Interior/CG or Active Set algorithm.

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the strategy.
1	(backtrack) Use a simple backtracking scheme.
2	(interpolate) Use a cubic interpolation scheme.
3	(weakwolfe) Use a linesearch that satisfies the weak Wolfe conditions (unconstrained only).

linesearch_maxtrials (*integer*): Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step ↔

Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step. This option has no effect on the Interior/CG or Active Set algorithm.

Range: {0, ..., ∞}

Default: 3

linsolver (*integer*): Indicates which linear solver to use to solve linear systems arising in Knitro algorithms ↔

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the linear solver.
1	(internal) Not currently used; reserved for future use. Same as auto for now.
2	(hybrid) Use a hybrid approach where the solver chosen depends on the particular linear system which needs to be solved.
3	(qr) Use a dense QR method. This approach uses LAPACK QR routines. Since it uses a dense method, it is only efficient for small problems. It may often be the most efficient method for small problems with dense Jacobians or Hessian matrices.
4	(ma27) Use the HSL MA27 sparse symmetric indefinite solver.
5	(ma57) Use the HSL MA57 sparse symmetric indefinite solver.
6	(mklpardiso) Use the Intel MKL PARDISO (parallel, deterministic) sparse symmetric indefinite solver.
7	(ma97) Use the HSL MA97 (parallel, deterministic) sparse symmetric indefinite solver.
8	(ma86) Use the HSL MA86 (parallel, non-deterministic) sparse symmetric indefinite solver.

linsolver_maxitref (*integer*): Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro ↔

Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro. Iterative refinement steps may be applied when there are significant errors (e.g. large residuals) in the linear system solves. Applying more iterative refinement steps may improve the numerical accuracy of the linear solves at extra cost.

Range: {0, ..., ∞}

Default: 2

linsolver_numthreads (*integer*): Specify the number of threads to use for linear system solve operations when `linsolver = 6` ↔

Range: $\{0, \dots, \infty\}$

Default: 0

linsolver_oooc (*integer*): Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when `linsolver = mklpardiso` ↔

Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when `linsolver = mklpardiso`. This option is only active when `linsolver = mklpardiso`.

Default: 0

value	meaning
0	(no) Do not use Intel MKL PARDISO out-of-core option.
1	(maybe) Maybe solve out-of-core depending on how much space is needed.
2	(yes) Solve linear systems out-of-core when using Intel MKL PARDISO.

linsolver_pivottol (*real*): Specifies the initial pivot threshold used in factorization routines ↔

Specifies the initial pivot threshold used in factorization routines. The value should be in the range $[0, \dots, 0.5]$ with higher values resulting in more pivoting (more stable factorizations). Values less than 0 will be set to 0 and values larger than 0.5 will be set to 0.5. If `linsolver_pivottol` is non-positive, initially no pivoting will be performed. Smaller values may improve the speed of the code but higher values are recommended for more stability (for example, if the problem appears to be very ill-conditioned).

Range: $[0, 0.5]$

Default: `1e-08`

lmsize (*integer*): Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option ↔

Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option. The value must be between 1 and 100 and is only used with `hessopt = 6`. Larger values may give a more accurate, but more expensive, Hessian approximation. Smaller values may give a less accurate, but faster, Hessian approximation. When using the limited memory BFGS approach it is recommended to experiment with different values of this parameter.

Range: $\{1, \dots, 100\}$

Default: 10

maxfevals (*integer*): Specifies the maximum number of function evaluations before termination ↔

Specifies the maximum number of function evaluations before termination. Values less than zero imply no limit.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

maxit (*integer*): Specifies the maximum number of iterations before termination ↔

Synonym: `iterlim`

Default: GAMS `iterlim`

value	meaning
0	Let Knitro automatically choose a value based on the problem type. Currently Knitro sets this value to 10000 for LPs/NLPs and 3000 for MIP problems.
n	At most n>0 iterations may be performed before terminating.

maxtime_cpu (*real*): Specifies, in seconds, the maximum allowable CPU time before termination ↔

Range: [0, 100000000]

Default: 100000000

maxtime_real (*real*): Specifies, in seconds, the maximum allowable real time before termination ↔

Synonym: reslim

Range: [0, 100000000]

Default: GAMS reslim

ma_maxtime_cpu (*real*): Specifies, in seconds, the maximum allowable CPU time before termination for the multi-algorithm ("MA") procedure ([algorithm=5](#)) ↔

Range: [0, ∞]

Default: 100000000

ma_maxtime_real (*real*): Specifies, in seconds, the maximum allowable real time before termination for the multi-algorithm ("MA") procedure ([algorithm=5](#)) ↔

Range: [0, ∞]

Default: 100000000

ma_outsub (*boolean*): Enable writing algorithm output to files for the multi-algorithm ([algorithm=5](#)) procedure ↔

Default: 0

value	meaning
0	Do not write detailed algorithm output to files.
1	Write detailed algorithm output to files named knitro_ma_*.log.

ma_terminate (*integer*): Define the termination condition for the multi-algorithm ([algorithm=5](#)) procedure ↔

Default: 1

value	meaning
0	Terminate after all algorithms have completed.
1	Terminate at first locally optimal solution.
2	Terminate at first feasible solution estimate.
3	Terminate at first solution estimate of any type.

mip_branchrule (*integer*): Specifies which branching rule to use for MIP branch and bound procedure ↔

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the branching rule.
1	(most_frac) Use most fractional (most infeasible) branching.
2	(pseudocost) Use pseudo-cost branching.
3	(strong) Use strong branching (see options <code>mip_strong_candlim</code> , <code>mip_strong_level</code> and <code>mip_strong_maxit</code> for further control of strong branching procedure).

mip_clique (*integer*): Specifies rules for adding clique cuts ↔

Default: 0

value	meaning
0	(none) Do not add clique cuts.
1	(root) Add cuts derived from equalities at the root node only.
2	(tree) Add cuts derived from equalities at every node depending on the solution of the relaxation and the cut generation strategy.
3	(all) Add cuts derived from equalities combining both root and tree cut generations.

mip_cutfactor (*real*): This value specifies a limit on the number of cuts added to a node subproblem ↔

This value specifies a limit on the number of cuts added to a node subproblem. If non-negative, a maximum of `mip_cutfactor` times the number of constraints is possibly appended.

Range: $[0, \infty]$

Default: 1

mip_cutoff (*real*): This value specifies the objective cutoff value for MIP ↔

Range: $[-\infty, \infty]$

Default: `maxdouble`

mip_cutting_plane (*boolean*): Specifies when to apply the cutting plane procedure ↔

Default: 0

value	meaning
0	(none) No cutting plane procedure enabled.
1	(root) Perform cutting plane procedure at the root node only.

mip_gub_branch (*boolean*): Specifies whether or not to branch on generalized upper bounds (GUBs) ↔

Default: 0

value	meaning
0	(no) Do not branch on GUBs.
1	(yes) Allow branching on GUBs.

mip_heuristic_diving (*integer*): Specifies whether or not to enable the MIP diving heuristic ↔

Specifies whether or not to enable the MIP diving heuristic. This option is a bit-valued option where various diving heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all diving heuristics. Otherwise, set this parameter value to the sum of the values for the individual diving heuristics you wish to enable. For example, to enable only the "fractional" and "linesearch" diving heuristics, you would set this option value to 9 (summing 1 for fractional and 8 for linesearch).

Default: -1

value	meaning
-1	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
1	(bit 0) Enable fractional diving heuristic.
2	(bit 1) Enable vector length diving heuristic.
4	(bit 2) Enable coefficient diving heuristic.
8	(bit 3) Enable linesearch diving heuristic.
16	(bit 4) Enable guided diving heuristic.

mip_heuristic_feaspump (*integer*): Specifies whether or not to enable the MIP feasibility pump heuristic ↔

Default: -1

value	meaning
-1	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
0	(off) Feasibility pump heuristic is not applied.
1	(on) Feasibility pump heuristic is enabled.

mip_heuristic_lns (*integer*): Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics ↔

Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics. This option is a bit-valued option where various LNS heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all LNS heuristics. Otherwise, set this parameter value to the sum of the values for the individual LNS heuristics you wish to enable. For example, to enable both the "RENS" and "RINS" LNS heuristics, you would set this option value to 3 (summing 1 for RENS and 2 for RINS).

Default: -1

value	meaning
-1	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
1	(bit 0) Enable relaxation enforced neighborhood search (RENS) heuristic.
2	(bit 1) Enable relaxation induced neighborhood search (RINS) heuristic.

mip_heuristic_maxit (*integer*): Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled ↔

Range: {0, ..., ∞}

Default: 100

mip_heuristic_mpec (*integer*): Specifies whether or not to enable the MIP MPEC heuristic ↔

Default: -1

value	meaning
-1	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
0	(off) MPEC heuristic is not applied.
1	(on) MPEC heuristic is enabled.

mip_heuristic_strategy (*integer*): Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point ↔

Default: -1

value	meaning
-1	(auto) Let Knitro choose the heuristic strategy to apply (if any).
0	(none) No heuristic search applied.
1	(basic) Apply basic heuristics.
2	(advanced) Apply more advanced heuristics.
3	(extensive) Apply most extensive heuristics.

mip_heuristic_terminate (*integer*): Specifies the condition for terminating the MIP heuristic ↔

Default: 1

value	meaning
1	(feasible) Terminate at first feasible point or iteration limit (whichever comes first).
2	(limit) Always run to the iteration limit.

mip_implications (*boolean*): Specifies whether or not to add constraints to the MIP derived from logical implications ↔

Default: 1

value	meaning
0	(no) Do not add constraints from logical implications.
1	(yes) Knitro adds constraints from logical implications.

mip_integer_tol (*real*): This value specifies the threshold for deciding whether or not a variable is determined to be an integer ↔

Range: [0, 1]

Default: 1e-08

mip_intvar_strategy (*integer*): Specifies how to handle integer variables ↔

Default: 0

value	meaning
0	(none) No special treatment applied.
1	(relax) Relax all integer variables.
2	(mpec) Convert all binary variables to complementarity constraints.

mip_knapsack (*integer*): Specifies rules for adding MIP knapsack cuts ↔

Default: 1

value	meaning
0	(none) Do not add knapsack cuts.
1	(ineqs) Add knapsack cuts derived from linear (in)equalities at the root node only.
2	(lifted) Add lifted separation cuts derived at every node from the solution of the relaxation.
3	(all) Add both root node cuts from (in)equalities and lifted separation cuts.

mip_liftproject (*boolean*): Specifies rules for adding lift and project cuts ↔

Default: 0

value	meaning
0	(none) Do not add lift and project cuts.
1	(root) Add lift and project cuts at the root node only.

mip_lpalg (*integer*): Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch and bound procedure ↔

Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch and bound procedure. LP subproblems may arise if the problem is a mixed integer linear program (MILP), or if using `mip_method = HQG`. (Nonlinear programming subproblems use the algorithm specified by the `algorithm` option.)

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose an algorithm, based on the problem characteristics.
1	(direct) Use the Interior/Direct (barrier) algorithm.
2	(cg) Use the Interior/CG (barrier) algorithm.
3	(active) Use the Active Set (simplex) algorithm.

mip_maxnodes (*integer*): Specifies the maximum number of nodes explored (0 means no limit) ↔

Synonym: `nodlim`

Range: $\{0, \dots, \infty\}$

Default: `GAMS nodlim`

mip_maxsolves (*integer*): Specifies the maximum number of subproblem solves allowed (0 means no limit) \leftrightarrow

Range: $\{0, \dots, \infty\}$

Default: 0

mip_maxtime_cpu (*real*): Specifies the maximum allowable CPU time in seconds for the complete MIP solution \leftrightarrow

Specifies the maximum allowable CPU time in seconds for the complete MIP solution. Use [maxtime_cpu](#) to additionally limit time spent per subproblem solve.

Range: $[0, \infty]$

Default: 100000000

mip_maxtime_real (*real*): Specifies the maximum allowable real time in seconds for the complete MIP solution \leftrightarrow

Specifies the maximum allowable real time in seconds for the complete MIP solution. Use [maxtime_real](#) to additionally limit time spent per subproblem solve.

Range: $[0, \infty]$

Default: `GAMS reslim`

mip_method (*integer*): Specifies which MIP method to use \leftrightarrow

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the method.
1	(BB) Use the standard branch and bound method.
2	(HQG) Use the hybrid Quesada-Grossman method (for convex, nonlinear problems only).
3	(MISQP) Use mixed-integer SQP method (allows for non-relaxable integer variables).

mip_mir (*integer*): Specifies rules for adding mixed integer rounding cuts \leftrightarrow

Default: -1

value	meaning
-1	(auto) Let Knitro decide whether to add mixed integer rounding cuts.
0	(none) Do not add mixed integer rounding cuts.
1	(all) Add cuts derived from equalities at every node depending on the solution of the relaxation and the cut generation strategy.

value	meaning
2	(nlp) Add mixed-integer rounding cuts at the root node and for nonlinear constraints.

mip_multistart (*boolean*): Use to enable MIP multi-start at the branch-and-bound level [↔](#)

Default: 0

value	meaning
0	(off) Do not enable MIP multi-start for branch-and-bound.
1	(on) Enable MIP multi-start for branch-and-bound.

mip_nodealg (*integer*): Specifies which algorithm to use for standard node subproblem solves in MIP (same options as [algorithm](#) user option) [↔](#)

Range: {0, ..., 5}

Default: 0

mip_numthreads (*integer*): Specify the number of threads to use for MIP branch and bound (when [mip_method](#) = 1) [↔](#)

Specify the number of threads to use for MIP branch and bound (when [mip_method](#) = 1). 0 Let Knitro choose the number of threads. n>0 Use n threads for the MIP branch and bound.

Range: {0, ..., ∞}

Default: 0

mip_opt_gap_abs (*real*): The absolute optimality gap stop tolerance for MIP [↔](#)

Synonym: optca

Range: [-1, ∞]

Default: GAMS optca

mip_opt_gap_rel (*real*): The relative optimality gap stop tolerance for MIP [↔](#)

Synonym: optcr

Range: [-1, ∞]

Default: GAMS optcr

mip_outinterval (*integer*): Specifies node printing interval for [mip_outlevel](#) when [mip_outlevel](#) > 0 [↔](#)

Default: 0

value	meaning
1	Print output every node.
2	Print output every 2nd node.
n	Print output every Nth node.

mip_outlevel (*integer*): Specifies how much MIP information to print ↔

Default: 2

value	meaning
0	(none) Do not print any MIP node information.
1	(iters) Print one line of output for every node.
2	(iterstime) Also print accumulated time for every node.
3	(root) Also print detailed log from root node solve.

mip_pseudoinit (*integer*): Specifies the method used to initialize pseudo-costs corresponding to variables that have not yet been branched on in the MIP method ↔

Default: 0

value	meaning
0	Let Knitro automatically choose the method.
1	Initialize using the average value of computed pseudo-costs.
2	Initialize using strong branching.

mip_relaxable (*boolean*): Specifies Whether integer variables are relaxable ↔

Default: 1

value	meaning
0	(none) Integer variables are not relaxable.
1	(all) All integer variables are relaxable.

mip_rootalg (*integer*): Specifies which algorithm to use for the root node solve in MIP (same options as [algorithm](#) user option) ↔

Range: {0, ..., 5}

Default: 0

mip_rounding (*integer*): Specifies the MIP rounding rule to apply ↔

Default: -1

value	meaning
-1	(auto) Let Knitro choose the rounding rule.
0	(none) No rounding heuristic is used.
2	(heur_only) Round using a fast heuristic only.
3	(nlp_sometimes) Round and solve a subproblem if likely to succeed.
4	(nlp_always) Always round and solve a subproblem.

mip_selectdir (*boolean*): Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch and bound tree ↔

Default: 0

value	meaning
0	(down) Choose the down (i.e. \leq) node first.
1	(up) Choose the up (i.e. \geq) node first.

mip_selectrule (*integer*): Specifies the MIP select rule for choosing the next node in the branch and bound tree [↔](#)

Default: 0

value	meaning
0	(auto) Let Knitro choose the node selection rule.
1	(depth_first) Search the tree using a depth first procedure.
2	(best_bound) Select the node with the best relaxation bound.
3	(combo_1) Use depth first unless pruned, then best bound.

mip_strong_candlim (*integer*): Specifies the maximum number of candidates to explore for MIP strong branching [↔](#)

Range: $\{-\infty, \dots, \infty\}$

Default: 128

mip_strong_level (*integer*): Specifies the maximum number of tree levels on which to perform MIP strong branching [↔](#)

Range: $\{-\infty, \dots, \infty\}$

Default: 10

mip_strong_maxit (*integer*): Specifies the maximum number of iterations to allow for MIP strong branching solves [↔](#)

Range: $\{-\infty, \dots, \infty\}$

Default: 1000

mip_terminate (*integer*): Specifies conditions for terminating the MIP algorithm [↔](#)

Default: 0

value	meaning
0	(optimal) Terminate at optimum.
1	(feasible) Terminate at first integer feasible point.

mip_zerohalf (*integer*): Specifies rules for adding zero-half cuts [↔](#)

Default: 0

value	meaning
0	(none) Do not add zero-half cuts.

value	meaning
1	(root) Add cuts derived from equalities at the root node only.
2	(tree) Add cuts derived from equalities at every node depending on the solution of the relaxation and the cut generation strategy.
3	(all) Add cuts derived from equalities combining both root and tree cut generations.

ms_deterministic (*boolean*): Indicates whether Knitro multi-start procedure will be deterministic (when `ms_terminate = 0`) ↔

Default: 1

value	meaning
0	(no) multithreaded multi-start is non-deterministic.
1	(yes) multithreaded multi-start is deterministic (when <code>ms_terminate = 0</code>).

ms_enable (*boolean*): Indicates whether Knitro will solve from multiple start points to find a better local minimum ↔

Default: 0

value	meaning
0	(no) Knitro solves from a single initial point.
1	(yes) Knitro solves using multiple start points.

ms_maxbndrange (*real*): Specifies the maximum range that an unbounded variable can take when determining new start points ↔

Specifies the maximum range that an unbounded variable can take when determining new start points. If a variable is unbounded in one or both directions, then new start point values are restricted by the option. If x_i is such a variable, then all initial values satisfy $\max\{b_i^L, x_i^0 - \text{ms_maxbndrange}/2\} \leq x_i \leq \min\{b_i^U, x_i^0 + \text{ms_maxbndrange}/2\}$, where x_i^0 is the initial value of x_i provided by the user, and b_i^L and b_i^U are the variable bounds (possibly infinite) on x_i . This option has no effect unless `ms.enable = yes`.

Range: $[-\infty, \infty]$

Default: 1000

ms_maxsolves (*integer*): Specifies how many start points to try in multi-start ↔

Specifies how many start points to try in multi-start. This option has no effect unless `ms.enable = yes`.

Default: 0

value	meaning
0	Let Knitro automatically choose a value based on the problem size. The value is $\min(200, 10 N)$, where N is the number of variables in the problem.
n	Try $n > 0$ start points.

ms_maxtime_cpu (*real*): Specifies, in seconds, the maximum allowable CPU time before termination ↔

Specifies, in seconds, the maximum allowable CPU time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of `maxtime_cpu` limits how long Knitro iterates from a single start point. Therefore, `ms_maxtime_cpu` should be greater than `maxtime_cpu`. This option has no effect unless `ms_enable = yes`.

Range: $[-\infty, \infty]$

Default: 100000000

ms_maxtime_real (*real*): Specifies, in seconds, the maximum allowable real time before termination ↔

Specifies, in seconds, the maximum allowable real time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of `maxtime_real` limits how long Knitro iterates from a single start point. Therefore, `ms_maxtime_real` should be greater than `maxtime_real`. This option has no effect unless `ms_enable = yes`.

Range: $[-\infty, \infty]$

Default: 100000000

ms_numthreads (*integer*): Specify the number of threads to use for multi-start (when `ms_enable = 1`) ↔

Specify the number of threads to use for multi-start (when `ms_enable = 1`). 0 Let Knitro choose the number of threads (currently sets `ms_numthreads` based on `numthreads`). $n > 0$ Use n threads for the multi-start (solve n problems in parallel).

Range: $\{0, \dots, \infty\}$

Default: 0

ms_num_to_save (*integer*): Specifies the number of distinct feasible points to save in a file named `knitro_mspoints` ↔

Specifies the number of distinct feasible points to save in a file named `knitro_mspoints.log`. Each point results from a Knitro solve from a different starting point, and must satisfy the absolute and relative feasibility tolerances. The file stores points in order from best objective to worst. Points are distinct if they differ in objective value or some component by the value of `ms_savetol` using a relative tolerance test. This option has no effect unless `ms_enable = yes`.

Range: $\{0, \dots, \infty\}$

Default: 0

ms_outsub (*boolean*): Enable writing algorithm output to files for the parallel multi-start procedure ↔

Default: 0

value	meaning
0	Do not write detailed algorithm output to files.
1	Write detailed algorithm output to files named <code>knitro_ms_*.log</code> .

ms_savetol (*real*): Specifies the tolerance for deciding if two feasible points are distinct ↔

Specifies the tolerance for deciding if two feasible points are distinct. Points are distinct if they differ in objective value or some component by the value of `ms_savetol` using a relative

tolerance test. A large value can cause the saved feasible points in the file `knitro_mspoints.log` to cluster around more widely separated points. This option has no effect unless `ms.enable = yes.` and `ms.num.to.save` is positive.

Range: $[-\infty, \infty]$

Default: `1e-06`

ms_seed (*integer*): Seed value used to generate random initial points in multi-start; should be a non-negative integer \leftrightarrow

Range: $\{0, \dots, \infty\}$

Default: `0`

ms_startptrange (*real*): Specifies the maximum range that each variable can take when determining new start points \leftrightarrow

Specifies the maximum range that each variable can take when determining new start points. If a variable has upper and lower bounds and the difference between them is less than or equal to `ms.startptrange`, then new start point values for the variable can be any number between its upper and lower bounds. If the variable is unbounded in one or both directions, or the difference between bounds is greater than `ms.startptrange`, then new start point values are restricted by the option. If x_i is such a variable, then all initial values satisfy $\max\{b_i^L, x_i^0 - \tau\} \leq x_i \leq \min\{b_i^U, x_i^0 + \tau\}$, $\tau = \min\{\text{ms.startptrange}/2, \text{ms.maxbndrange}/2\}$ where x_i^0 is the initial value of x_i provided by the user, and b_i^L and b_i^U are the variable bounds (possibly infinite) on x_i . This option has no effect unless `ms.enable = yes.`

Range: $[-\infty, \infty]$

Default: `1e+20`

ms_terminate (*integer*): Specifies the condition for terminating multi-start \leftrightarrow

Specifies the condition for terminating multi-start. This option has no effect unless `ms.enable = yes.`

Default: `0`

value	meaning
0	Terminate after <code>ms.maxsolves</code> .
1	Terminate after the first local optimal solution is found or <code>ms.maxsolves</code> , whichever comes first.
2	Terminate after the first feasible solution estimate is found or <code>ms.maxsolves</code> , whichever comes first.
3	Terminate after the first solution estimate of any type is found or <code>ms.maxsolves</code> , whichever comes first.

names (*boolean*): Enable to pass variable and equation names to Knitro \leftrightarrow

Default: `0`

ncvx_qcqp_init (*integer*): Specifies the initialization strategy used for non-convex QPs and QCQPs \leftrightarrow

Specifies the initialization strategy used for non-convex QPs and QCQPs. In particular, these strategies may be more likely to cause Knitro to find global or better local solutions

on non-convex quadratic programs (QPs) or non-convex quadratically constrained quadratic programs (QCQPs).

Default: -1

value	meaning
-1	(auto) Knitro will automatically determine the strategy.
0	(none) No special initialization strategy is used.
1	(linear) Initialize by solving a linear relaxation.
2	(hybrid) Initialize by solving a hybrid formulation.
3	(penalty) Initialize by solving a penalty formulation.
4	(cvxquad) Initialize by solving a convex quadratic relaxation.

newpoint (*integer*): Specifies additional action to take after every iteration in a solve of a continuous problem ↔

Specifies additional action to take after every iteration in a solve of a continuous problem. An iteration of Knitro results in a new point that is closer to a solution. The new point includes values of x and Lagrange multipliers λ . The "newpoint" feature in Knitro is currently only available for continuous problems (solved via `KN_solve()`).

Default: 0

value	meaning
0	(none) Knitro takes no additional action.
1	(saveone) Knitro writes x and λ to the file <code>knitro_newpoint.log</code> . Previous contents of the file are overwritten.
2	(saveall) Knitro appends x and λ to the file <code>knitro_newpoint.log</code> . Warning: this option can generate a very large file. All iterates, including the start point, crossover points, and the final solution are saved.

objrange (*real*): Specifies the extreme limits of the objective function for purposes of determining unboundedness ↔

Specifies the extreme limits of the objective function for purposes of determining unboundedness. If the magnitude of the objective function becomes greater than `objrange` for a feasible iterate, then the problem is determined to be unbounded and Knitro proceeds no further.

Range: $[0, \infty]$

Default: `1e+20`

option_file (*string*): additional option file name - read only by KNITRO solver lib ↔

opttol (*real*): Specifies the final relative stopping tolerance for the KKT (optimality) error ↔

Specifies the final relative stopping tolerance for the KKT (optimality) error. Smaller values of `opttol` result in a higher degree of accuracy in the solution with respect to optimality.

Range: $[0, \infty]$

Default: `1e-06`

opttolabs (*real*): Specifies the final absolute stopping tolerance for the KKT (optimality) error ↔

Synonym: opttolabs

Specifies the final absolute stopping tolerance for the KKT (optimality) error. Smaller values of opttolabs result in a higher degree of accuracy in the solution with respect to optimality.

Range: $[0, \infty]$

Default: 0.001

outappend (*boolean*): Specifies whether output should be started in a new file, or appended to existing files ↔

Specifies whether output should be started in a new file, or appended to existing files. The option affects knitro.log. It does not affect knitro_newpoint.log, which is controlled by option [newpoint](#).

Default: 0

value	meaning
0	(no) Erase any existing files when opening for output.
1	(yes) Append output to any existing files.

outdir (*string*): Specifies a single directory as the location to write all output files ↔

Specifies a single directory as the location to write all output files. The option should be a full pathname to the directory, and the directory must already exist.

outlev (*integer*): Controls the level of output produced by Knitro ↔

Default: 2

value	meaning
0	(none) Printing of all output is suppressed.
1	(summary) Print only summary information.
2	(iter_10) Print basic information every 10 iterations.
3	(iter) Print basic information at each iteration.
4	(iter_verbose) Print basic information and the function count at each iteration.
5	(iter_x) Print all the above, and the values of the solution vector x.
6	(all) Print all the above, and the values of the constraints c at x and the Lagrange multipliers lambda.

outmode (*integer*): Specifies where to direct the output from Knitro ↔

Default: 0

value	meaning
0	(screen) Output is directed to standard out (e.g., screen).
1	(file) Output is sent to a file named knitro.log.
2	(both) Output is directed to both the screen and file knitro.log.

outname (*string*): Use to specify a custom filename when output is written to a file using `outmode` ↔

output_time (*boolean*): print output on where time is used ↔

Default: 0

out_csvinfo (*boolean*): Controls whether or not to generates a file `knitro_solve` ↔

Controls whether or not to generates a file `knitro_solve.csv` containing solve information in comma separated format.

Default: 0

value	meaning
0	(no) No solution information file is generated.
1	(yes) The <code>knitro_solve.csv</code> solution file is generated.

out_csvname (*string*): Use to specify a custom csv filename when using `out_csvinfo` ↔

out_hints (*boolean*): Specifies whether to print diagnostic hints (e.g. about user option settings) after solving ↔

Default: 1

value	meaning
0	(no) Do not print any hints.
1	(yes) Print diagnostic hints on occasion.

presolve (*boolean*): Determine whether or not to use the Knitro presolver to try to simplify the model by removing variables or constraints ↔

Default: 1

value	meaning
0	(no) Do not use the Knitro presolver.
1	(yes) Enable the Knitro presolver.

presolveop_tighten (*integer*): Determine whether or not to enable the Knitro presolve operation to tighten variable bounds ↔

Default: -1

value	meaning
-1	(auto) Automatically determined (may depend on the algorithm).
0	(none) Do not tighten variable bounds (unless it removes a constraint).
1	(varbnd) Enable tightening variable bounds always.

presolve_initpt (*integer*): Control whether the Knitro presolver can shift a user-supplied initial point ↔

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose whether to allow shifting.
0	(noshift) Do not allow presolver to shift user-supplied initial point.
1	(linshift) Allow presolver to shift user-supplied initial point if it only appears in linear constraints.
2	(anyshift) Allow presolver to shift any user-supplied initial point.

presolve_level (*integer*): Set the level of presolve operations to enable through the Knitro presolver ↔

Set the level of presolve operations to enable through the Knitro presolver. A higher presolve level enables more complex presolve operations.

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the presolve level.
1	(level1) Enable the most basic presolve operations.
2	(level2) Enable more advanced presolve operations.

presolve_passes (*integer*): Set a maximum limit on the number of passes through the Knitro presolve operations ↔

Range: {0, ..., ∞}

Default: 10

presolve_tol (*real*): Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model ↔

Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model. If you believe the Knitro presolver is incorrectly modifying the model, use a smaller value for this tolerance (or turn the presolver off).

Range: [0, ∞]

Default: 1e-06

qextractalg (*integer*): quadratic extraction algorithm in GAMS interface ↔

Default: 0

value	meaning
0	Automatic
1	ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.
2	DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.

restarts (*integer*): Specifies whether or not to enable automatic restarts in Knitro ↔

Specifies whether or not to enable automatic restarts in Knitro. When enabled, if a Knitro algorithm seems to be converging slowly or not converging, the algorithm will automatically restart, which may help with convergence.

Default: -1

value	meaning
0	No automatic restarts allowed.
n	At most n>0 automatic restarts may be performed.

restarts_maxit (*integer*): When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart ↔

Default: 0

value	meaning
0	No iteration limit on restarts enforced.
n	At most n>0 iterations are allowed without convergence before enforcing an automatic restart, if restarts are enabled.

scale (*integer*): Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables ↔

Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables. If scaling is performed, internal computations, including some aspects of the optimality tests, are based on the scaled values, though the feasibility error is always computed in terms of the original, unscaled values.

Default: 1

value	meaning
0	(no) No scaling is performed.
1	(user_internal) User provided scaling is used if defined, otherwise Knitro internal scaling is applied.
2	(user_none) User provided scaling is used if defined, otherwise no scaling is applied.
3	(internal) Knitro internal scaling is applied.

soc (*integer*): Specifies whether or not to try second order corrections (SOC) ↔

Specifies whether or not to try second order corrections (SOC). A second order correction may be beneficial for problems with highly nonlinear constraints.

Default: 1

value	meaning
0	(no) No second order correction steps are attempted.
1	(maybe) Second order correction steps may be attempted on some iterations.
2	(yes) Second order correction steps are always attempted if the original step is rejected and there are nonlinear constraints.

strat_warm_start (*boolean*): Specifies whether or not to invoke a warm-start strategy ↔

Specifies whether or not to invoke a warm-start strategy. A warm-start strategy may be beneficial when an initial point close to the solution can be provided. For example, this may occur when solving a sequence of closely related problems, and the solution from one problem can be used to initialize (or warm-start) the next problem in the sequence. The Knitro warm-start strategy will use this information to tune the algorithms to try to converge more quickly in this case. If the initial point is not sufficiently close to the solution, or is too infeasible, the warm-start strategy may not be helpful. This option is currently only used for the Knitro barrier/interior-point algorithms. In this case it may also be useful to experiment with different (smaller than default) values for the initial barrier parameter `bar_initmu`. In general, the closer the initial point is to the solution, the smaller this value should be (Knitro will try by default to initialize this to a good value when applying a warm-start strategy).

Default: 0

value	meaning
0	(no) No warm-start strategy is applied.
1	(yes) Knitro will apply a warm-start strategy with special tunings.

threads (*integer*): default thread count ↔

Synonyms: `gthreads` `numthreads`

Controls the number of threads to use. Non-positive values are interpreted as the number of cores to leave free so setting `threads` to 0 uses all available cores while setting `threads` to -1 leaves one core free for other tasks.

By default, Knitro decides automatically how to use the threads specified. For example, if the multi-start method is enabled, it can run in parallel threads. If the multi-algorithm `algorithm=5` is selected, the different algorithms can be run in parallel threads if threads are allocated. In case only one algorithm is running, multiple threads can be allocated to the MKL BLAS library or to the PARDISO linear solver via the `threads` option: see the `blasoption`, `par_blasnumthreads`, and `par_lsnumthreads` options for details.

Range: $\{-\infty, \dots, \infty\}$

Default: GAMS `threads`

tuner (*boolean*): Indicates whether to invoke the Knitro-Tuner ↔

Default: 0

value	meaning
0	(off) Do not invoke the Knitro-Tuner.
1	(on) Invoke the Knitro-Tuner.

tuner_maxtime_cpu (*real*): Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner ↔

Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro-Tuner began. In contrast, the value of `maxtime_cpu` places a time limit on each individual Knitro-Tuner solve for a particular

option setting. Therefore, `tuner_maxtime_cpu` should be greater than `maxtime_cpu`. This option has no effect unless `tuner = on`.

Range: $[0, \infty]$

Default: 100000000

tuner_maxtime_real (*real*): Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner \leftrightarrow

Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro-Tuner began. In contrast, the value of `maxtime_real` places a time limit on each individual Knitro-Tuner solve for a particular option setting. Therefore, `tuner_maxtime_real` should be greater than `maxtime_real`. This option has no effect unless `tuner = on`.

Range: $[0, \infty]$

Default: 100000000

tuner_optionsfile (*string*): Can be used to specify the location of a Tuner options file \leftrightarrow

tuner_outsub (*integer*): Enable writing additional Tuner subproblem solve output to files for the Knitro-Tuner procedure (`tuner=1`) \leftrightarrow

Default: 0

value	meaning
0	Do not write detailed solve output to files.
1	Write summary solve output to a file named <code>knitro_tuner_summary.log</code> .
2	Write detailed individual solve output to files named <code>knitro_tuner_*.log</code> .

tuner_terminate (*integer*): Define the termination condition for the Knitro-Tuner procedure (`tuner=1`) \leftrightarrow

Default: 0

value	meaning
0	Terminate after all solves have completed.
1	Terminate at first locally optimal solution.
2	Terminate at first feasible solution estimate.
3	Terminate at first solution estimate of any type.

xtol (*real*): The optimization process will terminate if the relative change in all components of the solution point estimate is less than `xtol` for `xtol_iters` \leftrightarrow

The optimization process will terminate if the relative change in all components of the solution point estimate is less than `xtol` for `xtol_iters` consecutive iterations. If using the Interior/Direct or Interior/CG algorithm and the barrier parameter is still large, Knitro will first try decreasing the barrier parameter before terminating.

Range: $[0, \infty]$

Default: `1e-12`

xtol_iters (*integer*): The optimization process will terminate if the relative change in the solution estimate is less than **xtol** for **xtol_iters** consecutive iterations \leftrightarrow

The optimization process will terminate if the relative change in the solution estimate is less than **xtol** for **xtol_iters** consecutive iterations. If set to 0, Knitro chooses this value based on the solver and context. Currently Knitro sets this value to 3 unless the MISQP algorithm is being used, in which case the value is set to 1 by default.

Range: $\{0, \dots, \infty\}$

Default: 0

5.24.6 Knitro Termination Test and Optimality

5.24.6.1 Continuous problems

The first-order conditions for identifying a locally optimal solution of the problem (1) are:

$$\begin{aligned} \nabla_x \mathcal{L}(x, \lambda) = \nabla f(x) + \sum_{i=1 \dots m} \lambda_i^c \nabla c_i(x) + \sum_{j=1 \dots n} \lambda_j^b &= 0 \\ \lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))] &= 0, \quad i = 1 \dots m \\ \lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)] &= 0, \quad j = 1 \dots n \\ c_i^L \leq c_i(x) &\leq c_i^U, \quad i = 1 \dots m \\ b_j^L \leq x_j &\leq b_j^U, \quad j = 1 \dots n \\ \lambda_i^c &\geq 0, \quad i \in \mathcal{I}, \quad c_i^L = -\infty, \quad c_i^U \text{ finite} \\ \lambda_i^c &\leq 0, \quad i \in \mathcal{I}, \quad c_i^U = +\infty, \quad c_i^L \text{ finite} \\ \lambda_j^b &\geq 0, \quad j \in \mathcal{B}, \quad b_j^L = -\infty, \quad b_j^U \text{ finite} \\ \lambda_j^b &\leq 0, \quad j \in \mathcal{B}, \quad b_j^U = +\infty, \quad b_j^L \text{ finite} \end{aligned} \quad (3)$$

where \mathcal{I} and \mathcal{B} represent the sets of indices corresponding to the general inequality constraints and non-fixed variable bound constraints respectively, λ_i^c is the Lagrange multiplier corresponding to constraint $c_i(x)$, and λ_j^b is the Lagrange multiplier corresponding to the simple bounds on x_j . There is exactly one Lagrange multiplier for each constraint and variable. The Lagrange multiplier may be restricted to take on a particular sign depending on the corresponding constraint or variable bounds.

In Knitro we define the feasibility error (**FeasErr**) at a point x^k to be the maximum violation of the constraints of (1), i.e.,

$$\text{FeasErr} = \max_{i=1 \dots m, j=1 \dots n} (0, (c_i^L - c_i(x^k)), (c_i(x^k) - c_i^U), (b_j^L - x_j^k), (x_j^k - b_j^U)),$$

while the optimality error (**OptErr**) is defined as the maximum violation of the first three conditions of (3)

$$\text{OptErr} = \max_{i=1 \dots m, j=1 \dots n} (\|\nabla_x \mathcal{L}(x^k, \lambda^k)\|_\infty, \lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))], \lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)]).$$

The remaining conditions on the sign of the multipliers are enforced explicitly throughout the optimization. In order to take into account problem scaling in the termination test, the following scaling factors are defined. In order to take into account problem scaling in the termination test, the following scaling factors are defined

$$\begin{aligned} \tau_1 &= \max(1, (c_i^L - c_i(x^0)), (c_i(x^0) - c_i^U), (b_j^L - x_j^0), (x_j^0 - b_j^U)), \\ \tau_2 &= \begin{cases} \max(1, \|\nabla f(x^k)\|_\infty), & \text{for constrained problems,} \\ \max(1, \min(|f(x^k)|, \|\nabla f(x^0)\|_\infty)), & \text{for unconstrained problems,} \end{cases} \end{aligned}$$

where x^0 represents the initial point. The special treatment for unconstrained problems is necessary, as for these problems, $\|\nabla f(x^k)\|_\infty \rightarrow 0$ as a solution is approached, thus $\max(1, \|\nabla f(x^k)\|_\infty)$ would not be effective.

Knitro stops and declares `Locally optimal solution found` if the following stopping conditions are satisfied:

$$\text{FeasErr} \leq \max(\tau_1 * \text{feastol}, \text{feastolabs}) \quad (4)$$

$$\text{OptErr} \leq \max(\tau_2 * \text{opttol}, \text{opttolabs}) \quad (5)$$

where `feastol`, `opttol`, `feastolabs` and `opttolabs` are user-defined options (see section [Usage](#)).

This stopping test is designed to give the user much flexibility in deciding when the solution returned by Knitro is accurate enough. One can use a purely scaled stopping test (which is the recommended and default option) by setting `feastolabs` and `opttolabs` equal to `0.0e0`. Likewise, an absolute stopping test can be enforced by setting `feastol` and `opttol` equal to `0.0e0`.

Unbounded problems

Since by default Knitro uses a relative/scaled stopping test it is possible for the optimality conditions to be satisfied for an unbounded problem. For example, if $\tau_2 \rightarrow \infty$ while the optimality error `OptErr` stays bounded, condition (5) will eventually be satisfied for some `opttol` > 0. If you suspect that your problem may be unbounded, using an absolute stopping test will allow Knitro to detect this.

5.24.6.2 Discrete problems

Algorithms for solving versions of (1) where one or more of the variables are restricted to take on only discrete values, proceed by solving a sequence of continuous relaxations, where the discrete variables are *relaxed* such that they can take on any continuous value. The *global* solutions $f(x_R)$ of these relaxed problems provide a lower bound on the optimal objective value for problem (1) (upper bound if maximizing). If a feasible point is found for problem (1) that satisfies the discrete restrictions on the variables, then this provides an upper bound on the optimal objective value of problem (1) (lower bound if maximizing). We will refer to these feasible points as *incumbent* points and denote the objective value at an incumbent point by $f(x_I)$. Assuming all the continuous subproblems have been solved to global optimality (if the problem is convex, all local solutions are global solutions), an optimal solution of problem (1) is verified when the lower bound and upper bound are equal.

Knitro declares optimality for a discrete problem when the gap between the best (i.e., largest) lower bound $f(x_R)$ and the best (i.e., smallest) upper bound $f(x_I)$ is less than a threshold determined by the user options `mip_opt_gap_abs` and `mip_opt_gap_rel`. Specifically, Knitro declares optimality when either

$$f(x_I) - f(x_R) \leq \text{mip_integral_gap_abs}$$

or

$$f(x_I) - f(x_R) \leq \text{mip_integral_gap_rel} \cdot \max(1, |f(x_I)|),$$

where `mip_opt_gap_abs` and `mip_opt_gap_rel` are typically small positive numbers. Since these termination conditions assume that the continuous subproblems are solved to global optimality and Knitro only finds local solutions of nonconvex, continuous optimization problems, they are only reliable when solving convex, mixed integer problems. The integrality gap $f(x_I) - f(x_R)$ should be non-negative although it may become slightly negative from roundoff error, or if the continuous subproblems are not solved to sufficient accuracy. If the integrality gap becomes largely negative, this may be an indication that the model is nonconvex, in which case Knitro may not converge to the optimal solution, and will be unable to verify optimality (even if it claims otherwise).

Note that the default values for `mip_opt_gap_abs` and `mip_opt_gap_rel` are taken from the GAMS options `optCA` and `optCR`, but an explicit setting of `mip_opt_gap_abs` or `mip_opt_gap_rel` will override those.

5.24.7 Knitro Output

If `outlev=0` then all printing of output is suppressed. The description below assumes the default output level (`outlev=2`) except where indicated:

Nondefault Options:

This output lists all user options (see section [Usage](#)) which are different from their default values. If nothing is listed in this section then all user options are set to their default values.

Problem Characteristics:

The output begins with a description of the problem characteristics.

Iteration Information - Continuous Problems:

An iteration, in the context of Knitro, is defined as a step which generates a new solution estimate (i.e., a successful step). The columns of the iteration log are as follows:

- **Iter** Iteration number.
- **fCount** The cumulative number of function evaluations, only included if (`outlev>3`)
- **Objective** Gives the value of the objective function at the current iterate.
- **FeasErr** Gives a measure of the feasibility violation at the current iterate.
- **OptErr** Gives a measure of the violation of the Karush-Kuhn-Tucker (KKT) (first-order) optimality conditions (not including feasibility) at the current iterate.
- **||Step||** The 2-norm length of the step (i.e., the distance between the new iterate and the previous iterate).
- **CG its** The number of Projected Conjugate Gradient (CG) iterations required to compute the step.

If `outlev=2`, information is printed every 10 major iterations. If `outlev=3` information is printed at each major iteration. If `outlev>4` additional information is included in the log.

Iteration Information - Discrete Problems:

By default, the GAMS/Knitro link prints a log line at every 10th node. This frequency can be changed via the `mip_outinterval` option. To turn off the node log completely, set the `mip_outlevel` option to 0. The columns of the iteration log for discrete models are as follows:

- **Node** The node number. If an integer feasible point was found at a given node, it is marked with a *
 - **Left** The current number of active nodes left in the branch and bound tree.
 - **Iinf** The current number of active nodes left in the branch and bound tree.
 - **Objective** Gives the value of the objective function at the solution of the relaxed subproblem solved at the current node. If the subproblem was infeasible or failed, this is indicated. Additional symbols may be printed at some nodes if the node was pruned (**pr**), integer feasible (**f**), or an integer feasible point was found through rounding (**r**).
 - **Best relaxatn** The value of the current best relaxation (lower bound on the solution if minimizing).
 - **Best incumbent** The value of the current best integer feasible point (upper bound on the solution if minimizing).
-

Termination Message: At the end of the run a termination message is printed indicating whether or not the optimal solution was found and if not, why the solver terminated. Below is a list of some possible termination messages.

- **EXIT: Locally optimal solution found.**

Knitro found a locally optimal point which satisfies the stopping criterion (see section [Knitro Termination Test and Optimality](#)) for more detail on how this is defined). If the problem is convex (for example, a linear program), then this point corresponds to a globally optimal solution.
- **EXIT: Iteration limit reached.**

The iteration limit was reached before being able to satisfy the required stopping criteria.
- **EXIT: Convergence to an infeasible point. Problem appears to be locally infeasible.**

The algorithm has converged to an infeasible point from which it cannot further decrease the infeasibility measure. This happens when the problem is infeasible, but may also occur on occasion for feasible problems with nonlinear constraints or badly scaled problems. It is recommended to try various initial points. If this occurs for a variety of initial points, it is likely the problem is infeasible.
- **EXIT: Problem appears to be unbounded.**

The objective function appears to be decreasing without bound, while satisfying the constraints.
- **EXIT: Current point cannot be improved.**

No more progress can be made. If the current point is feasible it is likely it may be optimal, however the stopping tests cannot be satisfied perhaps because of degeneracy, ill-conditioning or bad scaling).
- **EXIT: Current point cannot be improved. Point appears to be optimal, but desired accuracy could not be achieved.**

No more progress can be made, but the stopping tests are close to being satisfied (within a factor of 100) and so the current approximate solution is believed to be optimal.
- **EXIT: Time limit reached.**

The time limit was reached before being able to satisfy the required stopping criteria.
- **EXIT: Evaluation error.**

This termination value indicates that an evaluation error occurred (e.g., divide by 0, taking the square root of a negative number), preventing the optimization from continuing.
- **EXIT: Not enough memory available to solve problem.**

This termination value indicates that there was not enough memory available to solve the problem.

Final Statistics:

Following the termination message some final statistics on the run are printed. Both relative and absolute error values are printed.

Solution Vector/Constraints:

If `outlev=5`, the values of the solution vector are printed after the final statistics. If `outlev=6`, the final constraint values are also printed before the solution vector and the values of the Lagrange multipliers (or dual variables) are printed next to their corresponding constraint or bound.

5.24.8 Algorithm Options

5.24.8.1 Automatic

By default, Knitro will automatically try to choose the best optimizer for the given problem based on the problem characteristics.

5.24.8.2 Interior/Direct

If the Hessian of the Lagrangian is ill-conditioned or the problem does not have a large-dense Hessian, it may be advisable to compute a step by directly factoring the KKT (primal-dual) matrix rather than using an iterative approach to solve this system. Knitro offers the Interior/Direct optimizer which allows the algorithm to take direct steps by setting `algorithm=1`. This option will try to take a direct step at each iteration and will only fall back on the iterative step if the direct step is suspected to be of poor quality, or if negative curvature is detected.

Using the Interior/Direct optimizer may result in substantial improvements over Interior/CG when the problem is ill-conditioned (as evidenced by Interior/CG taking a large number of Conjugate Gradient iterations). We encourage the user to try both options as it is difficult to predict in advance which one will be more effective on a given problem. In each case, also experiment with the [bar_murule](#) option, as it is difficult to predict which update rule will work best.

NOTE: Since the Interior/Direct algorithm in Knitro requires the explicit storage of a Hessian matrix, this version can only be used with Hessian options, `hessopt=1, 2, 3` or `6`. It may not be used with Hessian options, `hessopt=4` or `5`, which only provide Hessian-vector products. Both the Interior/Direct and Interior/CG methods can be used with the [bar_feasible](#) option.

5.24.8.3 Interior/CG

Since Knitro was designed with the idea of solving large problems, the Interior/CG optimizer in Knitro offers an iterative Conjugate Gradient approach to compute the step at each iteration. This approach has proven to be efficient in most cases and allows Knitro to handle problems with large, dense Hessians, since it does not require factorization of the Hessian matrix. The Interior/CG algorithm can be chosen by setting `algorithm=2`. It can use any of the Hessian options as well as the [bar_feasible](#) option.

5.24.8.4 Active Set

Knitro includes an active-set Sequential Linear-Quadratic Programming (SLQP) optimizer. This optimizer is particularly advantageous when "warm starting" (i.e., when the user can provide a good initial solution estimate, for example, when solving a sequence of closely related problems). This algorithm is also the preferred algorithm for detecting infeasible problems quickly. The Active Set algorithm can be chosen by setting `algorithm=3`. It can use any of the Hessian options.

5.24.9 Other Knitro special features

This section describes in more detail some of the more important special features of Knitro and provides some guidance on how use them so that Knitro runs most efficiently for the problem at hand.

5.24.9.1 Second derivative options

The default version of Knitro assumes that exact second derivatives of the objective function and constraint functions can be computed. If this is possible and the cost of computing the second derivatives is not overly expensive, it is highly recommended to use exact second derivatives. However, Knitro also offers other options which are described in detail below.

(Dense) Quasi-Newton BFGS

The quasi-Newton BFGS option uses gradient information to compute a symmetric, *positive-definite* approximation to the Hessian matrix. Typically this method requires more iterations to converge than the exact Hessian version. However, since it is only computing gradients rather than Hessians, this approach may be more efficient in many cases. This option stores a *dense* quasi-Newton Hessian approximation so it is only recommended for small to medium problems ($n < 1000$). The quasi-Newton BFGS option can be chosen by setting options value `hessopt=2`.

(Dense) Quasi-Newton SR1

As with the BFGS approach, the quasi-Newton SR1 approach builds an approximate Hessian using gradient information. However, unlike the BFGS approximation, the SR1 Hessian approximation is not restricted to be positive-definite. Therefore the quasi-Newton SR1 approximation may be a better approach, compared to the BFGS method, if there is a lot of negative curvature in the problem since it may be able to maintain a better approximation to the true Hessian in this case. The quasi-Newton SR1 approximation maintains a *dense* Hessian approximation and so is only recommended for small to medium problems ($n < 1000$). The quasi-Newton SR1 option can be chosen by setting options value `hessopt=3`.

Finite-difference Hessian-vector product option

If the problem is large and gradient evaluations are not the dominate cost, then Knitro can internally compute Hessian-vector products using finite-differences. Each Hessian-vector product in this case requires one additional gradient evaluation. This option can be chosen by setting options value `hessopt=4`. This option is generally only recommended if the exact gradients are provided.

NOTE: This option may not be used when `algorithm=1`.

Exact Hessian-vector products

In some cases the problem which the user wishes to solve may have a large, dense Hessian which makes it impractical to store or work with the Hessian directly. The performance of this option should be nearly identical to the exact Hessian option but requires much less storage. This option can be chosen by setting options value `hessopt=5`.

NOTE: This option may not be used when `algorithm=1`.

Limited-memory Quasi-Newton BFGS

The limited-memory quasi-Newton BFGS option is similar to the dense quasi-Newton BFGS option described above. However, it is better suited for large-scale problems since, instead of storing a dense Hessian approximation, it only stores a limited number of gradient vectors used to approximate the Hessian. In general it requires more iterations to converge than the dense quasi-Newton BFGS approach but will be much more efficient on large-scale problems. This option can be chosen by setting options value `hessopt=6`.

5.24.9.2 Feasible version

Knitro offers the user the option of forcing intermediate iterates to stay feasible with respect to the *inequality* constraints (it does not enforce feasibility with respect to the *equality* constraints however). Given an initial point which is *sufficiently* feasible with respect to all inequality constraints and selecting `bar_feasible = 1`, forces all the iterates to strictly satisfy the inequality constraints throughout the solution process. For the feasible mode to become active the iterate x must satisfy

$$cl + tol \leq c(x) \leq cu - tol \tag{21}$$

for *all* inequality constraints (i.e., for $cl \neq cu$). The tolerance $tol > 0$ by which an iterate must be strictly feasible for entering the feasible mode is determined by the parameter `bar_feasmodetol` which is $1.0e-4$ by default. If the initial point does not satisfy (21) then the default infeasible version of Knitro will run until it obtains a point which is sufficiently feasible with respect to all the inequality constraints. At this point it will switch to the feasible version of Knitro and all subsequent iterates will be forced to satisfy the inequality constraints.

For a detailed description of the feasible version of Knitro see [51].

NOTE: This option may only be used when `algorithm=2`.

5.24.9.3 Honor Bounds

By default Knitro does not enforce that the simple bounds on the variables (1c) are satisfied throughout the optimization process. Rather, satisfaction of these bounds is only enforced at the solution. In some applications, however, the user may want to enforce that the initial point and all intermediate iterates satisfy the bounds $bl \leq x \leq bu$. This can be enforced by setting `honorbnds=1`.

5.24.9.4 Crossover

Interior-point (or barrier) methods are a powerful tool for solving large-scale optimization problems. However, one drawback of these methods is that they do not always provide a clear picture of which constraints are active at the solution. In general they return a less exact solution and less exact sensitivity information. For this reason, Knitro offers a crossover feature in which the interior-point method switches to the Active Set method at the interior-point solution estimate, in order to "clean up" the solution and provide more exact sensitivity and active set information. The crossover procedure is controlled by the `bar_maxcrossit` option. If this option is greater than 0, then Knitro will attempt to perform `bar_maxcrossit` Active Set crossover iterations after the interior-point method has finished, to see if it can provide a more exact solution. This can be viewed as a form of post-processing. If `bar_maxcrossit` is not positive, then no crossover iterations are attempted.

The crossover procedure will not always succeed in obtaining a more exact solution compared with the interior-point solution. If crossover is unable to improve the solution within `bar_maxcrossit` crossover iterations, then it will restore the interior-point solution estimate and terminate. By default, Knitro will then print a message indicating that it was unable to improve the solution within the iterations allowed. In this case, you may want to increase the value of `bar_maxcrossit` and try again. If Knitro determines that the crossover procedure will not succeed, no matter how many iterations are tried, then a message of the form `Crossover mode unable to improve solution.` will be printed.

The extra cost of performing crossover is problem dependent. In most small or medium scale problems, the crossover cost is a small fraction of the total solve cost. In these cases it may be worth using the crossover procedure to obtain a more exact solution. On some large scale or difficult degenerate problems, however, the cost of performing crossover may be significant. It is recommended to experiment with this option to see whether improvement in the exactness of the solution is worth the additional cost.

5.24.9.5 Tuner

The Knitro-Tuner can help you identify some non-default options settings that may improve performance on a particular model or set of models. The Knitro tuner is enabled with the `tuner` option and controlled via the `tuner_` family of options. If you are unsure about what Knitro options should be tuned to try to improve performance, you can run the default Knitro-Tuner by simply setting the option `tuner=1` when solving with Knitro. This will cause Knitro to run your model with a variety of automatically determined option settings, and report some statistics at the end. Any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

If you have some ideas about which Knitro options you want to tune, you can tell Knitro which options you want it to tune, as well as specify the values for particular options that you want Knitro to explore. This can be done by specifying a Tuner options file. A Tuner options file is a simple text file that is similar to a standard Knitro options file, with some important differences:

- You can define multiple values (separated by spaces) for each option. This tells Knitro the values you want it to explore.
- You can specify an option name without any values. This will tell Knitro to explore all possible option values for that option. This only works for options that have a finite set of possible option value settings.
- A Tuner options file is loaded via the `tuner_optionsfile` option.

All possible combinations of options/values specified in a Tuner options file will be explored by Knitro, while any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

5.24.9.6 Solving Systems of Nonlinear Equations

Knitro is quite effective at solving systems of nonlinear equations. To solve a square system of nonlinear equations using Knitro one should specify the nonlinear equations as equality constraints (i.e., constraints with $cl = cu$), and specify the objective function (1a) as zero (i.e., $f(x) = 0$).

5.24.9.7 Solving Least Squares Problems

There are two ways of using Knitro for solving problems in which the objective function is a sum of squares of the form

$$f(x) = \frac{1}{2} \sum_{j=1}^q r_j(x)^2.$$

If the value of the objective function at the solution is not close to zero (the large residual case), the least squares structure of f can be ignored and the problem can be solved as any other optimization problem. Any of the Knitro options can be used.

On the other hand, if the optimal objective function value is expected to be small (small residual case) then Knitro can implement the Gauss-Newton or Levenberg-Marquardt methods which only require first derivatives of the residual functions, $r_j(x)$, and yet converge rapidly. To do so, the user need only define the Hessian of f to be

$$\nabla^2 f(x) = J(x)^T J(x),$$

where

$$J(x) = \begin{bmatrix} \frac{\partial r_j}{\partial x_i} \end{bmatrix} \begin{matrix} j = 1, 2, \dots, q \\ i = 1, 2, \dots, n \end{matrix} .$$

The actual Hessian is given by

$$\nabla^2 f(x) = J(x)^T J(x) + \sum_{j=1}^q r_j(x) \nabla^2 r_j(x);$$

the Gauss-Newton and Levenberg-Marquardt approaches consist of ignoring the last term in the Hessian.

Knitro will behave like a Gauss-Newton method by setting `algorithm=1`, and will be very similar to the classical Levenberg-Marquardt method when `algorithm=2`. For a discussion of these methods see, for example, [194].

5.25 LGO

János D. Pintér, Department of Industrial and Systems Engineering, Lehigh University, Bethlehem PA, jdp416@lehigh.edu, <https://wordpress.lehigh.edu/jdp416>

5.25.1 Introduction

5.25.1.1 The LGO Solver Suite

The *Lipschitz-Continuous Global Optimizer*³ (LGO) serves for the analysis and global solution of general nonlinear programming (NLP) models. The LGO solver system has been developed and gradually extended for more than a decade and it now incorporates a suite of robust and efficient global and local nonlinear solvers. It can also handle small LP models.

GAMS/LGO can be used in several search modes, providing a robust, effective, and flexible solver suite approach to a broad range of nonlinear models. The solver suite approach increases the reliability of the overall solution process. GAMS/LGO integrates the following global scope algorithms:

- Branch-and-bound (adaptive partition and sampling) based global search (BB)
- Adaptive global random search (GARS)
- Adaptive multistart global random search (MS)

LGO also includes the following local solver strategies:

- Heuristic global scope scatter search method (HSS)
- Bound-constrained local search, based on the use of an exact penalty function (EPM)
- Constrained local search, based on sequential model linearization (SLP)
- Constrained local search, based on a generalized reduced gradient approach (GRG).

The overall solution approach followed by GAMS/LGO is based on the seamless combination of the global and local search strategies. This allows for a broad range of operations. In particular, a solver suite approach supports the flexible usage of the component solvers: one can execute fully automatic (global and/or local search based) optimization, and can design customized interactive runs.

GAMS/LGO does not rely on any sub-solvers, and it does not require any structural information about the model. It is particularly suited to solve even 'black box' (closed, confidential), or other complex models, in which the available analytical information may be limited. GAMS/LGO needs only computable function values (without a need for higher order analytical information). GAMS/LGO can even solve models having constraints involving continuous, but non-differentiable functions. Thus, within GAMS, LGO is well suited to solve DNLP models.

GAMS/LGO can also be used in conjunction with other GAMS solvers. For instance, the local solver CONOPT can be used after LGO is finished to verify the solution and/or to provide additional information such as marginal values. To call CONOPT, the user can specify the LGO solver option 'callConopt'. See the [LGO Options](#) section for details.

The LGO solver suite has been successfully applied to complex, large-scale models both in educational/research and commercial contexts for over a decade. Possible application areas include advanced engineering design, econometrics and finance, medical research and biotechnology, chemical and process industries, and scientific modeling. Tractable model sizes depend only on the available hardware, although LGO has a 3000 variable, 2000 constraint size limit.

5.25.1.2 Running GAMS/LGO

GAMS/LGO is capable of solving the following model types: LP, RMIP, NLP, and DNLP. If LGO is not specified as the default solver for these models, it can be invoked by issuing the following command before the solve statement:

```
option (modeltype) = lgo;
```

where (modeltype) stands for LP, RMIP, NLP, or DNLP.

5.25.2 LGO Options

GAMS/LGO works like other GAMS solvers, and many options can be set directly within the GAMS model. The most relevant GAMS options are `reslim`, `iterlim`, and `optfile`. For details on these and other options, see the section on [GAMS Options](#).

In addition, LGO-specific options can be specified by using a solver option file. For details on creating and using solver options files, see the section [basic option file usage](#). The options supported by the GAMS/LGO solver are detailed below.

5.25.2.1 General LGO options

Option	Description	Default
acc_tr	Global search termination - acceptability threshold Global search termination criterion parameter (acceptability threshold). The global search phase (BB, GARS, or MS) ends, if an overall merit function value is found in the global search phase that is not greater than <code>acc_tr</code> . Range: $[-\infty, \infty]$	-1e10
con_tol	Maximal constraint violation tolerance in local search	1e-6
fct_trg	Partial stopping criterion in second local search phase Target objective function value. Range: $[-\infty, \infty]$	-1e10
fi_tol	Local search (merit function improvement) tolerance	1e-6
g_maxfct	Maximum number of function evaluations in global search Maximum number of merit (model) function evaluations before termination of global search phase (BB, GARS, or MS). In the default setting, <code>n</code> is the number of variables and <code>m</code> is the number of constraints. The difficulty of global optimization models varies greatly: for difficult models, <code>g_maxfct</code> can be increased as deemed necessary. Range: $\{-1, \dots, \infty\}$	500(n+m)
irngs	Random number seed	0
kt_tol	Kuhn-Tucker local optimality condition violation tolerance	1e-6
max_nosuc	Maximum number of function evaluations without improvement Maximum number of merit function evaluations in global search phase (BB, GARS, or MS) where no improvement is made. Algorithm phase terminates upon reaching this limit. A value of -1 resets this to the default of 100(n+m). Range: $\{-1, \dots, \infty\}$	100(n+m)

Option	Description	Default
opmode	Operational mode 0: LS. Local search from the given nominal solution without a preceding local search (LS) 1: BB + LS. Global branch-and-bound search and local search (BB+LS) 2: RS+LS. Global adaptive random search and local search (GARS+LS) 3: MS+LS. Global multistart random search and local search (MS+LS)	3
penmult	Constraint penalty multiplier. Global merit function is defined as objective + the constraint violations weighted by <code>penmult</code> .	100
tlimit	Time limit in seconds. This is equivalent to the GAMS option <code>reslim</code> . If specified, this overrides the GAMS <code>reslim</code> option.	1000

5.25.2.2 Gams system interface only

Option	Description	Default
bad_obj	Default value for objective function, if evaluation errors occur	1e8
CallConopt	call CONOPT to get duals for final point Number of seconds given for cleanup phase using CONOPT. CONOPT terminates after at most <code>CallConopt</code> seconds. The cleanup phase determines duals for final solution point.	5
debug	Debug option. Prints out complete LGO status report to listing file.	0
Include	Start reading from a new file	
log_err	Log first log_err errors Error reported (if applicable) every <code>log_err</code> iterations.	10
log_iter	Iteration log iteration interval. Log output occurs every <code>log_iter</code> iterations.	10
log_time	Iteration log time interval in seconds. Log output occurs every <code>log_time</code> seconds.	0.5
var_lo	Smallest (default) lower bound, unless set by user. Range: $[-\infty, \infty]$	-1e6
var_up	Largest (default) upper bound, unless set by user. Range: $[-\infty, \infty]$	1e6

Note that the local search operational mode (`opmode 0`) is the fastest, and that it will work for convex, as well as for some non-convex models. If the model has a highly non-convex (multiextremal) structure, then at least one of the global search modes should be used. It may be a good idea to apply all three global search modes, to verify the global solution, or perhaps to find alternative good solutions. Usually, `opmode 3` is the safest (and slowest), since it applies several local searches; `opmodes 1` and `2` launch only a single local search from the best point found in the global search phase.

Note that if model-specific information is known (more sensible target objective/merit function value, tolerances, tighter variable bounds), then such information should always be used, since it may help to solve the model far more efficiently than would be the case using the defaults.

5.25.3 The GAMS/LGO Log File

The GAMS/LGO log file gives much useful information about the current solver progress and its individual phases. To illustrate, we use the nonconvex model `mhw4d.gms` from the GAMS model library:

```

$title Nonlinear Test Problem (MHW4D,SEQ=84)

$ontext
Another popular testproblem for NLP codes.

Wright, M H, Numerical Methods for Nonlinearly Constrained Optimization.
PhD thesis, Stanford University, 1976.
$offtext

Variables m, x1, x2, x3, x4, x5;
Equations funct, eq1, eq2, eq3;

funct.. m =e= sqr(x1-1)      + sqr(x1-x2)      + power(x2-x3,3)
          + power(x3-x4,4) + power(x4-x5,4) ;
eq1.. x1 + sqr(x2) + power(x3,3) =e= 3*sqr(2) + 2 ;
eq2.. x2 - sqr(x3) + x4          =e= 2*sqr(2) - 2 ;
eq3.. x1*x5 =e= 2 ;

Model wright / all / ;

x1.l = -1; x2.l = 2; x3.l = 1; x4.l = -2; x5.l = -2;
Solve wright using nlp minimizing m;

```

Note that the solution given by LGO (shown on the next page) corresponds to the global minimum. For comparison, note that local scope nonlinear solvers will not find the global solution, unless started from a suitable neighbourhood (i.e., the model- and solver-specific region of attraction) of that solution.

In this example we use an option file to print out log information every 500 iterations, regardless of the elapsed time. Note that we set the `log_time` option to 0 to ignore the `log_time` interval.

```

LGO 1.0      May 15, 2003 LNX.LG.NA 21.0 001.000.000.LXI Lib001-030502

LGO Lipschitz Global Optimization
(C) Pinter Consulting Services, Inc.

E-mail : jdpinter@hfx.eastlink.ca
Website: www.dal.ca/~jdpinter

--- Using option file C:/GAMSPROJECTS/LGODOC/LGO.OPT
> log_iter 500
> log_time 0

3 defined, 0 fixed, 0 free
6 +/- INF bound(s) have been reset
1 LGO equations and 3 LGO variables

```

The first part prints out information about the model size after presolve. In this particular problem, the original model had 4 rows, 6 columns, and 14 non-zeroes, of which 3 were defined constraints, meaning that they could be eliminated via GAMS/LGO presolve techniques. Note that none of these were fixed or free constraints. Furthermore, LGO presolve reduced the model size further to 1 row (LGO equations) and 3 columns (LGO variables).

The main log gives information for every n iterations about current progress. The main fields are given in the table below:

Field	Description
Iter	Current iteration.
Objective	Current objective function value.
SumInf	Sum of constraint infeasibilities.
MaxInf	Maximum constraint infeasibility.
Seconds	Current elapsed time in seconds.
Errors	Number of errors and type. Type can either be D/E: Evaluation error B: Bound violation.

Iter	Objective	SumInf	MaxInf	Seconds	Errors
500	4.515428E-01	5.76E-02	5.8E-02	0.007	
1000	6.700705E-01	5.03E-05	5.0E-05	0.014	
1500	2.765930E+00	6.25E-04	6.2E-04	0.020	
2000	2.710653E+00	1.55E-02	1.6E-02	0.026	
2500	4.016702E+00	1.44E-02	1.4E-02	0.032	
3000	4.865399E+00	2.88E-04	2.9E-04	0.038	
3500	4.858826E+00	3.31E-03	3.3E-03	0.044	
4000	1.106472E+01	1.53E-02	1.5E-02	0.050	
4500	1.595505E+01	1.56E-06	1.6E-06	0.055	
5000	1.618715E+01	2.17E-05	2.2E-05	0.062	
5500	1.618987E+01	3.45E-04	3.5E-04	0.067	
6000	1.985940E+01	4.03E-04	4.0E-04	0.074	
6500	1.624319E+01	5.64E-03	5.6E-03	0.079	
7000	1.727653E+01	8.98E-05	9.0E-05	0.086	
7500	1.727033E+01	3.03E-03	3.0E-03	0.091	
7840	2.933167E-02	0.00E+00	0.0E+00	0.097	

LGO then reports the termination status, in this case globally optimal, together with the solver resource time. The resource time is also disaggregated by the total time spent performing function evaluations and the number of milliseconds (ms) spent for each function evaluation.

```
--- LGO Exit: Terminated by solver - Global solution
    0.047 LGO Secs (0.015 Eval Secs, 0.001 ms/eval)
```

A local solver such as CONOPT can be called to compute marginal values. To invoke a postsolve using CONOPT, the user specifies the `callConopt` option with a positive value, indicating the number of seconds CONOPT is given to solve. See the [LGO Options](#) section for details.

5.26 LINDO and LINDOGlobal

Lindo Systems, Inc.

5.26.1 Introduction

GAMS/LINDO finds guaranteed globally optimal solutions to general nonlinear problems with continuous and/or discrete variables. GAMS/LINDO supports most mathematical functions, including functions that are nonsmooth, such as $\text{abs}(x)$ and or even discontinuous, such as $\text{floor}(x)$. Nonlinear solvers employing methods like successive linear programming (SLP) or generalized reduced gradient (GRG) return a local optimal solution to an NLP problem. However, many practical nonlinear models are non-convex and have more than one local optimal solution. In some applications, the user may want to find a global optimal solution.

The LINDO global optimization procedure(GOP) employs branch-and-cut methods to break an NLP model down into a list of subproblems. Each subproblem is analyzed and either a) is shown to not have a feasible or optimal solution, or b) an optimal solution to the subproblem is found, e.g., because the subproblem is shown to be convex, or c) the subproblem is further split into two or more subproblems which are then placed on the list. Given appropriate tolerances, after a finite, though possibly large number of steps a solution provably global optimal to tolerances is returned. Traditional nonlinear solvers can get stuck at suboptimal, local solutions. This is no longer the case when using the global solver.

GAMS/LINDO can automatically linearize a number of nonlinear relationships, such as $\max(x,y)$, through the addition of constraints and integer variables, so the transformed linearized model is mathematically equivalent to the original nonlinear model. Keep in mind, however, that each of these strategies will require additional computation time. Thus, formulating models, so they are convex and contain a single extremum, is desirable. In order to decrease required computing power and time it is also possible to disable the global solver and use GAMS/LINDO like a regular nonlinear solver.

GAMS/LINDO has a multistart feature that restarts the standard (non-global) nonlinear solver from a number of intelligently generated points. This allows the solver to find a number of locally optimal points and report the best one found. This alternative can be used when global optimization is costly. A user adjustable parameter controls the maximum number of multistarts to be performed.

LINDO automatically detects problem type and uses an appropriate solver, e.g., if you submit an LP model to LINDO, it will be solved as an LP at LP speed, regardless of what you said in the "solve using" statement. With the NLP parameter *NLP_QUADCHK* turned on, LINDO can detect hidden quadratic expressions and automatically recognize convex QCPs, as well as second-order cones (SOCP), like in Value-at-Risk models, allowing dramatically faster solution times via the barrier solver. When such models have integer variables, LINDO would use the barrier solver to solve all subproblems leading to significantly improved solution times when compared to the case with the standard NLP solver.

5.26.1.1 Licensing and software requirements

In order to use GAMS/LINDOGlobal, two licenses are required: a GAMS/LINDOGlobal license and a GAMS/CONOPT license. The additional CONOPT license requirement exists because LINDOGlobal uses CONOPT to solve the nonlinear subproblems. The GAMS/LINDOGlobal license places upper limits on the model size of 3,000 variables and 2,000 constraints.

To use GAMS/LINDO, only a GAMS/LINDO license is required. It imposes no upper limit on the model size and includes the capability to solve stochastic models (see section [Stochastic Programming \(SP\) in GAMS/Lindo](#)).

Neither the GAMS/LINDO nor the GAMS/LINDOGlobal license includes the Barrier solver option. The Barrier option is enabled via a separate license for the GAMS/MOSEK barrier solver.

5.26.1.2 Running GAMS/LINDO

GAMS/LINDO is capable of solving models of the following types: EMP (stochastic), LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP and MINLP. If GAMS/LINDO is not specified as the default solver for these models, it can be invoked by issuing one of the following command before the solve statement:

```
option xxx=lindo;
option xxx=lindoglobal;
```

where xxx is one of: EMP, LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP, or MINLP.

You can also find global optima to math programs with equilibrium or complementarity constraints, type MPEC, by using the GAMS/NLPEC translator in conjunction with LINDO. You use NLPEC to translate complementarities into standard mathematical statements, e.g. $h*y = 0$, and then use LINDO as the DNLP(Discontinuous Nonlinear) solver to solve the translated model. The following little GAMS model illustrates:

```
$TITLE simple mpec example
variable f, x1, x2, y1, y2; positive
variable y1; y2.lo = -1; y2.up = 1;

equations cost, g, h1, h2;

cost.. f =E= x1 + x2;
      g.. sqr(x1) + sqr(x2) =L= 1;
      h1.. x1 =G= y1 - y2 + 1;
      h2.. x2 + y2 =N= 0;

* declare h and y complementary
model example / cost, g, h1.y1, h2.y2 /;

option mpec=nlpec;
option dnlp=lindo;
solve example using mpec min f;
```

5.26.2 Supported nonlinear functions

GAMS/LINDO supports most nonlinear functions in global mode, including +, -, *, /, floor, modulo, sign, min, max, sqr, exp, power, ln, log, sqrt, abs, cos, sin, tan, cosh, sinh, tanh, arccos, arcsin, arctan and logic expressions AND, OR, NOT, and IF. Be aware that using highly nonconvex functions may lead to long solve times.

5.26.3 Diagnosis of Infeasible or Unbounded Models

GAMS/LINDO offers two diagnostic tools, that can help users debug infeasible or unbounded optimization models. These tools can be called after the solver reports an infeasible or unbounded status for the model. When activating **IIS** Lindo finds an irreducible infeasible set (IIS) of constraints, whereas setting **IUS**, makes Lindo find an irreducible unbounded set (IUS) of variables. An IIS is a set of constraints that are infeasible taken together, but every strict subset is feasible. Similarly, an IUS is a set of unbounded variables such that fixing any one of them would make the model bounded. The IIS or IUS portion of the model will generally be much smaller than the original model. Thus, the user can track down formulation or data entry errors quickly. By isolating the source of infeasibility or unboundedness, the user can correct the model data such as right-hand side values, objective coefficients, senses of the constraints, and column bounds. Note that the IUS option is available for LPs only.

5.26.3.1 Infeasible Models

GAMS/Lindo's [IIS](#) option activates the IIS finder, after a model was tried to be solved and the solver returned a "no feasible solution" message. For an LP, if an infeasible basis is not resident in the solver, the IIS finder cannot initiate the process to isolate an IIS. This can occur if the infeasibility is detected in the pre-solver before a basis is created, or the barrier solver has terminated without performing a basis crossover. To obtain an IIS for such cases, the pre-solve option will be turned off automatically and the model gets optimized again.

The constraints and bounds in the IIS are further classified into two disjoint sets: a necessary set and a sufficient set. The *sufficient* set refers to a crucial subset of the IIS in the sense that removing any one of its members from the entire model renders the model feasible. Note that not all infeasible models have *sufficient* sets. The *necessary* set contains those constraints and bounds that are likely to contribute to the overall infeasibility of the entire model. Thus, the *necessary* set requires a correction in at least one member to make the original model feasible. A constraint that has been marked as *sufficient* has a high probability of containing an error. In fact, if the model contains only one bad coefficient, the constraint containing it will be marked as *sufficient*.

To control the level of analysis when locating an IIS, one can set the option [IIS_ANALYZE_LEVEL](#).

5.26.3.2 Unbounded Linear Programs

GAMS/Lindo's [IUS](#) option is similar to the IIS option, except that it is used to track down the source of an unbounded solution in a linear program. This tool analyzes the model and isolates an "irreducibly unbounded set" (IUS) of variables. As in the infeasibility case, the IUS is partitioned into *sufficient* and *necessary* sets to indicate the role of the member variables for the unboundedness of the overall model.

The variables in the *sufficient* set are crucial in the sense that fixing any of these variables makes the overall model bounded. However, fixing the variables in the *necessary* set does not ensure that there are no other sets of unbounded variables that cause unboundedness for the overall model.

To control the level of analysis when locating an IUS, one can set the option [IUS_ANALYZE_LEVEL](#).

5.26.4 GAMS/LINDO output

The log output below is obtained for the NLP model mhw4d.gms from the GAMS model library using LINDO's global solver.

After determining the different kinds of nonlinear operators LINDO tries to linearize these within the presolving. When a feasible starting point is found the optimization starts and the log provides information about the progress. At the end it is reported if an optimum could be found and then the results as well as the used resources are summarized.

The following flags can be seen in the progress log:

Flag	Description
(*FP)	found a new MIP solution with feasibility pump
(*SBB)	found a new MIP solution in tree reorder
(*SE)	found a new MIP solution in simple enumeration
(*AB)	found a new MIP solution in advanced branching
(*AH)	found a new MIP solution with advanced heuristics
(*C)	found a new MIP solution after cuts added
(*T)	found a new MIP solution on the top
(*SRH)	found a new MIP solution in simple rounding heuristics
(*SB)	found a new MIP solution in strong branching
(*K)	found a new MIP solution in knapsack enumerator
(*)	found a new MIP solution normal branching
(*?-)	found a new MIP solution with advanced heuristics (level\$>\$10)
(*N)	found a new incumbent GOP solution
(*I)	stored a box with the incumbent solution into the GOP solution list
(*F)	determined the final GOP status

5.26.5 The GAMS/LINDO Options

GAMS/LINDO offers a diverse range of user-adjustable parameters to control the behavior of its solvers. While the default values of these parameters work best for most purposes, there may be cases the users prefer to work with different settings for a subset of the available parameters. This section gives a list of available GAMS/LINDO parameters, categorized by type, along with their brief descriptions. A more detailed description is given in the section that follows.

5.26.5.1 GAMS/LINDO Options File

In order to set GAMS/LINDO options, you need to set up an option file *lindo.opt* or *lindoglobal.opt* in your GAMS project directory. You must indicate in the model that you want to use the option file by inserting before the solve statement, the line:

```
<modelname>.optfile = 1;
```

where

```
<modelname>
```

is the name of the model referenced in the model statement. The option file is in plain text format containing a single GAMS/LINDO option per line. Each option identifier is followed by its target value with space or tab characters separating them. The lines starting with * character are treated as comments.

A sample option file *lindo.opt* looks like below

```

* Use(1) or Disable(0) global optimization for NLP/MINLP models
USEGOP          0

* Enable Multistart NLP solver
NLP_SOLVER      9

* Allow a maximum of 3 multistart attempts
NLP_MAXLOCALSEARCH  3

* Set an overall time limit of 200 secs.
SOLVER_TIMLMT   200

```

5.26.6 Summary of GAMS/Lindo Options

5.26.6.1 General Options

Option	Description	Default
DECOMPOSITION_TYPE	decomposition to be performed on a linear or mixed integer model	1
FIND_BLOCK	graph partitioning method to find block structures	0
FIND_SYMMETRY_LEVEL	specifies the symmetry finding level.	-1
FIND_SYMMETRY_PRINT_LEVEL	specifies print level for symmetry finding	0
INSTRUCT_SUBOUT	flag to specify how to deal with fixed variables in the instruction list	-1
MULTITHREAD_MODE	threading mode	-1
NUM_THREADS	number of parallel threads to be used	GAMS Threads
PROFILER_LEVEL	specifies the profiler level to break down the total cpu time into.	0
SOLVER_CONCURRENT_OPTMODE	controls if simplex and interior-point optimizers will run concurrently	0
SOLVER_CUTOFFVAL	solver will exit if optimal solution is worse than this	0
SOLVER_FEASTOL	feasibility tolerance	1e-7
SOLVER_IPMSOL	basis crossover flag for barrier solver	0
SOLVER_IUSOL	flag for computing basic solution for infeasible model	0
SOLVER_METHOD	specifies the method to use when generic solver is invoked	0
SOLVER_MODE	controls some of the advanced strategies when solving LPs	1
SOLVER_OPTTOL	dual feasibility tolerance	1e-7
SOLVER_PRE_ELIM_FILL	fill-in introduced by the eliminations during pre-solve	1000
SOLVER_RESTART	starting basis flag	0
SOLVER_TIMLMT	time limit in seconds for continous solver	GAMS ResLim
SOLVER_USECUTOFFVAL	flag for using cutoff value	0
TUNER_PRINT_LEVEL	specifies the amount of print to do during parameter tuning	1

5.26.6.2 LP Options

Option	Description	Default
LP_AIJ_ZEROTOL	coefficient matrix zero tolerance	2.22045e-16
LP_BIGM	big-M for phase-I	1e6
LP_BNDINF	big-M to truncate lower and upper bounds in single phase dual-simplex	1e15
LP_DPSWITCH	specifies whether LP primal-dual simplex switch is enabled or not	1
LP_DRATIO	controls the dual min-ratio strategy	1
LP_DYNOBJFACT	Dynamic obj factor	0.75
LP_DYNOBJMODE	Dynamic obj mode	0
LP_ITRLMT	simplex iteration limit	infinity
LP_PIV_BIGTOL	simplex maximum pivot tolerance	1e-5
LP_PIV_ZEROTOL	simplex pivot zero tolerance	1e-8
LP_PPARTIAL	primal simplex partial pricing method	0
LP_PRELEVEL	controls the amount and type of LP pre-solving	126
LP_RATRANGE	controls the number of pivot-candidates to consider when searching for a stable pivot in LU decomposition	4
LP_SCALE	scaling flag	1
LP_SPRINT_COLFACT	maximum number of columns in Sprint as a factor of number of rows	10
LP_SPRINT_MAXPASS	maximum number of passes in Sprint method	100
LP_SPRINT_SUB	LP method for subproblem in Sprint method	0
PROB_TO_SOLVE	controls whether the explicit primal or dual form of the given LP problem will be solved	0
SPLEX_DPRICING	pricing option for dual simplex method	-1
SPLEX_DUAL_PHASE	controls the dual simplex strategy	0
SPLEX_PPRICING	pricing option for primal simplex method	-1
SPLEX_REFACTFRQ	number of simplex iterations between two consecutive basis re-factorizations	100

5.26.6.3 IPM Options

Option	Description	Default
IPM_BASIS_REL_TOL_S	maximum relative dual bound violation allowed in an optimal basic solution	1e-12
IPM_BASIS_TOL_S	maximum absolute dual bound violation in an optimal basic solution	1e-7
IPM_BASIS_TOL_X	maximum absolute primal bound violation allowed in an optimal basic solution	1e-7
IPM_BILLU_TOL_REL_PIV	relative pivot tolerance used in the LU factorization in the basis identification procedure	1e-2
IPM_CHECK_CONVEXITY	flag to check convexity of a quadratic program using barrier solver	1

Option	Description	Default
IPM_CO_TOL_INFEAS	maximum bound infeasibility tolerance for Conic solver	1e-10
IPM_MAX_ITERATIONS	ipm iteration limit	1000
IPM_NUM_THREADS	number of threads to run the interiorpoint optimizer on	1
IPM_OFF_COL_TRH	extent for detecting the offending columns in the Jacobian of the constraint matrix	40
IPM_TOL_DFEAS	dual feasibility tolerance	1e-8
IPM_TOL_DSAFE	controls the initial dual starting point	1
IPM_TOL_INFEAS	infeasibility tolerance	1e-10
IPM_TOL_MU_RED	relative complementarity gap tolerance	1e-16
IPM_TOL_PATH	how close to follow the central path	1e-8
IPM_TOL_PFEAS	primal feasibility tolerance	1e-8
IPM_TOL_PSAFE	controls the initial primal starting point	1
IPM_TOL_REL_STEP	relative step size to the boundary	0.9999

5.26.6.4 MIP Options

Option	Description	Default
MIP_ABS CUTTOL	MIP absolute cut tolerance	-1.0
MIP_ABS OPTTOL	MIP absolute optimality tolerance	GAMS OptCA
MIP_ADDCUTOBJTOL	required objective improvement to continue generating cuts	1.5625e-5
MIP_ADDCUTPER	percentage of constraint cuts that can be added	0.75
MIP_ADDCUTPER_TREE	percentage of constraint cuts that can be added at child nodes	0.5
MIP_AGGCUTLIM.TOP	max number of constraints involved in derivation of aggregation cut at root node	-1
MIP_AGGCUTLIM.TREE	max number of constraints involved in derivation of aggregation cut at tree nodes	-1
MIP_ANODES_SWITCH_DF	threshold on active nodes for switching to depth-first search	50000
MIP_AOPTTIMLIM	time in seconds beyond which the relative optimality tolerance will be applied	100
MIP_BIGM.FOR.INTTOL	threshold for which coefficient of a binary variable would be considered as big-M	1e8
MIP_BRANCHDIR	first branching direction	0
MIP_BRANCHRULE	rule for choosing the variable to branch	0
MIP_BRANCHLIMIT	limit on the total number of branches to be created during branch and bound	-1
MIP_BRANCHPRIO	controls how variable selection priorities are set and used	0
MIP_CUTDEPTH	threshold value for the depth of nodes in the branch and bound tree	8
MIP_CUTFREQ	frequency of invoking cut generation at child nodes	10

Option	Description	Default
MIP_CUTLEVEL_TOP	combination of cut types to try at the root node when solving a MIP	57342
MIP_CUTLEVEL_TREE	combination of cut types to try at child nodes in the branch and bound tree when solving a MIP	53246
MIP_CUTOFFOBJ	defines limit for branch and bound	1e30
MIP_CUTTIMLIM	time to be spent in cut generation	-1
MIP_DELTA	near-zero value used in linearizing nonlinear expressions	1e-6
MIP_DUAL_SOLUTION	flag for computing dual solution of LP relaxation	0
MIP_FP_ITRLIM	iteration limit for feasibility pump heuristic	500
MIP_FP_MODE	mode for the feasibility pump heuristic	-1
MIP_FP_OPT_METHOD	optimization and reoptimization method for feasibility pump heuristic	0
MIP_FP_TIMLIM	time limit for feasibility pump heuristic	1800
MIP_FP_WEIGHT	weight of the objective function in the feasibility pump	1
MIP_GENERAL_MODE	general strategy in solving MIPs	0
MIP_HEULEVEL	specifies heuristic used to find integer solution	3
MIP_HEUMINTIMLIM	minimum time in seconds to be spent in finding heuristic solutions	0
MIP_HEU_DROP_OBJ	flag for whether to use without OBJ heuristic	0
MIP_HEU_MODE	heuristic used in MIP solver	0
MIP_INTTOL	absolute integer feasibility tolerance	1e-6
MIP_ITRLIM	iteration limit for branch and bound	infinity
MIP_KBEST_USE_GOP	specifies whether to use gop solver in MIP KBest	0
MIP_KEEPMEM	flag for keeping LP bases in memory	1
MIP_LBIGM	Big-M value used in linearizing nonlinear expressions	10000
MIP_LSOLTIMLIM	time limit until finding a new integer solution	-1
MIP_MAKECUT_INACTIVE_COUNT	threshold for times a cut could remain active after successive reoptimization	10
MIP_MAXCUTPASS_TOP	number passes to generate cuts on the root node	200
MIP_MAXCUTPASS_TREE	number passes to generate cuts on the child nodes	2
MIP_MAXNONIMP_CUTPASS	number of passes allowed in cut-generation that does not improve current relaxation	3
MIP_MAXNUM_MIP_SOL_STORAGE	maximum number of k-best solutions to store	1
MIP_MINABSOBJSTEP	value to update cutoff value each time a mixed integer solution is found	0

Option	Description	Default
MIP_NODESELRULE	specifies the node selection rule	0
MIP_NUM_THREADS	number of parallel threads to use by the parallel MIP solver	1
MIP_PARA_FP	flag for whether to use parallelization on the feasibility pump heuristic	1
MIP_PARA_FP_MODE	flag for the mode of parallel feasibility pump	0
MIP_PARA_INIT_NODE	number of initial nodes for MIP parallelization	-1
MIP_PARA_ITR_MODE	flag for iteration mode in MIP parallelization	1
MIP_PARA_RND_ITRLMT	iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations	2.0
MIP_PARA_SUB	flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing	1
MIP_PEROPTTOL	MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds	1e-5
MIP_PERSPECTIVE_REFORM	flag for whether to use Perspective Reformulation	1
MIP_POLISH_ALPHA_TARGET	proportion solutions in the pool to initiate a polishing-task at the current node	0.6
MIP_POLISH_MAX_BRANCH_COUNT	maximum number of branches to polish	2000
MIP_POLISH_NUM_BRANCH_NEXT	number of branches to polish in the next round	4000
MIP_PREHEU_DFE_VSTLIM	limit for the variable visit in depth first enumeration	200
MIP_PREHEU_LEVEL	heuristic level for the prerelax solver	0
MIP_PREHEU_TC_ITERLIM	iteration limit for the two change heuristic	30000000
MIP_PREHEU_VAR_SEQ	sequence of the variable considered by the prerelax heuristic	-1
MIP_PRELEVEL	controls the amount and type of MIP pre-solving at root node	3070
MIP_PRELEVEL_TREE	amount and type of MIP pre-solving at tree nodes	1214
MIP_PRE_ELIM_FILL	controls fill-in introduced by eliminations during pre-solve	100
MIP_PSEUDOCOST_RULE	specifies the rule in pseudocost computations for variable selection	0
MIP_PSEUDOCOST_WEIGT	weight in pseudocost computations for variable selection	1.5625e-05
MIP_REDCOSTFIX_CUTOFF	cutoff value as a percentage of the reduced costs	0.9
MIP_REDCOSTFIX_CUTOFF_TREE	cutoff value as a percentage of the reduced costs at tree nodes	0.9
MIP_RELINTTOL	relative integer feasibility tolerance	8e-6
MIP_RELOPTTOL	MIP relative optimality tolerance	GAMS OptCR
MIP_REOPT	optimization method to use when doing reoptimization	0

Option	Description	Default
MIP_SCALING_BOUND	maximum difference between bounds of an integer variable for enabling scaling	10000
MIP_SOLLIM	integer solution limit for MIP solver	-1
MIP_SOLVERTYPE	optimization method to use when solving mixed-integer models	0
MIP_STRONGBRANCHDONUM	minimum number of variables to try the strong branching on	3
MIP_STRONGBRANCHLEVEL	depth from the root in which strong branching is used	10
MIP_SWITCHFAC_SIM_IPM_TIME	factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method	-1
MIP_SYMMETRY_MODE	specifies mip symmetry handling methods	0
MIP_TIMLIM	time limit in seconds for integer solver	GAMS ResLim
MIP_TOPOPT	optimization method to use when there is no previous basis	0
MIP_TREEREORDERLEVEL	tree reordering level	10
MIP_TREEREORDERMODE	tree reordering mode	1
MIP_USECUTOFFOBJ	flag for using branch and bound limit	1
MIP_USE_CUTS_HEU	controls if cut generation is enabled during MIP heuristics	-1
MIP_USE_ENUM_HEU	frequency of enumeration heuristic	4
MIP_USE_INT_ZERO_TOL	controls if all MIP calculations would be based on absolute integer feasibility tolerance	0

5.26.6.5 NLP Options

Option	Description	Default
NLP_AUTODERIV	defining type of computing derivatives	0
NLP_AUTOHESS	flag for using Second Order Automatic Differentiation for solving NLP	0
NLP_CONIC_REFORM	determines if to explore conic reformulation	1
NLP_CUTOFFOBJ	as soon as any multi-start thread achieves this value all threads stop	-1e30
NLP_DERIV_DIFFTYPE	flag indicating the technique used in computing derivatives with finite differences	0
NLP_FEASCHK	how to report results when solution satisfies tolerance of scaled but not original model	1
NLP_FEASTOL	feasibility tolerance for nonlinear constraints	1e-6
NLP_INF	numeric infinity for nonlinear models	1e30
NLP_IPM2GRG	switch from IPM solver to GRG solver when IPM fails due to numerical errors	1
NLP_ITERS_PER_LOGLINE	number of nonlinear iterations to elapse before next progress message	10

Option	Description	Default
NLP_ITRLMT	nonlinear iteration limit	GAMS IterLim
NLP_LINEARZ	extent to which the solver will attempt to linearize nonlinear models	0
NLP_LINEARZ_WB_CONSISTENT	determines if linearization process is consistent with WB/excel calculation	0
NLP_MAXLOCALSEARCH	maximum number of local searches	5
NLP_MAXLOCALSEARCH_TREE	maximum number of multistarts	1
NLP_MAX_RETRY	maximum number refinement retries to purify the final NLP solution	5
NLP_MSW_EUCDIST_THRES	euclidean distance threshold in multistart search	0.001
NLP_MSW_FILTERMODE	filtering mode to exclude certain domains during sampling in multistart search	-1
NLP_MSW_MAXNOIMP	maximum number of consecutive populations to generate without any improvements	-1
NLP_MSW_MAXPOP	maximum number of populations to generate in multistart search	-1
NLP_MSW_MAXREF	maximum number of reference points to generate trial points in multistart search	-1
NLP_MSW_NORM	norm to measure the distance between two points in multistart search	2
NLP_MSW_NUM_THREADS	number of parallel threads to be used when solving an NLP model with the multistart solver	1
NLP_MSW_OVERLAP_RATIO	rate of replacement in successive populations	0.1
NLP_MSW_POXDIST_THRES	penalty function neighborhood threshold in multistart search	0.01
NLP_MSW_PREPMODE	preprocessing strategies in multistart solver	-1
NLP_MSW_RG_SEED	random number generator seed for the multistart solver	1019
NLP_MSW_SOLIDX	index of the multistart solution to be loaded	0
NLP_MSW_XKKTRAD_FACTOR	KKT solution neighborhood factor in multistart search	0.85
NLP_MSW_XNULRAD_FACTOR	initial solution neighborhood factor in multistart search	0.5
NLP_PRELEVEL	controls the amount and type of NLP presolving	126
NLP_PSTEP_FINITEDIFF	value of the step length in computing the derivatives using finite differences	5e-7
NLP_QUADCHK	flag for checking if NLP is quadratic	1
NLP_REDGTOL	tolerance for the gradients of nonlinear functions	1e-7
NLP_SOLVER	type of nonlinear solver	7
NLP_SOLVE_AS_LP	flag indicating if the nonlinear model will be solved as an LP	0
NLP_STALL_ITRLMT	iteration limit before a sequence of non-improving NLP iterations is declared as stalling	100
NLP_STARTPOINT	flag for using initial starting solution for NLP	1

Option	Description	Default
NLP_SUBSOLVER	type of nonlinear subsolver	1
NLP_USECUTOFFOBJ	flag to use parameter NLP_CUTOFFOBJ	0
NLP_USE_CRASH	flag for using simple crash routines for initial solution	0
NLP_USE_LINDO_CRASH	flag for using advanced crash routines for initial solution	1
NLP_USE_SDP	flag to use SDP solver for POSD constraint	1
NLP_USE_SELCONVAL	flag for using selective constraint evaluations for solving NLP	1
NLP_USE_SLP	flag for using sequential linear programming step directions for updating solution	1
NLP_USE_STEEPEdge	flag for using steepest edge directions for updating solution	0

5.26.6.6 Global Options

Option	Description	Default
GOP_ABSOPTTOL	absolute optimality tolerance	GAMS OptCA
GOP_ALGREFORMMD	algebraic reformulation rule for a GOP	18
GOP_BBSRCHMD	node selection rule in GOP branch-and-bound	1
GOP_BNDLIM	max magnitude of variable bounds used in GOP convexification	1e10
GOP_BOXTOL	minimal width of variable intervals	1e-6
GOP_BRANCHMD	direction to branch first when branching on a variable	5
GOP_BRANCH_LIMIT	limit on the total number of branches to be created in GOP tree	-1
GOP_CMINLP	flag indicating if GOP exploits convex MINLP model	0
GOP_CONIC_REFORM	flag indicating if GOP explore conic reformulation	1
GOP_CORELEVEL	strategy of GOP branch-and-bound	14
GOP_DECOMPPTMD	decomposition point selection rule in GOP branch-and-bound	1
GOP_DELTATOL	delta tolerance in GOP convexification	1e-7
GOP_FLTTOL	floating-point tolerance	1e-10
GOP_HEU_MODE	heuristic used in global solver	0
GOP_ITRLIM	GOP iteration limit	infinity
GOP_ITRLIM_IPM	total barrier iteration limit summed over all branches in GOP	-1
GOP_ITRLIM_NLP	total nonlinear iteration limit summed over all branches in GOP	-1
GOP_ITRLIM_SIM	total simplex iteration limit summed over all branches in GOP	-1
GOP_LIM_MODE	flag indicating which heuristic limit on sub-solver in GOP is based	1
GOP_LINEARZ	flag indicating if GOP exploits linearizable model	1

Option	Description	Default
GOP_LSOLBRANLIM	branch limit until finding a new nonlinear solution	-1
GOP_MAXWIDMD	maximum width flag for the global solution	0
GOP_MULTILINEAR	flag indicating if GOP exploits multi linear feature	1
GOP_NUM_THREADS	number of parallel threads to be used when solving a nonlinear model with the global optimization solver	1
GOP_OBJ_THRESHOLD	threshold of objective value in the GOP solver	-1e+30
GOP_OPTCHKMD	criterion used to certify the global optimality	2
GOP_OPT_MODE	mode for GOP optimization	1
GOP_POSTLEVEL	amount and type of GOP postsolving	6
GOP_PRELEVEL	amount and type of GOP presolving	30
GOP_QUAD_METHOD	specifies if the GOP solver should solve the model as a QP when applicable	-1
GOP_RELBRNDMD	reliable rounding in the GOP branch-and-bound	0
GOP_RELOPTTOL	relative optimality tolerance	GAMS OptCR
GOP_SOLLIM	integer solution limit for GOP branch-and-bound	-1
GOP_SUBOUT_MODE	substituting out fixed variables	1
GOP_TIMLIM	time limit in seconds for GOP branch-and-bound	GAMS ResLim
GOP_USEBNDLIM	max magnitude of variable bounds flag for GOP convexification	2
GOP_WIDTOL	maximal width of variable intervals	1e-4
USEGOP	use global optimization	1

5.26.6.7 SP Options

Option	Description	Default
CORE_ORDER_BY_STAGE	order nontemporal models or not	1
REPORTEVSOL	solve and report the expected value solution	0
SAMP_CDSINC	correlation matrix diagonal shift increment	1e-6
SAMP_NCM_CUTOBJ	objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem	1e-30
SAMP_NCM_DSTORAGE	flag to enable or disable sparse mode in NCM computations	-1
SAMP_NCM_ITERLIM	iteration limit for NCM method	100
SAMP_NCM_METHOD	bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem	5
SAMP_NCM_OPTTOL	optimality tolerance for NCM method	1e-7
SAMP_SCALE	flag to enable scaling of raw sample data	0
STOC_ABSOPTTOL	absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver	GAMS OptCA

Option	Description	Default
STOC_ADD_MPI	flag to use add-instructions mode when building deteq	0
STOC_ALD_DUAL_FEASTOL	dual feasibility tolerance for ALD	1e-4
STOC_ALD_DUAL_STEPLEN	dual step length for ALD	0.9
STOC_ALD_INNER_ITER_LIM	inner loop iteration limit for ALD	1000
STOC_ALD_OUTER_ITER_LIM	outer loop iteration limit for ALD	200
STOC_ALD_PRIMAL_FEASTOL	primal feasibility tolerance for ALD	1e-4
STOC_ALD_PRIMAL_STEPLEN	primal step length for ALD	0.5
STOC_AUTOAGGR	flag to enable or disable autoaggregation	1
STOC_BENCHMARK_SCEN	benchmark scenario to compare EVPI and EVMU against	-2
STOC_BIGM	big-M value for linearization and penalty functions	1e7
STOC_BUCKET_SIZE	bucket size in Benders decomposition	-1
STOC_CALC_EVPI	flag to enable or disable calculation of EVPI	1
STOC_CORRELATION_TYPE	correlation type associated with correlation matrix	0
STOC_DEQOPT	method to solve the DETEQ problem	0
STOC_DETEQ_TYPE	type of deterministic equivalent	-1
STOC_DS_SUBFORM	subproblem formulation to use in DirectSearch	-1
STOC_ELIM_FXVAR	flag to enable elimination of fixed variables from deteq MPI	1
STOC_INFBND	value to truncate infinite bounds at non-leaf nodes	1e9
STOC_ITER_LIM	iteration limit for stochastic solver	infinity
STOC_MAP_MPI2LP	flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements	0
STOC_MAX_NUMSCENS	maximum number of scenarios before forcing automatic sampling	40000
STOC_METHOD	stochastic optimization method to solve the model	-1
STOC_NAMEDATA_LEVEL	name data level	1
STOC_NODELP_PRELEVEL	presolve level solving node-models	0
STOC_NSAMPLE_PER_STAGE	list of sample sizes per stage (starting at stage 2)	
STOC_NSAMPLE_SPAR	common sample size per stochastic parameter	-1
STOC_NSAMPLE_STAGE	common sample size per stage	-1
STOC_NUM_THREADS	number of parallel threads	1
STOC_RELOPTTOL	relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver	GAMS OptCR
STOC_REL_DSTEPTOL	dual-step tolerance	1e-7
STOC_REL_PSTEPTOL	primal-step tolerance	1e-8

Option	Description	Default
STOC_REOPT	reoptimization method to solve the node-models	0
STOC_RG_SEED	seed to initialize the random number generator	1031
STOC_SAMP_CONT_ONLY	flag to restrict sampling to continuous stochastic parameters only or not	1
STOC_SBD_MAXCUTS	max cuts to generate for master problem	-1
STOC_SBD_NUMCANDID	maximum number of candidate solutions to generate at SBD root	-1
STOC_SBD_OBJCUTFLAG	flag to enable objective cut in SBD master problem	1
STOC_SBD_OBJCUTVAL	RHS value of objective cut in SBD master problem	1e-30
STOC_SHARE_BEGSTAGE	stage beyond which node-models are shared	-1
STOC_TIME_LIM	time limit for stochastic solver	GAMS ResLim
STOC_TOPOPT	optimization method to solve the root problem	0
STOC_VARCONTROL_METHOD	sampling method for variance reduction	1
STOC_WSBAS	warm start basis for wait-see model	-1
SVR_LS_ANTITHETIC	Sample variance reduction map to Lindo Anti-thetic algorithm	
SVR_LS_LATINSQUARE	Sample variance reduction map to Lindo Latin Square algorithm	
SVR_LS_MONTECARLO	Sample variance reduction map to Lindo Monte-carlo algorithm	

5.26.6.8 IIS and IUS Options

Option	Description	Default
IIS	run the IIS finder if the problem is infeasible	0
IIS_ANALYZE_LEVEL	controls the level of analysis when locating an IIS	1
IIS_GETMODE	flag that controls whether variable bounds in the IIS should be retrieved or the integer restrictions	0
IIS_INFEAS_NORM	specifies the norm to measure infeasibilities in IIS search	0
IIS_ITER_LIMIT	the iteration limit for IIS search	-1
IIS_METHOD	specifies the method to use in analyzing infeasible models to locate an IIS	0
IIS_PRINT_LEVEL	specifies the amount of print to do during IIS search	2
IIS_REOPT	specifies which optimization method to use when starting from a given basis	0
IIS_TIME_LIMIT	the time limit for IIS search	-1
IIS_TOPOPT	specifies which optimization method to use when there is no previous basis	0
IIS_USE_EFILTER	flag that controls whether the Elastic Filter should be enabled as the supplementary filter in analyzing infeasible models	0
IIS_USE_GOP	flag that controls whether the global optimizer should be enabled in analyzing infeasible NLP models	0

Option	Description	Default
IIS_USE_SFILTER	flag indicating is sensitivity filter will be used during IIS search	1
IUS	run the IUS finder if the problem is unbounded	0
IUS_ANALYZE_LEVEL	controls the level of analysis when locating an IUS	2

5.26.6.9 Link Options

Option	Description	Default
CHECKRANGE	calculate feasible range for variables	<code>range.gdx</code>
READPARAMS	read Lindo parameter file	
WRITEDEMPI	write deterministic equivalent in MPI format	
WRITEDEMPS	write deterministic equivalent in MPS format	
WRITEMPI	write (S)MPI file of processed model	
WRITEMPS	write (S)MPS file of processed model	

5.26.7 Detailed Descriptions of GAMS/Lindo Options

CHECKRANGE (*string*): calculate feasible range for variables ↔

If this option is set, Lindo calculates the feasible range (determined by an upper and lower bound) for every variable in each equation while all other variables are fixed to their level. If set, the value of this option defines the name of the GDX file where the results are written to. For every combination of equation- and variable block there will be one symbol in the format *EquBlock_VarBlock(equ_Ind_1, ..., equ_Ind_M, var_Ind_1, ..., var_Ind_N, directions)*.

Default: `range.gdx`

CORE_ORDER_BY_STAGE (*integer*): order nontemporal models or not ↔

Order nontemporal models or not.

Default: 1

DECOMPOSITION_TYPE (*integer*): decomposition to be performed on a linear or mixed integer model ↔

This refers to the type of decomposition to be performed on a linear or mixed integer model.

Default: 1

value	meaning
0	Solver decides which type of decomposition to use
1	Solver does not perform any decompositions and uses the original model
2	Attempt total decomposition
3	Decomposed model will have dual angular structure
4	Decomposed model will have block angular structure
5	Decomposed model will have both dual and block angular structure

FIND_BLOCK (*integer*): graph partitioning method to find block structures ↔

Specifies the graph partitioning method to find block structures.

Default: 0

value	meaning
0	Use an edge-weight minimizing graph partitioning heuristic
1	Use a vertex-weight minimizing graph partitioning heuristic

FIND_SYMMETRY_LEVEL (*integer*): specifies the symmetry finding level. ↔

Default: -1

value	meaning
-1	Solver decides
0	Finding orbit only without MIP preprocessing
1	Finding orbit only with MIP preprocessing
2	Finding generators without MIP preprocessing
3	Finding generators with MIP preprocessing
4	Finding the first generator without MIP preprocessing
5	Finding the first generator with MIP preprocessing

FIND_SYMMETRY_PRINT_LEVEL (*integer*): specifies print level for symmetry finding ↔

Default: 0

value	meaning
0	Nothing printed
+2	General information
+4	Time information
+8	Orbit information
+16	Partition information

GOP_ABSOPTTOL (*real*): absolute optimality tolerance ↔

Synonym: ABSOPTTOL

This value is the GOP absolute optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCA

GOP_ALGREFORMMD (*integer*): algebraic reformulation rule for a GOP ↔

Synonym: ALGREFORMMD

This controls the algebraic reformulation rule for a GOP. The algebraic reformulation and analysis is very crucial in building a tight convex envelope to enclose the nonlinear/nonconvex functions. A lower degree of overestimation on convex envelopes helps increase the convergence rate to the global optimum.

Default: 18

value	meaning
+2	Rearrange and collect terms
+4	Expand all parentheses
+8	Retain nonlinear functions
+16	Selectively expand parentheses

GOP_BBSRCHMD (*integer*): node selection rule in GOP branch-and-bound ↔

Synonym: BBSRCHMD

This specifies the node selection rule for choosing between all active nodes in the GOP branch-and-bound tree when solving global optimization programs.

Default: 1

value	meaning
0	Depth first search
1	Choose node with worst bound

GOP_BNDLIM (*real*): max magnitude of variable bounds used in GOP convexification ↔

Synonym: BNDLIM

This value specifies the maximum magnitude of variable bounds used in the GOP convexification. Any lower bound smaller than the negative of this value will be treated as the negative of this value. Any upper bound greater than this value will be treated as this value. This helps the global solver focus on more productive domains.

Default: 1e10

GOP_BOXTOL (*real*): minimal width of variable intervals ↔

Synonym: BOXTOL

This value specifies the minimal width of variable intervals in a box allowed to branch.

Default: 1e-6

GOP_BRANCHMD (*integer*): direction to branch first when branching on a variable ↔

Synonym: BRANCHMD

This specifies the direction to branch first when branching on a variable. The branch variable is selected as the one that holds the largest magnitude in the measure.

Default: 5

value	meaning
0	Absolute width
1	Locally relative width
2	Globally relative width
3	Globally relative distance from the convex minimum to the bounds
4	Absolute violation between the function and its convex envelope at the convex minimum
5	Relative violation between the function and its convex envelope at the convex minimum

GOP_BRANCH_LIMIT (*integer*): limit on the total number of branches to be created in GOP tree ↔

Synonym: BRANCH_LIMIT

This is the limit on the total number of branches to be created during branch-and-bound in GOP tree. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible solution was found, it will be installed as the incumbent (best known) solution.

Range: $\{-1, \dots, \infty\}$

Default: -1

GOP_CMINLP (*integer*): flag indicating if GOP exploits convex MINLP model ↔

Default: 0

value	meaning
0	Off
1	On

GOP_CONIC_REFORM (*integer*): flag indicating if GOP explore conic reformulation ↔

Default: 1

value	meaning
0	Off
1	On

GOP_CORELEVEL (*integer*): strategy of GOP branch-and-bound ↔

Synonym: CORELEVEL

This controls the strategy of GOP branch-and-bound procedure.

Default: 14

value	meaning
+2	LP convex relaxation
+4	NLP solving
+8	Box Branching

GOP_DECOMPPTMD (*integer*): decomposition point selection rule in GOP branch-and-bound ↔

Synonym: DECOMPPTMD

This specifies the decomposition point selection rule. In the branch step of GOP branch-and-bound, a branch point M is selected to decompose the selected variable interval $[Lb, Ub]$ into two subintervals, $[Lb, M]$ and $[M, Ub]$.

Default: 1

value	meaning
0	Mid-point
1	Local minimum or convex minimum

GOP_DELTATOL (*real*): delta tolerance in GOP convexification [↔](#)

Synonym: DELTATOL

This value is the delta tolerance in the GOP convexification. It is a measure of how closely the additional constraints added as part of convexification should be satisfied.

Default: $1e-7$

GOP_FLTTOL (*real*): floating-point tolerance [↔](#)

Synonym: FLTTOL

This value is the GOP floating-point tolerance. It specifies the maximum rounding errors in the floating-point computation.

Default: $1e-10$

GOP_HEU_MODE (*integer*): heuristic used in global solver [↔](#)

Synonym: HEU_MODE

This specifies the heuristic used in the global solver to find a good solution. Typically, if a heuristic is used, this will put more efforts in searching for good solutions, and less in bound tightening.

Default: 0

value	meaning
0	No heuristic is used
1	A simple heuristic is used

GOP_ITRLIM (*real*): GOP iteration limit [↔](#)

Synonym: ITRLIM

This is the total iteration limit (including simplex, barrier and nonlinear iteration) summed over branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: $[-1, \infty]$

Default: *infinity*

GOP_ITRLIM_IPM (*real*): total barrier iteration limit summed over all branches in GOP [↔](#)

Synonym: ITRLIM_IPM

This is the total barrier iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: $[-1, \infty]$

Default: -1

GOP_ITRLIM_NLP (*real*): total nonlinear iteration limit summed over all branches in GOP ↔

Synonym: ITRLIM_NLP

This is the total nonlinear iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: $[-1, \infty]$

Default: -1

GOP_ITRLIM_SIM (*real*): total simplex iteration limit summed over all branches in GOP ↔

Synonym: ITRLIM_SIM

This is the total simplex iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: $[-1, \infty]$

Default: -1

GOP_LIM_MODE (*integer*): flag indicating which heuristic limit on sub-solver in GOP is based ↔

Synonym: LIM_MODE

This is a flag indicating which heuristic limit on sub-solver in GOP is based.

Default: 1

value	meaning
0	No limit
1	Time based limit
2	Iteration based limit
3	Both time and iteration based limit

GOP_LINEARZ (*integer*): flag indicating if GOP exploits linearizable model ↔

This is a flag indicating if GOP exploits linearizable model.

Default: 1

value	meaning
0	Exploit linearizable model
1	Do not exploit linearizable model

GOP_LSOLBRANLIM (*integer*): branch limit until finding a new nonlinear solution ↔

Synonym: LSOLBRANLIM

This value controls the branch limit until finding a new nonlinear solution since the last nonlinear solution is found. The default value is -1, which means no branch limit is imposed.

Range: $\{-1, \dots, \infty\}$

Default: -1

GOP_MAXWIDMD (*integer*): maximum width flag for the global solution ↔

Synonym: MAXWIDMD

This is the maximum width flag for the global solution. The GOP branch-and-bound may continue contracting a box with an incumbent solution until its maximum width is smaller than [GOP_WIDTOL](#).

Default: 0

value	meaning
0	The maximum width criterion is suppressed
1	The maximum width criterion is performed

GOP_MULTILINEAR (*integer*): flag indicating if GOP exploits multi linear feature ↔

This is a flag indicating if GOP exploits multi linear feature.

Default: 1

value	meaning
0	Off
1	On

GOP_NUM_THREADS (*integer*): number of parallel threads to be used when solving a nonlinear model with the global optimization solver ↔

This value specifies the number of parallel threads to be used when solving a nonlinear model with the global optimization solver.

Default: 1

GOP_OBJ_THRESHOLD (*real*): threshold of objective value in the GOP solver ↔

This value specifies the threshold of objective value in the GOP solver. For min problem, if current incumbent solution is less than the threshold GOP solver will stop.

Range: $[-1\text{e}+30, \infty]$

Default: $-1\text{e}+30$

GOP_OPTCHKMD (*integer*): criterion used to certify the global optimality ↔

Synonym: OPTCHKMD

This specifies the criterion used to certify the global optimality. When this value is 0, the absolute deviation of objective lower and upper bounds should be smaller than [GOP_ABSOPTTOL](#) at the global optimum. When its value is 1, the relative deviation of objective lower and upper bounds should be smaller than [GOP_RELOPTTOL](#) at the global optimum. 2 means either absolute or relative tolerance is satisfied at global optimum.

Default: 2

GOP_OPT_MODE (*integer*): mode for GOP optimization ↔

Synonym: OPT_MODE

This specifies the mode for GOP optimization.

Default: 1

value	meaning
0	Global search for a feasible solution (thus a feasibility certificate)
1	Global search for an optimal solution
2	Global search for an unboundedness certificate

GOP_POSTLEVEL (*integer*): amount and type of GOP postsolving ↔

Synonym: POSTLEVEL

This controls the amount and type of GOP post-solving. The default value is: 6 = 2+4 meaning to do both of the below options.

Default: 6

value	meaning
+2	Apply LSgetBestBound
+4	Reoptimize variable bounds

GOP_PRELEVEL (*integer*): amount and type of GOP presolving ↔

Synonym: PRELEVEL

This controls the amount and type of GOP pre-solving. The default value is: 30 = 2+4+8+16 meaning to do all of the below options.

Default: 30

value	meaning
+2	Initial local optimization
+4	Initial linear constraint propagation
+8	Recursive linear constraint propagation
+16	Recursive nonlinear constraint propagation

GOP_QUAD_METHOD (*integer*): specifies if the GOP solver should solve the model as a QP when applicable ↔

Default: -1

value	meaning
-1	Solver decides
0	General GOP solver
1	Specified QP solver

GOP_RELBRNDMD (*integer*): reliable rounding in the GOP branch-and-bound ↔

Synonym: RELBRNDMD

This controls the reliable rounding rule in the GOP branch-and-bound. The global solver applies many suboptimizations to estimate the lower and upper bounds on the global optimum.

A rounding error or numerical instability could unintentionally cut off a good solution. A variety of reliable approaches are available to improve the precision.

Default: 0

value	meaning
+2	Use smaller optimality or feasibility tolerances and appropriate presolving options
+4	Apply interval arithmetic to reverify the solution feasibility

GOP_RELOPTTOL (*real*): relative optimality tolerance ↔

Synonyms: OPTTOL RELOPTTOL

This value is the GOP relative optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCR

GOP_SOLLIM (*integer*): integer solution limit for GOP branch-and-bound ↔

Range: $\{-1, \dots, \infty\}$

Default: -1

GOP_SUBOUT_MODE (*integer*): substituting out fixed variables ↔

Synonym: SUBOUT_MODE

This is a flag indicating whether fixed variables are substituted out of the instruction list used in the global solver.

Default: 1

value	meaning
0	Do not substitute out fixed variables
1	Substitute out fixed variables

GOP_TIMLIM (*integer*): time limit in seconds for GOP branch-and-bound ↔

Synonym: TIMLIM

This is the time limit in seconds for GOP branch-and-bound.

Range: $\{-1, \dots, \infty\}$

Default: GAMS ResLim

GOP_USEBNDLIM (*integer*): max magnitude of variable bounds flag for GOP convexification ↔

Synonym: USEBNDLIM

This value is a flag for the parameter [GOP_BNDLIM](#).

Default: 2

value	meaning
0	Do not use the bound limit on the variables
1	Use the bound limit right at the beginning of global optimization
2	Use the bound limit after the initial local optimization if selected

GOP_WIDTOL (*real*): maximal width of variable intervals ↔

Synonym: WIDTOL

This value specifies the maximal width of variable intervals for a box to be considered as an incumbent box containing an incumbent solution. It is used when `GOP_MAXWIDMD` is set at 1.

Default: 1e-4

IIS (*boolean*): run the IIS finder if the problem is infeasible ↔

Default: 0

IIS_ANALYZE_LEVEL (*integer*): controls the level of analysis when locating an IIS ↔

Default: 1

value	meaning
+1	Search for necessary rows
+2	Search for necessary columns
+4	Search for sufficient rows
+8	Search for sufficient columns
+16	Consider integrality restrictions as the potential cause of infeasibilities and include it in the analysis
+32	Compute the underlying LTF matrix and use this as the basis of a ranking score to guide the IIS run
+64	If the underlying matrix is totally decomposable, rank blocks w.r.t their sizes and debug the smallest independent infeasible block
+128	Use the nonzero structure of the underlying matrix to compute a ranking score to guide the IIS run
+256	Treat iter/time limits as intractability

IIS_GETMODE (*integer*): flag that controls whether variable bounds in the IIS should be retrieved or the integer restrictions ↔

Default: 0

value	meaning
0	Variable bound
1	Integer restrictions

IIS_INFEAS_NORM (*integer*): specifies the norm to measure infeasibilities in IIS search ↔

Default: 0

value	meaning
0	Solver decides
1	Use L-1 norm
2	L-infinity norm

IIS_ITER_LIMIT (*integer*): the iteration limit for IIS search ↔

Range: $\{-1, \dots, \infty\}$

Default: -1

IIS_METHOD (*integer*): specifies the method to use in analyzing infeasible models to locate an IIS \leftrightarrow

Default: 0

value	meaning
0	Default filter
1	Standard deletion filter
2	Standard additive filter
3	Generalized-binary-search filter
4	Depth-first-binary-search filter
5	Fast-scan filter
6	Standard elastic filter

IIS_PRINT_LEVEL (*integer*): specifies the amount of print to do during IIS search \leftrightarrow

Default: 2

IIS_REOPT (*integer*): specifies which optimization method to use when starting from a given basis \leftrightarrow

Default: 0

value	meaning
0	Free
1	Primal Simplex
2	Dual Simplex
3	Barrier
4	NLP

IIS_TIME_LIMIT (*integer*): the time limit for IIS search \leftrightarrow

Range: $\{-1, \dots, \infty\}$

Default: -1

IIS_TOPOPT (*integer*): specifies which optimization method to use when there is no previous basis \leftrightarrow

Default: 0

value	meaning
0	Free
1	Primal Simplex
2	Dual Simplex
3	Barrier
4	NLP

IIS_USE_EFILTER (*integer*): flag that controls whether the Elastic Filter should be enabled as the supplementary filter in analyzing infeasible models \leftrightarrow

Default: 0

value	meaning
-1	Solver decides
0	Do not use elastic filter
1	Use elastic filter

IIS_USE_GOP (*integer*): flag that controls whether the global optimizer should be enabled in analyzing infeasible NLP models ↔

Default: 0

value	meaning
-1	Solver decides
0	Do not use GOP
1	Use GOP

IIS_USE_SFILTER (*integer*): flag indicating is sensitivity filter will be used during IIS search ↔

Default: 1

value	meaning
-1	Solver decides
0	Do not use sensitivity filter
1	Use sensitivity filter

INSTRUCT_SUBOUT (*integer*): flag to specify how to deal with fixed variables in the instruction list ↔

This is a flag indicating whether 1) fixed variables are substituted out of the instruction list, 2) performing numerical calculation on constant numbers and replacing with the results.

Default: -1

value	meaning
-1	Solver decides
0	Substitutions will not be performed
1	Substitutions will be performed

IPM_BASIS_REL_TOL_S (*real*): maximum relative dual bound violation allowed in an optimal basic solution ↔

Maximum relative dual bound violation allowed in an optimal basic solution.

Default: 1e-12

IPM_BASIS_TOL_S (*real*): maximum absolute dual bound violation in an optimal basic solution ↔

Maximum absolute dual bound violation in an optimal basic solution.

Default: 1e-7

IPM_BASIS_TOL_X (*real*): maximum absolute primal bound violation allowed in an optimal basic solution ↔

Maximum absolute primal bound violation allowed in an optimal basic solution.

Default: 1e-7

IPM_BI_LU_TOL_REL_PIV (*real*): relative pivot tolerance used in the LU factorization in the basis identification procedure ↔

Relative pivot tolerance used in the LU factorization in the basis identification procedure.

Range: [0, 0.999999]

Default: 1e-2

IPM_CHECK_CONVEXITY (*integer*): flag to check convexity of a quadratic program using barrier solver ↔

This is a flag to check convexity of a quadratic program using barrier solver.

Default: 1

value	meaning
-1	Check convexity only without solving the model
0	Use barrier solver to check convexity
1	Do not use barrier solver to check convexity

IPM_CO_TOL_INFEAS (*real*): maximum bound infeasibility tolerance for Conic solver ↔

Maximum bound infeasibility tolerance for Conic solver.

Default: 1e-10

IPM_MAX_ITERATIONS (*integer*): ipm iteration limit ↔

Controls the maximum number of iterations allowed in the interior-point optimizer.

Default: 1000

IPM_NUM_THREADS (*integer*): number of threads to run the interiorpoint optimizer on ↔

Number of threads to run the interiorpoint optimizer on. This value should be less than or equal to the actual number of processors or cores on a multi-core system.

Default: 1

IPM_OFF_COL_TRH (*integer*): extent for detecting the offending columns in the Jacobian of the constraint matrix ↔

Controls the extent for detecting the offending columns in the Jacobian of the constraint matrix. 0 means no offending columns will be detected. 1 means offending columns will be detected. In general, increasing the parameter value beyond the default value of 40 does not improve the result.

Default: 40

IPM_TOL_DFEAS (*real*): dual feasibility tolerance ↔

Dual feasibility tolerance used for linear and quadratic optimization problems.

Default: 1e-8

IPM_TOL_DSAFE (*real*): controls the initial dual starting point ↔

Controls the initial dual starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the dual variables associated with constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [1e-4, ∞]

Default: 1

IPM_TOL_INFEAS (*real*): infeasibility tolerance ↔

This is the tolerance to declare the model primal or dual infeasible using the interior-point optimizer. A smaller number means the optimizer gets more conservative about declaring the model infeasible.

Default: 1e-10

IPM_TOL_MU_RED (*real*): relative complementarity gap tolerance ↔

Relative complementarity gap tolerance.

Default: 1e-16

IPM_TOL_PATH (*real*): how close to follow the central path ↔

Controls how close the interior-point optimizer follows the central path. A large value of this parameter means the central path is followed very closely. For numerically unstable problems it might help to increase this parameter.

Range: [0, 0.5]

Default: 1e-8

IPM_TOL_PFEAS (*real*): primal feasibility tolerance ↔

Primal feasibility tolerance used for linear and quadratic optimization problems.

Default: 1e-8

IPM_TOL_PSAFE (*real*): controls the initial primal starting point ↔

Controls the initial primal starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [1e-2, ∞]

Default: 1

IPM_TOL_REL_STEP (*real*): relative step size to the boundary ↔

Relative step size to the boundary for linear and quadratic optimization problems.

Range: [0, 0.999999]

Default: 0.9999

IUS (*boolean*): run the IUS finder if the problem is unbounded ↔

Default: 0

IUS_ANALYZE_LEVEL (*integer*): controls the level of analysis when locating an IUS ↔

Default: 2

value	meaning
+2	Search for necessary columns
+8	Search for sufficient columns

LP_AIJ_ZEROTOL (*real*): coefficient matrix zero tolerance [↔](#)

Default: 2.22045e-16

LP_BIGM (*real*): big-M for phase-I [↔](#)

Default: 1e6

LP_BNDINF (*real*): big-M to truncate lower and upper bounds in single phase dual-simplex [↔](#)

Default: 1e15

LP_DPSWITCH (*integer*): specifies whether LP primal-dual simplex switch is enabled or not [↔](#)

Range: {0, ..., 1}

Default: 1

LP_DRATIO (*integer*): controls the dual min-ratio strategy [↔](#)

Range: {0, ..., 2}

Default: 1

LP_DYNOBJFACT (*real*): Dynamic obj factor [↔](#)

Range: [0, 1]

Default: 0.75

LP_DYNOBJMODE (*integer*): Dynamic obj mode [↔](#)

Default: 0

LP_ITRLMT (*integer*): simplex iteration limit [↔](#)

Synonym: SPLEX_ITRLMT

Range: {-1, ..., ∞}

Default: infinity

LP_PIV_BIGTOL (*real*): simplex maximum pivot tolerance [↔](#)

Default: 1e-5

LP_PIV_ZEROTOL (*real*): simplex pivot zero tolerance [↔](#)

Default: 1e-8

LP_PPARTIAL (*integer*): primal simplex partial pricing method [↔](#)

Range: {0, ..., 3}

Default: 0

LP_PRELEVEL (*integer*): controls the amount and type of LP pre-solving [↔](#)

This controls the amount and type of LP pre-solving to be used.

Default: 126

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+512	Maximum pass

LP_RATRANGE (*integer*): controls the number of pivot-candidates to consider when searching for a stable pivot in LU decomposition [↔](#)

Range: {1, ..., ∞}

Default: 4

LP_SCALE (*integer*): scaling flag [↔](#)

Synonym: SPLEX_SCALE

Default: 1

value	meaning
0	Scaling is suppressed
1	Scaling is performed

LP_SPRINT_COLFACT (*integer*): maximum number of columns in Sprint as a factor of number of rows [↔](#)

Range: {1, ..., ∞}

Default: 10

LP_SPRINT_MAXPASS (*integer*): maximum number of passes in Sprint method [↔](#)

Range: {1, ..., ∞}

Default: 100

LP_SPRINT_SUB (*integer*): LP method for subproblem in Sprint method [↔](#)

Default: 0

MIP_ABSCTTOL (*real*): MIP absolute cut tolerance [↔](#)

This is the MIP absolute cut tolerance. If the value is less than or equal to zero, it will use the internal decided tolerance, otherwise it will use this value as the absolute tolerance for adding cuts.

Range: [-1.0, ∞]

Default: -1.0

MIP_ABSOPTTOL (*real*): MIP absolute optimality tolerance [↔](#)

This is the MIP absolute optimality tolerance. Solutions must beat the incumbent by at least this absolute amount to become the new, best solution.

Default: GAMS OptCA

MIP_ADDCUTOBJTOL (*real*): required objective improvement to continue generating cuts ↔

This specifies the minimum required improvement in the objective function for the cut generation phase to continue generating cuts.

Default: 1.5625e-5

MIP_ADDCUTPER (*real*): percentage of constraint cuts that can be added ↔

This determines how many constraint cuts can be added as a percentage of the number of original rows in an integer programming model.

Default: 0.75

MIP_ADDCUTPER_TREE (*real*): percentage of constraint cuts that can be added at child nodes ↔

This determines how many constraint cuts can be added at child nodes as a percentage of the number of original rows in an integer programming model.

Default: 0.5

MIP_AGGCUTLIM_TOP (*integer*): max number of constraints involved in derivation of aggregation cut at root node ↔

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the root node. The default is .1, which means that the solver will decide.

Range: $\{-1, \dots, \infty\}$

Default: -1

MIP_AGGCUTLIM_TREE (*integer*): max number of constraints involved in derivation of aggregation cut at tree nodes ↔

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the tree nodes. The default is .1, which means that the solver will decide.

Range: $\{-1, \dots, \infty\}$

Default: -1

MIP_ANODES_SWITCH_DF (*integer*): threshold on active nodes for switching to depth-first search ↔

This specifies the threshold on active nodes for switching to depth-first search rule.

Default: 50000

MIP_AOPTTIMLIM (*integer*): time in seconds beyond which the relative optimality tolerance will be applied ↔

This is the time in seconds beyond which the relative optimality tolerance, [MIP_PEROPTTOL](#) will be applied.

Default: 100

MIP_BIGM_FOR_INTTOL (*real*): threshold for which coefficient of a binary variable would be considered as big-M ↔

This value specifies the threshold for which the coefficient of a binary variable would be considered as big-M (when applicable).

Default: 1e8

MIP_BRANCHDIR (*integer*): first branching direction ↔

This specifies the direction to branch first when branching on a variable.

Default: 0

value	meaning
0	Solver decides
1	Always branch up first
2	Always branch down first

MIP_BRANCHRULE (*integer*): rule for choosing the variable to branch ↔

This specifies the rule for choosing the variable to branch on at the selected node.

Default: 0

value	meaning
0	Solver decides
1	Basis rounding with pseudo reduced costs
2	Maximum infeasibility
3	Pseudo reduced costs only
4	Maximum coefficient only
5	Previous branching only

MIP_BRANCH_LIMIT (*integer*): limit on the total number of branches to be created during branch and bound ↔

This is the limit on the total number of branches to be created during branch-and-bound. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: $\{-1, \dots, \infty\}$

Default: -1

MIP_BRANCH_PRIO (*integer*): controls how variable selection priorities are set and used ↔

This controls how variable selection priorities are set and used.

Default: 0

value	meaning
0	If the user has specified priorities then use them Otherwise let LINDO API decide
1	If user has specified priorities then use them Overwrite users choices if necessary
2	If user has specified priorities then use them Otherwise do not use any priorities
3	Let LINDO API set the priorities and ignore any user specified priorities
4	Binaries always have higher priority over general integers

MIP_CUTDEPTH (*integer*): threshold value for the depth of nodes in the branch and bound tree ↔

This controls a threshold value for the depth of nodes in the B&B tree, so cut generation will be less likely at those nodes deeper than this threshold.

Default: 8

MIP_CUTFREQ (*integer*): frequency of invoking cut generation at child nodes ↔

This controls the frequency of invoking cut generation at child nodes. The default value is 10, indicating that the MIP solver will try to generate cuts at every 10 nodes.

Default: 10

MIP_CUTLEVEL_TOP (*integer*): combination of cut types to try at the root node when solving a MIP ↔

This controls the combination of cut types to try at the root node when solving a MIP. Bit settings are used to enable the various cut types.

Default: 57342

value	meaning
+2	GUB cover
+4	Flow cover
+8	Lifting
+16	Plant location
+32	Disaggregation
+64	Knapsack cover
+128	Lattice
+256	Gomory
+512	Coefficient reduction
+1024	GCD
+2048	Obj integrality
+4096	Basis Cuts
+8192	Cardinality Cuts
+16384	Disjunk Cuts
+32768	Soft Knapsack Cuts

MIP_CUTLEVEL_TREE (*integer*): combination of cut types to try at child nodes in the branch and bound tree when solving a MIP ↔

This controls the combination of cut types to try at child nodes in the B&B tree when solving a MIP.

Default: 53246

value	meaning
+2	GUB cover
+4	Flow cover
+8	Lifting
+16	Plant location
+32	Disaggregation
+64	Knapsack cover
+128	Lattice
+256	Gomory
+512	Coefficient reduction
+1024	GCD
+2048	Obj integrality
+4096	Basis Cuts
+8192	Cardinality Cuts
+16384	Disjunk Cuts
+32768	Soft Knapsack Cuts

MIP_CUTOFFOBJ (*real*): defines limit for branch and bound ↔

If this is specified, then any part of the branch-and-bound tree that has a bound worse than this value will not be considered. This can be used to reduce the running time if a good bound is known.

Default: 1e30

MIP_CUTTIMLIM (*integer*): time to be spent in cut generation ↔

This controls the total time to be spent in cut generation throughout the solution of a MIP. The default value is -1, indicating that no time limits will be imposed when generating cuts.

Range: $\{-1, \dots, \infty\}$

Default: -1

MIP_DELTA (*real*): near-zero value used in linearizing nonlinear expressions ↔

This refers to a near-zero value used in linearizing nonlinear expressions.

Default: 1e-6

MIP_DUAL_SOLUTION (*integer*): flag for computing dual solution of LP relaxation ↔

This flag controls whether the dual solution to the LP relaxation that yielded the optimal MIP solution will be computed or not.

Default: 0

value	meaning
0	Do not calculate dual solution for LP relaxation
1	Calculate dual solution for LP relaxation

MIP_FP_ITRLIM (*integer*): iteration limit for feasibility pump heuristic ↔

This is the iteration limit in seconds for feasibility pump heuristic. A value of -1 means no iteration limit is imposed.

Default: 500

MIP_FP_MODE (*integer*): mode for the feasibility pump heuristic ↔

Controls the mode for the feasibility pump heuristic.

Default: -1

value	meaning
-1	Solver decides
0	Off
1	On until the first solution
2	Try to get more than one solution

MIP_FP_OPT_METHOD (*integer*): optimization and reoptimization method for feasibility pump

heuristic [↔](#)

This specifies optimization and reoptimization method for feasibility pump heuristic.

Default: 0

value	meaning
0	Solver decides
1	Primal simplex
2	Dual simplex
3	Barrier

MIP_FP_TIMLIM (*real*): time limit for feasibility pump heuristic [↔](#)

This is the time limit in seconds for feasibility pump heuristic. A value of -1 implies no time limit is imposed.

Default: 1800

MIP_FP_WEIGHTH (*real*): weight of the objective function in the feasibility pump [↔](#)

Controls the weight of the objective function in the feasibility pump.

Range: [0, 1]

Default: 1

MIP_GENERAL_MODE (*integer*): general strategy in solving MIPs [↔](#)

This value specifies the general strategy in solving MIPs.

Default: 0

value	meaning
0	Solver decides
+2	Disable all time-driven events for reproducibility of runs
+16	Disable cut generation before branching

MIP_HEULEVEL (*integer*): specifies heuristic used to find integer solution [↔](#)

This specifies the heuristic used to find the integer solution. Possible values are: 0: No heuristic is used. 1: A simple heuristic is used. Typically, this will find integer solutions only on problems with a certain structure. However, it tends to be fast. 2: This is an advanced heuristic that tries to find a "good" integer solution fast. In general, a value of 2 seems to not increase the total solution time and will find an integer solution fast on many problems. A higher value may find an integer solution faster, or an integer solution where none would have been found with a lower level. Try level 3 or 4 on "difficult" problems where 2 does not help. Higher values cause more time to be spent in the heuristic. The value may be set arbitrarily high. However, >20 is probably not worthwhile. [MIP_HEUMINTIMLIM](#) controls the time to be spent in searching heuristic solutions.

Default: 3

MIP_HEUMINTIMLIM (*integer*): minimum time in seconds to be spent in finding heuristic solutions [↔](#)

This specifies the minimum time in seconds to be spent in finding heuristic solutions to the MIP model. `MIP_HEULEVEL` controls the heuristic used to find the integer solution.

Default: 0

MIP_HEU_DROP_OBJ (*integer*): flag for whether to use without OBJ heuristic ↔

This is a flag for whether to use without OBJ heuristic.

Default: 0

value	meaning
0	Off
1	On

MIP_HEU_MODE (*integer*): heuristic used in MIP solver ↔

This controls the MIP heuristic mode.

Default: 0

value	meaning
0	Solver decides when to stop the heuristic
1	Solver uses a pre-specified time limit to stop the heuristic.
2	Solver uses a pre-specified iteration limit to stop the heuristic

MIP_INTTOL (*real*): absolute integer feasibility tolerance ↔

An integer variable is considered integer feasible if the absolute difference from the nearest integer is smaller than this.

Default: 1e-6

MIP_ITRLIM (*real*): iteration limit for branch and bound ↔

This is the total LP iteration limit summed over all branches for branch-and-bound. Range for The default value is -1, which means no iteration limit is imposed. If this iteration limit is reached, branch-and-bound will stop and the best feasible integer solution found will be installed as the incumbent (best known) solution.

Range: [-1, ∞]

Default: infinity

MIP_KBEST_USE_GOP (*integer*): specifies whether to use gop solver in MIP KBest ↔

Default: 0

value	meaning
0	No
1	Yes

MIP_KEEPMEM (*integer*): flag for keeping LP bases in memory ↔

If this is set to 1, the integer pre-solver will try to keep LP bases in memory. This typically gives faster solution times, but uses more memory. Setting this parameter to 0 causes the pre-solver to erase bases from memory.

Default: 1

value	meaning
0	Do not keep LP bases in memory
1	Keep LP bases in memory

MIP_LBIGM (*real*): Big-M value used in linearizing nonlinear expressions ↔

This refers to the Big-M value used in linearizing nonlinear expressions.

Default: 10000

MIP_LSOLTIMLIM (*integer*): time limit until finding a new integer solution ↔

Range: $\{-1, \dots, \infty\}$

Default: -1

MIP_MAKECUT_INACTIVE_COUNT (*integer*): threshold for times a cut could remain active after successive reoptimization ↔

This value specifies the threshold for the times a cut could remain active after successive reoptimization during branch-and-bound. If the count is larger than the specified level the solver will inactive the cut.

Default: 10

MIP_MAXCUTPASS_TOP (*integer*): number passes to generate cuts on the root node ↔

This controls the number passes to generate cuts on the root node. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: 200

MIP_MAXCUTPASS_TREE (*integer*): number passes to generate cuts on the child nodes ↔

This controls the number passes to generate cuts on the child nodes. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: 2

MIP_MAXNONIMP_CUTPASS (*integer*): number of passes allowed in cut-generation that does not improve current relaxation ↔

This controls the maximum number of passes allowed in cut-generation that does not improve the current relaxation.

Default: 3

MIP_MAXNUM_MIP_SOL_STORAGE (*integer*): maximum number of k-best solutions to store ↔

This specifies the maximum number of k-best solutions to store. Possible values are positive integers.

Default: 1

MIP_MINABSOBJSTEP (*real*): value to update cutoff value each time a mixed integer solution is found ↩

This specifies the value to update the cutoff value each time a mixed integer solution is found.

Default: 0

MIP_NODESELRULE (*integer*): specifies the node selection rule ↩

This specifies the node selection rule for choosing between all active nodes in the branch-and-bound tree when solving integer programs. Possible selections are: 0: Solver decides (default). 1: Depth first search. 2: Choose node with worst bound. 3: Choose node with best bound. 4: Start with best bound. If no improvement in the gap between best bound and best integer solution is obtained for some time, switch to: if (number of active nodes < 10000) Best estimate node selection (5). else Worst bound node selection (2). 5: Choose the node with the best estimate, where the new objective estimate is obtained using pseudo costs. 6: Same as (4), but start with the best estimate.

Default: 0

value	meaning
0	Solver decides
1	Depth first search
2	Choose node with worst bound
3	Choose node with best bound
4	Start with best bound
5	Choose the node with the best estimate
6	Same as 4 but start with the best estimate

MIP_NUM_THREADS (*integer*): number of parallel threads to use by the parallel MIP solver ↩

This parameter specifies the number of parallel threads to use by the parallel MIP solver. Possible values are positive integers. The default is 1 implying that the parallel solver is disabled.

Range: {1, ..., ∞}

Default: 1

MIP_PARA_FP (*integer*): flag for whether to use parallelization on the feasibility pump heuristic ↩

This is a flag for whether to use parallelization on the feasibility pump heuristic.

Default: 1

value	meaning
0	Off
1	On

MIP_PARA_FP_MODE (*integer*): flag for the mode of parallel feasibility pump ↔

This is a flag for the mode of parallel feasibility pump.

Default: 0

value	meaning
0	Terminate when all threads finish
1	Terminate as soon as the master thread finishes

MIP_PARA_INIT_NODE (*real*): number of initial nodes for MIP parallelization ↔

This value specifies the number of initial nodes for MIP parallelization.

Range: $[-1, \infty]$

Default: -1

MIP_PARA_ITR_MODE (*integer*): flag for iteration mode in MIP parallelization ↔

This is a flag for iteration mode in MIP parallelization.

Default: 1

value	meaning
0	Each thread terminates as soon as arrives iteration limit
1	Each thread terminates until all threads get iteration limit

MIP_PARA_RND_ITRLMT (*real*): iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations ↔

This value specifies the iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations.

Default: 2.0

MIP_PARA_SUB (*integer*): flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing ↔

This is a flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing.

Default: 1

value	meaning
0	Off
1	On

MIP_PEROPTTOL (*real*): MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds ↔

This is the MIP relative optimality tolerance that will be in effect after T seconds following the start. The value T should be specified using the [MIP_AOPTTIMLIM](#) parameter.

Default: 1e-5

MIP_PERSPECTIVE_REFORM (*integer*): flag for whether to use Perspective Reformulation [↔](#)

This is the flag for whether to use Perspective Reformulation.

Default: 1

value	meaning
0	Off
1	On

MIP_POLISH_ALPHA_TARGET (*real*): proportion solutions in the pool to initiate a polishing-task at the current node [↔](#)

This value specifies the proportion solutions in the pool to initiate a polishing-task at the current node.

Range: [0.01, 0.99]

Default: 0.6

MIP_POLISH_MAX_BRANCH_COUNT (*integer*): maximum number of branches to polish [↔](#)

This value specifies the maximum number of branches to polish.

Default: 2000

MIP_POLISH_NUM_BRANCH_NEXT (*integer*): number of branches to polish in the next round [↔](#)

This value specifies the number of branches to polish in the next round.

Default: 4000

MIP_PREHEU_DFE_VSTLIM (*integer*): limit for the variable visit in depth first enumeration [↔](#)

Limit for the variable visit in depth first enumeration.

Default: 200

MIP_PREHEU_LEVEL (*integer*): heuristic level for the preresolver [↔](#)

The heuristic level for the preresolver.

Default: 0

value	meaning
0	Nothing
1	One-change
2	One-change and two-change
3	Depth first enumeration

MIP_PREHEU_TC_ITERLIM (*integer*): iteration limit for the two change heuristic [↔](#)

Iteration limit for the two change heuristic.

Default: 30000000

MIP_PREHEU_VAR_SEQ (*integer*): sequence of the variable considered by the prerelax heuristic ↔

The sequence of the variable considered by the prerelax heuristic.

Default: -1

value	meaning
-1	Backward
1	Forward

MIP_PRELEVEL (*integer*): controls the amount and type of MIP pre-solving at root node ↔

This controls the amount and type of MIP pre-solving at root node.

Default: 3070

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+128	Binary row presolving
+256	Row aggregation
+512	Coef Probe Lifting
+1024	Maximum pass
+2048	Similar row

MIP_PRELEVEL_TREE (*integer*): amount and type of MIP pre-solving at tree nodes ↔

This controls the amount and type of MIP pre-solving at tree nodes.

Default: 1214

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+128	Binary row presolving
+256	Row aggregation
+512	Coef Probe Lifting
+1024	Maximum pass

MIP_PRE_ELIM_FILL (*integer*): controls fill-in introduced by eliminations during pre-solve ↔

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly

more than the original model.

Default: 100

MIP_PSEUDOCOST_RULE (*integer*): specifies the rule in pseudocost computations for variable selection ↔

This specifies the rule in pseudocost computations for variable selection.

Default: 0

value	meaning
0	Solver decides
1	Only use min pseudo cost
2	Only use max pseudo cost
3	Use quadratic score function and the pseudo cost weight
4	Same as 3 without quadratic score

MIP_PSEUDOCOST_WEIGHT (*real*): weight in pseudocost computations for variable selection ↔

This specifies the weight in pseudocost computations for variable selection.

Default: 1.5625e-05

MIP_REDCOSTFIX_CUTOFF (*real*): cutoff value as a percentage of the reduced costs ↔

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic.

Default: 0.9

MIP_REDCOSTFIX_CUTOFF_TREE (*real*): cutoff value as a percentage of the reduced costs at tree nodes ↔

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic at tree nodes.

Default: 0.9

MIP_RELINTTOL (*real*): relative integer feasibility tolerance ↔

An integer variable is considered integer feasible if the difference between its value and the nearest integer value divided by the value of the nearest integer is less than this.

Default: 8e-6

MIP_RELOPTTOL (*real*): MIP relative optimality tolerance ↔

This is the MIP relative optimality tolerance. Solutions must beat the incumbent by at least this relative amount to become the new, best solution.

Default: GAMS OptCR

MIP_REOPT (*integer*): optimization method to use when doing reoptimization ↔

This specifies which optimization method to use when doing reoptimization from a given basis.

Default: 0

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver

MIP_SCALING_BOUND (*integer*): maximum difference between bounds of an integer variable for enabling scaling [↔](#)

This controls the maximum difference between the upper and lower bounds of an integer variable that will enable the scaling in the simplex solver when solving a subproblem in the branch-and-bound tree.

Default: 10000

MIP_SOLLIM (*integer*): integer solution limit for MIP solver [↔](#)

Range: $\{-1, \dots, \infty\}$

Default: -1

MIP_SOLVERTYPE (*integer*): optimization method to use when solving mixed-integer models [↔](#)

This specifies the optimization method to use when solving mixed-integer models.

Default: 0

value	meaning
0	Solver decides
1	Use Branch and Bound only
2	Use Enumeration and Knapsack solver only

MIP_STRONGBRANCHDONUM (*integer*): minimum number of variables to try the strong branching on [↔](#)

This value specifies the minimum number of variables, among all the candidates, to try the strong branching on.

Default: 3

MIP_STRONGBRANCHLEVEL (*integer*): depth from the root in which strong branching is used [↔](#)

This specifies the depth from the root in which strong branching is used. The default value of 10 means that strong branching is used on a level of 1 to 10 measured from the root. Strong branching finds the real bound for branching on a given variable, which, in most cases, requires a solution of a linear program and may therefore also be quite expensive in computing time. However, if used on nodes close to the root node of the tree, it also gives a much better bound for that part of the tree and can therefore reduce the size of the branch-and-bound tree.

Default: 10

MIP_SWITCHFAC_SIM_IPM_TIME (*real*): factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method [↔](#)

This specifies the (positive) factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method. A value of -1.0 means that no time limit is imposed.

Range: $[-1, \infty]$

Default: -1

MIP_SYMMETRY_MODE (*integer*): specifies mip symmetry handling methods [↔](#)

Default: 0

value	meaning
0	Do not use symmetries
1	Adding symmetry breaking cuts
2	Orbital fixing

MIP_TIMLIM (*integer*): time limit in seconds for integer solver [↔](#)

This is the time limit in seconds for branch-and-bound. The default value is -1, which means no time limit is imposed. However, the value of [SOLVER_TIMLMT](#) will be applied to each continuous subproblem solve. If the value of this parameter is greater than 0, then the value of [SOLVER_TIMLMT](#) will be disregarded. If this time limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: $\{-1, \dots, \infty\}$

Default: GAMS ResLim

MIP_TOPOPT (*integer*): optimization method to use when there is no previous basis [↔](#)

This specifies which optimization method to use when there is no previous basis.

Default: 0

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver

MIP_TREEREORDERLEVEL (*integer*): tree reordering level [↔](#)

This specifies the tree reordering level.

Default: 10

MIP_TREEREORDERMODE (*integer*): tree reordering mode [↔](#)

This specifies the tree reordering mode.

Default: 1

value	meaning
1	Use tree reordering only for subproblems
2	Use tree reordering for subproblems and the main bnb loop only when LP status is infeasible
3	Not use tree reordering
4	Use tree reordering based on MIP_TREEREORDERLEVEL

MIP_USECUTOFFOBJ (*integer*): flag for using branch and bound limit ↔

This is a flag for the parameter **MIP_CUTOFFOBJ**. If you do not want to lose the value of the parameter **MIP_CUTOFFOBJ**, this provides an alternative to disabling the cutoff objective.

Default: 1

value	meaning
0	Do not use current cutoff value
1	Use current cutoff value

MIP_USE_CUTS_HEU (*integer*): controls if cut generation is enabled during MIP heuristics ↔

This flag controls if cut generation is enabled during MIP heuristics. The default is -1 (i.e. the solver decides).

Default: -1

value	meaning
-1	Solver decides
0	Do not use cut heuristic
1	Use cut heuristic

MIP_USE_ENUM_HEU (*integer*): frequency of enumeration heuristic ↔

This specifies the frequency of enumeration heuristic.

Default: 4

value	meaning
0	Off
1	Only at top (root) node without cuts
2	Both at top (root) and tree nodes without cuts
3	Same as 1 with cuts
4	Same as 2 with cuts

MIP_USE_INT_ZERO_TOL (*integer*): controls if all MIP calculations would be based on absolute integer feasibility tolerance ↔

This flag controls if all MIP calculations would be based on the integrality tolerance specified by **MIP_INTTOL**.

Default: 0

value	meaning
0	Do not base MIP calculations on MIP_INTTOL
1	Base MIP calculations on MIP_INTTOL

MULTITHREAD_MODE (*integer*): threading mode ↔

This parameter controls the threading mode for solvers with multithreading support.

Default: -1

value	meaning
-1	Solver decides
1	Try parallel mode but if it is not available try concurrent mode
2	Try parallel mode only
3	Try concurrent mode but if it is not available try parallel mode
4	Try concurrent mode only

NLP_AUTODERIV (*integer*): defining type of computing derivatives ↔

This is a flag to indicate if automatic differentiation is the method of choice for computing derivatives and select the type of differentiation.

Default: 0

value	meaning
0	Finite Differences approach will be used
1	Forward type of Automatic Differentiation will be used
2	Backward type of Automatic Differentiation will be used

NLP_AUTOHESS (*integer*): flag for using Second Order Automatic Differentiation for solving NLP ↔

This is a flag to indicate if Second Order Automatic Differentiation will be performed in solving a nonlinear model. The second order derivatives provide an exact/precise Hessian matrix to the SQP algorithm, which may lead to less iterations and better solutions, but may also be quite expensive in computing time for some cases.

Default: 0

value	meaning
0	Do not use Second Order Automatic Differentiation
1	Use Second Order Automatic Differentiation

NLP_CONIC_REFORM (*integer*): determines if to explore conic reformulation ↔

Default: 1

value	meaning
0	No
1	Yes

NLP_CUTOFFOBJ (*real*): as soon as any multi-start thread achieves this value all threads stop ↔

If the current best objective of the NLP being solved in a multistart run is better than this value, the solver will terminate early without exhausting the maximum number of multistarts. This is a way of saving computer time if the current best solution is sufficiently attractive.

Range: $[-1\text{e}30, \infty]$

Default: $-1\text{e}30$

NLP_DERIV_DIFFTYPE (*integer*): flag indicating the technique used in computing derivatives with finite differences ↔

This is a flag indicating the technique used in computing derivatives with Finite Differences.

Default: 0

value	meaning
0	The solver decides
1	Use forward differencing method
2	Use backward differencing method
3	Use center differencing method

NLP_FEASCHK (*integer*): how to report results when solution satisfies tolerance of scaled but not original model ↔

This input parameter specifies how the NLP solver reports the results when an optimal or local-optimal solution satisfies the feasibility tolerance ([NLP_FEASTOL](#)) of the scaled model but not the original (descaled) one.

Default: 1

value	meaning
0	Perform no action accept the final solution
1	Declare the model status as FEASIBLE if maximum violation in the unscaled model is not higher than 10 times NLP_FEASTOL
2	Declare the model status as UNKNOWN if maximum violation in the unscaled model is higher than NLP_FEASTOL

NLP_FEASTOL (*real*): feasibility tolerance for nonlinear constraints ↔

This is the feasibility tolerance for nonlinear constraints. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: $1\text{e}-6$

NLP_INF (*real*): numeric infinity for nonlinear models ↔

Specifies the numeric infinity for nonlinear models. Possible values are positive real numbers. Smaller values could cause numerical problems.

`nlp_ipm2grg` This is a flag to switch from IPM solver to the standard NLP (GRG) solver when IPM fails due to numerical errors.

Default: $1\text{e}30$

NLP_IPM2GRG (*integer*): switch from IPM solver to GRG solver when IPM fails due to numerical errors ↔

Default: 1

value	meaning
0	Do not switch
1	Switch

NLP_ITERS_PER_LOGLINE (*integer*): number of nonlinear iterations to elapse before next progress message ↔

Number of nonlinear iterations to elapse before next progress message.

Range: {1, ..., ∞}

Default: 10

NLP_ITRLMT (*integer*): nonlinear iteration limit ↔

This controls the iteration limit on the number of nonlinear iterations performed.

Range: {-1, ..., ∞}

Default: GAMS IterLim

NLP_LINEARZ (*integer*): extent to which the solver will attempt to linearize nonlinear models ↔

This determines the extent to which the solver will attempt to linearize nonlinear models.

Default: 0

value	meaning
0	Solver decides
1	No linearization occurs
2	Linearize ABS MAX and MIN functions
3	Same as option 2 plus IF AND OR NOT and all logical operators are linearized

NLP_LINEARZ_WB_CONSISTENT (*integer*): determines if linearization process is consistent with WB/excel calculation ↔

Default: 0

value	meaning
0	No
1	Yes

NLP_MAXLOCALSEARCH (*integer*): maximum number of local searches ↔

This controls the maximum number of local searches (multistarts) when solving a NLP using the multistart solver.

Default: 5

NLP_MAXLOCALSEARCH_TREE (*integer*): maximum number of multistarts \leftrightarrow

Maximum number of multistarts (at tree nodes)

Default: 1

NLP_MAX_RETRY (*integer*): maximum number refinement retries to purify the final NLP solution \leftrightarrow

Maximum number refinement retries to purify the final NLP solution.

Range: $\{-1, \dots, \infty\}$

Default: 5

NLP_MSW_EUCDIST_THRES (*real*): euclidean distance threshold in multistart search \leftrightarrow

Euclidean distance threshold in multistart search

Default: 0.001

NLP_MSW_FILTERMODE (*integer*): filtering mode to exclude certain domains during sampling in multistart search \leftrightarrow

Filtering mode to exclude certain domains during sampling in multistart search.

Default: -1

value	meaning
-1	Solver decides
+1	Filter-out the points around known KKT or feasible points previously visited
+2	Filter-out the points whose p are in the vicinity of p(x)
+4	Filter-out the points in the vicinity of x where x are initial points of all previous local optimizations
+8	Filter-out the points whose p(.) values are below a dynamic threshold tolerance

NLP_MSW_MAXNOIMP (*integer*): maximum number of consecutive populations to generate without any improvements \leftrightarrow

Maximum number of consecutive populations to generate without any improvements.

Range: $\{-1, \dots, \infty\}$

Default: -1

NLP_MSW_MAXPOP (*integer*): maximum number of populations to generate in multistart search \leftrightarrow

Maximum number of populations to generate in multistart search.

Range: $\{-1, \dots, \infty\}$

Default: -1

NLP_MSW_MAXREF (*integer*): maximum number of reference points to generate trial points in multistart search \leftrightarrow

Maximum number of reference points in the solution space to generate trial points in multistart search.

Range: $\{-1, \dots, \infty\}$

Default: -1

NLP_MSW_NORM (*integer*): norm to measure the distance between two points in multistart search ↔

Norm to measure the distance between two points in multistart search.

Range: $\{-1, \dots, \infty\}$

Default: 2

NLP_MSW_NUM_THREADS (*integer*): number of parallel threads to be used when solving an NLP model with the multistart solver ↔

This value specifies the number of parallel threads to be used when solving an NLP model with the multistart solver.

Default: 1

NLP_MSW_OVERLAP_RATIO (*real*): rate of replacement in successive populations ↔

This value specifies the rate of replacement in successive populations. Higher values favors survival of points in the parent population.

Range: $[0.0, 1.0]$

Default: 0.1

NLP_MSW_POXDIST_THRES (*real*): penalty function neighborhood threshold in multistart search ↔

Penalty function neighborhood threshold in multistart search

Default: 0.01

NLP_MSW_PREPMODE (*integer*): preprocessing strategies in multistart solver ↔

This value specifies the preprocessing strategies in multistart solver.

Default: -1

value	meaning
-1	Solver decides
+1	Truncate free variables
+2	Scale reference points to origin
+4	Enable expansive scaling of radius[k] by hit[k]
+8	Skewed sampling allowing values in the vicinity of origin.
+16	Get best bounds by presolver
+32	Get best bounds using GOP
+64	Enable sampling of free variables (not recommended)
+128	Collect sufficiently many trial points prior to local solves
+256	Enable power solver, trying several different local strategies

NLP_MSW_RG_SEED (*integer*): random number generator seed for the multistart solver ↔

This value specified the random number generator seed for the multistart solver.

Default: 1019

NLP_MSW_SOLIDX (*integer*): index of the multistart solution to be loaded ↔

Index of the multistart solution to be loaded main solution structures.

Default: 0

NLP_MSW_XKKTRAD_FACTOR (*real*): KKT solution neighborhood factor in multistart search ↔

KKT solution neighborhood factor in multistart search

Default: 0.85

NLP_MSW_XNULRAD_FACTOR (*real*): initial solution neighborhood factor in multistart search ↔

Initial solution neighborhood factor in multistart search

Default: 0.5

NLP_PRELEVEL (*integer*): controls the amount and type of NLP pre-solving ↔

This controls the amount and type of NLP pre-solving.

Default: 126

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+512	Maximum pass

NLP_PSTEP_FINITEDIFF (*real*): value of the step length in computing the derivatives using finite differences ↔

This controls the value of the step length in computing the derivatives using finite differences.

Default: 5e-7

NLP_QUADCHK (*integer*): flag for checking if NLP is quadratic ↔

This is a flag indicating if the nonlinear model should be examined to check if it is a quadratic model.

Default: 1

value	meaning
0	Do not check if NLP is quadratic
1	Check if NLP is quadratic

NLP_REDGTOL (*real*): tolerance for the gradients of nonlinear functions ↔

This is the tolerance for the gradients of nonlinear functions. The (projected) gradient of a function is considered to be the zero-vector if its norm is below this tolerance.

Default: 1e-7

NLP_SOLVER (*integer*): type of nonlinear solver ↔

This value determines the type of nonlinear solver.

Default: 7

value	meaning
4	Solver decides
5	Uses Levenberg-Marquardt method to solve nonlinear least-squares problem
6	Uses Barrier solver for convex QCP models
7	Uses CONOPTs reduced gradient solver
8	Uses SLP solver
9	Uses CONOPT with multistart feature enabled

NLP_SOLVE_AS_LP (*integer*): flag indicating if the nonlinear model will be solved as an LP ↔

This is a flag indicating if the nonlinear model will be solved as an LP. 1 means that an LP using first order approximations of the nonlinear terms in the model will be used when optimizing the model with the LSoptimize() function.

Default: 0

value	meaning
0	NLP will not be solved as LP
1	NLP will be solved as LP

NLP_STALL_ITRLMT (*integer*): iteration limit before a sequence of non-improving NLP iterations is declared as stalling ↔

This specifies the iteration limit before a sequence of non-improving NLP iterations is declared as stalling, thus causing the solver to terminate.

Default: 100

NLP_STARTPOINT (*integer*): flag for using initial starting solution for NLP ↔

This is a flag indicating if the nonlinear solver should accept initial starting solutions.

Default: 1

value	meaning
0	Do not use initial starting solution for NLP
1	Use initial starting solution for NLP

NLP_SUBSOLVER (*integer*): type of nonlinear subsolver ↔

This controls the type of linear solver to be used for solving linear subproblems when solving nonlinear models.

Default: 1

value	meaning
1	Primal simplex method
2	Dual simplex method
3	Barrier solver with or without crossover

NLP_USECUTOFFOBJ (*integer*): flag to use parameter NLP_CUTOFFOBJ ↔

This is a flag for the parameter [NLP_CUTOFFOBJ](#). The value of 0 means NLP_CUTOFFOBJ will be ignored, else it will be used as specified.

Default: 0

value	meaning
-1	Solver decides
0	No
1	Yes

NLP_USE_CRASH (*integer*): flag for using simple crash routines for initial solution ↔

This is a flag indicating if an initial solution will be computed using simple crash routines.

Default: 0

value	meaning
0	Do not use simple crash routines
1	Use simple crash routines

NLP_USE_LINDO_CRASH (*integer*): flag for using advanced crash routines for initial solution ↔

This is a flag indicating if an initial solution will be computed using advanced crash routines.

Default: 1

value	meaning
0	Do not use advanced crash routines
1	Use advanced crash routines

NLP_USE_SDP (*integer*): flag to use SDP solver for POSD constraint ↔

Default: 1

value	meaning
0	No
1	Yes

NLP_USE_SELCONEVAL (*integer*): flag for using selective constraint evaluations for solving NLP ↔

This is a flag indicating if selective constraint evaluations will be performed in solving a nonlinear model.

Default: 1

value	meaning
0	Do not use selective constraint evaluations
1	Use selective constraint evaluations

NLP_USE_SLP (*integer*): flag for using sequential linear programming step directions for updating solution ↔

This is a flag indicating if sequential linear programming step directions should be used in updating the solution.

Default: 1

value	meaning
-1	Solver decides
0	Do not use sequential linear programming step directions
1	Use sequential linear programming step directions

NLP_USE_STEEPEGE (*integer*): flag for using steepest edge directions for updating solution ↔

This is a flag indicating if steepest edge directions should be used in updating the solution.

Default: 0

value	meaning
0	Do not use steepest edge directions
1	Use steepest edge directions

NUM_THREADS (*integer*): number of parallel threads to be used ↔

Synonym: gthreads

Number of threads to use in the solver routine to be called. It is a solver-independent parameter which internally sets solver-specific threading parameters automatically.

Range: {1, ..., ∞}

Default: GAMS Threads

PROB_TO_SOLVE (*integer*): controls whether the explicit primal or dual form of the given LP problem will be solved ↔

This flag controls whether the explicit primal or dual form of the given LP problem will be solved.

Default: 0

value	meaning
0	Solver decides
1	Explicit primal form
2	Explicit dual form

PROFILER_LEVEL (*integer*): specifies the profiler level to break down the total cpu time into. ↔

Specifies the profiler level to break down the total cpu time into.

Default: 0

value	meaning
0	Profiler is off
+1	Enable for simplex solver
+2	Enable for integer solver
+4	Enable for multistart solver
+8	Enable for global solver

READPARAMS (*string*): read Lindo parameter file ↔

REPORTEVSOL (*no value*): solve and report the expected value solution ↔

Default: 0

SAMP_CDSINC (*real*): correlation matrix diagonal shift increment ↔

Correlation matrix diagonal shift increment.

Default: 1e-6

SAMP_NCM_CUTOBJ (*real*): objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem ↔

Objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem.

Default: 1e-30

SAMP_NCM_DSTORAGE (*integer*): flag to enable or disable sparse mode in NCM computations ↔

Flag to enable/disable sparse mode in NCM computations.

Range: $\{-1, \dots, \infty\}$

Default: -1

SAMP_NCM_ITERLIM (*integer*): iteration limit for NCM method ↔

Iteration limit for NCM method.

Default: 100

SAMP_NCM_METHOD (*integer*): bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem ↔

Bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem.

Default: 5

SAMP_NCM_OPTTOL (*real*): optimality tolerance for NCM method ↔

Optimality tolerance for NCM method.

Default: 1e-7

SAMP_SCALE (*integer*): flag to enable scaling of raw sample data ↔

Flag to enable scaling of raw sample data.

Default: 0

SOLVER_CONCURRENT_OPTMODE (*integer*): controls if simplex and interior-point optimizers will run concurrently ↔

Controls if simplex and interior-point optimizers will run concurrently, 0 means no concurrent runs will be performed, 1 means both optimizers will run concurrently if at least two threads exist in system, 2 means both optimizers will run concurrently.

Default: 0

value	meaning
0	no concurrent runs
1	run concurrently if at least 2 threads exist
2	run concurrently

SOLVER_CUTOFFVAL (*real*): solver will exit if optimal solution is worse than this ↔

If the optimal objective value of the LP being solved is shown to be worse than this (e.g., if the dual simplex method is being used), then the solver will exit without finding a feasible solution. This is a way of saving computer time if there is no sufficiently attractive solution. **SOLVER_USECUTOFFVAL** needs to be set to 1 to activate this value.

Default: 0

SOLVER_FEASTOL (*real*): feasibility tolerance ↔

This is the feasibility tolerance. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: 1e-7

SOLVER_IPMSOL (*integer*): basis crossover flag for barrier solver ↔

This flag controls whether a basis crossover will be performed when solving LPs with the barrier solver. A value of 0 indicates that a crossover to a basic solution will be performed. If the value is 1, then the barrier solution will be left intact. For example, if alternate optima exist, the barrier method will return a solution that is, loosely speaking, the average of all alternate optima.

Default: 0

value	meaning
0	Perform crossover to basis solution
1	Leave barrier solution intact

SOLVER_IUSOL (*integer*): flag for computing basic solution for infeasible model [↔](#)

This is a flag that, when set to 1, will force the solver to compute a basic solution to an infeasible model that minimizes the sum of infeasibilities and a basic feasible solution to an unbounded problem from which an extreme direction originates. When set to the default of 0, the solver will return with an appropriate status flag as soon as infeasibility or unboundedness is detected. If infeasibility or unboundedness is declared with presolver's determination, no solution will be computed.

Default: 0

value	meaning
0	Return appropriate status if infeasibility is encountered
1	Force the solver to compute a basic solution to an infeasible model

SOLVER_METHOD (*integer*): specifies the method to use when generic solver is invoked [↔](#)

Default: 0

value	meaning
0	FREE
1	PSIMPLEX
2	DSIMPLEX
3	BARRIER
4	NLP
5	MIP
6	MULTIS
7	GOP
8	IIS
9	IUS
10	SBD
11	SPRINT
12	GA

SOLVER_MODE (*integer*): controls some of the advanced strategies when solving LPs [↔](#)

Default: 1

value	meaning
+1	add distinct basic solutions to the pool of alternate optimal solutions
+2	add edge/nonbasic solutions to the pool of alternate optimal solutions
+4	favor basic solutions with integer values when choosing solutions to add to the pool of alternate optimal solutions

SOLVER_OPTTOL (*real*): dual feasibility tolerance [↔](#)

This is the optimality tolerance. It is also referred to as the dual feasibility tolerance. A dual slack (reduced cost) is considered violated if it violates its lower bound by the optimality tolerance.

Default: 1e-7

SOLVER_PRE_ELIM_FILL (*integer*): fill-in introduced by the eliminations during pre-solve ↔

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: 1000

SOLVER_RESTART (*integer*): starting basis flag ↔

This is the starting basis flag. 1 means LINDO API will perform warm starts using any basis currently in memory. 0 means LINDO API will perform cold starts discarding any basis in memory and starting from scratch.

Default: 0

value	meaning
0	Perform cold start
1	Perform warm start

SOLVER_TIMLMT (*integer*): time limit in seconds for continuous solver ↔

This is a time limit in seconds for the LP solver. The default value of -1 imposes no time limit.

Range: $\{-1, \dots, \infty\}$

Default: GAMS ResLim

SOLVER_USECUTOFFVAL (*integer*): flag for using cutoff value ↔

This is a flag for the parameter [SOLVER_CUTOFFVAL](#)

Default: 0

value	meaning
0	Do not use cutoff value
1	Use cutoff value

SPLX_DPRICING (*integer*): pricing option for dual simplex method ↔

This is the pricing option to be used by the dual simplex method.

Default: -1

value	meaning
-1	Solver decides the dual pricing method
0	Partial pricing
1	Steepest edge

SPLEX_DUAL_PHASE (*integer*): controls the dual simplex strategy ↔

This controls the dual simplex strategy, single-phase versus two-phase.

Default: 0

value	meaning
0	Solver decides
1	Single-phase
2	Two-phase

SPLEX_PPRICING (*integer*): pricing option for primal simplex method ↔

This is the pricing option to be used by the primal simplex method.

Default: -1

value	meaning
-1	Solver decides the primal pricing method
0	Partial pricing
1	Devex

SPLEX_REFACTORQ (*integer*): number of simplex iterations between two consecutive basis re-factorizations ↔

This is a positive integer scalar referring to the simplex iterations between two consecutive basis re-factorizations. For numerically unstable models, setting this parameter to smaller values may help.

Default: 100

STOC_ABSOPTTOL (*real*): absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver ↔

Absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. . Possible values are reals in (0,1) interval.

Default: GAMS OptCA

STOC_ADD_MPI (*integer*): flag to use add-instructions mode when building deteq ↔

Flag to use add-instructions mode when building deteq.

Default: 0

STOC_ALD_DUAL_FEASTOL (*real*): dual feasibility tolerance for ALD ↔

Dual feasibility tolerance for ALD.

Default: 1e-4

STOC_ALD_DUAL_STEPLEN (*real*): dual step length for ALD ↔

Dual step length for ALD.

Default: 0.9

STOC_ALD_INNER_ITER_LIM (*integer*): inner loop iteration limit for ALD ↔

Inner loop iteration limit for ALD.

Default: 1000

STOC_ALD_OUTER_ITER_LIM (*integer*): outer loop iteration limit for ALD ↔

Outer loop iteration limit for ALD.

Default: 200

STOC_ALD_PRIMAL_FEASTOL (*real*): primal feasibility tolerance for ALD ↔

Primal feasibility tolerance for ALD.

Default: 1e-4

STOC_ALD_PRIMAL_STEPLEN (*real*): primal step length for ALD ↔

Primal step length for ALD.

Default: 0.5

STOC_AUTOAGGR (*integer*): flag to enable or disable autoaggregation ↔

Flag to enable or disable autoaggregation.

Default: 1

STOC_BENCHMARK_SCEN (*integer*): benchmark scenario to compare EVPI and EVMU against ↔

Benchmark scenario to compare EVPI and EVMU against.

Range: $\{-2, \dots, \infty\}$

Default: -2

STOC_BIGM (*real*): big-M value for linearization and penalty functions ↔

Big-M value for linearization and penalty functions.

Default: 1e7

STOC_BUCKET_SIZE (*integer*): bucket size in Benders decomposition ↔

Bucket size in Benders decomposition. Possible values are positive integers or (-1) for solver decides.

Range: $\{-1, \dots, \infty\}$

Default: -1

STOC_CALC_EVPI (*integer*): flag to enable or disable calculation of EVPI ↔

Flag to enable/disable calculation of lower bounds on EVPI.

Default: 1

value	meaning
0	disable
1	enable

STOC_CORRELATION_TYPE (*integer*): correlation type associated with correlation matrix [↔](#)

Correlation type associated with the correlation matrix.

Default: 0

value	meaning
-1	Target correlation
0	Pearson correlation
1	Kendall correlation
2	Spearman correlation

STOC_DEQOPT (*integer*): method to solve the DETEQ problem [↔](#)

This specifies the method to use when solving the deterministic equivalent.

Default: 0

value	meaning
0	Solver decides
10	Use simple Benders Decomposition

STOC_DETEQ_TYPE (*integer*): type of deterministic equivalent [↔](#)

Type of deterministic equivalent to be used by the solver. Implicit deterministic equivalent is valid for linear and integer models only.

Default: -1

value	meaning
-1	Solver decides
0	Implicit deterministic equivalent
1	Explicit deterministic equivalent

STOC_DS_SUBFORM (*integer*): subproblem formulation to use in DirectSearch [↔](#)

This parameter specifies the type of subproblem formulation to be used in heuristic search.

Default: -1

value	meaning
-1	Solver decides
0	Perform heuristic search in the original solution space
1	Perform heuristic search in the space of discrete variables coupled with optimizations in the linear space

STOC_ELIM_FXVAR (*integer*): flag to enable elimination of fixed variables from deteq MPI ↔

Flag to enable elimination of fixed variables from deteq MPI.

Default: 1

STOC_INFBND (*real*): value to truncate infinite bounds at non-leaf nodes ↔

Value to truncate infinite bounds at nonleaf nodes.

Default: 1e9

STOC_ITER_LIM (*integer*): iteration limit for stochastic solver ↔

Iteration limit for stochastic solver. Possible values are positive integers or (-1) no limit.

Range: $\{-1, \dots, \infty\}$

Default: **infinity**

STOC_MAP_MPI2LP (*integer*): flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements ↔

Flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements.

Default: 0

STOC_MAX_NUMSCENS (*integer*): maximum number of scenarios before forcing automatic sampling ↔

Maximum number of scenarios before forcing automatic sampling. Possible values are positive integers.

Default: 40000

STOC_METHOD (*integer*): stochastic optimization method to solve the model ↔

Stochastic optimization method to solve the model.

Default: -1

value	meaning
-1	Solve with the method chosen by the solver
0	Solve the deterministic equivalent (DETEQ)
1	Solve with the Nested Benders Decomposition (NBD) method

STOC_NAMEDATA_LEVEL (*integer*): name data level ↔

Name data level.

Default: 1

STOC_NODELP_PRELEVEL (*integer*): presolve level solving node-models ↔

Presolve level solving node-models.

Default: 0

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+512	Maximum pass

STOC_NSAMPLE_PER_STAGE (*string*): list of sample sizes per stage (starting at stage 2) ↔

Comma separated list of sample sizes per stage. The sample size of stage 1 is assumed to be 1 so that this list starts with stage stage 2.

STOC_NSAMPLE_SPAR (*integer*): common sample size per stochastic parameter ↔

Common sample size per stochastic parameter. Possible values are positive integers.

Range: $\{-1, \dots, \infty\}$

Default: -1

STOC_NSAMPLE_STAGE (*integer*): common sample size per stage ↔

Common sample size per stage.

Range: $\{-1, \dots, \infty\}$

Default: -1

STOC_NUM_THREADS (*integer*): number of parallel threads ↔

This value specifies the number of parallel threads to be used when solving a stochastic programming model.

Default: 1

STOC_RELOPTTOL (*real*): relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver ↔

Relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in (0,1) interval.

Default: GAMS OptCR

STOC_REL_DSTEPTOL (*real*): dual-step tolerance ↔

This value specifies the dual-step tolerance in decomposition based algorithms.

Default: 1e-7

STOC_REL_PSTEPTOL (*real*): primal-step tolerance ↔

This value specifies the primal-step tolerance in decomposition based algorithms.

Default: 1e-8

STOC_REOPT (*integer*): reoptimization method to solve the node-models ↔

Reoptimization method to solve the node-models.

Default: 0

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver
4	Use NLP solver

STOC_RG_SEED (*integer*): seed to initialize the random number generator [↔](#)

Seed to initialize the random number generator. Possible values are positive integers.

Default: 1031

STOC_SAMP_CONT_ONLY (*integer*): flag to restrict sampling to continuous stochastic parameters only or not [↔](#)

Flag to restrict sampling to continuous stochastic parameters only or not.

Default: 1

value	meaning
0	disable
1	enable

STOC_SBD_MAXCUTS (*integer*): max cuts to generate for master problem [↔](#)

Max cuts to generate for master problem.

Range: $\{-1, \dots, \infty\}$

Default: -1

STOC_SBD_NUMCANDID (*integer*): maximum number of candidate solutions to generate at SBD root [↔](#)

Maximum number of candidate solutions to generate at SBD root.

Range: $\{-1, \dots, \infty\}$

Default: -1

STOC_SBD_OBJCUTFLAG (*integer*): flag to enable objective cut in SBD master problem [↔](#)

Flag to enable objective cut in SBD master problem.

Default: 1

STOC_SBD_OBJCUTVAL (*real*): RHS value of objective cut in SBD master problem [↔](#)

RHS value of objective cut in SBD master problem.

Default: $1e-30$

STOC_SHARE_BEGSTAGE (*integer*): stage beyond which node-models are shared [↔](#)

Stage beyond which node-models share the same model structure. Possible values are positive integers less than or equal to number of stages in the model or (-1) for solver decides.

Range: $\{-1, \dots, \infty\}$

Default: -1

STOC_TIME_LIM (*real*): time limit for stochastic solver [↔](#)

Time limit for stochastic solver. Possible values are nonnegative real numbers or -1 for solver decides.

Range: $[-1, \infty]$

Default: GAMS ResLim

STOC_TOPOPT (*integer*): optimization method to solve the root problem [↔](#)

Optimization method to solve the root problem.

Default: 0

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver
4	Use NLP solver
6	Use multi-start solver
7	Use global solver

STOC_VARCONTROL_METHOD (*integer*): sampling method for variance reduction [↔](#)

Sampling method for variance reduction.

Default: 1

value	meaning
0	Montecarlo sampling
1	Latinsquare sampling
2	Antithetic sampling

STOC_WSBAS (*integer*): warm start basis for wait-see model [↔](#)

Warm start basis for wait-see model .

Range: $\{-1, \dots, \infty\}$

Default: -1

SVR_LS_ANTITHETIC (*string*): Sample variance reduction map to Lindo Antithetic algorithm [↔](#)

SVR_LS_LATINSQUARE (*string*): Sample variance reduction map to Lindo Latin Square algorithm ↔

SVR_LS_MONTECARLO (*string*): Sample variance reduction map to Lindo Montecarlo algorithm ↔

TUNER_PRINT_LEVEL (*integer*): specifies the amount of print to do during parameter tuning ↔

Default: 1

value	meaning
0	Do not print anything default
>0	Print more information

USEGOP (*integer*): use global optimization ↔

This value determines whether the global optimization will be used.

Default: 1

value	meaning
0	Do not use global optimization
1	Use global optimization

WRITEDEMPI (*string*): write deterministic equivalent in MPI format ↔

WRITEDEMPMS (*string*): write deterministic equivalent in MPS format ↔

WRITEMPI (*string*): write (S)MPI file of processed model ↔

If this option is set, Lindo write an MPI file of processed model. If set, the value of this option defines the name of the MPI file.

WRITEMPS (*string*): write (S)MPS file of processed model ↔

5.26.8 Stochastic Programming (SP) in GAMS/Lindo

GAMS/Lindo can also solve stochastic programming models. The syntax to set up an SP problem in GAMS is explained in the chapter [Stochastic Programming \(SP\) with EMP](#). The options to control LINDO's stochastic solver are described in the subsection SP Options.

5.27 MILES

Thomas F. Rutherford, University of Colorado

5.27.1 Abstract

MILES is a solver for nonlinear complementarity problems and nonlinear systems of equations. The solver can be accessed through GAMS to solve MPSGE or MCP models. This paper documents the solution algorithm, user options, and solver output. The purpose of the paper is to provide users of MILES an overview of how the solver works so that they can use it effectively.

5.27.2 Introduction

MILES is a Fortran-based solver for nonlinear complementarity problems and nonlinear systems of equations. The solution procedure is a generalized Newton method with a backtracking line search. This code is based on an algorithm investigated by Mathiesen (1985) who proposed a modeling format and sequential method for solving economic equilibrium models. The method is closely related to algorithms proposed by Robinson (1975), Hogan (1977), Eaves (1978) and Josephy (1979). In this implementation, subproblems are solved as linear complementarity problems (LCPs), using an extension of Lemke's almost-complementary pivoting scheme in which upper and lower bounds are represented implicitly. The linear solver employs the basis factorization package LUSOL, developed by Gill et al. (1991).

The class of problems for which MILES may be applied are referred to as "generalized" or "mixed" complementarity problems, which is defined as follows:

$$\begin{aligned} \text{Given: } & F : R^n \rightarrow R^n, \quad \ell, u \in R^n \\ \text{Find: } & z, w, v \in R^n \\ \text{such that } & F(z) = w - v \\ & \ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0 \\ & w^T(z - \ell) = 0, \quad v^T(u - z) = 0. \end{aligned}$$

When $\ell = -\infty$ and $u = \infty$ MCP reduces to a nonlinear system of equations. When $\ell = 0$ and $u = +\infty$, the MCP is a nonlinear complementarity problem. Finite dimensional variational inequalities are also MCP. MCP includes inequality-constrained linear, quadratic and nonlinear programs as special cases, although for these problems standard optimization methods may be preferred. MCP models which are not optimization problems encompass a large class of interesting mathematical programs. Specific examples of MCP formulations are not provided here. See Rutherford (1992a) for MCP formulations arising in economics. Other examples are provided by Harker and Pang (1990) and Dirkse (1993).

There are two types of GAMS models which can be presented to MILES:

1. MILES may be used to solve computable general equilibrium models generated by MPSGE as a GAMS subsystem. In the MPSGE language, a model-builder specifies classes of nonlinear functions using a specialized tabular input format embedded within a GAMS program. Using benchmark quantities and prices, MPSGE automatically calibrates function coefficients and generates nonlinear equations and Jacobian matrices. Large, complicated systems of nonlinear equations may be implemented and analyzed very easily using this interface to MILES. An introduction to general equilibrium modeling with GAMS/MPSGE is provided by Rutherford (1992a).

2. MILES may be accessed as a GAMS solver for mixed complementarity problems (MCP). If more than one MCP solver is available ⁴, the statement `OPTION MCP = MILES;` tells GAMS to use MILES as the MCP solution system. When problems are presented to MILES using the MCP format, the user specifies nonlinear functions using GAMS matrix algebra and the GAMS compiler automatically generates the Jacobian functions. An introduction to the GAMS/MCP modeling format is provided by Rutherford (1992b).

The purpose of this document is to provide users of MILES with an overview of how the solver works so that they can use the program more effectively. Section [The Newton Algorithm](#) introduces the Newton algorithm. Section [Lemke's Method with Implicit Bounds](#) describes the implementation of Lemke's algorithm which is used to solve linear subproblems. Section [The Options File](#) defines switches and tolerances which may be specified using the options file. Section [Log File Output](#) interprets the run-time log file which is normally directed to the screen. Section [Status File Output](#) interprets the status file and the detailed iteration reports which may be generated. Section [Termination Messages](#) lists and suggests remedies for abnormal termination conditions.

5.27.3 The Newton Algorithm

The iterative procedure applied within MILES to solve nonlinear complementarity problems is closely related to the classical Newton algorithm for nonlinear equations. This first part of this section reviews the classical procedure. A thorough introduction to these ideas is provided by Dennis and Schnabel (1983). For a practical perspective, see Press et al. (1986).

Newton algorithms for nonlinear equations begin with a local (Taylor series) approximation of the system of nonlinear equations. For a point z in the neighborhood of \bar{z} , the system of nonlinear functions is linearized:

$$LF(z) = F(\bar{z}) + \nabla F(\bar{z})(z - \bar{z}).$$

Solving the linear system $LF(z) = 0$ provides the Newton direction from \bar{z} which is given by $d = -\nabla F^{-1} F(\bar{z})$.

Newton iteration k begins at point z^k . First, the linear model formed at z^k is solved to determine the associated "Newton direction", d^k . Second, a line search in direction d^k determines the scalar steplength and the subsequent iterate: $z^{k+1} = z^k + \lambda d^k$. An Armijo or "back-tracking" line search initially considers $\lambda = 1$. If $\|F(z^k + \lambda d^k)\| \leq \|F(z^k)\|$, the step size λ is adopted, otherwise is multiplied by a positive factor α , $\alpha < 1$, and the convergence test is reapplied. This procedure is repeated until either an improvement results or $\lambda < \underline{\lambda}$. When $\underline{\lambda} = 0$, a positive step is taken provided that ⁵

$$\frac{d}{d\lambda} \|F(z^k + \lambda d^k)\| < 0.$$

Convergence theory for this algorithm is quite well developed. See, for example, Ortega and Rheinbolt (1970) or Dennis and Schnabel (1983). The most attractive aspect of the Newton scheme with the backtracking line search is that in the neighborhood of a well-behaved fixed point, $\lambda = 1$ is the optimal step length and the rate of convergence can be quadratic. If this method finds a solution, it does so very quickly.

The application of Newton methods to nonlinear complementarity problems involves a modification of the search direction. Here, d solves a *linear complementarity problem* (LCP) rather than a linear system of equations. For iteration k , d solves:

⁴There is one other MCP solver available through GAMS: PATH (Ferris and Dirkse, 1992)

⁵ α and $\underline{\lambda}$ correspond to user-specified tolerances 'DMPFAC' and 'MINSTP', respectively

$$F(z^k) + \nabla F(z^k)d - w + v = 0$$

$$\ell \leq d + z^k \leq u, \quad w \geq 0, \quad v \geq 0$$

$$w^T(d + z^k - \ell) = v^T(u - d - z^k) = 0.$$

Conceptually, we are solving for d , but in practice MILES solves the linear problem in terms of the original variables $z = z^k + d$:

$$F(z^k) - \nabla F(z^k)z_k + \nabla F(z^k)z = w - v$$

$$\ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0$$

$$w^T(z - \ell) = 0, \quad v^T(u - z) = 0.$$

After computing the solution z , MILES sets $d^k = z - z^k$.

The linear subproblem incorporates upper and lower bounds on any or all of the variables, assuring that the iterative sequence always remains within the bounds: ($\ell \leq z^k \leq u$). This can be helpful when, as is often the case, $F()$ is undefined for some $z \in R^n$.

Convergence of the Newton algorithm applied to MCP hinges on three questions:

1. Does the linearized problem always have a solution?
2. If the linearized problem has a solution, does Lemke's algorithm find it?
3. Is it possible to show that the computed direction d^k will provide an "improvement" in the solution?

Only for a limited class of functions $F()$ can all three questions be answered in the affirmative. For a much larger class of functions, the algorithm converges in practice but convergence is not "provable" ⁶

The answer to question 3. depends on the choice of a norm by which an improvement is measured. The introduction of bounds and complementarity conditions makes the calculation of an error index more complicated. In MILES, the deviation associated with a candidate solution z , $\epsilon(z)$, is based on a measure of the extent to which z , w and v violate applicable upper and lower bounds and complementarity conditions.

⁶Kaneko (1978) provides some convergence theory for the linearized subproblem

5.27.3.1 Evaluating Convergence

Let δ_i^L and δ_i^U be indicator variables for whether z_i is off its lower or upper bound. These are defined as ⁷

$$\delta_i^L = \min(1, (z_i - \ell_i)^+) \quad \text{and} \quad \delta_i^U = \min(1, (u_i - z_i)^+).$$

Given z , MILES uses the value of $F(z)$ to implicitly define the slack variables w and v :

$$w_i = F_i(z)^+, \quad v_i = \left(-F_i(z)\right)^+.$$

There are two components to the error term associated with index i , one corresponding to z_i 's violation of upper and lower bounds:

$$\varepsilon_i^B = (z_i - u_i)^+ + (\ell_i - z_i)^+$$

and another corresponding to violations of complementarity conditions:

$$\varepsilon_i^C = \delta_i^L w_i + \delta_i^U v_i.$$

The error assigned to point z is then taken:

$$\varepsilon(z) = \|\varepsilon^B(z) + \varepsilon^C(z)\|_p$$

for a pre-specified value of $p = 1, 2$ or $+\infty$. ⁸

5.27.4 Lemke's Method with Implicit Bounds

A mixed linear complementarity problem has the form:

$$\text{Given:} \quad M \in R^{n \times n}, \quad q, \ell, u \in R^n$$

$$\text{Find:} \quad z, w, v \in R^n$$

$$\begin{aligned} \text{such that} \quad & Mz + q = w - v, \\ & \ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0, \\ & w^T(z - \ell) = 0, \quad v^T(u - z) = 0. \end{aligned}$$

In the Newton subproblem at iteration k , the LCP data are given by $q = F(z^k) - \nabla F(z^k)z^k$ and $M = \nabla F(z^k)$.

⁷In the following $x^+ = \max(x, 0)$

⁸Parameter p may be selected with input parameter 'NORM'. The default value for p is $+\infty$.

5.27.4.1 The Working Tableau

In MILES, the pivoting scheme for solving the linear problem works with a re-labeled linear system of the form:

$$\backslash f [\quad B \ x^B + N \ x^N = q , \quad \backslash f]$$

where $x^B \in R^n$, $x^N \in R^{2n}$, and the tableau $[B|N]$ is a conformal "complementary permutation" of $[-M|I|-I]$. That is, every column i in B must either be the i th column of M, I or $-I$, while the corresponding columns i and $i+n$ in N must be the two columns which were not selected for B .

To move from the problem defined in terms of z, w and v to the problem defined in terms of x^B and x^N , we assign upper and lower bounds for the x^B variables as follows:

$$\underline{x}_i^B = \begin{cases} \ell_i, & \text{if } x_i^B = z_i \\ 0, & \text{if } x_i^B = w_i \text{ or } v_i, \end{cases}$$

$$\bar{x}_i^B = \begin{cases} u_i, & \text{if } x_i^B = z_i \\ \infty, & \text{if } x_i^B = w_i \text{ or } v_i \end{cases}$$

The values of the non-basic variables x_i^N and x_{i+n}^N are determined by the assignment of x_i^B :

$$x_i^B = \begin{cases} z_i \Rightarrow \begin{cases} x_i^N = w_i = 0 \\ x_{i+n}^N = v_i = 0 \end{cases} \\ w_i \Rightarrow \begin{cases} x_i^N = z_i = \ell_i \\ x_{i+n}^N = v_i = 0 \end{cases} \\ v_i \Rightarrow \begin{cases} x_i^N = w_i = 0 \\ x_{i+n}^N = z_i = u_i. \end{cases} \end{cases}$$

In words: if z_i is basic then both w_i and v_i equal zero. If z_i is non-basic at its lower bound, then w_i is possibly non-zero and v_i is non-basic at zero. If z_i is non-basic at its upper bound, then v_i is possibly non-zero and w_i is non-basic at zero.

Conceptually, we could solve the LCP by evaluating 3^n linear systems of the form:

$$x^B = B^{-1} \left(q - N x^N \right).$$

Lemke's pivoting algorithm provides a procedure for finding a solution by sequentially evaluating some (hopefully small) subset of these 3^n alternative linear systems.

5.27.4.2 Initialization

Let B^0 denote the initial basis matrix ⁹ The initial values for basic variables are then:

$$\hat{x}^B = (B^0)^{-1}(q - N \hat{x}^N).$$

If $\underline{x}^B \leq \hat{x}^B \leq \bar{x}^B$, then the initial basis is feasible and the complementarity problem is solved ¹⁰ Otherwise, MILES introduces an artificial variable z_0 and an artificial column h . Basic variables are then expressed as follows:

$$x^B = \hat{x}^B - \tilde{h}z_0,$$

where \tilde{h} is the "transformed artificial column" (the untransformed column is $h = B^0 \tilde{h}$). The coefficients of \tilde{h} are selected so that:

1. The values of "feasible" basis variables are unaffected by z_0 : ($\underline{x}_i^B \leq x_i^B \leq \bar{x}_i^B \implies \tilde{h}_i = 0$).
2. The "most infeasible" basic variable ($i = p$) is driven to its upper or lower bound when $z_0 = 1$:

$$\tilde{h}_p = \begin{cases} \hat{x}_p^B - \bar{x}_p^B, & \text{if } \hat{x}_p^B > \bar{x}_p^B \\ \hat{x}_p^B - \underline{x}_p^B, & \text{if } \hat{x}_p^B < \underline{x}_p^B. \end{cases}$$

3. All other *infeasible* basic variables assume values between their upper and lower bounds when z_0 increases to 1:

$$x_i^B = \begin{cases} 1 + \underline{x}_i^B, & \text{if } \underline{x}_i^B > -\infty, \quad \bar{x}_i^B = +\infty \\ \frac{\bar{x}_i^B + \underline{x}_i^B}{2}, & \text{if } \underline{x}_i^B > -\infty, \quad \bar{x}_i^B < +\infty \\ \bar{x}_i^B - 1, & \text{if } \underline{x}_i^B = -\infty, \quad \bar{x}_i^B < +\infty. \end{cases}$$

5.27.4.3 Pivoting Rules

When z_0 enters the basis, it assumes a value of unity, and at this point (barring degeneracy), the subsequent pivot sequence is entirely determined. The entering variable in one iteration is determined by the exiting basic variable in the previous iteration. For example, if z_i were in B^0 and introducing z_0 caused z_i to move onto its lower bound, then the subsequent iteration introduces w_i . Conversely, if w_i were in B^0 and z_0 caused w_i to fall to zero, the subsequent iteration increases z_i from ℓ_i . Finally, if v_i were in B^0 and z_0 's introduction caused v_i to fall to zero, the subsequent iteration *decreases* z_i from u_i .

Table 1 Pivot Sequence Rules for Lemke's Algorithm with Implicit Bounds

N	Exiting Variable	Entering Variable	Change in Non-basic Values
I	z_i at lower bound	w_i increases from 0	$x_i^N = z_i = \ell_i$
II	z_i at upper bound	v_i increases from 0	$x_{i+n}^N = z_i = u_i$
III	w_i at 0	z_i increases from ℓ_i	$x_i^N = x_{i+n}^N = 0$
IV	v_i at 0	z_i decreases from u_i	$x_i^N = x_{i+n}^N = 0$

⁹In Miles, B^0 is chosen using the initially assigned values for z . When $z_i \leq \ell_i$, then $x_i^B = w_i$; when $z_i \geq u_i$, then $x_i^B = v_i$; otherwise $x_i^B = z_i$.

¹⁰The present version of the code simply sets $B^0 = -I$ and $x^B = w$ when the user-specified basis is singular. A subsequent version of the code will incorporate the algorithm described by Anstreicher, Lee, and Rutherford [1992] for coping with singularity.

The full set of pivoting rules is displayed in Table 1. One difference between this algorithm and the original Lemke (type III) pivoting scheme (see Lemke (1965), Garcia and Zangwill (1981), or Cottle and Pang (1992)) is that structural variables (z_i 's) may enter or exit the basis at their upper bound values. The algorithm, therefore, must distinguish between pivots in which the entering variable increases from a lower bound and those in which the entering variable decreases from an upper bound.

Another difference with the "usual" Lemke pivot procedure is that an entering structural variable may move from one bound to another. When this occurs, the subsequent pivot introduces the corresponding slack variable. For example, if z_i is increased from ℓ_i to u_i without driving a basic variable infeasible, then z_i becomes non-basic at u_i , and the subsequent pivot introduces v_i . This type of pivot may be interpreted as z_i entering and exiting the basis in a single step ¹¹

In theory it is convenient to ignore degeneracy, while in practice degeneracy is unavoidable. The present algorithm does not incorporate a lexicographic scheme to avoid cycling, but it does implement a ratio test procedure which assures that when there is more than one candidate, priority is given to the most stable pivot. The admissible set of pivots is determined on both an absolute pivot tolerance (ZTOLPV) and a relative pivot tolerance (ZTOLRP). No pivot with absolute value smaller than $\min(\text{ZTOLPV}, \text{ZTOLRP} \|V\|)$ is considered, where $\|V\|$ is the norm of the incoming column.

5.27.4.4 Termination on a Secondary Ray

Lemke's algorithm terminates normally when the introduction of a new variable drives z_0 to zero. This is the desired outcome, but it does not always happen. The algorithm may be interrupted prematurely when no basic variable "blocks" an incoming variable, a condition known as "termination on a secondary ray". In anticipation of such outcomes, MILES maintains a record of the value of z_0 for successive iterations, and it saves basis information associated with the smallest observed value, z_0^* . (In Lemke's algorithm, the pivot sequence is determined without regard for the effect on z_0 , and the value of the artificial variable may follow an erratic (non-monotone) path from its initial value of one to the final value of zero.)

When MILES encounters a secondary ray, a restart procedure is invoked in which the set of basic variables associated with z_0^* are reinstalled. This basis (augmented with one column from the non-basic triplet to replace z_0) serves as B^0 , and the algorithm is restarted. In some cases this procedure permits the pivot sequence to continue smoothly to a solution, while in other cases may only lead to another secondary ray.

5.27.5 The Options File

The standard GAMS options (e.g. [iterlim](#), [reslim](#)) can be used to control MILES. For more details, see section [Controlling a Solver via GAMS Options](#).

In addition, MILES-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section [The Solver Options File](#).

The following is a typical MILES options file:

```
ITLIMT = 50
CONTOL = 1.0E-8
LUSIZE = 16
```

In the remainder of this section we describe the MILES options and give their default values.

¹¹If all structural variables are subject to finite upper and lower bounds, then no z_i variables may be part of a homogeneous solution adjacent to a secondary ray. This does not imply, however, that secondary rays are impossible when all z_i variables are bounded, as a ray may then be comprised of w_i and v_i variables.

Option	Description	Default
contol	convergence tolerance Whenever an iterate is encountered for which $\epsilon(z) < \text{CONTOL}$, the algorithm terminates. This corresponds to the GAMS/MINOS parameter "Row tolerance".	1e-6
dens1	LUSOL: density to start searching maxcol columns The density at which the Markowitz strategy should search maxcol columns and no rows. Range: [0, 1]	0.3
dens2	LUSOL: density to start searching 1 column The density at which the Markowitz strategy should search only 1 column or (preferably) use a dense LU for all the remaining rows and columns. Range: [0, 1]	0.6
dmpfac	damping factor in backtracking linesearch	0.5
elmax1	LUSOL: max multiplier allowed in L during factor	10
elmax2	LUSOL: max multiplier allowed in L during update	10
factim	basis reinversion time Indicates the maximum number of CPU seconds between recalculation of the basis factors.	120
invfrq	basis reinversion frequency Determines the maximum number of Lemke iterations between recalculation of the basis factors. This corresponds to the GAMS/MINOS parameter "Factorization frequency".	200
invlog	toggle Lemke inversion logging A switch which requests LUSOL to generate a report with basis statistics following each refactorization.	1
itch	iteration refinement frequency Indicates the frequency with which the factorization is checked. The number refers to the number of basis replacement operations between refinements. This corresponds to the GAMS/MINOS parameter "Check frequency".	25
iterlim	minor (Lemke) iterations limit Can also be set with the GAMS IterLim option, and takes its default from that. This corresponds to the GAMS/MINOS parameter "Iterations Limit".	GAMS IterLim
itlimt	major (Newton) iterations limit An upper bound on the number of Newton iterations. This corresponds to the GAMS/MINOS parameter "Major iterations". Range: {0, ..., 1000}	100
lcpdmp	LCP dump (post-scaling) A switch to generate a printout of the LCP data after scaling.	0
lcpech	LCP echo print (pre-scaling) A switch to generate a printout of the LCP data before scaling, as evaluated.	0
levout	set output level Sets the level of debug output written to the log and status files. The lowest meaningful value is -1 and the highest is 3. This corresponds, roughly, to the GAMS/MINOS parameter "Print level".	1

Option	Description	Default
lprint	LUSOL: print level Controls the amount of logging from the LUSOL routines. <0: suppresses output 0: gives error messages 1: gives debug output from some of the routines in LUSOL >=2: gives the pivot row and column and the no. of rows and columns involved at each elimination step in lu1fac	0
lusize	LUSOL: multiplier for estimating memory requirements Used to estimate the number of LU nonzeros which will be stored, as a multiple of the number of nonzeros in the Jacobian matrix. Range: {3, ..., ∞}	5
maxcol	LUSOL: max cols to search for pivot element Sets the maximum number of columns to search in a Markowitz-type search for the next pivot element. For some of the factorization, the number of rows searched is maxrow = maxcol - 1.	5
minstp	minimum step length in backtracking linesearch	0.01
norm	norm to use in measuring deviation Defines the vector norm to be used for evaluating <code>epsilon(z)</code> . Acceptable values are 1, 2 or 3 which correspond to $p = 1, 2$ and $+\text{INF}$.	1
nrsmax	restart limit Sets an upper bound on the number of restarts which the linear subproblem solver will undertake before giving up.	1
pivlog	toggle Lemke pivot logging A switch to generate a status file listing of the Lemke pivot sequence.	0
plinfy	infinity used by the solver The value assigned for "plus infinity" (" $+\text{INF}$ " in GAMS notation).	1e20
scale	turn on scaling at every iteration Invokes row and column scaling of the LCP tableau in every iteration. This corresponds, roughly, to the GAMS/MINOS switch "scale all variables".	1
small	LUSOL: absolute zero tolerance The absolute tolerance for treating reals as zero.	3.0e-13
uspace	LUSOL: factor limiting waste space in U The row or column lists are compressed if their length exceeds this value times the length of either file after the last compression. Range: [1, ∞]	3
utol1	LUSOL: absolute tolerance U diagonal The absolute tol for flagging small diagonals of U.	3.64e-11
utol2	LUSOL: relative tolerance U diagonal The relative tol for flagging small diagonals of U.	3.64e-11
ztolda	zero tolerance on matrix coefficients, default: $\text{sqrt}(\text{machEps})$	1.48e-08
ztolpv	absolute zero tolerance on pivots, default: $\text{machEps}^{2/3}$ The absolute pivot tolerance. This corresponds, roughly, to the GAMS/MINOS parameter "Pivot tolerance" as it applies for nonlinear problems.	3.64e-11
ztolrp	relative zero tolerance on pivots, default: $\text{machEps}^{2/3}$ The relative pivot tolerance. This corresponds, roughly, to the GAMS/MINOS parameter "Pivot tolerance" as it applies for nonlinear problems.	3.64e-11
ztolz0	absolute tolerance for installing covering vector elements	1e-6

Option	Description	Default
ztolze	feasibility tolerance Used in the subproblem solution to determine when any variable has exceeded an upper or lower bound. This corresponds to GAMS/MINOS parameter "Feasibility tolerance".	1e-6

5.27.6 Log File Output

The log file is intended for display on the screen in order to permit monitoring progress. Relatively little output is generated.

A sample iteration log is displayed in [Table 2](#). This output is from two cases solved in succession. This and subsequent output comes from program TRNSP.FOR which calls the MILES library directly. (When MILES is invoked from within GAMS, at most one case is processed at a time.)

The first line of the log output gives the MILES program date and version information. This information is important for bug reports.

The line beginning "Work space..." reports the amount of memory which has been allocated to solve the model - 10K for this example. Thereafter is reported the initial deviation together with the name of the variable associated with the largest imbalance ($\epsilon_i^B + \epsilon_i^C$). The next line reports the convergence tolerance.

The lines beginning 0 and 1 are the major iteration reports for those iterations. the number following the iteration number is the current deviation, and the third number is the Armijo step length. The name of the variable complementary to the equation with the largest associated deviation is reported in parenthesis at the end of the line.

Following the final iteration is a summary of iterations, refactorizations, and final deviation. The final message reports the solution status. In this case, the model has been successfully processed ("Solved.").

Table 2 Sample Iteration Log

5.27.7 Status File Output

The status file reports more details regarding the solution process than are provided in the log file. Typically, this file is written to disk and examined only if a problem arises. Within GAMS, the status file appears in the listing only following the GAMS statement `OPTION SYSOUT=ON;`

The level of output to the status file is determined by the options passed to the solver. In the default configuration, the status file receives all information written to the log file together with a detailed listing of all switches and tolerances and a report of basis factorization statistics.

When output levels are increased from their default values using the options file, the status file can receive considerably more output to assist in debugging. [Table 3](#) - [Table 6](#) present a status file generated with `LEVOUT=3` (maximum), `PIVLOG=T`, and `LCPECH=T`.

The status file begins with the same header as the log file. Thereafter is a complete echo-print of the user-supplied option file when one is provided. Following the core allocation report is a full echo-print of control parameters, switches and tolerance as specified for the current run.

[Table 4](#) continues the status file. The iteration-by- iteration report of variable and function values is produced whenever `LEVOUT >= 2`. [Table 4](#) also contains an LCP echo-print. This report has two sections: `$ROWS` and `$COLUMNS`. The four columns of numbers in the `$ROWS` section are the constant vector (q), the current estimate of level values for the associated variables (z), and the lower and upper bounds vectors (ℓ and u). The letters L and U which appear between the `ROW` and `Z` columns are used to identify variables which are non-basic at their lower and upper bounds, respectively. In this example, all upper bounds equal $+\infty$, so no variables are non-basic at their upper bound.

By convention, only variable (and not equation names) appear in the status file. An equation is identified by the corresponding variable. We therefore see in the `$COLUMNS:` section of the matrix echo-print, the row names correspond to the names of z variables. The names assigned to variables z_i , w_i and v_i are

z - <name i >, w - <name i >, and v - <name i >, as shown in the \$COLUMNS section. The nonzeros for w - <> and v - <> variables are not shown because they are assumed to be $-/+I$.

The status file output continues on Table 5 where the first half of the table reports output from the matrix scaling procedure, and the second half reports the messages associated with initiation of Lemke's procedure.

The "lu6chk warning" is a LUSOL report. Thereafter are two factorization reports. Two factorizations are undertaken here because the first basis was singular, so the program installs all the lower bound slacks in place of the matrix defined by the initial values, z .

Following the second factorization report, at the bottom of Table 5 is a summary of the initial pivot. "Infeasible in 3 rows." indicates that \tilde{h} contains 3 nonzero elements. "Maximum infeasibility" reports the largest amount by which a structural variable violates an upper or lower bound. "Artificial column with 3 elements." indicates that the vector $h = B^0\tilde{h}$ contains 3 elements (note that in this case $B^0 = -I$ because the initial basis was singular, hence the equivalence between the number of nonzeros in \tilde{h} and h).

Table 6 displays the final section of the status file. At the top of the table is the Lemke iteration log. The columns are interpreted as follows:

- ITER is the iteration index beginning with 0.
- STATUS is a statistic representing the efficiency of the Lemke path. Formally, status is the ratio of the minimum number of pivots from B_0 to the current basis divided by the actual number of pivots. When the status is 1, Lemke's algorithm is performing virtually as efficiently as a direct factorization (apart from the overhead of basis factor updates.)
- Z% indicates the percentage of columns in the basis are "structural" (z 's).
- Z0 indicates the value of the artificial variable. Notice that in this example, the artificial variable declines monotonically from its initial value of unity.
- ERROR is a column in which the factorization error is reported, when it is computed. For this run, ITCH=30 and hence no factorization errors are computed.
- INFEAS is a column in which the magnitude of the infeasibility introduced by the artificial column (defined using the box-norm) is reported. (In MILES the cover vector h contains many different nonzero values, not just 1's; so there may be a large difference between the magnitude of the artificial variable and the magnitude of the induced infeasibility.
- PIVOTS reports the pivot magnitude in both absolute terms (the first number) and relative terms (the second number). The relative pivot size is the ratio of the pivot element to the norm of the incoming column.
- IN/OUT report the indices (not names) of the incoming and outgoing columns for every iteration. Notice that Lemke's iteration log concludes with variable z_0 exiting the basis.

The convergence report for iteration 1 is no different from the report written to the log file, and following this is a second report of variable and function values. We see here that a solution has been obtained following a single subproblem. This is because the underlying problem is, in fact, linear.

The status file (for this case) concludes with an iteration summary identical to the log file report and a summary of how much CPU time was employed overall and within various subtasks. (Don't be alarmed if the sum of the last five numbers does not add up to the first number - some cycles are not monitored precisely.)

5.27.8 Termination Messages

Basis factorization error in INVERT. An unexpected error code returned by LUSOL. This should normally not occur. Examine the status file for a message from LUSOL ¹².

¹²Within GAMS, insert the line "OPTION SYSOUT=ON;" prior to the solve statement and resubmit the program in order to pass the MILES solver status file through to the listing.

Failure to converge. Two successive iterates are identical - the Newton search direction is not defined. This should normally not occur.

Inconsistent parameters ZTOLZO, ZTOLZE. ZTOLZO determines the smallest value loaded into the cover vector h , whereas ZTOLZE is the feasibility tolerance employed in the Harris pivot selection procedure. If $ZTOLZO < -ZTOLZE$, Lemke's algorithm cannot be executed because the initial basis is infeasible.

Insufficient space for linearization. Available memory is inadequate for holding the nonzeros in the Jacobian. More memory needs to be allocated. If there is insufficient space for the {Jacobi} matrix, there is far too little memory for holding the LU factors of the same matrix.

Insufficient space to invert. More memory needs to be allocated for basis factors. Increase the value of LUSIZE in the options file, or assign a larger value to `<model>.workspace`.

Iteration limit exceeded. This can result from either exceeding the major (Newton) or minor (Lemke) iterations limit. When MILES is invoked from GAMS, the cumulative Lemke iteration limit can be set with the statement `<model>.iterlim = xx`; . The Newton iteration limit is 100 by default, and it can be modified only through the ITLIMIT option.

Resource interrupt. Elapsed CPU time exceeds options parameter RESLIM. To increase this limit, either add `RESLIM = xxx` in the options file or add a GAMS statement `<model>.RESLIM = xxx`;

Singular matrix encountered. Lemke's algorithm has been interrupted due to a singularity arising in the basis factorization, either during a column replacement or during a refactorization. For some reason, a restart is not possible.

Termination on a secondary ray. Lemke's algorithm terminated on a secondary ray. For some reason, a restart is not possible.

Unknown termination status. The termination status flag has not been set, but the code has interrupted. Look in the status file for a previous message. This termination code should not happen often.

5.28 MINOS and QUADMINOS

Bruce A. Murtagh; Graduate School of Management, Macquarie University, Sydney, Australia

Michael A. Saunders, Walter Murray; Department of EESOR, Stanford University, CA

Philip E. Gill; Department of Mathematics, University of California, San Diego, La Jolla, CA

5.28.1 Introduction

This document describes the GAMS interface to MINOS which is a general purpose nonlinear programming solver. For a quad-precision MINOS, see [quadMINOS](#).

GAMS/MINOS is a specially adapted version of the solver that is used for solving linear and nonlinear programming problems in a GAMS environment.

GAMS/MINOS is designed to find solutions that are *locally optimal*. The nonlinear functions in a problem must be *smooth* (i.e., their first derivatives must exist). The functions need not be separable. Integer restrictions cannot be imposed directly.

A certain region is defined by the linear constraints in a problem and by the bounds on the variables. If the nonlinear objective and constraint functions are convex within this region, any optimal solution obtained will be a *global optimum*. Otherwise there may be several local optima, and some of these may not be global. In such cases the chances of finding a global optimum are usually increased by choosing a starting point that is "sufficiently close", but there is no general procedure for determining what "close" means, or for verifying that a given local optimum is indeed global.

Linearly constrained models are solved with a very efficient and reliable reduced gradient technique that takes advantage of the sparsity of the model. Models with nonlinear constraints are solved with a method that iteratively solves subproblems with linearized constraints and an augmented Lagrangian objective function. This iterative scheme implies that only the final, optimal solution is sure to be feasible w.r.t the nonlinear constraints. This is in contrast to the feasible path method used by some other NLP solvers, e.g., CONOPT. MINOS and CONOPT are very complementary to each other as they employ very different algorithms. See [MINOS vs CONOPT](#) for a comparison of the two solvers.

GAMS allows you to specify values for many parameters that control GAMS/MINOS, and with careful experimentation you may be able to influence the solution process in a helpful way. All MINOS options available through GAMS/MINOS are summarized at the end of this document.

5.28.2 How to Run a Model with GAMS/MINOS

MINOS is capable of solving many types of models, including LP, NLP, DNLP and QCP. If MINOS is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select MINOS:

```
option nlp=minos;
```

The option statement should appear before the `solve` statement.

To be complete, we mention that the solver can be also specified on the command line, as in:

```
> gams camcge nlp=minos
```

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

5.28.3 Overview of GAMS/MINOS

GAMS/MINOS is a system designed to solve large-scale optimization problems expressed in the following form:

$$\begin{array}{llll} \text{NLP :} & & \text{minimize} & F(x) + c^T x + d^T y & (1) \\ & & \text{subject to} & f(x) + A_1 y \sim b_1 & (2) \\ & & & A_2 x + A_3 y \sim b_2 & (3) \\ & & & \ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u & (4) \end{array}$$

where the vectors c , d , b_1 , b_2 , ℓ , u and the matrices A_1 , A_2 , A_3 are constant, $F(x)$ is a smooth scalar function, and $f(x)$ is a vector of smooth functions. The \sim signs mean that individual constraints may be defined using \leq , $=$ or \geq corresponding to the GAMS constructs `=L=`, `=E=` and `=G=`.

The components of x are called the nonlinear variables, and the components of y are the linear variables. Similarly, the equations in (2) are called the nonlinear constraints, and the equations in (3) are the linear constraints. Equations (2) and (3) together are called the general constraints.

Let m_1 and n_1 denote the number of nonlinear constraints and variables, and let m and n denote the total number of (general) constraints and variables. Thus, A_3 has $m - m_1$ rows and $n - n_1$ columns. The constraints (4) specify upper and lower bounds on all variables. These are fundamental to many problem formulations and are treated specially by the solution algorithms in GAMS/MINOS. Some of the components of ℓ and u may be $-\infty$ or $+\infty$ respectively, in accordance with the GAMS use of `-INF` and `+INF`.

The vectors b_1 and b_2 are called the right-hand side, and together are denoted by b .

5.28.3.1 Linear Programming

If the functions $F(x)$ and $f(x)$ are absent, the problem becomes a *linear program*. Since there is no need to distinguish between linear and nonlinear variables, we use x rather than y . GAMS/MINOS converts all general constraints into equalities, and the only remaining inequalities are simple bounds on the variables. Thus, we write linear programs in the form

$$\begin{aligned} \text{LP :} \quad & \text{minimize} && c^T x \\ & \text{subject to} && Ax + Is = 0 \\ & && \ell \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u \end{aligned}$$

where the elements of x are your own GAMS variables, and s is a set of *slack variables*: one for each general constraint. For computational reasons, the right-hand side b is incorporated into the bounds on s .

In the expression $Ax + Is = 0$ we write the identity matrix explicitly if we are concerned with columns of the associated matrix $(A \ I)$. Otherwise we will use the equivalent notation $Ax + s = 0$.

GAMS/MINOS solves linear programs using a reliable implementation of the *primal simplex method* [62], in which the constraints $Ax + Is = 0$ are partitioned into the form

$$Bx_B + Nx_N = 0,$$

where the *basis matrix* is square and nonsingular. The elements of x_B and x_N are called the basic or nonbasic variables respectively. Together they are a permutation of the vector

$$\begin{pmatrix} x \\ s \end{pmatrix}.$$

Normally, each nonbasic variable is equal to one of its bounds, and the basic variables take on whatever values are needed to satisfy the general constraints. (The basic variables may be computed by solving the linear equations $Bx_B = Nx_N$.) It can be shown that if an optimal solution to a linear program exists, then it has this form.

The simplex method reaches such a solution by performing a sequence of *iterations*, in which one column of B is replaced by one column of N (and vice versa), until no such interchange can be found that will reduce the value of $c^T x$.

As indicated nonbasic variables usually satisfy their upper and lower bounds. If any components of x_B lie significantly outside their bounds, we say that the current point is *infeasible*. In this case, the simplex method uses a Phase 1 procedure to reduce the sum of infeasibilities to zero. This is similar to the subsequent Phase 2 procedure that optimizes the true objective function $c^T x$.

If the solution procedures are interrupted, some of the nonbasic variables may lie strictly *between* their bounds $\ell_j < x_j < u_j$. In addition, at a "feasible" or "optimal" solution, some of the basic variables may lie slightly outside their bounds: $\ell_j - \delta < x_j < \ell_j$ or $u_j < x_j < u_j + \delta$ where δ is a *feasibility tolerance* (typically 10^{-6}). In rare cases, even nonbasic variables might lie outside their bounds by as much as δ .

GAMS/MINOS maintains a sparse *LU* factorization of the basis matrix B , using a Markowitz ordering scheme and Bartels-Golub updates, as implemented in the Fortran package LUSOL [111] (see [29] [30] [203] [204]). The basis factorization is central to the efficient handling of sparse linear and nonlinear constraints.

5.28.3.2 Problems with a Nonlinear Objective

When nonlinearities are confined to the term $F(x)$ in the objective function, the problem is a linearly constrained nonlinear program. GAMS/MINOS solves such problems using a *reduced-gradient* algorithm [263] combined with a *quasi-Newton* algorithm that is described in [190]. In the reduced-gradient method, the constraints $Ax + Is = 0$ are partitioned into the form

$$Bx_B + Sx_S + Nx_N = 0$$

where x_s is a set of *superbasic variables*. At a solution, the basic and superbasic variables will lie somewhere between their bounds (to within the feasibility tolerance δ , while nonbasic variables will normally be equal to one of their bounds, as before. Let the number of superbasic variables be s , the number of columns in S . (The context will always distinguish s from the vector of slack variables.) At a solution, s will be no more than n_1 , the number of nonlinear variables. In many practical cases we have found that s remains reasonably small, say 200 or less, even if n_1 is large.

In the reduced-gradient algorithm, x_s is regarded as a set of "independent variables" or "free variables" that are allowed to move in any desirable direction, namely one that will improve the value of the objective function (or reduce the sum of infeasibilities). The basic variables can then be adjusted in order to continue satisfying the linear constraints.

If it appears that no improvement can be made with the current definition of B , S and N , some of the nonbasic variables are selected to be added to S , and the process is repeated with an increased value of s . At all stages, if a basic or superbasic variable encounters one of its bounds, the variable is made nonbasic and the value of s is reduced by one.

A step of the reduced-gradient method is called a *minor iteration*. For linear problems, we may interpret the simplex method as being the same as the reduced-gradient method, with the number of superbasic variable oscillating between 0 and 1.

A certain matrix Z is needed now for descriptive purposes. It takes the form

$$\begin{pmatrix} -B^{-1}S \\ I \\ 0 \end{pmatrix}$$

though it is never computed explicitly. Given an LU factorization of the basis matrix B , it is possible to compute products of the form Zq and Z^Tg by solving linear equations involving B or B^T . This in turn allows optimization to be performed on the superbasic variables, while the basic variables are adjusted to satisfy the general linear constraints.

An important feature of GAMS/MINOS is a stable implementation of a quasi-Newton algorithm for optimizing the superbasic variables. This can achieve superlinear convergence during any sequence of iterations for which the B , S , N partition remains constant. A *search direction* q for the superbasic variables is obtained by solving a system of the form

$$R^T Rq = -Z^T g$$

where g is a gradient of $F(x)$, Z^Tg is the *reduced gradient*, and R is a dense upper triangular matrix. GAMS computes the gradient vector g analytically, using automatic differentiation. The matrix R is updated in various ways in order to approximate the *reduced Hessian* according to $R^T R \approx Z^T H Z$ where H is the matrix of second derivatives of $F(x)$ (the *Hessian*).

Once q is available, the search direction for all variables is defined by $p = Zq$. A *line search* is then performed to find an approximate solution to the one-dimensional (w.r.t. α) problem

$$\begin{aligned} & \text{minimize } F(x + \alpha p) \\ & \text{subject to } 0 < \alpha < \beta \end{aligned}$$

where β is determined by the bounds on the variables. Another important piece in GAMS/MINOS is a step-length procedure used in the linesearch to determine the step-length α (see [109]). The number of nonlinear function evaluations required may be influenced by setting the **Linesearch tolerance**, as discussed in Section [Detailed Description of MINOS Options](#).

As in a linear programming solver, an equation $B^T \pi = gB$ is solved to obtain the *dual variables* or *shadow prices* π where gB is the gradient of the objective function associated with basic variables. It follows that $gB - B^T \pi = 0$. The analogous quantity for superbasic variables is the reduced-gradient vector $Z^T g = gs - s^T \pi$; this should also be zero at an optimal solution. (In practice its components will be of order $r \|\pi\|$ where r is the optimality tolerance, typically 10^{-6} , and $\|\pi\|$ is a measure of the size of the elements of π .)

5.28.3.3 Problems with Nonlinear Constraints

If any of the constraints are nonlinear, GAMS/MINOS employs a *project Lagrangian* algorithm, based on a method due to [206], see [191]. This involves a sequence of *major iterations*, each of which requires the solution of a *linearly constrained subproblem*. Each subproblem contains linearized versions of the nonlinear constraints, as well as the original linear constraints and bounds.

At the start of the k^{th} major iteration, let x_k be an estimate of the nonlinear variables, and let λ_k be an estimate of the Lagrange multipliers (or dual variables) associated with the nonlinear constraints. The constraints are linearized by changing $f(x)$ in equation (2) to its linear approximation:

$$f'(x, x_k) = f(x_k) + J(x_k)(x - x_k)$$

or more briefly

$$f' = f_k + J_k(x - x_k)$$

where $J(x_k)$ is the *Jacobian matrix* evaluated at x_k . (The i -th row of the Jacobian is the gradient vector of the i -th nonlinear constraint function. As with the objective gradient, GAMS calculates the Jacobian using automatic differentiation).

The subproblem to be solved during the k -th major iteration is then

$$\text{minimize } F(x) + c^T x + d^T y - \lambda_k^T (f - f') + 0.5\rho(f - f')^T (f - f') \quad (5)$$

$$\text{subject to } f' + A_1 y \sim b_1 \quad (6)$$

$$A_2 x + A_3 y \sim b_2 \quad (7)$$

$$\ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u \quad (8)$$

The objective function (5) is called an *augmented Lagrangian*. The scalar ρ is a *penalty parameter*, and the term involving ρ is a modified *quadratic penalty function*.

GAMS/MINOS uses the reduced-gradient algorithm to minimize (5) subject to (6) – (8). As before, slack variables are introduced and b_1 and b_2 are incorporated into the bounds on the slacks. The linearized constraints take the form

$$\begin{pmatrix} J_k & A_1 \\ A_2 & A_3 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \begin{pmatrix} J_k x_k - f_k \\ 0 \end{pmatrix}$$

This system will be referred to as $Ax + Is = 0$ as in the linear case. The Jacobian J_k is treated as a sparse matrix, the same as the matrices A_1 , A_2 , and A_3 .

In the output from GAMS/MINOS, the term *Feasible subproblem* indicates that the *linearized constraints* have been satisfied. In general, the nonlinear constraints are satisfied only in the limit, so that *feasibility* and *optimality* occur at essentially the same time. The nonlinear constraint violation is printed every major iteration. Even if it is zero early on (say at the initial point), it may increase and perhaps fluctuate before tending to zero. On "well behaved problems", the constraint violation will decrease quadratically (i.e., very quickly) during the final few major iterations.

5.28.4 Modeling Issues

Formulating nonlinear models requires that the modeler pays attention to some details that play no role when dealing with linear models.

5.28.4.1 Starting Points

The first issue is specifying a *starting point*. It is advised to specify a good starting point for as many nonlinear variables as possible. The GAMS default of zero is often a very poor choice, making this even more important.

As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points (x_i, y_i) :

$$\begin{array}{ll} \text{Example :} & \text{minimize } r \\ & \text{subject to } (x_i - a)^2 + (y_i - b)^2 \leq r^2, \quad r \geq 0. \end{array}$$

This problem can be modeled in GAMS as follows.

```

set i 'points' /p1*p10/;

parameters
    x(i)    'x coordinates',
    y(i)    'y coordinates';

* fill with random data
x(i) = uniform(1,10);
y(i) = uniform(1,10);

variables
    a      'x coordinate of center of circle'
    b      'y coordinate of center of circle'
    r      'radius';

equations
    e(i)   'points must be inside circle';

e(i).. sqr(x(i)-a) + sqr(y(i)-b) =l= sqr(r);

r.lo = 0;

model m /all/;
option nlp=minos;
solve m using nlp minimizing r;
```

Without help, MINOS will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

$$\begin{aligned} x_{\min} &= \min_i x_i, \\ y_{\min} &= \min_i y_i, \\ x_{\max} &= \max_i x_i, \\ y_{\max} &= \max_i y_i, \end{aligned}$$

then good estimates are

$$\begin{aligned} a &= (x_{\min} + x_{\max})/2, \\ b &= (y_{\min} + y_{\max})/2, \\ r &= \sqrt{(a - x_{\min})^2 + (b - y_{\min})^2}. \end{aligned}$$

Thus we include in our model:

```
parameters xmin,ymin,xmax,ymax;
xmin = smin(i, x(i));
ymin = smin(i, y(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin+xmax)/2;
b.l = (ymin+ymax)/2;
r.l = sqrt( sqr(a.l-xmin) + sqr(b.l-ymin) );
```

and now the model solves very easily.

Level values can also be set away from zero implicitly as a result of assigning bounds. When a variable is bounded away from zero, for instance by the statement `Y.LO = 1;`, the implicit projection of variable levels onto their bounds that occurs when a model is solved will initialize `Y` away from zero.

5.28.4.2 Bounds

Setting appropriate bounds can be very important to steer the algorithm away from uninteresting areas, and to prevent *function evaluation errors* from happening.

If your model contains a real power of the form `x**y` it is important to add a bound $x > 0.001$, as real exponentiation is evaluated in GAMS as $\exp(y \log(x))$. In some cases one cannot write a bound directly, e.g. if the equation is $z = x^{f(y)}$. In that case it is advised to introduce an extra variable and equation:

$$\begin{aligned} z &= x^{\vartheta} \\ \vartheta &= f(y) \\ \vartheta &\geq \varepsilon \end{aligned}$$

(Note that the functions `SQR(x)` and `POWER(x,k)` are integer powers and do not require x to be positive).

If the model produces *function evaluation errors* adding bounds is preferred to raising the `DOMLIM` limit.

Bounds in GAMS are specified using `X.LO(i)=0.001` and `X.UP(i) = 1000`.

5.28.4.3 Scaling

Although MINOS has some facilities to scale the problem before starting to optimize it, it remains an important task for the modeler to provide a well-scaled model. This is especially the case for nonlinear models. GAMS has special syntax features to specify row and column scales that allow the modeler to keep the equations in a most natural form. For more information consult the GAMS User's Guide.

5.28.4.4 The Objective Function

The first step GAMS/MINOS performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. MINOS however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```
obj.. z =e= sum(i, sqr(resid(i)));

model m /all/;
solve m using nlp minimizing z;
```

This can be cast in form NLP (equations (1) – (4)) by saying minimize z subject to $z = \sum_i resid_i^2$ and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize $\sum_i resid_i^2$ directly. This can be achieved by a simple reformulation: z can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable z is a free continuous variable (no bounds are defined on z),
- z appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- z is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by MINOS. For instance the model [CHEM] from the model library solves in 21 iterations. When we add the bound

```
energy.lo = 0;
```

to the objective variable `energy` and thus prevent it from being substituted out, MINOS will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```
Variables x,y,z;
Equations e1,e2;

e1..z =e= y;
e2..y =e= sqr(1+x);

model m /all/;

option nlp=minos;
solve m using nlp minimizing z;
```

will be reformulated as an *unconstrained* optimization problem

$$\text{minimize } f(x) = (1 + x)^2.$$

These additional reformulations can be turned off by using the statement `option reform = 0;` (see Section [GAMS Options](#)).

5.28.5 GAMS Options

The standard GAMS options (e.g. [iterlim](#), [domlim](#)) can be used to control GAMS/MINOS. For more details, see section [Controlling a Solver via GAMS Options](#). We highlight some of the details of this usage below for cases of special interest.

iterlim

Sets the *minor* iteration limit. MINOS will stop as soon as the number of *minor iterations* exceeds the iteration limit and report the current solution.

domlim

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate \sqrt{x} for $x < 0$. Other examples include taking logs of negative numbers, and evaluating the real power x^y for $x < \varepsilon$ (x^y is evaluated as $\exp(y \log x)$). When such an error occurs the count of domain errors is incremented: MINOS will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and MINOS continues. For example, in the case of $\sqrt{x}, x < 0$ a zero is passed back for the function value and a large value for the derivative. In many cases MINOS will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don't occur. For example, when an expression $\log(x)$ is present in the model, add a statement like `x.lo = 0.001;`.

bratio

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to MINOS so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead *crash* a new basis. The `bratio` determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.

workfactor

By default, GAMS/MINOS computes an estimate of the amount of workspace needed by MINOS, and passes this workspace on to MINOS for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeros, etc. In most cases this is sufficient to solve the model. In some rare cases MINOS may need more memory, and the user can provide this by specifying a value of `workfactor` greater than 1. The computed memory estimate is multiplied by the `workfactor` to determine the amount of workspace made available to MINOS for the solve.

workspace

The `workspace` option is *deprecated*: use the `workfactor` option instead. The `workspace` option specifies the amount of memory, in MB, that MINOS will use.

reform

This option controls the objective reformulation mechanism described in Section [The Objective Function](#). The default value of 100 will cause GAMS/MINOS to try further substitutions along the diagonal after the objective variable has been removed. Any other value will disable this diagonal procedure.

5.28.6 Summary of MINOS Options

The performance of GAMS/MINOS is controlled by a number of parameters or "options." Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-standard values for some or all of the options through the MINOS option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section [The Solver Options File](#).

Note that the option file is not case sensitive. Examples for using the option file can be found at the end of this section. The tables below contain summary information about the MINOS options, default values, and links to more detailed explanations.

5.28.6.1 Output related options

Option	Description	Default
debug level	Controls amount of debug information written	0
log frequency	Controls iteration logging to listing file	100
print level	Controls amount of information printed during optimization	0
scale print	Print scaling factors	
solution	Prints MINOS solution	NO
summary frequency	Controls iteration logging to summary (log file)	100

5.28.6.2 Tolerances

Option	Description	Default
crash tolerance	Allow crash procedure to ignore small elements in eligible columns	0.1
feasibility tolerance	Feasibility tolerance for linear constraints	1.0e-6
linesearch tolerance	Controls accuracy of steplength selected	0.1
LU density tolerance	When to use dense factorization	0.5
LU factor tolerance	Trade-off between stability and sparsity in basis factorization	100.0
LU singularity tolerance	Protection against ill-conditioned basis matrices	1.0e-11
LU update tolerance	Trade-off between stability and sparsity in basis updating	10.0
optimality tolerance	Reduced gradient optimality check	1.0e-6
row tolerance	Accuracy requirement for nonlinear rows	1.0e-6
scale print tolerance	Scale print flag and set tolerance	0.9
scale tolerance	Scale tolerance	0.9
subspace tolerance	Determines when nonbasics becomes superbasic	0.5

5.28.6.3 Limits

Option	Description	Default
hessian dimension	Size of Hessian matrix	1
iterations limit	Minor iteration limit	GAMS iterlim
major iterations	Max number of major iterations	50
minor iterations	Max number of minor iterations between linearizations of nonlinear constraints	40
superbasics limit	Maximum number of superbasics	1
unbounded objective value	Determines when a problem is called unbounded	1.0e20
unbounded step size	Determines when a problem is called unbounded	1.0e10

5.28.6.4 Other algorithmic options

Option	Description	Default
check frequency	Controls frequency of linear constraint satisfaction test	60
completion	Completion level for subproblems (full/partial)	FULL
crash option	Controls the basis crash algorithm	3
expand frequency	Setting for anti-cycling mechanism	10000
factorization frequency	Number of iterations between basis factorizations	100
lagrangian	Determines form of objection function in the linearized subproblems	YES
LU complete pivoting	LUSOL pivoting strategy	
LU partial pivoting	LUSOL pivoting strategy	
LU rook pivoting	LUSOL pivoting strategy	
major damping parameter	Prevents large relative changes between subproblem solutions	2.0
minor damping parameter	Limit change in x during linesearch	2.0
multiple price	Multiple pricing	1
partial price	Number of segments in partial pricing strategy	10
penalty parameter	Used in modified augmented Lagrangian	automatic
radius of convergence	controls final reduction of penalty parameter	0.01
scale all variables	Synonym to scale option 2	
scale linear variables	Synonym to scale option 1	
scale no	Synonym to scale option 0	
scale nonlinear variables	Synonym to scale option 2	
scale option	Scaling	1
scale yes	Synonym to scale option 1	
start assigned nonlinears	Starting strategy when there is no basis	SUPERBASIC

Option	Description	Default
verify constraint gradients	Synonym to verify level 2	
verify gradients	Synonym to verify level 3	
verify level	Controls verification of gradients	0
verify no	Synonym to verify level 0	
verify objective gradients	Synonym to verify level 1	
verify yes	Synonym to verify level 3	
weight on linear objective	Composite objective weight	0.0

5.28.6.5 Examples of GAMS/MINOS Option File

The following example illustrates the use of certain options that might be helpful for "difficult" models involving nonlinear constraints. Experimentation may be necessary with the values specified, particularly if the sequence of major iterations does not converge using default values.

```
* These options might be relevant for very nonlinear models.
Major damping parameter 0.2 * may prevent divergence.
Minor damping parameter 0.2 * if there are singularities
                          * in the nonlinear functions.
Penalty parameter        10.0 * or 100.0 perhaps-a value
                          * higher than the default.
Scale linear variables   * (This is the default.)
```

Conversely, nonlinearly constrained models that are very nearly linear may optimize more efficiently if some of the cautious defaults are relaxed:

```
* Suggestions for models with MILDLY nonlinear constraints
Completion Full
Penalty parameter        0.0 * or 0.1 perhaps-a value
                          * smaller than the default.
                          * Scale one of the following
Scale all variables      * if starting point is VERY GOOD.
Scale linear variables   * if they need it.
Scale No                 * otherwise.
```

Most of the options should be left at their default values for any given model. If experimentation is necessary, we recommend changing just one option at a time.

5.28.7 Special Notes

5.28.7.1 Modeling Hints

Unfortunately, there is no guarantee that the algorithm just described will converge from an arbitrary starting point. The concerned modeler can influence the likelihood of convergence as follows:

- Specify initial activity levels for the nonlinear variables as carefully as possible (using the GAMS suffix .L).
- Include sensible upper and lower bounds on all variables.
- Specify a *Major damping parameter* that is lower than the default value, if the problem is suspected of being highly nonlinear
- Specify a *Penalty parameter* ρ that is higher than the default value, again if the problem is highly nonlinear.

In rare cases it may be safe to request the values $\lambda_k = 0$ and $\rho = 0$ for all subproblems, by specifying *Lagrangian=No*. However, convergence is much more likely with the default setting, *Lagrangian=Yes*. The initial estimate of the Lagrange multipliers is then $\lambda_0 = 0$, but for later subproblems λ_k is taken to be the Lagrange multipliers associated with the (linearized) nonlinear constraints at the end of the previous major iteration.

For the first subproblem, the default value for the penalty parameter is $\rho = 100.0/m_1$ where m_1 is the number of nonlinear constraints. For later subproblems, ρ is reduced in stages when it appears that the sequence $\{x_k, \lambda_k\}$ is converging. In many cases it is safe to specify $\lambda = 0$, particularly if the problem is only mildly nonlinear. This may improve the overall efficiency.

5.28.7.2 Storage

GAMS/MINOS uses one large array of memory for most of its workspace. The implementation places no fixed limit on the size of a problem or on its shape (many constraints and relatively few variables, or *vice versa*). In general, the limiting factor will be the amount of physical memory available on a particular machine, and the amount of computation time one is willing to spend.

Some detailed knowledge of a particular model will usually indicate whether the solution procedure is likely to be efficient. An important quantity is m , the total number of general constraints in (2) and (3). The amount of workspace required by GAMS/MINOS is roughly $100m$ doubles, or $800m$ bytes for workspace. A further 300K bytes, approximately, are needed for the program itself, along with buffer space for several files. Very roughly, then, a model with m general constraints requires about $(m + 300)$ K bytes of memory.

Another important quantity is n , the total number of variables in x and y . The above comments assume that n is not much larger than m , the number of constraints. A typical ratio for n/m is 2 or 3.

If there are many nonlinear variables (i.e., if n_1 is large), much depends on whether the objective function or the constraints are highly nonlinear or not. The degree of nonlinearity affects s , the number of superbasic variables. Recall that s is zero for purely linear problems. We know that s need never be larger than $n_1 + 1$. In practice, s is often very much less than this upper limit.

In the quasi-Newton algorithm, the dense triangular matrix R has dimension s and requires about $s^2/2$ words of storage. If it seems likely that s will be very large, some aggregation or reformulation of the problem should be considered.

5.28.8 The GAMS/MINOS Log File

MINOS writes different logs for LPs, NLPs with linear constraints, and NLPs with non-linear constraints. In this section, a sample log file is shown for each case, and the messages that appear are explained.

5.28.8.1 Linear Programs

MINOS uses a standard two-phase simplex method for LPs. In the first phase, the sum of the infeasibilities at each iteration is minimized. Once feasibility is attained, MINOS switches to phase 2 where it minimizes (or maximizes) the original objective function. The different objective functions are called the phase 1 and phase 2 objectives. Notice that the marginals in phase 1 are with respect to the phase 1 objective. This means that if MINOS interrupts in phase 1, the marginals are "wrong" in the sense that they do not reflect the original objective.

The log for the problem **TURKPOW** is as follows:

The first line that is written by MINOS is the version string: **GAMS/MINOS Aug 18, 2010 23.5.2 WIN 19143.19383 VS8 x86/MS Windows** This line identifies which version of the MINOS libraries and links you are using, and is only to be deciphered by GAMS support personnel.

After some advertisement text we see the amount of work space (i.e. memory) that is allocated: *1.60 Mb*. When MINOS is loaded, the amount of memory needed is first estimated. This estimate is based on

statistics like the number of rows, columns and non-zeros. This amount of memory is then allocated and the problem loaded into MINOS.

The columns have the following meaning:

Itn

Iteration number.

ninf

Number of infeasibilities. If nonzero the current iterate is still infeasible.

sinf

The sum of the infeasibilities. This number is minimized during Phase I. Once the model is feasible this number is zero.

objective

The value of the objective function: $z = \sum c_i x_i$. In phase II this number is maximized or minimized. In phase I it may move in the wrong direction.

The final line indicates the exit status of MINOS.

5.28.8.2 Linearly Constrained NLP's

The log is basically the same as for linear models. The only difference is that not only matrix rows and columns need to be loaded, but also instructions for evaluating functions and gradients.

The log for the problem **WEAPONS** is as follows:

```

5.28.8.3 NLP's with Nonlinear Constraints

For models with nonlinear constraints the log is more complicated. The library model [CAMCGE] from the model library is such an example: the log output resulting from running it is shown below.

Two sets of iterations, *major* and *minor*, are now reported. A description of the various columns present in this log file follows:

Major

A major iteration involves linearizing the nonlinear constraints and performing a number of minor iterations on the resulting subproblem. The objective for the subproblem is an augmented Lagrangian, not the true objective function.

minor

The number of minor iterations performed on the linearized subproblem. If it is a simple number like 90, then the subproblem was solved to optimality. Here, $2T$ means that the subproblem was terminated. In general the T is not something to worry about. Other possible flags are I and U , which mean that the subproblem was infeasible or unbounded. MINOS may have difficulty if these keep occurring.

step

The step size taken towards the solution suggested by the last major iteration. Ideally this should be 1.0, especially near an optimum. If the subproblem solutions are widely different, MINOS may reduce the step size under control of the *Major Damping parameter*.

objective

The objective function for the original nonlinear program.

Feasible

Primal infeasibility, indicating the maximum non-linear constraint violation.

Optimal

The maximum dual infeasibility, measured as the maximum departure from complementarity. If we call d_j the reduced cost of variable x_j , then the dual infeasibility of x_j is $d_j \times \min\{x_j - \ell_j, 1\}$ or $-d_j \times \min\{u_j - x_j, 1\}$ depending on the sign of d_j .

nsb

Number of superbasics. If the model is feasible this number cannot exceed the superbasic limit, which may need to be reset to a larger number if the numbers in this column become larger.

ncon

The number of times MINOS has evaluated the nonlinear constraints and their derivatives.

penalty

The current value of the penalty parameter in the augmented Lagrangian (the objective for the subproblems). If the major iterations appear to be converging, MINOS will decrease the penalty parameter. If there appears to be difficulty, such as unbounded subproblems, the penalty parameter will be increased.

BSswp

Number of basis swaps: the number of ($B \ S$) (i.e. basic vs. superbasic) changes.

Note: The **CAMCGE** model (like many CGE models or other almost square systems) can better be solved with the MINOS option *Start Assigned Nonlinears Basic*.

5.28.9 Detailed Description of MINOS Options

The following is an alphabetical list of the keywords that may appear in the GAMS/MINOS options file, and a description of their effect. Options not specified will take the default values shown.

check frequency (*integer*): Controls frequency of linear constraint satisfaction test \leftrightarrow

Every i^{th} iteration after the most recent basis factorization, a numerical test is made to see if the current solution x satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax+s = 0$ where s is the set of slack variables. To perform the numerical test, the residual vector $r = Ax + s$ is computed. If the largest component of r is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Range: $\{1, \dots, \infty\}$

Default: 60

completion (*string*): Completion level for subproblems (full/partial) \leftrightarrow

When there are nonlinear constraints, this determines whether subproblems should be solved to moderate accuracy (partial completion) or to full accuracy (full completion). GAMS/MINOS implements the option by using two sets of convergence tolerances for the subproblems.

Use of partial completion may reduce the work during early major iterations, unless the Minor iterations limit is active. The optimal set of basic and superbasic variables will probably be determined for any given subproblem, but the reduced gradient may be larger than it would have been with full completion. An automatic switch to full completion occurs when it appears that the sequence of major iterations is converging. The switch is made when the nonlinear constraint error is reduced below $100 * (\text{Row tolerance})$, the relative change in Lambda_k is 0.1 or less, and the previous subproblem was solved to optimality. Full completion tends to give better Langrange-multiplier estimates. It may lead to fewer major iterations, but may result in more minor iterations.

Default: FULL

value	meaning
FULL	Solve subproblems to full accuracy
PARTIAL	Solve subproblems to moderate accuracy

crash option (*integer*): Controls the basis crash algorithm \leftrightarrow

If a restart is not being performed, an initial basis will be selected from certain columns of the constraint matrix ($A \ I$). The value of the parameter i determines which columns of A are eligible. Columns of I are used to fill gaps where necessary. If $i > 0$, three passes are made through the relevant columns of A , searching for a basis matrix that is essentially triangular. A column is assigned to pivot on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis). Pass 1 selects pivots from free columns (corresponding to variables with no upper and lower bounds). Pass 2 requires pivots to be in rows associated with equality (=E=) constraints. Pass 3 allows the pivots to be in inequality rows. For remaining (unassigned) rows, the associated slack variables are inserted to complete the basis.

Default: 3

value	meaning
0	Initial basis will be a slack basis

value	meaning
1	All columns are eligible
2	Only linear columns are eligible
3	Columns appearing nonlinearly in the objective are not eligible
4	Columns appearing nonlinearly in the constraints are not eligible

crash tolerance (*real*): Allow crash procedure to ignore small elements in eligible columns \leftrightarrow

The *Crash tolerance* r allows the starting procedure *CRASH* to ignore certain small nonzeros in each column of A . If a_{max} is the largest element in column j , other nonzeros a_{ij} in the column are ignored if $|a_{ij}| < a_{max} * r$. To be meaningful, the parameter r should be in the range $0 \leq r < 1$. When $r > 0.0$ the basis obtained by *CRASH* may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of A and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems. For example, suppose the first m columns of A are the matrix shown under LU factor tolerance; i.e., a tridiagonal matrix with entries -1, 4, -1. To help *CRASH* choose all m columns for the initial basis, we could specify *Crash tolerance* r for some value of $r > 0.25$.

Range: [0, 1.0]

Default: 0.1

debug level (*integer*): Controls amount of debug information written \leftrightarrow

This causes various amounts of information to be output. Most debug levels will not be helpful to GAMS users, but they are listed here for completeness. Note that you will need to use the GAMS statement `OPTION SYSOUT=on;` to echo the MINOS listing to the GAMS listing file.

- **debug level 0**
No debug output.
- **debug level 2**(or more)
Output from *M5SETX* showing the maximum residual after a row check.
- **debug level 40**
Output from *LU8RPC* (which updates the LU factors of the basis matrix), showing the position of the last nonzero in the transformed incoming column.
- **debug level 50**
Output from *LU1MAR* (which updates the LU factors each refactorization), showing each pivot row and column and the dimensions of the dense matrix involved in the associated elimination.
- **debug level 100**
Output from *M2BFAC* and *M5LOG* listing the basic and superbasic variables and their values at every iteration.

Default: 0

expand frequency (*integer*): Setting for anti-cycling mechanism \leftrightarrow

This option is part of an anti-cycling procedure designed to guarantee progress even on highly degenerate problems. For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose the specified feasibility tolerance is δ and the expand frequency is k . Over a period of k iterations, the tolerance actually used by GAMS/MINOS increases from $0.5*\delta$ to δ (in steps $0.5*\delta/k$). For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is

at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced. At least every k iterations, a resetting procedure eliminates any infeasible nonbasic variables. Increasing k helps to reduce the number of these slightly infeasible nonbasic variables. However, it also diminishes the freedom to choose a large pivot element (see Pivot tolerance).

Range: $\{1, \dots, \infty\}$

Default: 10000

factorization frequency (*integer*): Number of iterations between basis factorizations \leftrightarrow

At most i basis updates will occur between factorizations of the basis matrix. With linear programs, basis updates usually occur at every iteration. The default i is reasonable for typical problems. Higher values up to $i = 200$ (say) may be more efficient on problems that are extremely sparse and well scaled. When the objective function is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the Check frequency) to ensure that the general constraints are satisfied. If necessary the basis will be re-factorized before the limit of i updates is reached. When the constraints are nonlinear, the Minor iterations limit will probably preempt i .

Range: $\{1, \dots, \infty\}$

Default: 100

feasibility tolerance (*real*): Feasibility tolerance for linear constraints \leftrightarrow

When the constraints are linear, a feasible solution is one in which all variables, including slacks, satisfy their upper and lower bounds to within the absolute tolerance r . (Since slacks are included, this means that the general linear constraints are also satisfied within r .) GAMS/MINOS attempts to find a feasible solution before optimizing the objective function. If the sum of infeasibilities cannot be reduced to zero, the problem is declared infeasible. Let $SINF$ be the corresponding sum of infeasibilities. If $SINF$ is quite small, it may be appropriate to raise r by a factor of 10 or 100. Otherwise, some error in the data should be suspected. If $SINF$ is not small, there may be other points that have a significantly smaller sum of infeasibilities. GAMS/MINOS does not attempt to find a solution that minimizes the sum. If *Scale option* = 1 or 2, feasibility is defined in terms of the scaled problem (since it is then more likely to be meaningful). A nonlinear objective function $F(x)$ will be evaluated only at feasible points. If there are regions where $F(x)$ is undefined, every attempt should be made to eliminate these regions from the problem. For example, for a function $F(x) = \text{sqrt}(x_1) + \log(x_2)$, it should be essential to place lower bounds on both variables. If *Feasibility tolerance* = 10^{-6} , the bounds $x_1 > 10^{-5}$ and $x_2 > 10^{-4}$ might be appropriate. (The log singularity is more serious; in general, keep variables as far away from singularities as possible.) If the constraints are nonlinear, the above comments apply to each major iteration. A feasible solution satisfies the current linearization of the constraints to within the tolerance r . The associated subproblem is said to be feasible. As for the objective function, bounds should be used to keep x more than r away from singularities in the constraint functions $f(x)$. At the start of major iteration k , the constraint functions $f(x_k)$ are evaluated at a certain point x_k . This point always satisfies the relevant bounds ($l < x_k < u$), but may not satisfy the general linear constraints. During the associated minor iterations, $F(x)$ and $f(x)$ will be evaluated only at points x that satisfy the bound and the general linear constraints (as well as the linearized nonlinear constraints). If a subproblem is infeasible, the bounds on the linearized constraints are relaxed temporarily, in several stages. Feasibility with respect to the nonlinear constraints themselves is measured against the Row tolerance (not against r). The relevant test is made at the start of a major iteration.

Default: 1.0e-6

hessian dimension (*integer*): Size of Hessian matrix ↔

This specifies that an $r \times r$ triangular matrix R is to be available for use by the quasi-Newton algorithm. The matrix R approximates the reduced Hessian in that $R^T R$ approximates $Z^T H Z$. Suppose there are s superbasic variables at a particular iteration. Whenever possible, r should be greater than s . If $r > s$, the first s columns of R will be used to approximate the reduced Hessian in the normal manner. If there are no further changes to the set of superbasic variables, the rate of convergence will ultimately be superlinear. If $r < s$, a matrix of the form

$$R = \text{diag}(R_r, D)$$

will be used to approximate the reduced Hessian, where R_r is an $r \times r$ upper triangular matrix and D is a diagonal matrix of order $s - r$. The rate of convergence will no longer be superlinear (and may be arbitrarily slow). The storage required is of the order $sqr(r)/2$, i.e. quadratic in r . In general, r should be a slight over-estimate of the final number of superbasic variables, whenever storage permits. It need never be larger than $n_1 + 1$, where n_1 is the number of nonlinear variables. For many problems it can be much smaller than n_1 . If *Superbasics limit* s is specified, the default value of r is the same number, s (and conversely). This is a safeguard to ensure super-linear convergence wherever possible. If neither r nor s is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: {1, ..., ∞ }

Default: 1

iterations limit (*integer*): Minor iteration limit ↔

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the reduced-gradient method). This option, if set, overrides the GAMS *ITERLIM* specification. If $i = 0$, no minor iterations are performed, but the starting point is tested for both feasibility and optimality.

Default: GAMS `iterlim`

lagrangian (*string*): Determines form of objection function in the linearized subproblems ↔

This determines the form of the objective function used for the linearized subproblems. The default value *yes* is highly recommended. The *Penalty parameter* value is then also relevant. If *No* is specified, the nonlinear constraint functions will be evaluated only twice per major iteration. Hence this option may be useful if the nonlinear constraints are very expensive to evaluate. However, in general there is a great risk that convergence may not occur.

Default: YES

value	meaning
NO	Nondefault value (not recommended)
YES	Default value (recommended)

linesearch tolerance (*real*): Controls accuracy of steplength selected ↔

For nonlinear problems, this controls the accuracy with which a steplength $alpha$ is located in the one-dimensional problem

$$\begin{aligned} &\text{minimize } F(x+alpha*p) \\ &\text{subject to } 0 < alpha \leq beta \end{aligned}$$

A linesearch occurs on most minor iterations for which x is feasible. (If the constraints are nonlinear, the function being minimized is the augmented Lagrangian.) r must be a real value in the range $0.0 < r < 1.0$. The default value $r = 0.1$ requests a moderately accurate search. It should be satisfactory in most cases. If the nonlinear functions are cheap to evaluate, a more accurate search may be appropriate: try $r = 0.01$ or $r = 0.001$. The number of iterations should decrease, and this will reduce total run time if there are many linear or nonlinear constraints. If the nonlinear function are expensive to evaluate, a less accurate search may be appropriate; try $r = 0.5$ or perhaps $r = 0.9$. (The number of iterations will probably increase but the total number of function evaluations may decrease enough to compensate.)

Range: $[0, 1.0]$

Default: 0.1

log frequency (*integer*): Controls iteration logging to listing file \leftrightarrow

In general, one line of the iteration log is printed every i^{th} minor iteration. A heading labels the printed items, which include the current iteration number, the number and sum of feasibilities (if any), the subproblem objective value (if feasible), and the number of evaluations of the nonlinear functions. A value such as $i = 10, 100$ or larger is suggested for those interested only in the final solution. *Log frequency 0* may be used as shorthand for *Log frequency 99999*. If *Print level* > 0 , the default value of i is 1. If *Print level* $= 0$, the default value of i is 100. If *Print level* $= 0$ and the constraints are nonlinear, the minor iteration log is not printed (and the *Log frequency* is ignored). Instead, one line is printed at the beginning of each major iteration.

Range: $\{1, \dots, \infty\}$

Default: 100

LU complete pivoting (*no value*): LUSOL pivoting strategy \leftrightarrow

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

LU density tolerance (*real*): When to use dense factorization \leftrightarrow

The density tolerance is used during LUSOL's basis factorization $B=LU$. Columns of L and rows of U are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds this tolerance, the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense LU procedure. Raising the tolerance towards 1.0 may give slightly sparser factors, with a slight increase in factorization time.

Range: $[0, 1.0]$

Default: 0.5

LU factor tolerance (*real*): Trade-off between stability and sparsity in basis factorization \leftrightarrow

This tolerance affects the stability and sparsity of the basis factorization $B = LU$ during factorization. The value r specified must satisfy $r \geq 1.0$.

- The default value $r = 100.0$ usually strikes a good compromise between stability and sparsity.

- For large and relatively dense problems, a larger value may give a useful improvement in sparsity without impairing stability to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to set r to a value smaller than the default in order to achieve stability.

Range: [1.0, ∞]

Default: 100.0

LU partial pivoting (*no value*): LUSOL pivoting strategy [↔](#)

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

LU rook pivoting (*no value*): LUSOL pivoting strategy [↔](#)

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

LU singularity tolerance (*real*): Protection against ill-conditioned basis matrices [↔](#)

When the basis is refactorized, the diagonal elements of U are tested as follows: if $|U_{jj}| \leq r$ or $|U_{jj}| < r * \max_i |U_{ii}|$, the j^{th} column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart, or at the start of a major iteration.) In some cases, the Jacobian matrix may converge to values that make the basis very ill-conditioned, causing the optimization to progress very slowly (if at all). Setting $r = 1.0^{-5}$, say, may help cause a judicious change of basis.

Default: 1.0e-11

LU update tolerance (*real*): Trade-off between stability and sparsity in basis updating [↔](#)

This tolerance affects the stability and sparsity of the basis factorization $B = LU$ during updates. The value r specified must satisfy $r \geq 1.0$.

- The default value $r = 10.0$ usually strikes a good compromise between stability and sparsity.
- For large and relatively dense problems, $r = 25.0$ (say) may give a useful improvement in sparsity without impairing stability to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to set r to a value smaller than the default in order to achieve stability.

Range: [1.0, ∞]

Default: 10.0

major damping parameter (*real*): Prevents large relative changes between subproblem solutions [↔](#)

The parameter may assist convergence on problems that have highly nonlinear constraints. It is intended to prevent large relative changes between subproblem solutions (x_k, λ_k) and (x_{k+1}, λ_{k+1}) . For example, the default value 2.0 prevents the relative change in either x_k or λ_k from exceeding 200 percent. It will not be active on well behaved problems. The parameter is used to interpolate between the solutions at the beginning and end of each major iteration. Thus x_{k+1} and λ_{k+1} are changed to $x_k + \sigma(x_{k+1} - x_k)$ and $\lambda_k + \sigma(\lambda_{k+1} - \lambda_k)$ for some step-length $\sigma < 1$. In the case of nonlinear equations (where the number of constraints is the same as the number of variables) this gives a damped Newton method. This is a very crude control. If the sequence of major iterations does not appear to be converging, one should first re-run the problem with a higher Penalty parameter (say 10 or 100 times the default ρ). (Skip this re-run in the case of nonlinear equations: there are no degrees of freedom and the value of ρ is irrelevant.) If the subproblem solutions continue to change violently, try reducing ρ to 0.2 or 0.1 (say). For implementation reasons, the shortened step to σ applies to the nonlinear variables x , but not to the linear variables y or the slack variables s . This may reduce the efficiency of the control.

Default: 2.0

major iterations (*integer*): Max number of major iterations \leftrightarrow

The maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the nonlinear constraints, since in some cases the sequence of major iterations may not converge. The progress of the major iterations can be best monitored using *Print level 0* (the default).

Default: 50

minor damping parameter (*real*): Limit change in x during linesearch \leftrightarrow

This parameter limits the change in x during a linesearch. It applies to all nonlinear problems, once a feasible solution or feasible subproblem has been found. A linesearch of the form

$$\text{minimize}_{\alpha} F(x + \alpha p)$$

is performed over the range $0 < \alpha \leq \beta$, where β is the step to the nearest upper or lower bound on x . Normally, the first step length tried is $\alpha_1 = \min(1, \beta)$. In some cases, such as $F(x) = ae^{bx}$ or $F(x) = ax^b$, even a moderate change in the components of x can lead to floating-point overflow. The parameter r is therefore used to define a limit

$$\beta_2 = r(1 + \|x\|)/\|p\|$$

and the first evaluation of $F(x)$ is at the potentially smaller steplength $\alpha_1 = \min(1, \beta, \beta_2)$. Wherever possible, upper and lower bounds on x should be used to prevent evaluation of nonlinear functions at meaningless points. The *Minor damping parameter* provides an additional safeguard. The default value $r = 2.0$ should not affect progress on well behaved problems, but setting $r = 0.1$ or 0.01 may be helpful when rapidly varying functions are present. A good starting point may be required. An important application is to the class of nonlinear least squares problems. In cases where several local optima exist, specifying a small value for r may help locate an optimum near the starting point.

Default: 2.0

minor iterations (*integer*): Max number of minor iterations between linearizations of nonlinear constraints \leftrightarrow

The the maximum number of feasible minor iterations allowed between successive linearizations of the nonlinear constraints. A moderate value (e.g., $20 \leq i \leq 50$) prevents excessive efforts being expended on early major iterations, but allows later subproblems to be solved to completion. The limit applies to both infeasible and feasible iterations. In some cases, a large number of iterations (say K) might be required to obtain a feasible subproblem. If good starting values are supplied for variables appearing nonlinearly in the constraints, it may be sensible to specify a limit $> K$, to allow the first major iteration to terminate at a feasible (and perhaps optimal) subproblem solution. If a good initial subproblem is arbitrarily interrupted by a small limit, the subsequent linearization may be less favorable than the first. In general it is unsafe to specify a value as small as $i = 1$ or 2 . Even when an optimal solution has been reached, a few minor iterations may be needed for the corresponding subproblem to be recognized as optimal. The *Iteration limit* provides an independent limit on the total minor iterations (across all subproblems). If the constraints are linear, only the *Iteration limit* applies: the minor iterations value is ignored.

Default: 40

multiple price (*integer*): Multiple pricing \leftarrow

Pricing refers to a scan of the current non-basic variables to determine which, if any, are eligible to become (super)basic. The multiple pricing parameter k controls the number of entering variables to choose: the k best non-basic variables are selected for admission to the set of (super)basic variables. The default $k = 1$ is best for linear programs, since an optimal solution will have zero superbasic variables. *Warning*: If $k > 1$, GAMS/MINOS will use the reduced-gradient method rather than the simplex method, even on purely linear problems. The subsequent iterations do not correspond to the efficient minor iterations carried out by commercial linear programming systems using multiple pricing. (In the latter systems, the classical simplex method is applied to a tableau involving k dense columns of dimension m , and k is therefore limited for storage reasons typically to the range $2 \leq k \leq 7$.) GAMS/MINOS varies all superbasic variables simultaneously. For linear problems its storage requirements are essentially independent of k . Larger values of k are therefore practical, but in general the iterations and time required when $k > 1$ are greater than when the simplex method is used ($k = 1$). On large nonlinear problems it may be important to set $k > 1$ if the starting point does not contain many superbasic variables. For example, if a problem has 3000 variables and 500 of them are nonlinear, the optimal solution may well have 200 variables superbasic. If the problem is solved in several runs, it may be beneficial to use $k = 10$ (say) for early runs, until it seems that the number of superbasics has leveled off. If *Multiple price* k is specified, it is also necessary to specify *Superbasic limit* s for some $s > k$.

Range: $\{1, \dots, \infty\}$

Default: 1

optimality tolerance (*real*): Reduced gradient optimality check \leftarrow

This is used to judge the size of the reduced gradients $d_j = g_j - p_i^T a_j$, where g_j is the gradient of the objective function corresponding to the j^{th} variable, a_j is the associated column of the constraint matrix (or Jacobian), and p_i is the set of dual variables. By construction, the reduced gradients for basic variables are always zero. Optimality will be declared if the reduced gradients for nonbasic variables at their lower or upper bounds satisfy $d_j/||p_i|| \geq -r$ or $d_j/||p_i|| \leq r$ respectively, and if $d_j/||p_i|| \leq r$ for superbasic variables. The $||p_i||$ is a measure of the size of the dual variables. It is included to make the tests independent of a scale factor on the objective function. The quantity actually used is defined by

$$\text{sigma} = \text{sum}(i, \text{abs}(p_i(i))), \quad ||p_i|| = \text{max}\{\text{sigma}/\text{sqrt}(m), 1\}$$

so that only large scale factors are compensated for. As the objective scale decreases, the optimality test tends to become an absolute (instead of a relative) test.

Default: 1.0e-6

partial price (*integer*): Number of segments in partial pricing strategy ↔

This parameter is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each pricing operation (when a nonbasic variable is selected to become basic or superbasic). When $i = 1$, all columns of the constraints matrix ($A \ I$) are searched. Otherwise, A_j and I are partitioned to give i roughly equal segments A_j, I_j ($j = 1$ to i). If the previous search was successful on A_{j-1}, I_{j-1} , the next search begins on the segments A_j, I_j . (All subscripts here are modulo i .) If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. (Several may be selected if multiple pricing has been specified.) If nothing is found, the search continues on the next segments A_{j+1}, I_{j+1} and so on. *Partial price* t (or $t/2$ or $t/3$) may be appropriate for time-stage models having t time periods

Range: $\{1, \dots, \infty\}$

Default: 10

penalty parameter (*real*): Used in modified augmented Lagrangian ↔

This specifies the value of ρ in the modified augmented Lagrangian. It is used only when *Lagrangian* = *yes* (the default setting). For early runs on a problem with unknown characteristics, the default value should be acceptable. If the problem is known to be highly nonlinear, specify a large value, such as 10 times the default. In general, a positive value of ρ may be necessary to ensure convergence, even for convex programs. On the other hand, if ρ is too large, the rate of convergence may be unnecessarily slow. If the functions are not highly nonlinear or a good starting point is known, it will often be safe to specify *penalty parameter* 0.0. When solving a sequence of related problems, initially, use a moderate value for ρ (such as the default) and a reasonably low *Iterations* and/or *major iterations limit*. If successive major iterations appear to be terminating with radically different solutions, the *penalty parameter* should be increased. (See also the *Major damping parameter*.) If there appears to be little progress between major iterations, it may help to reduce the *penalty parameter*.

Default: `automatic`

print level (*integer*): Controls amount of information printed during optimization ↔

This varies the amount of information that will be output during optimization. *Print level* 0 sets the default log and summary frequencies to 100. It is then easy to monitor the progress of the run. *Print level* 1 (or more) sets the default log and summary frequencies to 1, giving a line of output for every minor iteration. *Print level* 1 also produces basis statistics, i.e., information relating to LU factors of the basis matrix whenever the basis is re-factorized. For problems with nonlinear constraints, certain quantities are printed at the start of each major iteration. The option value is best thought of as a binary number of the form

Print level JFLXB

where each letter stands for a digit that is either 0 or 1. The quantities referred to are:

- **B** Basis statistics, as mentioned above
- **X** x_k , the nonlinear variables involved in the objective function or the constraints.
- **L** λ_k , the Lagrange-multiplier estimates for the nonlinear constraints. (Suppressed if *Lagrangian*=*No*, since then $\lambda_k = 0$.)
- **F** $f(x_k)$, the values of the nonlinear constraint functions.
- **J** $J(x_k)$, the Jacobian matrix.

To obtain output of any item, set the corresponding digit to 1, otherwise to 0. For example, *Print level 10* sets $X = 1$ and the other digits equal to zero; the nonlinear variables will be printed each major iteration. If $J = 1$, the Jacobian matrix will be output column-wise at the start of each major iteration. Column j will be preceded by the value of the corresponding variable x_j and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence if $J = 1$, there is no reason to specify $X = 1$ unless the objective contains more nonlinear variables than the Jacobian.) A typical line of output is

```
3 1.250000D+01 BS 1 1.00000D+00 4 2.00000D+00
```

which would mean that x_3 is basic at value 12.5, and the third column of the Jacobian has elements of 1.0 and 2.0 in rows 1 and 4. (Note: the GAMS/MINOS row numbers are usually different from the GAMS row numbers; see the Solution option.)

Default: 0

radius of convergence (*real*): controls final reduction of penalty parameter ↔

This determines when the penalty parameter ρ will be reduced, assuming ρ was initially positive. Both the nonlinear constraint violation (see *ROWERR* below) and the relative change in consecutive Lagrange multiplier estimates must be less than r at the start of a major iteration before ρ is reduced or set to zero. A few major iterations later, full completion will be requested if not already set, and the remaining sequence of major iterations should converge quadratically to an optimum.

Default: 0.01

row tolerance (*real*): Accuracy requirement for nonlinear rows ↔

This specifies how accurately the nonlinear constraints should be satisfied at a solution. The default value is usually small enough, since model data is often specified to about this accuracy. Let *ROWERR* be the maximum component of the residual vector $f(x) + A_1y - b_1$, normalized by the size of the solution. Thus

$$ROWERR = \|f(x) + A_1y - b_1\|_{inf} / (1 + XNORM)$$

where *XNORM* is a measure of the size of the current solution (x, y) . The solution is considered to be feasible if *ROWERR* $\leq r$. If the problem functions involve data that is known to be of low accuracy, a larger *Row tolerance* may be appropriate.

Default: 1.0e-6

scale all variables (*no value*): Synonym to scale option 2 ↔

scale linear variables (*no value*): Synonym to scale option 1 ↔

scale no (*no value*): Synonym to scale option 0 ↔

scale nonlinear variables (*no value*): Synonym to scale option 2 ↔

scale option (*integer*): Scaling ↔

Scale Yes sets the default. (*Caution*: If all variables are nonlinear, *Scale Yes* unexpectedly does nothing, because there are no linear variables to scale). *Scale No* suppresses scaling (equivalent to *Scale Option 0*). If nonlinear constraints are present, *Scale option 1* or *0* should generally be tried at first. *Scale option 2* gives scales that depend on the initial Jacobian, and should therefore be used only if (a) a good starting point is provided, and (b) the problem is not highly nonlinear.

Default: 1

value	meaning
0	No scaling If storage is at a premium, this option should be used.
1	Scale linear variables Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see [5]). This will sometimes improve the performance of the solution procedures. <i>Scale linear variables</i> is an equivalent option.
2	Scale linear + nonlinear variables All constraints and variables are scaled by the iterative procedure. Also, a certain additional scaling is performed that may be helpful if the right-hand side b or the solution x is large. This takes into account columns of $(A \ I)$ that are fixed or have positive lower bounds or negative upper bounds. <i>Scale nonlinear variables</i> or <i>Scale all variables</i> are equivalent options.

scale print (*no value*): Print scaling factors ↔

This causes the row-scales $r(i)$ and column-scales $c(j)$ to be printed. The scaled matrix coefficients are $\hat{a}_{ij} = a_{ij}c(j)/r(i)$. The scaled bounds on the variables and slacks are $l_j = l_j/c(j)$ and $\hat{u}_j = u_j/c(j)$, where $c(j) = r(j - n)$ if $j > n$. If a Scale option has not already been specified, *Scale print* sets the default scaling.

scale print tolerance (*real*): Scale print flag and set tolerance ↔

See *Scale Tolerance*. This option also turns on printing of the scale factors.

Range: [0, 1.0]

Default: 0.9

scale tolerance (*real*): Scale tolerance ↔

All forms except *Scale option* may specify a tolerance r where $0 < r < 1$ (for example: *Scale Print Tolerance = 0.99*). This affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$\rho_j = \max_i |a_{ij}| / \min_i |a_{ij}| \quad (a_{ij} \neq 0)$$

If $\max_j \rho_j$ is less than r times its previous value, another scaling pass is performed to adjust the row and column scales. Raising r from 0.9 to 0.99 (say) usually increases the number of scaling passes through A . At most 10 passes are made. If a *Scale option* has not already been specified, *Scale tolerance* sets the default scaling.

Range: [0, 1.0]

Default: 0.9

scale yes (*no value*): Synonym to scale option 1 ↔

solution (*string*): Prints MINOS solution ↔

This controls whether or not GAMS/MINOS prints the final solution obtained. There is one line of output for each constraint and variable. The lines are in the same order as in the GAMS solution, but the constraints and variables labeled with internal GAMS/MINOS numbers rather than GAMS names. (The numbers at the left of each line are GAMS/MINOS column numbers, and those at the right of each line in the rows section are GAMS/MINOS slacks.) The GAMS/MINOS solution may be useful occasionally to interpret certain messages that occur during the optimization, and to determine the final status of certain variables (basic, superbasic or nonbasic).

Default: NO

value	meaning
NO	Turn off printing of solution
YES	Turn on printing of solution

start assigned nonlinears (*string*): Starting strategy when there is no basis ↔

This option affects the starting strategy when there is no basis (i.e., for the first solve or when the GAMS statement *option bratio = 1* is used to reject an existing basis.) This option applies to all nonlinear variables that have been assigned nondefault initial values and are strictly between their bounds. Free variables at their default value of zero are excluded. Let K denote the number of such assigned nonlinear variables.

Default: SUPERBASIC

value	meaning
SUPERBASIC	Default Specify <i>superbasic</i> for highly nonlinear models, as long as K is not too large (say $K < 100$) and the initial values are good.
BASIC	Good for square systems Specify <i>basic</i> for models that are essentially square (i.e., if there are about as many general constraints as variables).
NONBASIC	Specify <i>nonbasic</i> if K is large.
ELIGIBLE FOR CRASH	Specify <i>Eligible for Crash</i> for linear or nearly linear models. The nonlinear variables will be treated in the manner described under <i>Crash</i> option.

subspace tolerance (*real*): Determines when nonbasics becomes superbasic ↔

This controls the extent to which optimization is confined to the current set of basic and superbasic variables (Phase 4 iterations), before one or more nonbasic variables are added to the superbasic set (Phase 3). The parameter r must be a real number in the range $0 < r \leq 1$. When a nonbasic variable x_j is made superbasic, the resulting norm of the reduced-gradient vector (for all superbasics) is recorded. Let this be $\|Z^T g_0\|$. (In fact, the norm will be $|d_j|$, the size of the reduced gradient for the new superbasic variable x_j . Subsequent Phase 4 iterations will continue at least until the norm of the reduced-gradient vector satisfies $\|Z^T g_0\| \leq r \|Z^T g_0\|$ is the size of the largest reduced-gradient component among the superbasic variables.) A smaller value of r is likely to increase the total number of iterations, but may reduce the number of basic changes. A larger value such as $r = 0.9$ may sometimes lead to improved overall efficiency, if the number of superbasic variables has to increase substantially between the starting point and an optimal solution. Other convergence tests on the change in the function being minimized and the change in the variables may prolong Phase 4 iterations. This helps to make the overall performance insensitive to larger values of r .

Range: [0, 1.0]

Default: 0.5

summary frequency (*integer*): Controls iteration logging to summary (log file) ↔

A brief form of the iteration log is output to the MINOS summary file (i.e. the GAMS log file). In general, one line is output every i^{th} minor iteration. In an interactive environment, the output normally appears at the terminal and allows a run to be monitored. If something looks wrong, the run can be manually terminated. The summary frequency controls summary output in the same way as the log frequency controls output to the print file. A value such as

Summary Frequency = 10 or 100 is often adequate to determine if the solve is making progress. If *Print level* = 0, the default value of *Summary Frequency* is 100. If *Print level* > 0, the default value of *Summary Frequency* is 1. If *Print level* = 0 and the constraints are nonlinear, the *Summary Frequency* is ignored. Instead, one line is printed at the beginning of each major iteration.

Range: {1, ..., ∞}

Default: 100

superbasics limit (*integer*): Maximum number of superbasics ↔

This places a limit on the storage allocated for superbasic variables. Ideally, the parameter *i* should be set slightly larger than the number of degrees of freedom expected at an optimal solution. For linear problems, an optimum is normally a basic solution with no degrees of freedom. (The number of variables lying strictly between their bounds is not more than *m*, the number of general constraints.) The default value of *i* is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the number of independent variables. Normally, *i* need not be greater than $n_1 + 1$, where n_1 is the number of nonlinear variables. For many problems, *i* may be considerably smaller than n_1 . This will save storage if n_1 is very large. This parameter also sets the Hessian dimension, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: {1, ..., ∞}

Default: 1

unbounded objective value (*real*): Determines when a problem is called unbounded ↔

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$\text{minimize}_{\alpha} F(x + \alpha * p)$$

If $|F|$ exceeds the parameter *r* or if *alpha* exceeds the *unbounded stepsize*, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in $F(x)$ may be manifested by a floating-point overflow (during the evaluation of $F(x + \alpha * p)$), before the test against *r* can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the *Minor damping parameter*.

Default: 1.0e20

unbounded step size (*real*): Determines when a problem is called unbounded ↔

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$\text{minimize}_{\alpha} F(x + \alpha * p)$$

If *alpha* exceeds the parameter *r* or if $|F|$ exceeds the *unbounded objective value*, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in $F(x)$ may be manifested by a floating-point overflow (during the evaluation of $F(x + \alpha * p)$), before the test against *r* can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the *Minor damping parameter*.

Default: 1.0e10

verify constraint gradients (*no value*): Synonym to verify level 2 ↔

verify gradients (*no value*): Synonym to verify level 3 ↔

verify level (*integer*): Controls verification of gradients ↔

This option controls the finite-difference check performed by MINOS on the gradients (first derivatives) computed by GAMS for each nonlinear function. GAMS computes gradients analytically, and the values obtained should normally be taken as correct.

Default: 0

value	meaning
0	Cheap test Only a cheap test is performed, requiring three evaluations of the nonlinear objective and two evaluations of the nonlinear constraints. <i>Verify No</i> is an equivalent option.
1	Check objective A more reliable check is made on each component of the objective gradient. <i>Verify objective gradients</i> is an equivalent option.
2	Check Jacobian A check is made on each column of the Jacobian matrix associated with the nonlinear constraints. <i>Verify constraint gradients</i> is an equivalent option.
3	Check objective and Jacobian A detailed check is made on both the objective and the Jacobian. <i>Verify</i> , <i>Verify gradients</i> , and <i>Verify Yes</i> are equivalent options.
-1	No check

verify no (*no value*): Synonym to verify level 0 ↔

verify objective gradients (*no value*): Synonym to verify level 1 ↔

verify yes (*no value*): Synonym to verify level 3 ↔

weight on linear objective (*real*): Composite objective weight ↔

This option controls the so-called composite objective technique. If the first solution obtained is infeasible, and if the objective function contains linear terms, and the objective weight w is positive, this technique is used. While trying to reduce the sum of infeasibilities, the method also attempts to optimize the linear portion of the objective. At each infeasible iteration, the objective function is defined to be

$$\text{minimize}_x \sigma * w(c^T x) + (\text{sum of infeasibilities})$$

where $\sigma = 1$ for minimization and $\sigma = -1$ for maximization and c is the linear portion of the objective. If an optimal solution is reached while still infeasible, w is reduced by a factor of 10. This helps to allow for the possibility that the initial w is too large. It also provides dynamic allowance for the fact the sum of infeasibilities is tending towards zero. The effect of w is disabled after five such reductions, or if a feasible solution is obtained. This option is intended mainly for linear programs. It is unlikely to be helpful if the objective function is nonlinear.

Default: 0.0

5.28.10 Exit Conditions

This section discusses the exit codes printed by MINOS at the end of the optimization run.

EXIT – Optimal solution found

This is the message we all hope to see! It is certainly preferable to every other message. Of course it is quite possible that there are model formulation errors, which will (hopefully) lead to unexpected objective values and solutions. The reported optimum may be a local, and other much better optima may exist.

EXIT – The problem is infeasible

When the constraints are linear, this message can probably be trusted. Feasibility is measured with respect to the upper and lower bounds on the variables (the bounds on the slack variables correspond to the GAMS constraints). The message tells us that among all the points satisfying the general constraints $Ax + s = 0$, there is apparently no point that satisfies the bounds on x and s . Violations as small as the `FEASIBILITY TOLERANCE` are ignored, but at least one component of x or s violates a bound by more than the tolerance.

Note: Although the objective function is the sum of the infeasibilities, this sum will usually not have been *minimized* when MINOS recognizes the situation and exits. There may exist other points that have significantly lower sum of infeasibilities.

When nonlinear constraints are present, infeasibility is *much* harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation MINOS may relax the bounds on the slacks associated with nonlinear rows. This perturbation is allowed a fixed number of times. Normally a feasible point will be obtained relative to the perturbed constraints, and optimization can continue on the subproblem. However, if several consecutive subproblems require such perturbation, the problem is terminated and declared `INFEASIBLE`. Clearly this is an ad-hoc procedure. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

EXIT – The problem is unbounded (or badly scaled)

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased by an arbitrary amount without causing a basic variable to violate a bound. A simple way to diagnose such a model is to add an appropriate bound on the objective variable.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the `SCALE` option.

For nonlinear problems, MINOS monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (as judged by the `UNBOUNDED` parameter), the problem is terminated and declared `UNBOUNDED`. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

EXIT – User Interrupt

This exit code is a result of interrupting the optimization process by hitting `Ctrl-C`. Inside the IDE this is accomplished by hitting the `Interrupt` button. The solver will finish its current iteration, and return the current solution. This solution can be still intermediate infeasible or intermediate non-optimal.

EXIT – Too many iterations

The iteration limit was hit. Either the ITERLIM, or in some cases the ITERATIONS LIMIT or MAJOR ITERATION LIMIT was too small to solve the problem. In most cases increasing the GAMS ITERLIM option will resolve the problem. In other cases you will need to create a MINOS option file and set a MAJOR ITERATION LIMIT. The listing file will give more information regarding what limit was hit.

The GAMS iteration limit is displayed in the listing file under the section SOLVE SUMMARY. If the ITERLIM was hit, the message will look like:

```
ITERATION COUNT, LIMIT      10001      10000
```

EXIT – Resource Interrupt

The solver hit the RESLIM resource limit, which is a time limit. It returned the solution at that time, which may be still intermediate infeasible or intermediate non-optimal.

The GAMS resource limit is displayed in the listing file under the section SOLVE SUMMARY. If the GAMS RESLIM was hit, the message will look like:

```
RESOURCE USAGE, LIMIT      1001.570      1000.000
```

EXIT – The objective has not changed for many iterations

This is an emergency measure for the rare occasions when the solution procedure appears to be *cycling*. Suppose that a zero step is taken for several consecutive iterations, with a basis change occurring each time. It is theoretically possible for the set of basic variables to become the same as they were one or more iterations earlier. The same sequence of iterations would then occur *ad infinitum*.

EXIT – The Superbasics Limit is too small

The problem appears to be more non-linear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and an increase in the number of superbasics is needed. You can use the option SUPERBASICS LIMIT to increase the limit. See also option HESSIAN DIMENSION.

EXIT – Constraint and objective function could not be calculated

The function or gradient could not be evaluated. For example, this can occur when MINOS attempts to take a log or a square root of a negative number, when evaluating the expression x^y with $x \leq 0$, or when evaluating $\exp(x)$ for large x and the result is too large to store. The listing file will contain details about where and why evaluation errors occur. To fix this problem, add bounds so that all functions can be properly evaluated. E.g. if you have an expression x^y , add a lower bound `X.L0=0.001` to your model.

In many cases the algorithm can recover from function evaluation errors, for instance if they happen in the line search while evaluating trial points. The message above appears in cases where the algorithm can not recover, and requires a reliable function or gradient evaluation.

EXIT – Function evaluation error limit

The limit of allowed function evaluation errors DOMLIM has been exceeded.

Function evaluation errors occur when MINOS attempts to evaluate the objective and/or constraints at points where these functions or their derivatives are not defined or where overflows occur. Some examples are given above. The listing file contains details about these errors.

The quick and dirty way to solve this is to increase the GAMS DOMLIM setting, but in general it is better to add bounds. E.g. if you have an expression x^y , then add a bound `X.LO=0.001` to your model.

EXIT – The current point can not be improved

The line search failed. This can happen if the model is very nonlinear or if the functions are nonsmooth (using a DNLP model type).

If the model is non-smooth, consider a smooth approximation. It may be useful to check the scaling of the model and think more carefully about choosing a good starting point. Sometimes it can help to restart the model with full scaling turned on:

```
option nlp=minos;
solve m minimizing z using nlp; // this one gives "current point cannot be improved"
file fopt /minos.opt/; // write option file
putclose fopt "scale all variables"/;
m.optfile=1;
solve m minimizing z using nlp; // solve with "scale all variables"
```

EXIT – Numerical error in trying to satisfy the linear constraints (or the linearized constraints)

The basis is very ill-conditioned.

This is often a scaling problem. Try the full scaling option *scale all variables* or, better yet, rescale the model in GAMS via the `.scale` suffix or by choosing more appropriate units for variables and RHS values.

EXIT – Not enough storage to solve the model

The amount of workspace allocated for MINOS to solve the model is insufficient. Consider increasing the [GAMS option workfactor](#) to increase the workspace allocated for MINOS to use. The listing file and log file (screen) will contain information about the current workspace allocation. Increasing the workfactor by 50% is a reasonable strategy.

EXIT– Systems error

This is a catch all return for other serious problems. Check the listing file for more messages. If needed rerun the model with `OPTION SYSOUT=ON;`.

5.29 MOSEK

5.29.1 Introduction

MOSEK is a software package for the solution of linear, mixed-integer linear, quadratic, mixed-integer quadratic, quadratically constraint, conic, and semidefinite mathematical optimization problems. MOSEK is particularly well suited for solving large-scale linear, convex quadratically constraint, and conic programs using an extremely efficient interior point algorithm.

These problem classes can be solved using an appropriate optimizer built into MOSEK. All the optimizers available in MOSEK are built for the solution of large-scale sparse problems. Current optimizers include:

- Interior-point optimizers for continuous and conic problems
- Simplex optimizer for linear problems
- Branch-and-cut optimizer for mixed-integer linear, quadratic, and conic problems

5.29.1.1 Licensing

Licensing of GAMS/MOSEK is similar to other GAMS solvers. MOSEK is licensed in three different ways:

- **GAMS/MOSEK:**
All model types.
- **GAMS/MOSEK Solver Link:**
Users must have a separate, licensed MOSEK system. For users who wish to use MOSEK within GAMS and also in other environments.
- **GAMS/OsiMosek:**
Finally, a bare-bone interface to the LP and MIP solver of Mosek is available under the name [OSIMOSEK](#). It comes free of charge with any GAMS system.

For information regarding MOSEK standalone or interfacing MOSEK with other applications contact sales@mosek.com.

5.29.1.2 Solving Problems in Parallel

MOSEK can exploit multiple CPUs (or a CPU with multiple cores) to solve an optimization problem when using the interior-point or the mixed-integer optimizers.

This implies that whenever the MOSEK interior-point optimizer should solve an optimization problem, then it will try to divide the work so each CPU gets a share of the work. The user decides how many CPUs MOSEK should exploit. Unfortunately, it is not always easy to divide the work. Also some of the coordination work must occur in sequential. Therefore, the speed-up obtained when using multiple CPUs is highly problem dependent. However, as a rule of thumb, if the problem solves very quickly, i.e., in less than 60 seconds, then there is no advantage in using the parallel option.

The parameter [MSK_IPAR_NUM_THREADS](#) sets the number of threads (and therefore the number of CPU's) that the optimizer will use.

5.29.1.3 Infeasible/Unbounded Models

5.29.1.3.1 Farkas Certificates MOSEK determines if either the primal or the dual problem is infeasible by means of a Farkas certificate. In such a case MOSEK returns a certificate indicating primal or dual infeasibility.

The primal infeasibility certificate indicates a primal infeasible model. For a minimization problem

$$\begin{aligned} & \text{minimize} && \langle c, x \rangle \\ & \text{subject to} && Ax = b, \\ & && x \geq 0, \end{aligned}$$

the primal infeasibility certificate is the solution y satisfying $A'y \leq 0$ and $\langle b, y \rangle > 0$.

A primal infeasibility certificate is reported in the marginal records of the variables and equations. As no primal solution is available in this case, the level values for variables and equations and the objective function value are set to 0 (setting them to NA would be more appropriate, but GAMS does not support this well). At the moment, primal infeasibility certificate are not available for conic programs.

Since GAMS reports all model statuses in the primal space, the notion of dual infeasibility does not exist and GAMS reports a status of unboundedness, which assumes that the primal problem is feasible. Although GAMS reports the primal as unbounded, there is the possibility that both the primal *and* dual problem are infeasible. To check if this is the case, the user can set appropriate lower and upper bounds on the objective variable, using the `(variable).LO` and `(variable).UP` suffixes and resolve.

The dual infeasibility certificate is reported in the level values for the variables. As no dual solution exists, the marginal values for both variables and equations are set to NA.

For more details on primal and dual infeasibility certificates see the [MOSEK Modeling Cookbook](#).

5.29.1.3.2 Infeasibility Report MOSEK has some facilities for diagnosing the cause of a primal or dual infeasibility. They can be turned on using the parameter setting `MSK_IPAR_INFEAS_REPORT_AUTO`. This causes MOSEK to print a report about an infeasible subset of the constraints, when an infeasibility is encountered. Moreover, the parameter `MSK_IPAR_INFEAS_REPORT_LEVEL` controls the amount of information presented in the infeasibility report. We will use the **TRANSPORT example from the GAMS Model Library** with increased demand ($b(j) \leftarrow 1.6b(j)$) to make the model infeasible. MOSEK produces the following infeasibility report:

MOSEK PRIMAL INFEASIBILITY REPORT.

Problem status: The problem is primal infeasible

The following constraints are involved in the primal infeasibility.

Index	Name	Lower bound	Upper bound	Dual lower	Dual upper
1	supply(seattle)	none	3.500000e+002	0.000000e+000	1.000000e+000
2	supply(san-diego)	none	6.000000e+002	0.000000e+000	1.000000e+000
3	demand(new-york)	5.200000e+002	none	1.000000e+000	0.000000e+000
4	demand(chicago)	4.800000e+002	none	1.000000e+000	0.000000e+000
5	demand(topeka)	4.400000e+002	none	1.000000e+000	0.000000e+000

The following bound constraints are involved in the infeasibility.

Index	Name	Lower bound	Upper bound	Dual lower	Dual upper
-------	------	-------------	-------------	------------	------------

The report indicates which constraints and bounds are causing the infeasibility. In this case, the constraints causing infeasibility are **supply** and **demand**. The values in the columns **Dual lower** and **Dual upper** are also useful, because if the dual lower value is different from zero for a constraint, then it implies that the lower bound on the constraint is important for the infeasibility. Similarly, if the dual upper value is different from zero on a constraint, then this implies the upper bound on the constraint is important for infeasibility.

5.29.1.4 Conic Programming

MOSEK is well suited for solving generalized linear programs involving certain conic constraints.

For an overview of quadratic conic programming and how these conic constraints are implemented in GAMS, see the Section [Conic Programming](#) in the GAMS User's Guide. Note, that for Mosek no variable can appear in more than one conic constraint.

Additionally, the primal power cone, defined as

$$x_0^\alpha x_1^{(1-\alpha)} \geq \sqrt{\sum_{i=2}^n x_i^2}, \quad x_0, x_1 \geq 0,$$

with $\alpha \in (0, 1)$, and the primal exponential cone, defined as

$$x_0 \geq x_1 \exp(x_2/x_1), \quad x_0, x_1 \geq 0,$$

are available.

Since GAMS does not offer capabilities to directly restrict a variable to one of these cones, the GAMS/MOSEK link tries to detect the above algebra from a general nonlinear equation. For example, the following GAMS code should work with MOSEK:

```
Set i / 0*10 /;
Variable x(i);
Equations e1, e2;
Scalar alpha;
e1.. x('0')**alpha * x('1')**(1-alpha) =G= sqrt(sum(i$(ord(i)>2), sqr(x(i))));
e2.. x('0') =G= x('1') * exp(x('2') / x('1'));
x.lo('0') = 0;
x.lo('1') = 0;
```

See also testlib models `powercone1`, `powercone2`, and `expcone1`.

5.29.2 Solver Options

MOSEK works like other GAMS solvers, and many options can be set in the GAMS model (see [GAMS Options](#)). The most relevant GAMS options are [reslim](#), [nodlim](#), [iterlim](#) (iteration limit for simplex and interior point algorithms), [optca](#), [optcr](#), and [optfile](#). A description of all available GAMS options can be found in [GAMS Options](#) and [Solver related options](#).

We remark that MOSEK contains many complex solver options, many of which require a deep understanding of the algorithms used. For information on how to use a GAMS/Mosek options file, see [The Solver Option File](#). For example, an option file

```
MSK_IPAR_INTPNT_MAX_ITERATIONS      20
MSK_IPAR_INTPNT_SCALING              MSK_SCALING_NONE
```

limits the number of interior-point iterations to 20 and disables scaling.

In the following, we summarize the MOSEK options that are available through the GAMS/MOSEK interface. For details, see [Detailed Descriptions of MOSEK Options](#).

5.29.2.1 General

Option	Description	Default
MSK_DPAR_OPTIMIZER_MAX_TIME	Maximum amount of time the optimizer is allowed to spent on the optimization.	GAMS ResLim
MSK_DPAR_SEMIDEFINITE_TOL_APPROX	Tolerance to define a matrix to be positive semidefinite.	1e-10
MSK_IPAR_AUTO_SORT_A_BEFORE_OPT	Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed.	MSK.OFF
MSK_IPAR_NUM_THREADS	Controls the number of threads employed by the optimizer.	GAMS Threads
MSK_IPAR_OPTIMIZER	The parameter controls which optimizer is used to optimize the task.	MSK_OPTIMIZER_FREE
MSK_IPAR_TIMING_LEVEL	Controls the amount of timing performed inside MOSEK.	1
MSK_SPAR_PARAM_READ_FILE_NAME	Modifications to the parameter database is read from this file.	

5.29.2.2 Problem Data

Option	Description	Default
MSK_DPAR_CHECK_CONVEXITY_REL_TOL	This parameter controls when the full convexity check declares a problem to be non-convex.	1e-10
MSK_DPAR_DATA_SYM_MAT_TOL	Absolute zero tolerance for elements in in symmetric matrices.	1e-12
MSK_DPAR_DATA_SYM_MAT_TOL_HUGE	An element in a symmetric matrix which is larger than this value in absolute size causes an error.	1e+20
MSK_DPAR_DATA_SYM_MAT_TOL_LARGE	An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.	1e+10
MSK_DPAR_DATA_TOL_AIJ_HUGE	An element in the constraint matrix which is larger than this value in absolute size causes an error.	1e+20
MSK_DPAR_DATA_TOL_AIJ_LARGE	An element in the constraint matrix which is larger than this value in absolute size causes a warning message.	1e+10
MSK_DPAR_DATA_TOL_BOUND_INF	Any bound which in absolute value is greater than this parameter is considered infinite.	1e+16
MSK_DPAR_DATA_TOL_BOUND_WRN	If a bound value is larger than this value in absolute size, then a warning message is issued.	1e+08
MSK_DPAR_DATA_TOL_CJ_LARGE	A coefficient in the objective function which is larger than this value in absolute terms causes a warning message.	1e+08
MSK_DPAR_DATA_TOL_C_HUGE	A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error.	1e+16

Option	Description	Default
MSK_DPAR_DATA_TOL_QIJ	Absolute zero tolerance for coefficients of quadratic terms.	1e-16
MSK_DPAR_DATA_TOL_X	Zero tolerance for constraints and variables i.e. if the distance between the lower and upper bound is less than this value, then the lower and upper bound is considered identical.	1e-08
MSK_DPAR_LOWER_OBJ_CUT	Lower objective limit.	-1e+30
MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH	Lower objective limit threshold.	-5e+29
MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL	This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems.	1e-15
MSK_DPAR_UPPER_OBJ_CUT	Upper objective limit.	1e+30
MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH	Upper objective limit threshold.	5e+29
MSK_IPAR_CHECK_CONVEXITY	Specify the level of convexity check on quadratic problems.	MSK_CHECK_CONVEXITY_FULL
QEXTRACTALG	Switch to choose extraction algorithm for quadratic equations in GAMS interface.	0
SDPCHECKVARS	Switch to disable checking that for every entry of a PSD matrix variable also a corresponding GAMS variable is present.	1

5.29.2.3 Presolving

Option	Description	Default
MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP	Absolute tolerance employed by the linear dependency checker.	1e-06
MSK_DPAR_PRESOLVE_TOL_AIJ	Absolute zero tolerance employed for constraint coefficients in presolve.	1e-12
MSK_DPAR_PRESOLVE_TOL_REL_LINDEP	Relative tolerance employed by the linear dependency checker.	1e-10
MSK_DPAR_PRESOLVE_TOL_S	Absolute zero tolerance employed for dual variables in presolve.	1e-08
MSK_DPAR_PRESOLVE_TOL_X	Absolute zero tolerance employed for primal variables in presolve.	1e-08
MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL	Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve.	-1
MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_NUM_TRIES	Control the maximum number of times the eliminator is tried.	-1
MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRH	Controls the linear dependency check, which is potentially computationally expensive.	100

Option	Description	Default
MSK_IPAR_PRESOLVE_LINDEP_REL_WORK_TRH	Controls the linear dependency check, which is potentially computationally expensive.	100
MSK_IPAR_PRESOLVE_LINDEP_USE	Controls whether the linear constraints are checked for linear dependencies.	MSK_ON
MSK_IPAR_PRESOLVE_MAX_NUM_PASS	Control the maximum number of times presolve passes over the problem.	-1
MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS	Controls the maximum number of reductions performed by the presolve.	-1
MSK_IPAR_PRESOLVE_USE	Controls whether the presolve is applied to a problem before it is optimized.	MSK_PRESOLVE_MODE_FREE

5.29.2.4 Simplex Optimizer

Option	Description	Default
MSK_DPAR_BASIS_REL_TOL_S	Maximum relative dual bound violation allowed in an optimal basic solution.	1e-12
MSK_DPAR_BASIS_TOL_S	Maximum absolute dual bound violation in an optimal basic solution.	1e-06
MSK_DPAR_BASIS_TOL_X	Maximum absolute primal bound violation allowed in an optimal basic solution.	1e-06
MSK_DPAR_SIMPLEX_ABS_TOL_PIV	Absolute pivot tolerance employed by the simplex optimizers.	1e-07
MSK_DPAR_SIM_LU_TOL_REL_PIV	Relative pivot tolerance for LU factorization in simplex optimizers and basis identification.	0.01
MSK_IPAR_SIM_BASIS_FACTOR_USE	Controls whether an LU factorization of the basis is used in a hot-start.	MSK_ON
MSK_IPAR_SIM_DEGEN	Controls how aggressively degeneration is handled.	MSK_SIM_DEGEN_FREE
MSK_IPAR_SIM_DUAL_CRASH	Controls whether crashing is performed in the dual simplex optimizer.	90
MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION	Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex.	50
MSK_IPAR_SIM_DUAL_SELECTION	Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer.	MSK_SIM_SELECTION_FREE
MSK_IPAR_SIM_EXPLOIT_DUPVEC	Controls if the simplex optimizers are allowed to exploit duplicated columns.	MSK_SIM_EXPLOIT_DUPVEC_OFF

Option	Description	Default
MSK_IPAR_SIM_HOTSTART	Controls the type of hot-start that the simplex optimizer perform.	MSK_SIM_HOTSTART_FREE
MSK_IPAR_SIM_HOTSTART_LU	Determines if the simplex optimizer should exploit the initial factorization.	MSK_ON
MSK_IPAR_SIM_MAX_ITERATIONS	Maximum number of iterations that can be used by a simplex optimizer.	GAMS IterLim
MSK_IPAR_SIM_MAX_NUM_SETBACKS	Controls how many set-backs are allowed within a simplex optimizer.	250
MSK_IPAR_SIM_NON_SINGULAR	Controls if the simplex optimizer ensures a non-singular basis, if possible.	MSK_ON
MSK_IPAR_SIM_PRIMAL_CRASH	Controls whether crashing is performed in the primal simplex optimizer.	90
MSK_IPAR_SIM_PRIMAL_RESTRICT_SELECTION	Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the primal simplex.	50
MSK_IPAR_SIM_PRIMAL_SELECTION	Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer.	MSK_SIM_SELECTION_FREE
MSK_IPAR_SIM_REFORMULATION	Controls if the simplex optimizers are allowed to reformulate the problem.	MSK_SIM_REFORMULATION_OFF
MSK_IPAR_SIM_SAVE_LU	Controls if the LU factorization stored should be replaced with the LU factorization corresponding to the initial basis.	MSK_OFF
MSK_IPAR_SIM_SCALING	Controls how much effort is used in scaling the problem before a simplex optimizer is used.	MSK_SCALING_FREE
MSK_IPAR_SIM_SCALING_METHOD	Controls how the problem is scaled before a simplex optimizer is used.	MSK_SCALING_METHOD_POW2
MSK_IPAR_SIM_SEED	Sets the random seed used for randomization in the simplex optimizers.	23456
MSK_IPAR_SIM_SOLVE_FORM	Controls whether the primal or the dual problem is solved by the primal-/dual-simplex optimizer.	MSK_SOLVE_FREE
MSK_IPAR_SIM_STABILITY_PRIORITY	Controls how high priority the numerical stability should be given.	50
MSK_IPAR_SIM_SWITCH_OPTIMIZER	Controls the simplex behavior.	MSK_OFF

5.29.2.5 Interior Point Optimizer and Basis Identification

Option	Description	Default
MSK_DPAR_INTPNT_CO_TOL_DFEAS	Dual feasibility tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_CO_TOL_INFEAS	Infeasibility tolerance used by the interior-point optimizer for conic problems.	1e-12
MSK_DPAR_INTPNT_CO_TOL_MU_RED	Relative complementarity gap tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_CO_TOL_NEAR_REL	Termination tolerance multiplier that is used if no accurate solution can be found.	1
MSK_DPAR_INTPNT_CO_TOL_PFEAS	Primal feasibility tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_CO_TOL_REL_GAP	Relative gap termination tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_QO_TOL_DFEAS	Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.	1e-08
MSK_DPAR_INTPNT_QO_TOL_INFEAS	Infeasibility tolerance used by the interior-point optimizer for quadratic problems.	1e-12
MSK_DPAR_INTPNT_QO_TOL_MU_RED	Relative complementarity gap tolerance used by the interior-point optimizer for quadratic problems.	1e-08
MSK_DPAR_INTPNT_QO_TOL_NEAR_REL	Termination tolerance multiplier that is used if no accurate solution can be found.	1
MSK_DPAR_INTPNT_QO_TOL_PFEAS	Primal feasibility tolerance used by the interior-point optimizer for quadratic problems.	1e-08
MSK_DPAR_INTPNT_QO_TOL_REL_GAP	Relative gap termination tolerance used by the interior-point optimizer for quadratic problems.	1e-08
MSK_DPAR_INTPNT_TOL_DFEAS	Dual feasibility tolerance used by the interior-point optimizer for linear problems.	1e-08
MSK_DPAR_INTPNT_TOL_DSAFE	Controls the initial dual starting point used by the interior-point optimizer.	1
MSK_DPAR_INTPNT_TOL_INFEAS	Infeasibility tolerance used by the interior-point optimizer for linear problems.	1e-10
MSK_DPAR_INTPNT_TOL_MU_RED	Relative complementarity gap tolerance used by the interior-point optimizer for linear problems.	1e-16
MSK_DPAR_INTPNT_TOL_PATH	Controls how close the interior-point optimizer follows the central path.	1e-08

Option	Description	Default
MSK_DPAR_INTPNT_TOL_PFEAS	Primal feasibility tolerance used by the interior-point optimizer for linear problems.	1e-08
MSK_DPAR_INTPNT_TOL_PSAFE	Controls the initial primal starting point used by the interior-point optimizer.	1
MSK_DPAR_INTPNT_TOL_REL_GAP	Relative gap termination tolerance used by the interior-point optimizer for linear problems.	1e-08
MSK_DPAR_INTPNT_TOL_REL_STEP	Relative step size to the boundary for linear and quadratic optimization problems.	0.9999
MSK_DPAR_INTPNT_TOL_STEP_SIZE	Step size tolerance.	1e-06
MSK_IPAR_BI_CLEAN_OPTIMIZER	Controls which simplex optimizer is used in the clean-up phase.	MSK_OPTIMIZER_FREE
MSK_IPAR_BI_IGNORE_MAX_ITER	Controls if basis identification is performed under certain conditions.	MSK_OFF
MSK_IPAR_BI_IGNORE_NUM_ERROR	Turns on basis identification if interior-point optimizer is terminated due to a numerical problem.	MSK_ON
MSK_IPAR_BI_MAX_ITERATIONS	Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification.	1000000
MSK_IPAR_INTPNT_BASIS	Controls whether the interior-point optimizer also computes an optimal basis.	MSK_BI_ALWAYS
MSK_IPAR_INTPNT_DIFF_STEP	Controls whether different step sizes are allowed in the primal and dual space.	MSK_ON
MSK_IPAR_INTPNT_MAX_ITERATIONS	Controls the maximum number of iterations allowed in the interior-point optimizer.	GAMS IterLim
MSK_IPAR_INTPNT_MAX_NUM_COR	Controls the maximum number of correctors allowed by the multiple corrector procedure.	-1
MSK_IPAR_INTPNT_MAX_NUM_REFINEMENT_STEPS	Maximum number of steps to be used by the iterative refinement of the search direction.	-1
MSK_IPAR_INTPNT_MULTI_THREAD	Controls whether the interior-point optimizers can employ multiple threads if available.	MSK_ON
MSK_IPAR_INTPNT_OFF_COL_TRH	Controls how aggressively offending columns are detected in the Jacobian of the constraint matrix.	40
MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS	The GP ordering is dependent on a random seed.	0
MSK_IPAR_INTPNT_ORDER_METHOD	Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system.	MSK_ORDER_METHOD_FREE
MSK_IPAR_INTPNT_REGULARIZATION_USE	Controls whether regularization is allowed.	MSK_ON

Option	Description	Default
MSK_IPAR_INTPNT_SCALING	Controls how the problem is scaled before the interior-point optimizer is used.	MSK_SCALING_FREE
MSK_IPAR_INTPNT_SOLVE_FORM	Controls whether the primal or the dual problem is solved.	MSK_SOLVE_FREE
MSK_IPAR_INTPNT_STARTING_POINT	Starting point used by the interior-point optimizer.	MSK_STARTING_POINT_FREE

5.29.2.6 Mixed Integer Optimizer

Option	Description	Default
FIXOPTFILE	Name of option file which is read just before solving the fixed problem.	
MSK_DPAR_MIO_MAX_TIME	This parameter limits the maximum time spent by the mixed-integer optimizer.	-1
MSK_DPAR_MIO_REL_GAP_CONST	This value is used to compute the relative gap for the solution to an integer optimization problem.	1e-10
MSK_DPAR_MIO_TOL_ABS_GAP	Absolute optimality tolerance employed by the mixed-integer optimizer.	GAMS OptCA
MSK_DPAR_MIO_TOL_ABS_RELAX_INT	Absolute relaxation tolerance of the integer constraints.	1e-05
MSK_DPAR_MIO_TOL_FEAS	Feasibility tolerance for mixed integer solver.	1e-06
MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT	If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.	0
MSK_DPAR_MIO_TOL_REL_GAP	Relative optimality tolerance employed by the mixed-integer optimizer.	GAMS OptCR
MSK_IPAR_MIO_BRANCH_DIR	Controls whether the mixed-integer optimizer is branching up or down by default.	MSK_BRANCH_DIR_FREE
MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION	If this option is turned on outer approximation is used when solving relaxations of conic problems; otherwise interior point is used.	MSK_OFF
MSK_IPAR_MIO_CUT_CLIQUE	Controls whether clique cuts should be generated.	MSK_ON
MSK_IPAR_MIO_CUT_CMIR	Controls whether mixed integer rounding cuts should be generated.	MSK_ON
MSK_IPAR_MIO_CUT_GMI	Controls whether GMI cuts should be generated.	MSK_ON
MSK_IPAR_MIO_CUT IMPLIED_BOUND	Controls whether implied bound cuts should be generated.	MSK_OFF
MSK_IPAR_MIO_CUT_KNAPSACK_COVER	Controls whether knapsack cover cuts should be generated.	MSK_OFF

Option	Description	Default
MSK_IPAR_MIO_CUT_SELECTION_LEVEL	Controls how aggressively generated cuts are selected to be included in the relaxation.	-1
MSK_IPAR_MIO_FEASPUMP_LEVEL	Controls the way the Feasibility Pump heuristic is employed by the mixed-integer optimizer.	-1
MSK_IPAR_MIO_HEURISTIC_LEVEL	Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution.	-1
MSK_IPAR_MIO_MAX_NUM_BRANCHES	Maximum number of branches allowed during the branch and bound search.	-1
MSK_IPAR_MIO_MAX_NUM_RELAXS	Maximum number of relaxations allowed during the branch and bound search.	GAMS NodLim
MSK_IPAR_MIO_MAX_NUM_ROOT_CUT_ROUNDS	Maximum number of cut separation rounds at the root node.	100
MSK_IPAR_MIO_MAX_NUM_SOLUTIONS	The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located.	-1
MSK_IPAR_MIO_NODE_OPTIMIZER	Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer.	MSK_OPTIMIZER_FREE
MSK_IPAR_MIO_NODE_SELECTION	Controls the node selection strategy employed by the mixed-integer optimizer.	MSK_MIO_NODE_SELECTION_FREE
MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE	Enables or disables perspective reformulation in presolve.	MSK_ON
MSK_IPAR_MIO_PROBING_LEVEL	Controls the amount of probing employed by the mixed-integer optimizer in presolve.	-1
MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT	Use objective domain propagation.	MSK_OFF
MSK_IPAR_MIO_RINS_MAX_NODES	Controls the maximum number of nodes allowed in each call to the RINS heuristic.	-1
MSK_IPAR_MIO_ROOT_OPTIMIZER	Controls which optimizer is employed at the root node in the mixed-integer optimizer.	MSK_OPTIMIZER_FREE
MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL	Controls whether presolve can be repeated at root node.	-1
MSK_IPAR_MIO_SEED	Sets the random seed used for randomization in the mixed integer optimizer.	42
MSK_IPAR_MIO_VB_DETECTION_LEVEL	Controls how much effort is put into detecting variable bounds.	-1
SOLVEFINAL	Switch to resolve the problem with fixed discrete variables after the MOSEK optimizer finished.	1

5.29.2.7 Infeasibility Analyser for Continuous Problems

Option	Description	Default
MSK_DPAR_ANA_SOL_INFEAS_TOL	If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer.	1e-06
MSK_IPAR_INFEAS_PREFER_PRIMAL	If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on.	MSK_ON
MSK_IPAR_INFEAS_REPORT_AUTO	Controls whether an infeasibility report is automatically produced after the optimization if the problem is primal or dual infeasible.	MSK_OFF
MSK_IPAR_INFEAS_REPORT_LEVEL	Controls the amount of information presented in an infeasibility report.	1

5.29.2.8 Output

Option	Description	Default
MSK_IPAR_LOG	Controls the amount of log information.	10
MSK_IPAR_LOG_BI	Controls the amount of output printed by the basis identification procedure.	1
MSK_IPAR_LOG_BI_FREQ	Controls logging frequency of the basis identification	2500
MSK_IPAR_LOG_CHECK_CONVEXITY	Controls logging in convexity check on quadratic problems.	0
MSK_IPAR_LOG_FEAS_REPAIR	Controls the amount of output printed when performing feasibility repair.	1
MSK_IPAR_LOG_INFEAS_ANA	Controls amount of output printed by the infeasibility analyzer procedures.	1
MSK_IPAR_LOG_INTPNT	Controls amount of output printed by the interior-point optimizer.	1
MSK_IPAR_LOG_MIO	Controls the log level for the mixed-integer optimizer.	4
MSK_IPAR_LOG_MIO_FREQ	Controls how frequent the mixed-integer optimizer prints the log line.	10
MSK_IPAR_LOG_ORDER	If turned on, then factor lines are added to the log.	1
MSK_IPAR_LOG_PRESOLVE	Controls amount of output printed by the presolve procedure.	1
MSK_IPAR_LOG_RESPONSE	Controls amount of output printed when response codes are reported.	0
MSK_IPAR_LOG_SIM	Controls amount of output printed by the simplex optimizer.	4
MSK_IPAR_LOG_SIM_FREQ	Controls simplex optimizer logging frequency.	1000
MSK_IPAR_LOG_STORAGE	When turned on, MOSEK prints messages regarding the storage usage and allocation.	0

Option	Description	Default
MSK_IPAR_OPF_WRITE_HEADER	Write a text header with date and MOSEK version in an OPF file.	MSK_ON
MSK_IPAR_OPF_WRITE_HINTS	Write a hint section with problem dimensions in the beginning of an OPF file.	MSK_ON
MSK_IPAR_OPF_WRITE_LINE_LENGTH	Aim to keep lines in OPF files not much longer than this.	80
MSK_IPAR_OPF_WRITE_PARAMETERS	Write a parameter section in an OPF file.	MSK_OFF
MSK_IPAR_OPF_WRITE_PROBLEM	Write objective, constraints, bounds etc.	MSK_ON
MSK_IPAR_OPF_WRITE_SOLUTIONS	Enable inclusion of solutions in the OPF files.	MSK_OFF
MSK_IPAR_OPF_WRITE_SOL_BAS	Whether to include basic solution in OPF files.	MSK_ON
MSK_IPAR_OPF_WRITE_SOL_ITG	Whether to include integer solution in OPF files.	MSK_ON
MSK_IPAR_OPF_WRITE_SOL_I TR	Whether to include interior solution in OPF files.	MSK_ON
MSK_IPAR_PTF_WRITE_TRANSFORM	If enabled, then constraint blocks with identifiable conic slacks are transformed into conic constraints and the slacks are eliminated.	MSK_ON
MSK_IPAR_WRITE_COMPRESSION	Controls whether the data file is compressed while it is written.	9
MSK_IPAR_WRITE_DATA_PARAM	If this option is turned on the parameter settings are written to the data file as parameters.	MSK_OFF
MSK_IPAR_WRITE_GENERIC_NAMES	Controls whether generic names should be used instead of user-defined names when writing to the data file.	MSK_ON
MSK_IPAR_WRITE_GENERIC_NAMES_IO	Index origin used in generic names.	1
MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_ITEMS	Controls if the writer ignores incompatible problem items when writing files.	MSK_OFF
MSK_IPAR_WRITE_LP_FULL_OBJ	Write all variables, including the ones with 0-coefficients, in the objective.	MSK_ON
MSK_IPAR_WRITE_LP_LINE_WIDTH	Maximum width of line in an LP file written by MOSEK.	80
MSK_IPAR_WRITE_LP_QUOTED_NAMES	If this option is turned on, then MOSEK will quote invalid LP names when writing an LP file.	MSK_ON
MSK_IPAR_WRITE_LP_STRICT_FORMAT	Controls whether LP output files satisfy the LP format strictly.	MSK_OFF
MSK_IPAR_WRITE_LP_TERMS_PER_LINE	Maximum number of terms on a single line in an LP file written by MOSEK.	10
MSK_IPAR_WRITE_MPS_FORMAT	Controls in which format the MPS is written.	MSK_MPS_FORMAT_FREE

Option	Description	Default
MSK_IPAR_WRITE_MPS_INT	Controls if marker records are written to the MPS file to indicate whether variables are integer restricted.	MSK_ON
MSK_IPAR_WRITE_PRECISION	Controls the precision with which double numbers are printed in the MPS data file.	15
MSK_IPAR_WRITE_TASK_INC_SOL	Controls whether the solutions are stored in the task file too.	MSK_ON
MSK_IPAR_WRITE_XML_MODE	Controls if linear coefficients should be written by row or column when writing in the XML file format.	MSK_WRITE_XML_MODE_ROW
MSK_SPAR_DATA_FILE_NAME	If set, problem data is written to this file. File extension determines format.	
MSK_SPAR_PARAM_WRITE_FILE_NAME	The parameter database is written to this file.	
MSK_SPAR_WRITE_LP_GEN_VAR_NAME	Sometimes when an LP file is written additional variables must be inserted.	"xmskgen"
SDPSOLUFILE	Name of GDY file to write primal solution of all PSD matrix variables and dual solution for PSD constraints.	

5.29.3 The MOSEK Log File

The MOSEK log output gives much useful information about the current solver progress and individual phases.

5.29.3.1 Log Using the Interior Point Optimizer

The following is a MOSEK log output from running the **TRANSPORT** model from the GAMS Model Library:

```

Optimizer started.
Interior-point optimizer started.
Presolve started.
Linear dependency checker started.
Linear dependency checker terminated.
Eliminator - tries           : 0                time           : 0.00
Lin. dep. - tries           : 1                time           : 0.00
Lin. dep. - number         : 0
Presolve terminated. Time: 0.00
Optimizer - threads         : 1
Optimizer - solved problem  : the primal
Optimizer - Constraints      : 5
Optimizer - Cones           : 0
Optimizer - Scalar variables : 11              conic           : 0
Optimizer - Semi-definite variables: 0          scalarized      : 0

Return code - 0 [MSK_RES_OK]: No error occurred.

The last section gives details about the model and solver status, primal and dual feasibilities, as well as solver resource times. Furthermore, the log gives information about the basis identification phase. Some of this information is listed in the GAMS solve summary in the model listing (.LST) file as well.

The fields in the main MOSEK log output are:

Field	Description
ITE	The number of the current iteration.
PFEAS	Primal feasibility.
DFEAS	Dual feasibility.
GFEAS	The numbers in this column should converge monotonically toward to zero but may stall at low level due to rounding errors.
PRSTATUS	This number converges to 1 if the problem has an optimal solution whereas it converges to -1 if that is not the case.
POBJ	Current objective function value of primal problem.

Field	Description
DOBJ	Current objective function value of dual problem.
MU	Relative complementary gap.
TIME	Current elapsed solving time in seconds.

Return code - 10004 [MSK_RES_TRM_MIO_NEAR_ABS_GAP]: The mixed-integer optimizer terminated because t

The fields in the main MOSEK log output are:

Field	Description
BRANCHES	Current number of branches in tree.
RELAXS	Current number of nodes in branch and bound tree.
ACT_NDS	Current number of active nodes.
BEST_INT_OBJ	Current best integer solution (primal bound).
BEST_RELAX_OBJ	Current best relaxed solution (dual bound).
REL_GAP(%)	Relative gap between current BEST_INT_OBJ and BEST_RELAX_OBJ.
TIME	Current elapsed solving time in seconds.

The log then gives information about solving the model with discrete variables fixed in order to determine marginals. Option [SOLVEFINAL](#) can be used to disable this step. The fixed problem is solved as a regular LP with warm start information. So the log looks identical to the MOSEK simplex optimizer for linear programs:

```

5.29.4 Semidefinite Programming with GAMS/MOSEK (experimental)

With Version 7, MOSEK introduced a semidefinite programming (SDP) solver into their portfolio. The following introduction is taken from the [Mosek Documentation](#).

Semidefinite programming is a generalization of quadratic conic programming, allowing the use of matrix variables belonging to the convex cone of positive semidefinite matrices

$$\mathcal{S}_r^+ = \{X \in \mathcal{S}_r : z^T X z \geq 0, \forall z \in \mathbb{R}^r\},$$

where \mathcal{S}_r is the set of $r \times r$ real-valued symmetric matrices. MOSEK can solve semidefinite optimization problems of the form

$$\begin{aligned} & \text{minimize} && \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle \bar{C}_j, \bar{X}_j \rangle + c^f \\ & \text{subject to} && l_i^c \leq \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \langle \bar{A}_{ij}, \bar{X}_j \rangle \leq u_i^c, \quad i = 0, \dots, m-1, \\ & && l_j^x \leq x_j \leq u_j^x, \quad j = 0, \dots, n-1, \\ & && x \in \mathcal{C}, \bar{X}_j \in \mathcal{S}_{r_j}^+, \quad j = 0, \dots, p-1, \end{aligned} \quad (\text{SDP})$$

where the problem has p symmetric positive semidefinite (PSD) variables $\bar{X}_j \in \mathcal{S}_{r_j}^+$ of dimension r_j with symmetric coefficient matrices $\bar{C}_j \in \mathcal{S}_{r_j}$ and $\bar{A}_{i,j} \in \mathcal{S}_{r_j}$. We use the standard notation for the matrix inner product, i.e., for $A, B \in \mathbb{R}^{m \times n}$ we have

$$\langle A, B \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} A_{ij} B_{ij}.$$

5.29.4.1 Example

An example for a mixed semidefinite and conic quadratic programming problem with a 3-dimensional PSD matrix variable is the following:

$$\begin{aligned} & \text{minimize} && \left\langle \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, \bar{X} \right\rangle + x_0 \\ & \text{subject to} && \left\langle \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \bar{X} \right\rangle + x_0 = 1 \\ & && \left\langle \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \bar{X} \right\rangle + x_1 + x_2 = \frac{1}{2} \\ & && x_0 \geq \sqrt{x_1^2 + x_2^2} \\ & && \bar{X} \succeq 0 \end{aligned}$$

The GAMS/MOSEK interface offers an experimental interface to MOSEK's SDP solver. It allows to state SDP's of the form (SDP) in GAMS language. For instance, the example problem from above can be formulated as follows (**sdp01** in the GAMS Test Library):

```
Set i / 0 * 2 /;
alias(i, ip);
Variables barX(i,i) PSDMATRIX
          x(i)      simple vars
          z          objective var
;
x.lo('0') = 0;
Parameters barAobj(i,i) coefficients of barX in objective
           barAe1(i,i) coefficients of barX in e1
           barAe2(i,i) coefficients of barX in e2
;
Table barAobj(i,i)
```

```

0 1 2
0 2.0 1.0 0.0
1 1.0 2.0 1.0
2 0.0 1.0 2.0
;
identity matrix
barAe1(i,i) = 1.0;
all-one matrix
barAe2(i,ip) = 1.0;
Equations obj, e1, e2, e3;
obj.. z =e= sum((i,ip), barAobj(i,ip) * barX(i,ip)) + x('0');
e1.. 1 =e= sum((i,ip), barAe1(i,ip) * barX(i,ip)) + x('0');
e2.. 0.5 =e= sum((i,ip), barAe2(i,ip) * barX(i,ip)) + x('1') + x('2');
e3.. -sqr(x('0')) + sqr(x('1')) + sqr(x('2')) =1= 0;
Model m / all /;

```

We see that the matrix \bar{X} is defined via the 2-dimensional GAMS variable `barX`. Additionally, the keyword `PSDMATRIX` at the beginning of the descriptive text (!) of the variable is used to indicate that the variables belonging to symbol `barX` are *to be interpreted* as a matrix variable with PSD constraint.

The Model shown above can be solved with MOSEK via the statements

```

option qcp = mosek;
Solve m minimizing z using QCP;

```

As GAMS has no native support for conic programming, the `modeltype` is specified as `QCP`.

The solve statement produces the following log output (see also [Log Using the Interior Point Optimizer](#)):

```

M O S E K      version 7.0.0.75 (Build date: 2013-7-1 19:28:43)

```

5.29.4.2 Usage

The general syntax for defining a symmetric matrix or an (indexed) set of symmetric matrices with PSD constraints in GAMS is

```
Variable X(a,b,c,...,i1,...,ik,i1,...,ik) "PSDMATRIX_k <explanatory text>";
```

The number $k > 0$ specifies the number of indices that define the row/column dimension of the matrix. Specifying only the term PSDMATRIX is equivalent to PSDMATRIX_1. For a given k , the $2k$ -last indices are used to index the rows and columns of the matrix. The dimensions a, b, c, \dots are optional and can be used to index a set of matrices. In the GAMS/MOSEK output, a number in parenthesis is used to indicate the number of PSD matrices that have been found for one symbol. For example, the code

```
Set i / a,b /;
Set j / s01 * s42 /;
Variables z, X(j,i,i) PSDMATRIX;
```

generates the output

```
Recognizing SDP variables for symbols X (42)
```

if all matrices $X(j, \dots)$ also occur in a model instantiation.

Note

The current syntax for declaring PSD matrix variables via the explanatory text a variable is a temporary solution that will hopefully be replaced by a GAMS language feature in the future.

Variables that were tagged as belonging to a PSD matrix can only occur in linear constraints. Within these constraints, the coefficient matrix for a PSD matrix needs to be specified in symmetric form. That is, if the parameter matrix `barAobj` in [the example above](#) is equivalently specified as

```
Table barAobj(i,i)
      0      1      2
0      2.0    0.0    0.0
1      2.0    2.0    0.0
2      0.0    2.0    2.0
;
```

the GAMS/MOSEK interface will quit with the error message

```
SDP coefficient matrix not symmetric: defObj_z: 2*barX(1,0) != 0*barX(0,1)
```

Bounds on entries in a PSD matrix variable can be specified as usual with `.lo` and `.up` attributes. These bound constraints are translated into linear constraints by the interface. If different bounds are given to symmetric entries of a PSD matrix variable ($\bar{X}_{i,j}$ vs. $\bar{X}_{j,i}$), the stronger bounds are used, which is equivalent to adding constraints for each of the matrix entries. For nonpositive lower bounds on diagonal entries, no extra constraints are added, as they are implied by the PSD constraint.

5.29.4.3 GAMS variables vs. PSD matrix entries

As GAMS is not aware that a indexed variable will be interpreted as PSD matrix variable, it may not generate variables for all matrix entries when instantiating a model. This is especially critical if the modeler specified bounds on matrix entries that do not appear in any of the model equations, as these bounds would not be visible to the GAMS/MOSEK interface.

As an example, consider the SDP relaxation $\max\{-\langle W, \bar{X} \rangle : X_{i,i} = 1 \forall i, X \succeq 0\}$ corresponding to the Goemans-Williamson Randomized Approximation Algorithm for MaxCut:

```
Parameter W(i,i)    edge weights;
Variable X(i,j)    PSDMATRIX
                sdobjvar objective var;
Equation sdobj     objective function;
sdobj.. sum((i,j), -W(i,j)*(X(i,j) + X(j,i))) =e= sdobjvar;
X.fx(i,i) = 1.0;
model maxcutsdp / all /;
```

As $W(i,i)=0$, GAMS will not create any variables for $X(i,i)$ when instantiating the model in a solve statement. As a consequence, the constraints $X(i,i)=1$ will not be visible to GAMS/MOSEK. However, as MOSEK will compute values for the full matrix X , it will also compute values for the diagonal entries of X .

Further, the GAMS/MOSEK interface can pass primal solution values only for those entries of a PSD matrix variable that have a corresponding GAMS variable. This may make a solution matrix appear not to be PSD in GAMS, because not all entries have been passed back.

To be aware of such problems, the GAMS/MOSEK interface checks that it has a GAMS variable available for every entry of a PSD matrix variable. If not, it will report an error like

```
ERROR: Have 1600 GAMS variables for entries of 400 x 400 PSD Variable X(,), expected 160000 many.
```

This check can be disabled by setting the option `SDPCHECKVARS` to 0. Note, that the check is not able to alarm the user in situations where no GAMS variables were created for all entries of a row and corresponding column.

A simple workaround for this issue is to force all variables to be generated when a model is instantiated. This can be done by adding something like `eps*sum((i,j),X(i,j))` to one of the equations. Note, that `eps` is numerically equal to a 0.0 in GAMS, but has the effect that the term `sum((i,j),X(i,j))` is passed to the solver with 0.0-coefficient.

5.29.4.4 Dual Values for PSD constraints

The PSD constraint on a matrix variable \bar{X} is associated with a dual PSD matrix variable \bar{Y} . As GAMS is not aware of the PSD constraints, it is also not aware of the corresponding dual variables. Thus, there is no native way to pass the duals for the PSD constraints back to GAMS. (Recall, that the marginals for a PSDMATRIX variable X are used to store the dual values associated with the bound constraints on matrix entries.)

To work around this issue, the GAMS/MOSEK interface offers the option `SDPSOLUFILE`. This option allows to specify the name of a GDX file that stores primal values for all entries of a matrix variable and dual values of the corresponding PSD constraint. For a variable $X(i,j)$, the GDX file stores the primal matrix value for all entries (i,j) (i.e., not just the ones for which GAMS variables were created, therefor offering another workaround for the issue discussed in the previous section) as level values of variable X and the dual matrix for the PSD constraint as marginal values.

5.29.4.5 Infeasible and Unbounded SDPs

The GAMS/Mosek link currently does not pass on certificates for primal or dual infeasibility from Mosek to GAMS if PSD variables are present.

5.29.5 Detailed Descriptions of MOSEK Options

FIXOPTFILE (*string*): Name of option file which is read just before solving the fixed problem. ↔

MSK_DPAR_ANA_SOL_INFEAS_TOL (*real*): If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer. ↔

Default: 1e-06

MSK_DPAR_BASIS_REL_TOL_S (*real*): Maximum relative dual bound violation allowed in an optimal basic solution. ↔

Default: 1e-12

MSK_DPAR_BASIS_TOL_S (*real*): Maximum absolute dual bound violation in an optimal basic solution. ↔

Range: [1e-09, ∞]

Default: 1e-06

MSK_DPAR_BASIS_TOL_X (*real*): Maximum absolute primal bound violation allowed in an optimal basic solution. ↔

Range: [1e-09, ∞]

Default: 1e-06

MSK_DPAR_CHECK_CONVEXITY_REL_TOL (*real*): This parameter controls when the full convexity check declares a problem to be non-convex. ↔

Increasing this tolerance relaxes the criteria for declaring the problem non-convex. A problem is declared non-convex if negative (positive) pivot elements are detected in the Cholesky factor of a matrix which is required to be PSD (NSD). This parameter controls how much this non-negativity requirement may be violated. The matrix Q is considered to not be PSD if the pivot element for column i is less or equal $-|Q_{ii}| * \text{MSK_DPAR_CHECK_CONVEXITY_REL_TOL}$.

Default: 1e-10

MSK_DPAR_DATA_SYM_MAT_TOL (*real*): Absolute zero tolerance for elements in symmetric matrices. ↔

If any value in a symmetric matrix is smaller than this parameter in absolute terms MOSEK will treat the values as zero and generate a warning.

Range: [1e-16, 1e-06]

Default: 1e-12

MSK_DPAR_DATA_SYM_MAT_TOL_HUGE (*real*): An element in a symmetric matrix which is larger than this value in absolute size causes an error. [↔](#)

Default: 1e+20

MSK_DPAR_DATA_SYM_MAT_TOL_LARGE (*real*): An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed. [↔](#)

Default: 1e+10

MSK_DPAR_DATA_TOL_AIJ_HUGE (*real*): An element in the constraint matrix which is larger than this value in absolute size causes an error. [↔](#)

Default: 1e+20

MSK_DPAR_DATA_TOL_AIJ_LARGE (*real*): An element in the constraint matrix which is larger than this value in absolute size causes a warning message. [↔](#)

Default: 1e+10

MSK_DPAR_DATA_TOL_BOUND_INF (*real*): Any bound which in absolute value is greater than this parameter is considered infinite. [↔](#)

Default: 1e+16

MSK_DPAR_DATA_TOL_BOUND_WRN (*real*): If a bound value is larger than this value in absolute size, then a warning message is issued. [↔](#)

Default: 1e+08

MSK_DPAR_DATA_TOL_CJ_LARGE (*real*): A coefficient in the objective function which is larger than this value in absolute terms causes a warning message. [↔](#)

Default: 1e+08

MSK_DPAR_DATA_TOL_C_HUGE (*real*): A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error. [↔](#)

Default: 1e+16

MSK_DPAR_DATA_TOL_QIJ (*real*): Absolute zero tolerance for coefficients of quadratic terms. [↔](#)

Default: 1e-16

MSK_DPAR_DATA_TOL_X (*real*): Zero tolerance for constraints and variables i.e. if the distance between the lower and upper bound is less than this value, then the lower and upper bound is considered identical. [↔](#)

Default: 1e-08

MSK_DPAR_INTPNT_CO_TOL_DFEAS (*real*): Dual feasibility tolerance used by the interior-point optimizer for conic problems. [↔](#)

Range: [0, 1]

Default: 1e-08

See also: [MSK_DPAR_INTPNT_CO_TOL_NEAR_REL](#).

MSK_DPAR_INTPNT_CO_TOL_INFEAS (*real*): Infeasibility tolerance used by the interior-point optimizer for conic problems. [↔](#)

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: [0, 1]

Default: 1e-12

MSK_DPAR_INTPNT_CO_TOL_MU_RED (*real*): Relative complementarity gap tolerance used by the interior-point optimizer for conic problems. [↔](#)

Range: [0, 1]

Default: 1e-08

MSK_DPAR_INTPNT_CO_TOL_NEAR_REL (*real*): Termination tolerance multiplier that is used if no accurate solution can be found. [↔](#)

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: [1, ∞]

Default: 1

MSK_DPAR_INTPNT_CO_TOL_PFEAS (*real*): Primal feasibility tolerance used by the interior-point optimizer for conic problems. [↔](#)

Range: [0, 1]

Default: 1e-08

See also: [MSK_DPAR_INTPNT_CO_TOL_NEAR_REL](#).

MSK_DPAR_INTPNT_CO_TOL_REL_GAP (*real*): Relative gap termination tolerance used by the interior-point optimizer for conic problems. [↔](#)

Range: [0, 1]

Default: 1e-08

See also: [MSK_DPAR_INTPNT_CO_TOL_NEAR_REL](#).

MSK_DPAR_INTPNT_QO_TOL_DFEAS (*real*): Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem. [↔](#)

Range: [0, 1]

Default: 1e-08

See also: [MSK_DPAR_INTPNT_QO_TOL_NEAR_REL](#).

MSK_DPAR_INTPNT_QO_TOL_INFEAS (*real*): Infeasibility tolerance used by the interior-point optimizer for quadratic problems. [↔](#)

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: $[0, 1]$

Default: $1e-12$

MSK_DPAR_INTPNT_QO_TOL_MU_RED (*real*): Relative complementarity gap tolerance used by the interior-point optimizer for quadratic problems. [↔](#)

Range: $[0, 1]$

Default: $1e-08$

MSK_DPAR_INTPNT_QO_TOL_NEAR_REL (*real*): Termination tolerance multiplier that is used if no accurate solution can be found. [↔](#)

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: $[1, \infty]$

Default: 1

MSK_DPAR_INTPNT_QO_TOL_PFEAS (*real*): Primal feasibility tolerance used by the interior-point optimizer for quadratic problems. [↔](#)

Range: $[0, 1]$

Default: $1e-08$

See also: [MSK_DPAR_INTPNT_QO_TOL_NEAR_REL](#).

MSK_DPAR_INTPNT_QO_TOL_REL_GAP (*real*): Relative gap termination tolerance used by the interior-point optimizer for quadratic problems. [↔](#)

Range: $[0, 1]$

Default: $1e-08$

See also: [MSK_DPAR_INTPNT_QO_TOL_NEAR_REL](#).

MSK_DPAR_INTPNT_TOL_DFEAS (*real*): Dual feasibility tolerance used by the interior-point optimizer for linear problems. [↔](#)

Range: $[0, 1]$

Default: $1e-08$

MSK_DPAR_INTPNT_TOL_DSAFE (*real*): Controls the initial dual starting point used by the interior-point optimizer. [↔](#)

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: $[0.0001, \infty]$

Default: 1

MSK_DPAR_INTPNT_TOL_INFEAS (*real*): Infeasibility tolerance used by the interior-point optimizer for linear problems. [↔](#)

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: [0, 1]

Default: 1e-10

MSK_DPAR_INTPNT_TOL_MU_RED (*real*): Relative complementarity gap tolerance used by the interior-point optimizer for linear problems. [↔](#)

Range: [0, 1]

Default: 1e-16

MSK_DPAR_INTPNT_TOL_PATH (*real*): Controls how close the interior-point optimizer follows the central path. [↔](#)

A large value of this parameter means the central path is followed very closely. On numerically unstable problems it may be worthwhile to increase this parameter.

Range: [0, 0.9999]

Default: 1e-08

MSK_DPAR_INTPNT_TOL_PFEAS (*real*): Primal feasibility tolerance used by the interior-point optimizer for linear problems. [↔](#)

Range: [0, 1]

Default: 1e-08

MSK_DPAR_INTPNT_TOL_PSAFE (*real*): Controls the initial primal starting point used by the interior-point optimizer. [↔](#)

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it may be worthwhile to increase this value.

Range: [0.0001, ∞]

Default: 1

MSK_DPAR_INTPNT_TOL_REL_GAP (*real*): Relative gap termination tolerance used by the interior-point optimizer for linear problems. [↔](#)

Range: [1e-14, ∞]

Default: 1e-08

MSK_DPAR_INTPNT_TOL_REL_STEP (*real*): Relative step size to the boundary for linear and quadratic optimization problems. [↔](#)

Range: [0.0001, 0.999999]

Default: 0.9999

MSK_DPAR_INTPNT_TOL_STEP_SIZE (*real*): Step size tolerance. [↔](#)

If the step size falls below the value of this parameter, then the interior-point optimizer assumes it is stalled. In other words the interior-point optimizer does not make any progress and therefore it is better stop.

Range: $[0, 1]$

Default: $1e-06$

MSK_DPAR_LOWER_OBJ_CUT (*real*): Lower objective limit. [↔](#)

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval $(\text{MSK_DPAR_LOWER_OBJ_CUT}, \text{MSK_DPAR_UPPER_OBJ_CUT})$, then MOSEK is terminated.

Range: $[-\infty, \infty]$

Default: $-1e+30$

See also: [MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH](#).

MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH (*real*): Lower objective limit threshold. [↔](#)

If the lower objective cut ([MSK_DPAR_LOWER_OBJ_CUT](#)) is less than this value, then it is treated as infinity.

Range: $[-\infty, \infty]$

Default: $-5e+29$

MSK_DPAR_MIO_MAX_TIME (*real*): This parameter limits the maximum time spent by the mixed-integer optimizer. [↔](#)

A negative number means infinity.

Range: $[-\infty, \infty]$

Default: -1

MSK_DPAR_MIO_REL_GAP_CONST (*real*): This value is used to compute the relative gap for the solution to an integer optimization problem. [↔](#)

Range: $[1e-15, \infty]$

Default: $1e-10$

MSK_DPAR_MIO_TOL_ABS_GAP (*real*): Absolute optimality tolerance employed by the mixed-integer optimizer. [↔](#)

Default: GAMS OptCA

MSK_DPAR_MIO_TOL_ABS_RELAX_INT (*real*): Absolute relaxation tolerance of the integer constraints. [↔](#)

That means if the fractional part of a discrete variable ($\min(|x| - \lfloor x \rfloor, \lceil x \rceil - |x|)$) is less than the tolerance, then the integer restriction is assumed to be satisfied.

Range: $[1e-09, \infty]$

Default: $1e-05$

MSK_DPAR_MIO_TOL_FEAS (*real*): Feasibility tolerance for mixed integer solver. ↔

Range: [1e-09, 0.001]

Default: 1e-06

MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT (*real*): If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation. ↔

A value of 0.0 means that the value is selected automatically.

Range: [0, 1]

Default: 0

MSK_DPAR_MIO_TOL_REL_GAP (*real*): Relative optimality tolerance employed by the mixed-integer optimizer. ↔

Default: GAMS OptCR

MSK_DPAR_OPTIMIZER_MAX_TIME (*real*): Maximum amount of time the optimizer is allowed to spent on the optimization. ↔

A negative number means infinity.

Range: [-∞, ∞]

Default: GAMS ResLim

MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP (*real*): Absolute tolerance employed by the linear dependency checker. ↔

Default: 1e-06

MSK_DPAR_PRESOLVE_TOL_AIJ (*real*): Absolute zero tolerance employed for constraint coefficients in presolve. ↔

Range: [1e-15, ∞]

Default: 1e-12

MSK_DPAR_PRESOLVE_TOL_REL_LINDEP (*real*): Relative tolerance employed by the linear dependency checker. ↔

Default: 1e-10

MSK_DPAR_PRESOLVE_TOL_S (*real*): Absolute zero tolerance employed for dual variables in presolve. ↔

Default: 1e-08

MSK_DPAR_PRESOLVE_TOL_X (*real*): Absolute zero tolerance employed for primal variables in presolve. ↔

Default: 1e-08

MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL (*real*): This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems. ↔

Default: 1e-15

MSK_DPAR_SEMIDEFINITE_TOL_APPROX (*real*): Tolerance to define a matrix to be positive semidefinite. [↔](#)

Range: [1e-15, ∞]

Default: 1e-10

MSK_DPAR_SIMPLEX_ABS_TOL_PIV (*real*): Absolute pivot tolerance employed by the simplex optimizers. [↔](#)

Range: [1e-12, ∞]

Default: 1e-07

MSK_DPAR_SIM_LU_TOL_REL_PIV (*real*): Relative pivot tolerance for LU factorization in simplex optimizers and basis identification. [↔](#)

A value closer to 1.0 generally improves numerical stability but typically also implies an increase in the computational work.

Range: [1e-06, 0.999999]

Default: 0.01

MSK_DPAR_UPPER_OBJ_CUT (*real*): Upper objective limit. [↔](#)

If either a primal or dual feasible solution is found proving that the optimal objective value is outside the interval (MSK_DPAR_LOWER_OBJ_CUT, MSK_DPAR_UPPER_OBJ_CUT), then MOSEK is terminated.

Range: [-∞, ∞]

Default: 1e+30

See also: [MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH](#).

MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH (*real*): Upper objective limit threshold. [↔](#)

If the upper objective cut [MSK_DPAR_UPPER_OBJ_CUT](#) is greater than this value, then it is treated as infinity.

Range: [-∞, ∞]

Default: 5e+29

MSK_IPAR_AUTO_SORT_A_BEFORE_OPT (*string*): Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed. [↔](#)

This is not required but makes the optimization insusceptible to reorderings of variables.

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_BI_CLEAN_OPTIMIZER (*string*): Controls which simplex optimizer is used in the clean-up phase. ↩

Anything else than primal or dual simplex is equivalent to free simplex.

Default: MSK_OPTIMIZER_FREE

value	meaning
MSK_OPTIMIZER_FREE	The optimizer is chosen automatically.
MSK_OPTIMIZER_PRIMAL_SIMPLEX	The primal simplex optimizer is used.
MSK_OPTIMIZER_DUAL_SIMPLEX	The dual simplex optimizer is used.
MSK_OPTIMIZER_FREE_SIMPLEX	One of the simplex optimizers is used.

MSK_IPAR_BI_IGNORE_MAX_ITER (*string*): Controls if basis identification is performed under certain conditions. ↩

If the parameter **MSK_IPAR_INTPNT_BASIS** has the value **MSK_BI_NO_ERROR** and the interior-point optimizer has terminated due to maximum number of iterations, then basis identification is performed if this parameter has the value **MSK_ON**.

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_BI_IGNORE_NUM_ERROR (*string*): Turns on basis identification if interior-point optimizer is terminated due to a numerical problem. ↩

If the parameter **MSK_IPAR_INTPNT_BASIS** has the value **MSK_BI_NO_ERROR** and the interior-point optimizer has terminated due to a numerical problem, then basis identification is performed if this parameter has the value **MSK_ON**.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_BI_MAX_ITERATIONS (*integer*): Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification. ↩

Default: 1000000

MSK_IPAR_CHECK_CONVEXITY (*string*): Specify the level of convexity check on quadratic problems. ↩

Default: MSK_CHECK_CONVEXITY_FULL

value	meaning
MSK_CHECK_CONVEXITY_NONE	No convexity check.
MSK_CHECK_CONVEXITY_SIMPLE	Perform simple and fast convexity check.
MSK_CHECK_CONVEXITY_FULL	Perform a full convexity check.

MSK_IPAR_INFEAS_PREFER_PRIMAL (*string*): If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_INFEAS_REPORT_AUTO (*string*): Controls whether an infeasibility report is automatically produced after the optimization if the problem is primal or dual infeasible. [↔](#)

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_INFEAS_REPORT_LEVEL (*integer*): Controls the amount of information presented in an infeasibility report. [↔](#)

Higher values imply more information.

Default: 1

MSK_IPAR_INTPNT_BASIS (*string*): Controls whether the interior-point optimizer also computes an optimal basis. [↔](#)

Default: MSK_BI_ALWAYS

value	meaning
MSK_BI_NEVER	Never do basis identification.
MSK_BI_ALWAYS	Basis identification is always performed even if the interior-point optimizer terminates abnormally.
MSK_BI_NO_ERROR	Basis identification is performed if the interior-point optimizer terminates without an error.
MSK_BI_IF_FEASIBLE	Basis identification is not performed if the interior-point optimizer terminates with a problem status saying that the problem is primal or dual infeasible.

See also: [MSK_IPAR_BI_CLEAN_OPTIMIZER](#), [MSK_IPAR_BI_IGNORE_MAX_ITER](#), [MSK_IPAR_BI_IGNORE_NUM_ERROR](#), [MSK_IPAR_BI_MAX_ITERATIONS](#).

MSK_IPAR_INTPNT_DIFF_STEP (*string*): Controls whether different step sizes are allowed in the primal and dual space. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_INTPNT_MAX_ITERATIONS (*integer*): Controls the maximum number of iterations allowed in the interior-point optimizer. ↩

Default: GAMS IterLim

MSK_IPAR_INTPNT_MAX_NUM_COR (*integer*): Controls the maximum number of correctors allowed by the multiple corrector procedure. ↩

A negative value means that MOSEK is making the choice.

Range: $\{-1, \dots, \infty\}$

Default: -1

MSK_IPAR_INTPNT_MAX_NUM_REFINEMENT_STEPS (*integer*): Maximum number of steps to be used by the iterative refinement of the search direction. ↩

A negative value implies that the optimizer chooses the maximum number of iterative refinement steps.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_INTPNT_MULTI_THREAD (*string*): Controls whether the interior-point optimizers can employ multiple threads if available. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_INTPNT_OFF_COL_TRH (*integer*): Controls how aggressively offending columns are detected in the Jacobian of the constraint matrix. ↩

0 means no detection, 1 means aggressive detection, and higher values mean less aggressive detection.

Default: 40

MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS (*integer*): The GP ordering is dependent on a random seed. ↩

Therefore, trying several random seeds may lead to a better ordering. This parameter controls the number of random seeds tried. A value of 0 means that MOSEK makes the choice.

Default: 0

MSK_IPAR_INTPNT_ORDER_METHOD (*string*): Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system. ↩

Default: MSK_ORDER_METHOD_FREE

value	meaning
MSK_ORDER_METHOD_FREE	The ordering method is chosen automatically.

value	meaning
MSK_ORDER_METHOD_APPMINLOC	Approximate minimum local fill-in ordering is employed.
MSK_ORDER_METHOD_TRY_GRAPHPAR	Always try the graph partitioning based ordering.
MSK_ORDER_METHOD_FORCE_GRAPHPAR	Always use the graph partitioning based ordering even if it is worse than the approximate minimum local fill ordering.
MSK_ORDER_METHOD_NONE	No ordering is used.

MSK_IPAR_INTPNT_REGULARIZATION_USE (*string*): Controls whether regularization is allowed. ↵

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_INTPNT_SCALING (*string*): Controls how the problem is scaled before the interior-point optimizer is used. ↵

Default: MSK_SCALING_FREE

value	meaning
MSK_SCALING_FREE	The optimizer chooses the scaling heuristic.
MSK_SCALING_NONE	No scaling is performed.
MSK_SCALING_MODERATE	A conservative scaling is performed.
MSK_SCALING_AGGRESSIVE	A very aggressive scaling is performed.

MSK_IPAR_INTPNT_SOLVE_FORM (*string*): Controls whether the primal or the dual problem is solved. ↵

Default: MSK_SOLVE_FREE

value	meaning
MSK_SOLVE_FREE	The optimizer is free to solve either the primal or the dual problem.
MSK_SOLVE_PRIMAL	The optimizer should solve the primal problem.
MSK_SOLVE_DUAL	The optimizer should solve the dual problem.

MSK_IPAR_INTPNT_STARTING_POINT (*string*): Starting point used by the interior-point optimizer. ↵

Default: MSK_STARTING_POINT_FREE

value	meaning
MSK_STARTING_POINT_FREE	The starting point is chosen automatically.
MSK_STARTING_POINT_GUESS	The optimizer guesses a starting point.
MSK_STARTING_POINT_CONSTANT	The optimizer constructs a starting point by assigning a constant value to all primal and dual variables. This starting point is normally robust.

value	meaning
MSK_STARTING_POINT_SATISFY_BOUNDS	The starting point is chosen to satisfy all the simple bounds on nonlinear variables. If this starting point is employed, then more care than usual should be employed when choosing the bounds on the nonlinear variables. In particular very tight bounds should be avoided.

MSK_IPAR_LOG (*integer*): Controls the amount of log information. [↔](#)

The value 0 implies that all log information is suppressed. A higher level implies that more information is logged.

Default: 10

MSK_IPAR_LOG_BI (*integer*): Controls the amount of output printed by the basis identification procedure. [↔](#)

A higher level implies that more information is logged.

Default: 1

MSK_IPAR_LOG_BI_FREQ (*integer*): Controls logging frequency of the basis identification [↔](#)

Default: 2500

MSK_IPAR_LOG_CHECK_CONVEXITY (*integer*): Controls logging in convexity check on quadratic problems. [↔](#)

Set to a positive value to turn logging on. If a quadratic coefficient matrix is found to violate the requirement of PSD (NSD) then a list of negative (positive) pivot elements is printed. The absolute value of the pivot elements is also shown.

Default: 0

MSK_IPAR_LOG_FEAS_REPAIR (*integer*): Controls the amount of output printed when performing feasibility repair. [↔](#)

Default: 1

MSK_IPAR_LOG_INFEAS_ANA (*integer*): Controls amount of output printed by the infeasibility analyzer procedures. [↔](#)

A higher level implies that more information is logged.

Default: 1

MSK_IPAR_LOG_INTPNT (*integer*): Controls amount of output printed by the interior-point optimizer. [↔](#)

A higher level implies that more information is logged.

Default: 1

MSK_IPAR_LOG_MIO (*integer*): Controls the log level for the mixed-integer optimizer. [↔](#)

A higher level implies that more information is logged.

Default: 4

MSK_IPAR_LOG_MIO_FREQ (*integer*): Controls how frequent the mixed-integer optimizer prints the log line. [↔](#)

It will print a line every time **MSK_INTPAR_LOG_MIO_FREQ** relaxations have been solved.

Range: $\{-\infty, \dots, \infty\}$

Default: 10

MSK_IPAR_LOG_ORDER (*integer*): If turned on, then factor lines are added to the log. [↔](#)

Default: 1

MSK_IPAR_LOG_PRESOLVE (*integer*): Controls amount of output printed by the presolve procedure. [↔](#)

A higher level implies that more information is logged.

Default: 1

MSK_IPAR_LOG_RESPONSE (*integer*): Controls amount of output printed when response codes are reported. [↔](#)

A higher level implies that more information is logged.

Default: 0

MSK_IPAR_LOG_SIM (*integer*): Controls amount of output printed by the simplex optimizer. [↔](#)

A higher level implies that more information is logged.

Default: 4

MSK_IPAR_LOG_SIM_FREQ (*integer*): Controls simplex optimizer logging frequency. [↔](#)

Default: 1000

MSK_IPAR_LOG_STORAGE (*integer*): When turned on, MOSEK prints messages regarding the storage usage and allocation. [↔](#)

Default: 0

MSK_IPAR_MIO_BRANCH_DIR (*string*): Controls whether the mixed-integer optimizer is branching up or down by default. [↔](#)

Default: **MSK_BRANCH_DIR_FREE**

value	meaning
MSK_BRANCH_DIR_FREE	The mixed-integer optimizer decides which branch to choose.
MSK_BRANCH_DIR_UP	The mixed-integer optimizer always chooses the up branch first.
MSK_BRANCH_DIR_DOWN	The mixed-integer optimizer always chooses the down branch first.
MSK_BRANCH_DIR_NEAR	Branch in direction nearest to selected fractional variable.
MSK_BRANCH_DIR_FAR	Branch in direction farthest from selected fractional variable.
MSK_BRANCH_DIR_ROOT_LP	Chose direction based on root lp value of selected variable.

MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION (*string*): If this option is turned on outer approximation is used when solving relaxations of conic problems; otherwise interior point is used. [↔](#)

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_CLIQUE (*string*): Controls whether clique cuts should be generated. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_CMIR (*string*): Controls whether mixed integer rounding cuts should be generated. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_GMI (*string*): Controls whether GMI cuts should be generated. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_IMPLIED_BOUND (*string*): Controls whether implied bound cuts should be generated. [↔](#)

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_KNAPSACK_COVER (*string*): Controls whether knapsack cover cuts should be generated. [↔](#)

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_SELECTION_LEVEL (*integer*): Controls how aggressively generated cuts are selected to be included in the relaxation. ↔

Default: -1

value	meaning
-1	The optimizer chooses the level of cut selection.
0	Generated cuts less likely to be added to the relaxation.
1	Cuts are more aggressively selected to be included in the relaxation.

MSK_IPAR_MIO_FEASPUMP_LEVEL (*string*): Controls the way the Feasibility Pump heuristic is employed by the mixed-integer optimizer. ↔

Default: -1

value	meaning
-1	The optimizer chooses how the Feasibility Pump is used.
0	The Feasibility Pump is disabled.
1	The Feasibility Pump is enabled with an effort to improve solution quality.
2	The Feasibility Pump is enabled with an effort to reach feasibility early.

MSK_IPAR_MIO_HEURISTIC_LEVEL (*integer*): Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution. ↔

A value of zero means the heuristic is not used at all. A larger value than 0 means that a gradually more sophisticated heuristic is used which is computationally more expensive. A negative value implies that the optimizer chooses the heuristic. Normally a value around 3 to 5 should be optimal.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_MIO_MAX_NUM_BRANCHES (*integer*): Maximum number of branches allowed during the branch and bound search. ↔

A negative value means infinite.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_MIO_MAX_NUM_RELAXS (*integer*): Maximum number of relaxations allowed during the branch and bound search. ↔

A negative value means infinite.

Range: $\{-\infty, \dots, \infty\}$

Default: GAMS NodLim

MSK_IPAR_MIO_MAX_NUM_ROOT_CUT_ROUNDS (*integer*): Maximum number of cut separation rounds at the root node. ↔

Default: 100

MSK_IPAR_MIO_MAX_NUM_SOLUTIONS (*integer*): The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located. ↔

If this parameter has the value $n > 0$, then the mixed-integer optimizer will be terminated when n feasible solutions have been located.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_MIO_NODE_OPTIMIZER (*string*): Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer. ↔

Default: MSK_OPTIMIZER_FREE

value	meaning
MSK_OPTIMIZER_FREE	The optimizer is chosen automatically.
MSK_OPTIMIZER_INTPNT	The interior-point optimizer is used.
MSK_OPTIMIZER_CONIC	The optimizer for problems having conic constraints.
MSK_OPTIMIZER_PRIMAL_SIMPLEX	The primal simplex optimizer is used.
MSK_OPTIMIZER_DUAL_SIMPLEX	The dual simplex optimizer is used.
MSK_OPTIMIZER_FREE_SIMPLEX	One of the simplex optimizers is used.
MSK_OPTIMIZER_MIXED_INT	The mixed-integer optimizer.

MSK_IPAR_MIO_NODE_SELECTION (*string*): Controls the node selection strategy employed by the mixed-integer optimizer. ↔

Default: MSK_MIO_NODE_SELECTION_FREE

value	meaning
MSK_MIO_NODE_SELECTION_FREE	The optimizer decides the node selection strategy.
MSK_MIO_NODE_SELECTION_FIRST	The optimizer employs a depth first node selection strategy.
MSK_MIO_NODE_SELECTION_BEST	The optimizer employs a best bound node selection strategy.
MSK_MIO_NODE_SELECTION_PSEUDO	The optimizer employs selects the node based on a pseudo cost estimate.

MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE (*string*): Enables or disables perspective reformulation in presolve. ↔

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_PROBING_LEVEL (*integer*): Controls the amount of probing employed by the mixed-integer optimizer in presolve. ↔

Default: -1

value	meaning
-1	The optimizer chooses the level of probing employed
0	Probing is disabled
1	A low amount of probing is employed
2	A medium amount of probing is employed
3	A high amount of probing is employed

MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT (*string*): Use objective domain propagation. ↔

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_RINS_MAX_NODES (*integer*): Controls the maximum number of nodes allowed in each call to the RINS heuristic. ↔

The default value of -1 means that the value is determined automatically. A value of zero turns off the heuristic.

Range: $\{-1, \dots, \infty\}$

Default: -1

MSK_IPAR_MIO_ROOT_OPTIMIZER (*string*): Controls which optimizer is employed at the root node in the mixed-integer optimizer. ↔

Default: MSK_OPTIMIZER_FREE

value	meaning
MSK_OPTIMIZER_FREE	The optimizer is chosen automatically.
MSK_OPTIMIZER_INTPNT	The interior-point optimizer is used.
MSK_OPTIMIZER_CONIC	The optimizer for problems having conic constraints.
MSK_OPTIMIZER_PRIMAL_SIMPLEX	The primal simplex optimizer is used.
MSK_OPTIMIZER_DUAL_SIMPLEX	The dual simplex optimizer is used.
MSK_OPTIMIZER_FREE_SIMPLEX	One of the simplex optimizers is used.

MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL (*integer*): Controls whether presolve can be repeated at root node. ↔

Default: -1

value	meaning
-1	The optimizer chooses whether presolve is repeated.

value	meaning
0	Never repeat presolve.
1	Always repeat presolve.

MSK_IPAR_MIO_SEED (*integer*): Sets the random seed used for randomization in the mixed integer optimizer. ↩

Selecting a different seed can change the path the optimizer takes to the optimal solution.

Default: 42

MSK_IPAR_MIO_VB_DETECTION_LEVEL (*integer*): Controls how much effort is put into detecting variable bounds. ↩

Default: -1

value	meaning
-1	The optimizer chooses.
0	No variable bounds are detected.
1	Only detect variable bounds that are directly represented in the problem.
2	Detect variable bounds in probing.

MSK_IPAR_NUM_THREADS (*integer*): Controls the number of threads employed by the optimizer. ↩

If set to 0 the number of threads used will be equal to the number of cores detected on the machine. If using the conic optimizer, the value of this parameter set at first optimization remains constant through the lifetime of the process. MOSEK will allocate a thread pool of given size, and changing the parameter value later will have no effect. It will, however, remain possible to demand single-threaded execution by setting [MSK_IPAR_INTPNT_MULTI_THREAD](#). For the mixed-integer optimizer and interior-point linear optimizer there is no such restriction.

Default: GAMS Threads

MSK_IPAR_OPF_WRITE_HEADER (*string*): Write a text header with date and MOSEK version in an OPF file. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_HINTS (*string*): Write a hint section with problem dimensions in the beginning of an OPF file. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_LINE_LENGTH (*integer*): Aim to keep lines in OPF files not much longer than this. ↔

Default: 80

MSK_IPAR_OPF_WRITE_PARAMETERS (*string*): Write a parameter section in an OPF file. ↔

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_PROBLEM (*string*): Write objective, constraints, bounds etc. ↔

to an OPF file.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOLUTIONS (*string*): Enable inclusion of solutions in the OPF files. ↔

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOL_BAS (*string*): Whether to include basic solution in OPF files. ↔

If [MSK_IPAR_OPF_WRITE_SOLUTIONS](#) is MSK_ON and a basic solution is defined, include the basic solution in OPF files.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOL_ITG (*string*): Whether to include integer solution in OPF files. ↔

If [MSK_IPAR_OPF_WRITE_SOLUTIONS](#) is MSK_ON and an integer solution is defined, write the integer solution to OPF files.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOL_ITR (*string*): Whether to include interior solution in OPF files. [↔](#)

If [MSK_IPAR_OPF_WRITE_SOLUTIONS](#) is MSK_ON and an interior solution is defined, write the interior solution to OPF files.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPTIMIZER (*string*): The parameter controls which optimizer is used to optimize the task. [↔](#)

Default: MSK_OPTIMIZER_FREE

value	meaning
MSK_OPTIMIZER_FREE	The optimizer is chosen automatically.
MSK_OPTIMIZER_INTPNT	The interior-point optimizer is used.
MSK_OPTIMIZER_CONIC	The optimizer for problems having conic constraints.
MSK_OPTIMIZER_PRIMAL_SIMPLEX	The primal simplex optimizer is used.
MSK_OPTIMIZER_DUAL_SIMPLEX	The dual simplex optimizer is used.
MSK_OPTIMIZER_FREE_SIMPLEX	One of the simplex optimizers is used.
MSK_OPTIMIZER_MIXED_INT	The mixed-integer optimizer.

MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL (*integer*): Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve. [↔](#)

A negative value means the parameter value is selected automatically.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_NUM_TRIES (*integer*): Control the maximum number of times the eliminator is tried. [↔](#)

A negative value implies MOSEK decides.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRH (*integer*): Controls the linear dependency check, which is potentially computationally expensive. [↔](#)

Range: $\{-\infty, \dots, \infty\}$

Default: 100

MSK_IPAR_PRESOLVE_LINDEP_REL_WORK_TRH (*integer*): Controls the linear dependency check, which is potentially computationally expensive. [↔](#)

Range: $\{-\infty, \dots, \infty\}$

Default: 100

MSK_IPAR_PRESOLVE_LINDEP_USE (*string*): Controls whether the linear constraints are checked for linear dependencies. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_PRESOLVE_MAX_NUM_PASS (*integer*): Control the maximum number of times presolve passes over the problem. ↔

A negative value implies MOSEK decides.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS (*integer*): Controls the maximum number of reductions performed by the presolve. ↔

The value of the parameter is normally only changed in connection with debugging. A negative value implies that an infinite number of reductions are allowed.

Range: $\{-\infty, \dots, \infty\}$

Default: -1

MSK_IPAR_PRESOLVE_USE (*string*): Controls whether the presolve is applied to a problem before it is optimized. ↔

Default: MSK_PRESOLVE_MODE_FREE

value	meaning
MSK_PRESOLVE_MODE_OFF	The problem is not presolved before it is optimized.
MSK_PRESOLVE_MODE_ON	The problem is presolved before it is optimized.
MSK_PRESOLVE_MODE_FREE	It is decided automatically whether to presolve before the problem is optimized.

MSK_IPAR_PTF_WRITE_TRANSFORM (*string*): If enabled, then constraint blocks with identifiable conic slacks are transformed into conic constraints and the slacks are eliminated. ↔

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_BASIS_FACTOR_USE (*string*): Controls whether an LU factorization of the basis is used in a hot-start. ↔

Forcing a refactorization sometimes improves the stability of the simplex optimizers, but in most cases there is a performance penalty.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_DEGEN (*string*): Controls how aggressively degeneration is handled. ↔

Default: MSK_SIM_DEGEN_FREE

value	meaning
MSK_SIM_DEGEN_NONE	The simplex optimizer should use no degeneration strategy.
MSK_SIM_DEGEN_FREE	The simplex optimizer chooses the degeneration strategy.
MSK_SIM_DEGEN_AGGRESSIVE	The simplex optimizer should use an aggressive degeneration strategy.
MSK_SIM_DEGEN_MODERATE	The simplex optimizer should use a moderate degeneration strategy.
MSK_SIM_DEGEN_MINIMUM	The simplex optimizer should use a minimum degeneration strategy.

MSK_IPAR_SIM_DUAL_CRASH (*integer*): Controls whether crashing is performed in the dual simplex optimizer. ↔

In general if a basis consists of more than $(100 * \text{MSK_IPAR_SIM_DUAL_CRASH})$ percent fixed variables, then a crash will be performed.

Default: 90

MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION (*integer*): Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex. ↔

The dual simplex optimizer can use a so-called restricted selection/pricing strategy to choose the outgoing variable. Hence, if restricted selection is applied, then the dual simplex optimizer first choose a subset of all the potential outgoing variables. Next, for some time it will choose the outgoing variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: {0, ..., 100}

Default: 50

MSK_IPAR_SIM_DUAL_SELECTION (*string*): Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer. ↔

Default: MSK_SIM_SELECTION_FREE

value	meaning
MSK_SIM_SELECTION_FREE	The optimizer chooses the pricing strategy.
MSK_SIM_SELECTION_FULL	The optimizer uses full pricing.
MSK_SIM_SELECTION_ASE	The optimizer uses approximate steepest-edge pricing.
MSK_SIM_SELECTION_DEVEX	The optimizer uses devex steepest-edge pricing. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_SE	The optimizer uses steepest-edge selection. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_PARTIAL	The optimizer uses a partial selection approach. The approach is usually beneficial if the number of variables is much larger than the number of constraints.

MSK_IPAR_SIM_EXPLOIT_DUPVEC (*string*): Controls if the simplex optimizers are allowed to exploit duplicated columns. ↔

Default: MSK_SIM_EXPLOIT_DUPVEC_OFF

value	meaning
MSK_SIM_EXPLOIT_DUPVEC_ON	Allow the simplex optimizer to exploit duplicated columns.
MSK_SIM_EXPLOIT_DUPVEC_OFF	Disallow the simplex optimizer to exploit duplicated columns.
MSK_SIM_EXPLOIT_DUPVEC_FREE	The simplex optimizer can choose freely.

MSK_IPAR_SIM_HOTSTART (*string*): Controls the type of hot-start that the simplex optimizer perform. ↔

Default: MSK_SIM_HOTSTART_FREE

value	meaning
MSK_SIM_HOTSTART_NONE	The simplex optimizer performs a coldstart.
MSK_SIM_HOTSTART_FREE	The simplex optimize chooses the hot-start type.
MSK_SIM_HOTSTART_STATUS_KEYS	Only the status keys of the constraints and variables are used to choose the type of hot-start.

MSK_IPAR_SIM_HOTSTART_LU (*string*): Determines if the simplex optimizer should exploit the initial factorization. ↔

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_MAX_ITERATIONS (*integer*): Maximum number of iterations that can be used by a simplex optimizer. ↔

Default: GAMS IterLim

MSK_IPAR_SIM_MAX_NUM_SETBACKS (*integer*): Controls how many set-backs are allowed within a simplex optimizer. ↔

A set-back is an event where the optimizer moves in the wrong direction. This is impossible in theory but may happen due to numerical problems.

Default: 250

MSK_IPAR_SIM_NON_SINGULAR (*string*): Controls if the simplex optimizer ensures a non-singular basis, if possible. ↔

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_PRIMAL_CRASH (*integer*): Controls whether crashing is performed in the primal simplex optimizer. ↔

In general if a basis consists of more than $(100 * \text{MSK_IPAR_SIM_PRIMAL_CRASH})$ percent fixed variables, then a crash will be performed.

Default: 90

MSK_IPAR_SIM_PRIMAL_RESTRICT_SELECTION (*integer*): Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the primal simplex. ↔

The primal simplex optimizer can use a so-called restricted selection/pricing strategy to choose the outgoing variable. Hence, if restricted selection is applied, then the primal simplex optimizer first choose a subset of all the potential incoming variables. Next, for some time it will choose the incoming variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: {0, ..., 100}

Default: 50

MSK_IPAR_SIM_PRIMAL_SELECTION (*string*): Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer. ↔

Default: MSK_SIM_SELECTION_FREE

value	meaning
MSK_SIM_SELECTION_FREE	The optimizer chooses the pricing strategy.
MSK_SIM_SELECTION_FULL	The optimizer uses full pricing.
MSK_SIM_SELECTION_ASE	The optimizer uses approximate steepest-edge pricing.
MSK_SIM_SELECTION_DEVEX	The optimizer uses devex steepest-edge pricing. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_SE	The optimizer uses steepest-edge selection. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_PARTIAL	The optimizer uses a partial selection approach. The approach is usually beneficial if the number of variables is much larger than the number of constraints.

MSK_IPAR_SIM_REFORMULATION (*string*): Controls if the simplex optimizers are allowed to reformulate the problem. ↔

Default: MSK_SIM_REFORMULATION_OFF

value	meaning
MSK_SIM_REFORMULATION_ON	Allow the simplex optimizer to reformulate the problem.
MSK_SIM_REFORMULATION_OFF	Disallow the simplex optimizer to reformulate the problem.
MSK_SIM_REFORMULATION_FREE	The simplex optimizer can choose freely.
MSK_SIM_REFORMULATION_AGGRESSIVE	The simplex optimizer should use an aggressive reformulation strategy.

MSK_IPAR_SIM_SAVE_LU (*string*): Controls if the LU factorization stored should be replaced with the LU factorization corresponding to the initial basis. [↔](#)

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_SCALING (*string*): Controls how much effort is used in scaling the problem before a simplex optimizer is used. [↔](#)

Default: MSK_SCALING_FREE

value	meaning
MSK_SCALING_FREE	The optimizer chooses the scaling heuristic.
MSK_SCALING_NONE	No scaling is performed.
MSK_SCALING_MODERATE	A conservative scaling is performed.
MSK_SCALING_AGGRESSIVE	A very aggressive scaling is performed.

MSK_IPAR_SIM_SCALING_METHOD (*string*): Controls how the problem is scaled before a simplex optimizer is used. [↔](#)

Default: MSK_SCALING_METHOD_POW2

value	meaning
MSK_SCALING_METHOD_POW2	Scales only with power of 2 leaving the mantissa untouched.
MSK_SCALING_METHOD_FREE	The optimizer chooses the scaling heuristic.

MSK_IPAR_SIM_SEED (*integer*): Sets the random seed used for randomization in the simplex optimizers. [↔](#)

Range: {0, ..., 32749}

Default: 23456

MSK_IPAR_SIM_SOLVE_FORM (*string*): Controls whether the primal or the dual problem is solved by the primal-/dual-simplex optimizer. [↔](#)

Default: MSK_SOLVE_FREE

value	meaning
MSK_SOLVE_FREE	The optimizer is free to solve either the primal or the dual problem.
MSK_SOLVE_PRIMAL	The optimizer should solve the primal problem.
MSK_SOLVE_DUAL	The optimizer should solve the dual problem.

MSK_IPAR_SIM_STABILITY_PRIORITY (*integer*): Controls how high priority the numerical stability should be given. [↔](#)

Range: {0, ..., 100}

Default: 50

MSK_IPAR_SIM_SWITCH_OPTIMIZER (*string*): Controls the simplex behavior. ↔

The simplex optimizer sometimes chooses to solve the dual problem instead of the primal problem. This implies that if you have chosen to use the dual simplex optimizer and the problem is dualized, then it actually makes sense to use the primal simplex optimizer instead. If this parameter is on and the problem is dualized and furthermore the simplex optimizer is chosen to be the primal (dual) one, then it is switched to the dual (primal).

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_TIMING_LEVEL (*integer*): Controls the amount of timing performed inside MOSEK. ↔

Default: 1

MSK_IPAR_WRITE_COMPRESSION (*integer*): Controls whether the data file is compressed while it is written. ↔

0 means no compression while higher values mean more compression.

Default: 9

MSK_IPAR_WRITE_DATA_PARAM (*string*): If this option is turned on the parameter settings are written to the data file as parameters. ↔

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_GENERIC_NAMES (*string*): Controls whether generic names should be used instead of user-defined names when writing to the data file. ↔

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_GENERIC_NAMES_IO (*integer*): Index origin used in generic names. ↔

Default: 1

MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_ITEMS (*string*): Controls if the writer ignores incompatible problem items when writing files. ↔

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_LP_FULL_OBJ (*string*): Write all variables, including the ones with 0-coefficients, in the objective. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_LP_LINE_WIDTH (*integer*): Maximum width of line in an LP file written by MOSEK. [↔](#)

Range: {40, ..., ∞}

Default: 80

MSK_IPAR_WRITE_LP_QUOTED_NAMES (*string*): If this option is turned on, then MOSEK will quote invalid LP names when writing an LP file. [↔](#)

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_LP_STRICT_FORMAT (*string*): Controls whether LP output files satisfy the LP format strictly. [↔](#)

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_LP_TERMS_PER_LINE (*integer*): Maximum number of terms on a single line in an LP file written by MOSEK. [↔](#)

0 means unlimited.

Default: 10

MSK_IPAR_WRITE_MPS_FORMAT (*string*): Controls in which format the MPS is written. [↔](#)

Default: MSK_MPS_FORMAT_FREE

value	meaning
MSK_MPS_FORMAT_STRICT	It is assumed that the input file satisfies the MPS format strictly.
MSK_MPS_FORMAT_RELAXED	It is assumed that the input file satisfies a slightly relaxed version of the MPS format.
MSK_MPS_FORMAT_FREE	It is assumed that the input file satisfies the free MPS format. This implies that spaces are not allowed in names. Otherwise the format is free.
MSK_MPS_FORMAT_CPLEX	The CPLEX compatible version of the MPS format is employed.

MSK_IPAR_WRITE_MPS_INT (*string*): Controls if marker records are written to the MPS file to indicate whether variables are integer restricted. ↔

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_PRECISION (*integer*): Controls the precision with which double numbers are printed in the MPS data file. ↔

In general it is not worthwhile to use a value higher than 15.

Default: 15

MSK_IPAR_WRITE_TASK_INC_SOL (*string*): Controls whether the solutions are stored in the task file too. ↔

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_XML_MODE (*string*): Controls if linear coefficients should be written by row or column when writing in the XML file format. ↔

Default: MSK_WRITE_XML_MODE_ROW

value	meaning
MSK_WRITE_XML_MODE_ROW	Write in row order.
MSK_WRITE_XML_MODE_COL	Write in column order.

MSK_SPAR_DATA_FILE_NAME (*string*): If set, problem data is written to this file. File extension determines format. ↔

Synonym: writeprob

MSK_SPAR_PARAM_READ_FILE_NAME (*string*): Modifications to the parameter database is read from this file. ↔

MSK_SPAR_PARAM_WRITE_FILE_NAME (*string*): The parameter database is written to this file. ↔

MSK_SPAR_WRITE_LP_GEN_VAR_NAME (*string*): Sometimes when an LP file is written additional variables must be inserted. ↔

They will have the prefix denoted by this parameter.

Default: "xmskgen"

QEXTRACTALG (*integer*): Switch to choose extraction algorithm for quadratic equations in GAMS interface. ↔

Default: 0

value	meaning
0	Choose automatically.
1	ThreePass: uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage
2	DoubleForward: uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.

SDPCHECKVARS (*boolean*): Switch to disable checking that for every entry of a PSD matrix variable also a corresponding GAMS variable is present. ↔

Default: 1

SDPSOLUFILE (*string*): Name of GDX file to write primal solution of all PSD matrix variables and dual solution for PSD constraints. ↔

SOLVEFINAL (*boolean*): Switch to resolve the problem with fixed discrete variables after the MOSEK optimizer finished. ↔

Default: 1

value	meaning
0	Do not solve the fixed problem.
1	Solve the fixed problem and return duals.

5.29.6 Setting up a GAMS/MOSEK-Link license

To use the GAMS/MOSEK solver with a GAMS/MOSEK-Link license you have save a MOSEK standalone license and point to the MOSEK license file via environment variable **MOSEKLM_LICENSE_FILE**.

5.30 MSNLP

Optimal Methods Inc, 7134 Valburn Dr., Austin, TX 78731 www.optimalmeth.com, 512-346-7837

OptTek System, Inc., 1919 7th St., Boulder, CO 80302, www.opttek.com, 303-447-3255

5.30.1 Introduction

MSNLP is a multistart heuristic algorithm designed to find global optima of smooth constrained nonlinear programs (NLPs). By "multistart" we mean that the algorithm calls an NLP solver from multiple starting points, keeps track of all feasible solutions found by that solver, and reports back the best of these as its final solution. The starting points are computed by a randomized driver, which generates starting points using probability distributions. There are currently two randomized drivers, Pure Random and Smart Random - see the description of the `POINT_GENERATION` parameter. The Smart Random generator uses an initial coarse search to define a promising region within which random starting points are concentrated. When interfaced with the GAMS modeling language, any GAMS NLP solver can be called. When used as a callable system, MSNLP uses the LSGRG2 or any GAMS NLP solver (see www.optimalmeth.com and (Smith and Lasdon, 1992)), and this is also provided (optionally) in the GAMS version.

If a problem is nonsmooth (discontinuous functions and/or derivatives, GAMS problem type DNLP), the NLP solver calls may be less reliable than if the problem was smooth.

There is no guarantee that the final solution is a global optimum, and no bound is provided on how far that solution is from the global optimum. However, the algorithm has been tested extensively on 135 problems from the set gathered by Chris Floudas [Floudas, et al., 1999], and it found the best known solution on all but three of them to within a percentage gap of 1%, using default parameters and options (which specify 1000 iterations). It solved two of those three to within 1% given 2000 iterations. It also solved 332 of 339 problems from the GAMS Globallib library (which has been integrated into the `MINLPlib`) to within 1% of the best known solution using default parameters, and solved most of the seven remaining ones by increasing the iteration limit or using another NLP solver. These results are described in [Lasdon et al., 2004].

A multistart algorithm can improve the reliability of any NLP solver, by calling it with many starting points. If you have a problem where you think the current NLP solver is failing to find even a local solution, choose an NLP solver and a limit on the number of solver calls, and try MSNLP. Even if a single call to the solver fails, multiple calls from the widely spaced starting points provided by this algorithm have a much better chance of success.

Often an NLP solver fails when it terminates at an infeasible solution. In this situation, the user is not sure if the problem is really infeasible or if the solver is at fault (if all constraints are linear or convex the problem is most likely infeasible). A multistart algorithm can help in such cases. To use it, the problem can be solved in its original form, and some solver calls may terminate with feasible solutions. The algorithm will return the best of these. If all solver calls terminate infeasible, the problem can be reformulated as a feasibility problem. That is, introduce "deviation" or "elastic" variables into each constraint, which measure the amount by which it is violated, and minimize the sum of these violations, ignoring the true objective. MSNLP can be applied to this problem, and either has a much better chance of finding a feasible solution (if one exists) than does a single call to an NLP solver. If no feasible solution is found, you have much more confidence that the problem is truly infeasible.

The randomized drivers generate trial points which are candidate starting points for the NLP solver. These are filtered to provide a smaller subset from which the solver attempts to find a local optimum. In the discussion which follows, we refer to this NLP solver as *L*, for Local solver.

The most general problem MSNLP can solve has the form

$$\text{minimize } f(x) \tag{5.15}$$

subject to the nonlinear constraints

$$gl \leq G(x) \leq gu \tag{5.16}$$

and the linear constraints

$$l \leq Ax \leq u \tag{5.17}$$

$$x \in S, \tag{5.18}$$

where x is an n -dimensional vector of continuous decision variables and the vectors gl , gu , l , and u contain upper and lower bounds for the nonlinear and linear constraints respectively. The matrix A is m_2 by n and contains the coefficients of any linear constraint. The set S is defined by simple bounds on x , and we assume that it is closed and bounded, i.e., that each component of x has a finite upper and lower bound. This is required by all drivers (see parameter [ARTIFICIAL_BOUND](#) which provides bounds when none are specified in the model). The objective function f and the m_1 - dimensional vector of constraint functions G are assumed to have continuous first partial derivatives at all points in S . This is necessary so that L can be applied to the NLP problems formed from (5.15) - (5.18).

An important function used in this multistart algorithm is the L_1 exact penalty function, defined as

$$P_1(x, w) = f(x) + \sum_{i=1}^m W_i \text{viol}(g_i(x)) \tag{5.19}$$

where the w_i are nonnegative penalty weights, $m = m_1 + m_2$, and the vector g has been extended to include the linear constraints (5.18). The function $\text{viol}(g_i(x))$ is equal to the absolute amount by which the i th constraint is violated at the point x . It is well known (see [Nash and Sofer, 1996]) that if x^* is a local optimum of (5.15) - (5.18), u^* is a corresponding optimal multiplier vector, the second order sufficiency conditions are satisfied at (x^*, u^*) , and

$$w_t > \text{abs}(u_t^*) \tag{5.20}$$

then x^* is a local unconstrained minimum of P_1 . If (5.15) - (5.18) has several local minima, and each w_i is larger than the maximum of all absolute multipliers for constraint i over all these optima, then P_1 has a local minimum at each of these local constrained minima. We will use P_1 to set thresholds in the merit filter.

5.30.2 Combining Search Methods and Gradient-Based NLP Solvers

For smooth problems, the relative advantages of a search method over a gradient-based NLP solver are its ability to locate an approximation to a good local solution (often the global optimum), and the fact that it can handle discrete variables. Gradient-based NLP solvers converge to the "nearest" local solution, and have no facilities for discrete variables, unless they are embedded in a rounding heuristic or branch-and-bound method. Relative disadvantages of search methods are their limited accuracy, and their weak abilities to deal with equality constraints (more generally, narrow feasible regions). They find it difficult to satisfy many nonlinear constraints to high accuracy, but this is a strength of gradient-based NLP solvers. Search methods also require an excessive number of iterations to find approximations to local or global optima accurate to more than two or three significant figures, while gradient-based solvers usually achieve four to eight-digit accuracy rapidly. The motivation for combining search and gradient-based solvers in a multi-start procedure is to achieve the advantages of both while avoiding the disadvantages of either.

5.30.3 Output

5.30.3.1 Log File

When it operates as a GAMS solver, MSNLP will by default write information on their progress to the GAMS log file. When used as a callable system, this information, if requested, will be written to a file opened in the users calling program. The information written consists of:

1. Echos of important configuration and setup values
2. Echo (optionally) of options file settings processed
3. Echos of important algorithm settings, parameters, and termination criteria
4. The iteration log
5. Final results, termination messages, and status report

A segment of that iteration log from stages 1 and 2 of the algorithm is shown below for the problem *ex8_6_2_30.gms*, which is one of a large set of problems described in [Floudas, et al., 1999]. There are 200 iterations in stage one and 1000 total iterations (see [Appendix A](#) for an algorithm description), with output every 20 iterations and every solver call.

The headings below have the following meanings:

Heading	Meaning
Itn	iteration number
Penval	Penalty function value
Merit Filter	ACC if the merit filter accepts the point, REJ if it rejects
Merit Threshold	threshold value for merit filter: accepts if Penval < Threshold
Dist Filter	ACC if the distance filter accepts the point, REJ if it rejects
Best Obj	Best feasible objective value found thus far
Solver Obj	Objective value found by NLP solver at this iteration
Term Code	Code indicating reason for termination of NLP solver: KTC means Kuhn-Tucker optimality conditions satisfied FRC means that the fractional objective change is less than a tolerance for some number of consecutive iterations INF means solver stopped at an infeasible point
Sinf	sum of infeasibilities at point found by NLP solver

Iterations 0 through 200 below show the initial NLP solver call (at the user-specified initial point, which finds a local minimum with objective value -161.8), and every 20th iteration of stage 1, which has no other solver calls. At iteration 200 stage 1 ends, and the solver is started at the best of the 200 stage 1 points, finding a local min with objective -176.0. The next solver call at iteration 207 finds a better objective of -176.4. Note that, at iteration 207, the OptQuest trial solution has a Penval of -23.18, and this is less than the merit threshold of -20.75, so the merit filter ACCepts the trial solution, as does the distance filter. The next 9 solver calls fail to improve this value, so **Best Obj** remains the same, until at iteration 432 a solution with value -176.6 is found. At iteration 473, the solver call finds a value of -177.5. Further

solver calls do not find an improved solution and are not shown. The solution with value -177.5 is the best known solution, but MSNLP cannot guarantee this.

Itn	Penval	Merit	Merit	Dist	Best	Solver	Term	Sinf
		Filter	Threshold	Filter	Obj	Obj	Code

5.30.3.2 The LOCALS File

The LOCALS file is a text file containing objective and variable values for all local solutions found by MSNLP. It is controlled by the `LOCALS_FILE` and `LOCALS_FILE_FORMAT` keywords in the MSNLP options file. An example for the problem EX_8_1_5 (available on [MINLPLib])(http://www.minlplib.org/gms/ex2_1_5.gms) from the Floudas problem set is shown below. The headings, included for explanatory purposes and not part of the file, have the following meaning:

Heading	Meaning
No.	index of local solution
Obj	objective value of local solution
Var	variable index
Value	variable value

No.	Obj	Var	Value
1	-1.03163e+000	1	-8.98448e-002
1	-1.03163e+000	2	7.12656e-001
2	-1.03163e+000	1	8.98418e-002
2	-1.03163e+000	2	-7.12656e-001
3	-2.15464e-001	1	1.70361e+000
3	-2.15464e-001	2	-7.96084e-001
4	-2.15464e-001	1	-1.70361e+000
4	-2.15464e-001	2	7.96084e-001
5	0.00000e+000	1	0.00000e+000
5	0.00000e+000	2	0.00000e+000
6	2.10425e+000	1	1.60710e+000
6	2.10425e+000	2	5.68656e-001
7	2.10425e+000	1	-1.60711e+000
7	2.10425e+000	2	-5.68651e-001

Thus local solutions 1 and 2 both have objective values of -1.03163. The first solution has variable values $x = -8.98448e-002$, $y = 7.12656e-001$, where these are in the same order as they are defined in the gams model. The second local solution has $x = 8.98418e-002$, $y = -7.12656e-001$. Seven local solutions are found. This output is produced with all default parameter values for MSNLP options and tolerances, except the distance and merit filters were turned off, i.e the keywords [USE_DISTANCE_FILTER](#) and [USE_MERIT_FILTER](#) were set to 0 in the MSNLP options file. This causes the NLP solver to be called at every stage 2 trial point, and is recommended if you wish to obtain as many local solutions as possible.

5.30.4 The Options File

The options file is a text file containing a set of records, one per line. Each record has the form <keyword> <value>, where the keyword and value are separated by one or more spaces. All relevant options are listed in this guide. You can also get a sample option file with all options and their default values by specifying the single option `help` in an option file. The list of all options appears in the log file. The options are described below.

Option	Description	Default
artificial_bound	default upper/lower bound	10000
basin_decrease_factor	reduction of MAXDIST	0.2
basin_overlap_fix	switch for MAXDIST logic	1
distance_factor	distance activation factor	1
distance_waitcycle	iterations before distance filter threshold is increased	20
dynamic_distance_filter	switch for MAXDIST reduction logic	1
dynamic_merit_filter	switch for merit threshold increase logic	1
enable_screen_output	switch for log output	0

Option	Description	Default
<code>enable_statistics_log</code>	switch for statistics file stats.log	0
<code>feasibility_tolerance</code>	feasibility check for point returned by NLP solver	0.0001
<code>iteration_limit</code>	total number of MSNLP iterations	1000
<code>iteration_print_frequency</code>	frequency of iteration print	20
<code>locals_file</code>	filename for local file	
<code>locals_file_format</code>	file format for local file	report
<code>maxtime</code>	maximum runtime in seconds	GAMS ResLim
<code>max_locals</code>	maximum number of local optima found	1000
<code>max_solver_calls</code>	maximum number of NLP solver calls	1000
<code>max_solver_calls_noimprovement</code>	maximum number non-improving solver calls	0
<code>merit_waitcycle</code>	iterations before merit filter threshold is increased	20
<code>nlp_solver</code>	NLP solver to be used	Conopt if licensed otherwise lsgrg
<code>oqnlp_debug</code>	enable debug info	0
<code>point_generation</code>	starting point generator	smartrandom1
<code>sampling_distribution</code>	distribution for smartrandom1	0
<code>solverlink</code>	solverlink for GAMS NLP solver	5
<code>solver_log_to_gams_log</code>	switch to copy the NLP solver log to the normal log file	0
<code>stage1_iterations</code>	number of iterations in stage 1	200
<code>threshold_increase_factor</code>	factor to increase merit filter threshold	0.2
<code>use_distance_filter</code>	distance filter	1
<code>use_merit_filter</code>	merit filter	1

artificial_bound (*real*): default upper/lower bound ↔

This value (its negative) is given to the driver as the upper (lower) bound for any variable with no upper or lower bound. However, the original bounds are given to the local solver, so it can produce solutions not limited by this artificial bound. All drivers must have finite upper and lower bounds for each variable. If **artificial_bound** (or any of the user-supplied bounds) is much larger than any component of the optimal solution, the driver will be less efficient because it is searching over a region that is much larger than needed. Hence the user is advised to try to provide realistic values for all upper and lower bounds. It is even more dangerous to make **artificial_bound** smaller than some component of a globally optimal solution, since the driver can never generate a trial point near that solution. It is possible, however, for the local solver to reach a global solution in this case, since the artificial bounds are not imposed on it

Default: 10000

basin_decrease_factor (*real*): reduction of MAXDIST ↔

This value must be between 0 and 1. If [dynamic_distance_filter](#) is set to 1, the *MAXDIST* value associated with any local solution is reduced by $(1-\text{basin_decrease_factor})$ if [distance_waitcycle](#) consecutive trial points have distance from that solution less than *MAXDIST*.

Range: [0, 1]

Default: 0.2

basin_overlap_fix (*boolean*): switch for MAXDIST logic ↔

A value of 1 turns on logic which checks the *MAXDIST* values of all pairs of local solutions, and reduces any pair of *MAXDIST* values if their sum is greater than the distance between the 2 solutions. This ensures that the spherical models of their basins of attracting do not overlap. A value of 0 turns off this logic. Turning it off can reduce the number of NLP solver calls, but can also cause the algorithm to miss the global solution.

Default: 1

distance_factor (*real*): distance activation factor ↔

If the distance between a trial point and any local solution found previously is less than $\text{distance_factor} * \text{MAXDIST}$, the NLP solver is not started from that trial point. *MAXDIST* is the largest distance ever traveled to get to that local solution. Increasing [distance_factor](#) leads to fewer solver calls and risks finding a worse solution. Decreasing it leads to more solver calls and possibly a better solution.

Default: 1

distance_waitcycle (*integer*): iterations before distance filter threshold is increased ↔

This value must be a positive integer. If the distance filter is used, and there are [distance_waitcycle](#) consecutive iterations where the distance filter logic causes the NLP solver not to be started, the distance filter threshold is increased by the factor [threshold_increase_factor](#). Increasing [distance_waitcycle](#) usually leads to fewer solver calls, but risks finding a worse solution. Decreasing it leads to more solver calls, but may find a better solution.

Default: 20

dynamic_distance_filter (*boolean*): switch for MAXDIST reduction logic ↔

A value of 1 turns on logic which reduces the value of *MAXDIST* (described under the [use_distance_filter](#) keyword) for a local solution if [use_distance_filter](#) consecutive trial points have a their distances from that solution less than *MAXDIST*. *MAXDIST* is multiplied by $(1-\text{basin_decrease_factor})$. A value of 0 turns off this logic. Turning it off can decrease the number of NLP solver calls, but can also lead to a worse final solution.

Default: 1

dynamic_merit_filter (*integer*): switch for merit threshold increase logic ↔

A value of 1 turns on logic which dynamically varies the parameter which increases the merit filter threshold, [threshold_increase_factor](#). If [merit_waitcycle](#) consecutive trial points have been rejected by the merit filter, this value is replaced by $\max(\text{threshold_increase_factor}, \text{val})$, where *val* is the value of [threshold_increase_factor](#) which causes the merit filter to just accept the best of the previous [merit_waitcycle](#) trial points. A value of 0 turns off this logic. Turning it off can reduce NLP solver calls, but may lead to a worse final solution.

Default: 1

enable_screen_output (*boolean*): switch for log output ↔

A value of 0 turns off the writing of the iteration log and termination messages to the GAMS log file that appears on the screen, while 1 enables it.

Default: 0

enable_statistics_log (*boolean*): switch for statistics file stats.log ↔

Using a value of 1 creates a text file called `stats.log` in the project directory containing one line of problem (name, variables, constraints) and performance information (best objective value, total solver time, iterations, iterations to best solution, etc) for each problem solved.

Default: 0

feasibility_tolerance (*real*): feasibility check for point returned by NLP solver ↔

This tolerance is used to check each point returned by an NLP solver for feasibility. If the largest absolute infeasibility at the point is larger than this tolerance, the point is classified infeasible. This test is made because points returned by NLP solvers may occasionally be infeasible despite feasible status codes. Some NLP solvers use internal scaling before testing for feasibility. The unscaled problem may be infeasible, while the scaled one is feasible. If this occurs, increasing this tolerance (to 1.e-2 or larger) often eliminates the problem.

Default: 0.0001

iteration_limit (*integer*): total number of MSNLP iterations ↔

Increasing this limit can allow MSNLP to find a better solution. Try it if your run using 1000 iterations does not take too long. Surprisingly, the best solution using, say 2000 iterations, may be found in the first 1000 iterations, and that solution may be better than the one found with an iteration limit of 1000. This is because OptQuest changes its search strategy depending on the iteration limit. Because of this, it is also possible that increasing the iteration limit will yield a worse solution, but this is rare. Decreasing this iteration limit usually leads to a worse solution, but also reduces run time. MSNLP iterations can not be set using GAMS IterLim. The GAMS IterLim is used as the iteration limit for the NLP subsolves in a MSNLP run.

Default: 1000

iteration_print_frequency (*integer*): frequency of iteration print ↔

Synonym: `gams.itn.print.frequency`

If the MSNLP iteration log is written to the GAMS log file, one line of output is written every *k*th iteration, where *k* is the value given here.

Default: 20

locals_file (*string*): filename for local file ↔

Specify a complete path and name for a file to which the objective value and values of all variables for all local solutions found will be written. For example, `C:\mydirectory\locals.out`. There are 2 possible formats for this file, specified by the [locals_file_format](#) option below. If there is no `locals_file` record in the options file, the locals file will not be created.

locals_file_format (*string*): file format for local file ↔

There are 2 possible values for this option. The `report` entry creates the locals file in a format designed to be examined easily by eye, but processed less easily by a computer program or spreadsheet. The `data1` entry creates a file with many records, each on a single line, each line having the following format: [index of local optimum] [objval] [var index] [var value]

Default: `report`

value	meaning
report	Report file format
data1	Data1 file format

maxtime (*integer*): maximum runtime in seconds ↔

Synonym: reslim

When the execution time exceeds this value, the system will stop, returning the best solution found.

Default: GAMS ResLim

max_locals (*integer*): maximum number of local optima found ↔

When the number of distinct local solutions found exceeds the value specified here, the system will stop, returning the best solution found.

Default: 1000

max_solver_calls (*integer*): maximum number of NLP solver calls ↔

When the number of calls to the NLP solver exceeds the value specified here, the system will stop, returning the best solution found.

Default: 1000

max_solver_calls_noimprovement (*integer*): maximum number non-improving solver calls ↔

The positive integer specified here will cause the system to stop whenever the number of consecutive solver calls with a fractional improvement in the best objective value found less than 1.e-4 exceeds that value. In other words, if the value specified is 50, and there are more than 50 consecutive solver calls where the relative change in the best objective was less than 1.e-4 in all iterations, the system will stop.

Default: 0

merit_waitcycle (*integer*): iterations before merit filter threshold is increased ↔

This value must be a positive integer. If the merit filter is used, and there are **merit_waitcycle** consecutive iterations where the merit filter logic causes the NLP solver not to be started, the merit filter threshold is increased by the factor **threshold_increase_factor**. Increasing **merit_waitcycle** usually leads to fewer solver calls, but risks finding a worse solution. Decreasing it leads to more solver calls, but may find a better solution.

Default: 20

nlpsolver (*string*): NLP solver to be used ↔

This option is available only within GAMS. It specifies the NLP solver to be called. Any GAMS NLP solver for which the user has a license can be used. Further, one can specify an option file for the GAMS NLP solver by appending a **.n** with $n=1..999$ to the solver name. For example, **NLPSOLVER conopt.1** will instruct the NLP solver CONOPT to use option file **conopt.opt**, **NLPSOLVER conopt.2** will make CONOPT read option file **conopt.op2** and so on.

Default: Conopt if licensed otherwise lsgrg

oqnlp_debug (*integer*): enable debug info ↔

Synonym: msnlp_debug

Range: {0, ..., 2}

Default: 0

point_generation (*string*): starting point generator ↔

Selection of point generation algorithm.

Default: smartrandom1

value	meaning
random	random point generation Causes trial points to be generated by sampling each variable from a uniform distribution defined within its bounds
hitandrun	hit and run point generation
smartrandom1	smart random point generation Generates trial points by sampling each variable independently from either normal or triangular distributions, whose parameters are determined as described in Appendix A of the MSNLP User Guide.
test2	test2 point generation
test3	test3 point generation

sampling_distribution (*integer*): distribution for smartrandom1 [↔](#)

This keyword is relevant only when [point_generation](#) is set to `smartrandom1`. Then a value of 0 causes normal distributions to be used to generate trial points, while a value of 1 causes triangular distributions to be used.

Default: 0

value	meaning
0	normal
1	triangular

solverlink (*integer*): solverlink for GAMS NLP solver [↔](#)

Default: 5

value	meaning
1	Call GAMS NLP solver via script
2	Call GAMS NLP solver via module
5	Call GAMS NLP solver in memory

solver_log_to_gams_log (*boolean*): switch to copy the NLP solver log to the normal log file [↔](#)

Setting the parameter to 1 instructs MSNLP to copy the log from the NLP subsolver to the MSNLP log. It can be very helpful to inspect the NLP subsolver log especially if the solver termination code is ???.

Default: 0

stage1_iterations (*integer*): number of iterations in stage 1 [↔](#)

Specifies the total number of iterations in stage 1 of the algorithm, where no NLP solver calls are made. Increasing this sometimes leads to a better starting point for the first local solver call in stage 2, at the cost of delaying that call. Decreasing it can lead to more solver calls, but the first call occurs sooner.

Default: 200

threshold_increase_factor (*real*): factor to increase merit filter threshold [↔](#)

This value must be nonnegative. If there are `merit_waitcycle` consecutive MSNLP iterations where the merit filter logic causes the NLP solver not to be called, the merit threshold is increased by multiplying it by $(1+\text{threshold_increase_factor})$. The same applies to the `distance_waitcycle`.

Default: 0.2

use_distance_filter (*boolean*): distance filter \leftrightarrow

Use 0 to turn off the distance filter, the logic which starts the NLP solver at a trial point only if the (Euclidean) distance from that point to any local solution found thus far is greater than the distance threshold. Turning off the distance filter leads to more solver calls and more run time, and increases the chances of finding a global solution. Turn off both distance and merit filters to find (almost) all local solutions.

Default: 1

use_merit_filter (*boolean*): merit filter \leftrightarrow

Use 0 to turn off the merit filter, the logic which starts the NLP solver at a trial point only if the penalty function value at that point is below the merit threshold. This will lead to more solver calls, but increases the chances of finding a global solution. Turn off both filters if you want to find (almost) all local solutions. This will cause the solver to be called at each stage 2 iteration.

Default: 1

5.30.5 Use as a Callable System

MSNLP is also available as a callable system. It currently uses the LSGRG2 or any GAMS NLP solver as its local solver. A sample calling program is available from Optimal Methods which a user can easily adapt. The user must provide a C function which computes values of the objective and all constraint functions, given current values of all variables. First partial derivatives of these functions can be approximated by forward or central differences, or may be computed in a user-provided function.

5.30.6 Appendix

5.30.6.1 Appendix A: Description of the Algorithm

A pseudo-code description of the MSNLP algorithm follows, in which SP (xt) denotes the starting point generator and xt is the candidate starting point produced. We refer to the local NLP solver as $L(xs, xf)$, where xs is the starting point and xf the final point. The function UPDATE LOCALS (xs, xf, w) processes and stores solver output xf , using the starting point xs to compute the distance from xs to xf , and produces updated penalty weights, w . For more details, see [Lasdon, Plummer et al., 2004].

MSNLP Algorithm

STAGE 1

x_0 = user initial point

Call $L(x_0, xf)$

Call UPDATE LOCALS (x_0, xf, w)

FOR $i = 1, n1$ **DO**

Call SP ($xt(i)$)

Evaluate P ($xt(i), w$)

ENDDO

xt^* = point yielding best value of P ($xt(i), w$) over all stage one points, ($i = 1, 2, \dots, n1$).

call $L(xt^*, xf)$

Call UPDATE LOCALS (xt^*, xf, w)

threshold = P (xt^*, w)

STAGE 2

FOR $i = 1, n2$ **DO**

Call SP ($xt(i)$)

Evaluate P ($xt(i), w$)

Perform merit and distance filter tests:

Call distance filter($xt(i), dstatus$)

Call merit filter($xt(i), threshold, mstatus$)

IF ($dstatus$ and $mstatus = \text{"accept"}$) **THEN**

Call $L(xt(i), xf)$

Call UPDATE LOCALS ($xt(i), xf, w$)

ENDIF

ENDDO

After an initial call to L at the user-provided initial point, x_0 , stage 1 of the algorithm performs $n1$ iterations in which SP (xt) is called, and the L1 exact penalty value P (xt, w) is calculated. The user can set $n1$ through the MSNLP options file using the [STAGE1.ITERATIONS](#) keyword. The point with the smallest of these P values is chosen as the starting point for the next call to L , which begins stage 2. In this stage, $n2$ iterations are performed in which candidate starting points are generated and L is started at any one which passes the distance and merit filter tests.

The distance filter helps insure that the starting points for L are diverse, in the sense that they are not too close to any previously found local solution. Its goal is to prevent L from starting more than once within the basin of attraction of any local optimum. When a local solution is found, it is stored in a linked list, ordered by its objective value, as is the Euclidean distance between it and the starting point that led to it. If a local solution is located more than once, the maximum of these distances, $maxdist$, is updated and stored. For each trial point, t , if the distance between t and any local solution already found is less than [DISTANCE_FACTOR](#)* $maxdist$, L is not started from the point, and we obtain the next trial solution from the generator.

This distance filter implicitly assumes that the attraction basins are spherical, with radii at least $maxdist$. The default value of [DISTANCE_FACTOR](#) is 1.0, and it can be set to any positive value in the MSNLP options file - see Section [Output](#). As [DISTANCE_FACTOR](#) approaches zero, the filtering effect vanishes, as would be appropriate if there were many closely spaced local solutions. As it becomes larger than 1, the filtering effect increases until eventually L is never started.

The merit filter helps insure that the starting points for L have high quality, by not starting from candidate points whose exact penalty function value P_1 (see equation (5), Section [Introduction](#)) is greater than a threshold. This threshold is set initially to the P_1 value of the best candidate point found in the first stage of the algorithm. If trial points are rejected by this test for more than `WAITCYCLE` consecutive iterations, the threshold is increased by the updating rule:

$$\text{threshold} \leftarrow \text{threshold} + \text{THRESHOLD_INCREASE_FACTOR} * (1.0 + \text{abs}(\text{threshold}))$$

where the default value of `THRESHOLD_INCREASE_FACTOR` is 0.2 and that for `WAITCYCLE` is 20. The additive 1.0 term is included so that threshold increases by at least `THRESHOLD_INCREASE_FACTOR` when its current value is near zero. When a trial point is accepted by the merit filter, threshold is decreased by setting it to the P_1 value of that point.

The combined effect of these 2 filters is that L is started at only a few percent of the trial points, yet global optimal solutions are found for a very high percentage of the test problems. However, the chances of finding a global optimum are increased by increasing `ITERATION_LIMIT` (which we recommend trying first) or by "loosening" either or both filters, although this is rarely necessary in our tests if the dynamic filters and basin overlap fix are used, as they are by default. If the ratio of stage 2 iterations to solver calls is more than 20 using the current filter parameters, and computation times with the default filter parameters are reasonable, you can try loosening the filters. This is achieved for the merit filter either by decreasing `WAITCYCLE` or by increasing `THRESHOLD_INCREASE_FACTOR` (or doing both), and for the distance filter by decreasing `DISTANCE_FACTOR`. Either or both filters may be turned off, by setting `USE_DISTANCE_FILTER` and/or `USE_MERIT_FILTER` to 0. Turning off both causes an NLP solver call at every stage 2 trial point. This is the best way to insure that all local optima are found, but it can take a long time.

5.30.6.2 Appendix B: Pure and 'Smart' Random Drivers

The "pure" random (PR) driver generates uniformly distributed points within the hyper-rectangle S defined by the variable bounds. However, this rectangle is often very large, because users often set bounds to $(-\infty, +\infty)$, $(0, +\infty)$, or to large positive and/or negative numbers, particularly in problems with many variables. This usually has little adverse impact on a good local solver, as long as the starting point is chosen well inside the bounds. But the PR generator will often generate starting points with very large absolute component values when some bounds are very large, and this sharply degrades solver performance. Thus we were motivated to develop random generators which control the likelihood of generating candidate points with large components, and intensify the search by focusing points into promising regions. We present two variants, one using normal, the other triangular distributions. Pseudo-code for this "smart random" generator using normal distributions follows, where w is the set of penalty weights determined by the "update locals" logic discussed above, after the first solver call at the user-specified initial point.

Smart Random Generator with Normal Distributions, SRN (xt)

IF (first call) **THEN**

Generate k_1 (default 400) diverse points in S and evaluate the exact penalty function $P(x, w)$ at each point.

$B =$ subset of S with k_2 (default 10) best P values

FOR $i = 1, nvars$ **DO**

$x_{\max}(i) =$ max of component i of points in B

$x_{\min}(i) =$ min of component i of points in B

$\mu(i) = (x_{\max}(i) + x_{\min}(i))/2$

```
ratio(i) = (xmax(i) - xmin(i))/(1+buvar(i)-blvar(i))
```

```
sigfactor = 2.0
```

```
IF (ratio > 0.7) sigfactor = f(ratio)
```

```
sigma(i) = (xmax(i) - xmin(i))/sigfactor
```

```
ENDDO
```

```
ENDIF
```

```
FOR i =1,nvars DO
```

```
    Generate a normally distributed random variable rv(i) with mean mu(i) and standard deviation
    sigma(i)
```

```
    If rv(i) is between blvar(i) and buvar(i), xt(i) = rv(i)
```

```
    If rv(i) < blvar(i), generate xt(i) uniformly between blvar(i) and xmin(i)
```

```
    If rv(i) < buvar(i), generate xt(i) uniformly between xmax(i) and buvar(i)
```

```
ENDDO
```

```
Return xt
```

This SRN generator attempts to find a subset, B , of k_2 "good" points, and generates most of its trial points xt , within the smallest rectangle containing B . It first generates a set of k_1 diverse points within the bounds using a stratified random sampling procedure with frequency-based memory. For each variable $x(i)$, this divides the interval $[blvar(i), buvar(i)]$ into 4 equal segments, chooses a segment with probability inversely proportional to the frequency with which it has been chosen thus far, then generates a random point in this segment. We choose k_2 of these points having the best $P(x, w)$ penalty values, and use the smallest rectangle containing these, intersecting the i th axis at points $[xmin(i), xmax(i)]$, to define n univariate normal distributions (driver SRN) or n univariate triangular distributions (driver SRT). The mean of the i th normal distribution, $\mu(i)$, is the midpoint of the interval $[xmin(i), xmax(i)]$, and this point is also the mode of the i th triangular distribution, whose lower and upper limits are $blvar(i)$ and $buvar(i)$. The standard deviation of the i th normal distribution is selected as described below. The trial point xt is generated by sampling n times independently from these distributions. For the driver using normals, if the generated point lies within the bounds, it is accepted. Otherwise, we generate a uniformly distributed point between the violated bound and the start of the interval.

To determine the standard deviation of the normal distributions, we compute *ratio*, roughly the ratio of interval width to distance between bounds, where the factor 1.0 is included to avoid division by zero when the bounds are equal (fixed variables). If the interval width is small relative to the distance between bounds for variable i ($ratio \leq 0.7$), then the standard deviation $\sigma(i)$ is half the interval width, so about 1/3 of the $xt(i)$ values fall outside the interval, providing diversity when the interval does not contain an optimal value for $x(i)$. If the bounds are large, then ratio should be small, say less than 0.1, so $xt(i)$ values near the bounds are very unlikely. If $ratio > 0.7$, the function f sets sigfactor equal to 2.56 if ratio is between 0.7 and 0.8, increasing in steps to 6.2 if $ratio > 0.999$. Thus if *ratio* is near 1.0, more than 99% of the values fall within the interval, and few have to be projected back within the bounds. The projecting back process avoids undesirable clustering of trial points at a bound, by generating points uniformly between the violated bound and the nearest edge of the interval $[xmin(i), xmax(i)]$. When the interval $[xmin(i), xmax(i)]$ is sharply skewed toward one of the variable bounds and is much narrower than the distance between the bounds, a symmetric distribution like the normal, combined with our projection procedure, generates too many points between the interval and its nearest bound. A quick scan of the test results indicates that this happens rarely, but an asymmetric distribution like the triangular overcomes this difficulty, and needs no projection.

5.31 NLPEC

5.31.1 Introduction

The GAMS/NLPEC solver, developed jointly by Michael Ferris of UW-Madison and GAMS Development, solves MPEC and MCP models via reformulation of the complementarity constraints. The resulting sequence of NLP models are parameterized by a scalar μ and solved by existing NLP solvers. The resulting solutions are used to recover an MPEC or MCP solution.

GAMS/NLPEC serves a number of purposes. In many cases, it is an effective tool for solving MPEC models, the first such tool available within GAMS. It also serves as a way to experiment with the many reformulation strategies proposed for solving MPEC and MCP models. Without something like NLPEC (and a library of models to test with) a comprehensive and thorough test and comparison of the various reformulation strategies would not be possible. To better serve these purposes, NLPEC has an open architecture. The model reformulations are written out as GAMS source for solution via an NLP solver, so it is possible to view this source and modify it if desired.

A brief note about notation is in order. The GAMS keyword `positive` is used to indicate nonnegative variables. The same holds for nonpositive variables and the GAMS keyword `negative`.

5.31.2 Usage

GAMS/NLPEC can solve models of two types: MPEC and MCP. If you did not specify NLPEC as the default MPEC or MCP solver, use the following statement in your GAMS model before the solve statement:

```
option MPEC=nlpec; { or MCP }
```

You can also make NLPEC the default solver via the command line:

```
gams nash MPEC=nlpec MCP=nlpec
```

You can use NLPEC with its default strategy and formulation, but most users will want to use an options file (Section [Options](#)) after reading about the different types of reformulations possible (Section [Reformulation](#)). In addition, an understanding of the architecture of NLPEC (Section [Open Architecture](#)) will be helpful in understanding how GAMS options are treated. Although NLPEC doesn't use the GAMS options `workspace`, `workfactor`, `optcr`, `optca`, `reslim`, `iterlim`, and `domlim` directly, it passes these options on in the reformulated model so they are available to the NLP subsolver.

5.31.3 Reformulation

In this section we describe the different ways that the NLPEC solver can reformulate an MPEC as an NLP. The description also applies to MCP models: just consider MCP to be an MPEC with a constant objective. The choice of reformulation, and the subsidiary choices each reformulation entails, are controlled by the options described in the section on [Setting the Reformulation Options](#) and referenced throughout this section.

The original MPEC model is given as:

$$\min_{x \in \mathbf{R}^n, y \in \mathbf{R}^m} f(x, y) \quad (1)$$

subject to the constraints

$$g(x, y) \leq 0 \quad (2)$$

and

$$y \text{ solves } \text{MCP}(h(x, \cdot), \mathbf{B}). \quad (3)$$

In most of the reformulations, the objective function (1) is included in the reformulated model without change. In some cases, it may be augmented with a penalty function. The variables x are typically called upper level variables (because they are associated with the upper level optimization problem) whereas the variables y are sometimes termed lower level variables.

The constraints (2) are standard nonlinear programming constraints specified in GAMS in the standard fashion. In particular, these constraints may be less than inequalities as shown above, or equalities or greater than inequalities. The constraints will be unaltered by all our reformulations. These constraints may involve both x and y , or just x or just y , or may not be present at all in the problem.

The constraints of interest are the equilibrium constraints (3), where (3) signifies that $y \in \mathbf{R}^m$ is a solution to the mixed complementarity problem (MCP) defined by the function $h(x, \cdot)$ and the box \mathbf{B} containing (possibly infinite) simple bounds on the variables y . A point y with $a_i \leq y_i \leq b_i$ solves (3) if for each i at least one of the following holds:

$$\begin{aligned} h_i(x, y) &= 0 \\ h_i(x, y) &\geq 0, y_i = a_i; \\ h_i(x, y) &\leq 0, y_i = b_i. \end{aligned} \quad (4)$$

As a special case of (4), consider the case where $a = 0$ and $b = +\infty$. Since y_i can never be $+\infty$ at a solution, (4) simplifies to the nonlinear complementarity problem (NCP):

$$0 \leq h_i(x, y), 0 \leq y_i \text{ and } y_i h_i(x, y) = 0, i = 1, \dots, m \quad (5)$$

namely that h and y are nonnegative vectors with h perpendicular to y . This motivates our shorthand for (4), the "perp to" symbol \perp :

$$h_i(x, y) \perp y_i \in [a_i, b_i] \quad (6)$$

The different ways to force (6) to hold using (smooth) NLP constraints are the basis of the NLPEC solver.

We introduce a simple example now that we will use throughout this document for expositional purposes:

$$\begin{aligned} \min_{x_1, x_2, y_1, y_2} \quad & x_1 + x_2 \\ \text{subject to} \quad & x_1^2 + x_2^2 \leq 1 \\ & y_1 - y_2 + 1 \leq x_1 \perp y_1 \geq 0 \\ & x_2 + y_2 \perp y_2 \in [-1, 1] \end{aligned}$$

This problem has the unique solution $x_1 = 0$, $x_2 = -1$, $y_1 = 0$, $y_2 = 1$. Note that $f(x, y) = x_1 + x_2$ and $g(x, y) = x_1^2 + x_2^2 - 1$ are the objective function and the standard nonlinear programming constraints for this problem. The function $h(x, y)$ is given by:

$$h(x, y) = \begin{bmatrix} x_1 - y_1 + y_2 - 1 \\ x_2 + y_2 \end{bmatrix}$$

and

$$a = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \quad b = \begin{bmatrix} \infty \\ 1 \end{bmatrix}.$$

This example is written very succinctly in GAMS notation as:

```
$TITLE simple mpec example

variable f, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up = 1;

equations cost, g, h1, h2;

cost.. f =E= x1 + x2;
g..    sqr(x1) + sqr(x2) =L= 1;
h1..   x1 =G= y1 - y2 + 1;
h2..   x2 + y2 =N= 0;

model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min f;
```

Note that the equation `cost` is used to define f , the constraint `g` defines the function g , and h is defined by `h1` and `h2`. The complementarity constraints utilize the standard GAMS convention of specifying the orthogonality relationship between h and y in the `model` statement. The interpretation of the “.” relies on the bounds a and b that are specified using `positive`, `negative`, or `lo` and `up` keywords in GAMS. Note that since `h2` really specifies a function h_2 and not a constraint $h_2(x, y) = 0$, we use the GAMS syntax `=N=` to ensure this is clear here. Since the relationships satisfied by h_1 and h_2 are determined by the bounds, `=G=` could also be replaced by `=N=` in `h1`.

In describing the various reformulations for (6), it is convenient to partition the y variables into free \mathcal{F} , lower bounded \mathcal{L} , upper bounded \mathcal{U} and doubly bounded \mathcal{B} variables respectively, that is:

$$\mathbf{B} := \{y = (y_{\mathcal{F}}, y_{\mathcal{L}}, y_{\mathcal{U}}, y_{\mathcal{B}}) : a_{\mathcal{L}} \leq y_{\mathcal{L}}, y_{\mathcal{U}} \leq b_{\mathcal{U}}, a_{\mathcal{B}} \leq y_{\mathcal{B}} \leq b_{\mathcal{B}}\}.$$

We will assume (without loss of generality) that $a_{\mathcal{B}} < b_{\mathcal{B}}$. If $a_i = b_i$ then (6) holds trivially for the index i and we can remove the constraint h_i and its corresponding (fixed) variable y_i from the model. The complementarity condition for variables in $y_i \in \mathcal{F}$ is simply the equality $h_i(x, y) = 0$ so these equality constraints are moved directly into the NLP constraints g of the original model as equalities. Thus, NLPEC needs only to treat the singly-bounded variables in \mathcal{L} and \mathcal{U} and the doubly-bounded variables in \mathcal{B} . In the above example, $\mathcal{L} = \{1\}$, $\mathcal{U} = \emptyset$ and $\mathcal{B} = \{2\}$.

5.31.3.1 Product reformulations

Product reformulations all involve products of y_i with h_i , or products of y_i with some auxiliary or slack variables that are set equal to h_i . The underlying point is that the constraints (3) are entirely equivalent to the following system of equalities and inequalities:

$$\begin{aligned} w_{\mathcal{L}} &= h_{\mathcal{L}}(x, y), \quad a_{\mathcal{L}} \leq y_{\mathcal{L}}, \quad w_{\mathcal{L}} \geq 0 \quad \text{and} \quad (y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} = 0 \\ v_{\mathcal{U}} &= -h_{\mathcal{U}}(x, y), \quad y_{\mathcal{U}} \leq b_{\mathcal{U}}, \quad v_{\mathcal{U}} \geq 0 \quad \text{and} \quad (b_{\mathcal{U}} - y_{\mathcal{U}})^T v_{\mathcal{U}} = 0 \\ w_{\mathcal{B}} - v_{\mathcal{B}} &= h_{\mathcal{B}}(x, y), \quad a_{\mathcal{B}} \leq y_{\mathcal{B}} \leq b_{\mathcal{B}}, \quad w_{\mathcal{B}} \geq 0, \quad v_{\mathcal{B}} \geq 0 \\ &\quad (y_{\mathcal{B}} - a_{\mathcal{B}})^T w_{\mathcal{B}} = 0, \quad (b_{\mathcal{B}} - y_{\mathcal{B}})^T v_{\mathcal{B}} = 0. \end{aligned} \tag{7}$$

Note that each inner product is a summation of products of nonnegative terms: a slack variable and the difference between a variable and its bound. In each of these products, either the slack variable or its complement must be zero in order to have a solution. Complementarity is forced by the multiplication of these two terms. The above reformulation is specified using option `reftype mult`.

There are a number of variations on this theme, all of which can be specified via an options file. All of the inner products could be put into the same equation, left as in (7) above, or broken out into individual products (one for each $i \in \mathcal{L} \cup \mathcal{U}$, two for each $i \in \mathcal{B}$). For example, the complementarity constraints associated with lower bounded variables involve nonnegativity of $w_{\mathcal{L}}$, $y_{\mathcal{L}} \geq a_{\mathcal{L}}$ and either of the following alternatives:

$$(y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} = \sum_{i \in \mathcal{L}} (y_i - a_i) w_i = 0$$

or

$$(y_i - a_i) w_i = 0, \quad i = 1, \dots, m$$

These different levels of aggregation are chosen using option `aggregate none|partial|full`.

Since all of the inner products in (7) involve nonnegative terms, we can set the inner products equal to zero or set them ≤ 0 without changing the feasible set. To choose one or the other, use the option `constraint equality|inequality`.

As a concrete example, consider the option file

```
reftype mult
aggregate none
constraint inequality
```

applied to the simple example given above. Such an option file generates the nonlinear programming model:

$$\begin{aligned} \min_{x_1, x_2, y_1, y_2, w_1, w_2, v_2} \quad & x_1 + x_2 \\ \text{subject to} \quad & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\ & w_1 y_1 \leq \mu \\ & w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1] \\ & (y_2 + 1)w_2 \leq \mu, (1 - y_2)v_2 \leq \mu \end{aligned} \tag{8}$$

By default, a single model is generated with the value μ set to 0. There are many examples (e.g. interior point codes, many LP and NLP packages, published results on reformulation approaches to MPEC) that illustrate the value of starting with a "nearly-complementary" solution and pushing the complementarity gap down to zero. For this reason, the inner products in (7) above are always set equal to (or \leq) a scalar μ instead of zero. By default μ is zero, but options exist to start μ at a positive value (e.g. `InitMu 1e-2`), to decrease it by a constant factor in a series of looped solves (e.g. `NumSolves 4, UpdateFac 0.1`), and to solve one last time with a final value for μ (e.g. `FinalMu 0`). If the following lines are added to the option file

```
initmu 1.0
numsolves 4
```

then five consecutive solves of the nonlinear program (8) are performed, the first one using $\mu = 1$ and each subsequent solve dividing μ by 10 (and starting the NLP solver at the solution of the previous model in this sequence).

As a final example, we use a combination of these options to generate a sequence of nonlinear programs whose solutions attempt to trace out the "central path" favored by interior point and barrier algorithms:

```
reftype mult
constraint equality
initmu 1.0
numsolves 4
updatefac 0.1
finalmu 1e-6
```

produces 6 nonlinear programs of the form

$$\begin{array}{ll} \min_{x_1, x_2, y_1, y_2, w_1, w_2, v_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\ & w_1 y_1 = \mu \\ & w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1], (y_2 + 1)w_2 = \mu, (y_2 - 1)v_2 = \mu \end{array}$$

for values of $\mu = 1, 0.1, 0.01, 0.001, 0.0001$ and $1e - 6$.

5.31.3.1.1 Slacks and doubly bounded variables Slack variables can be used to reduce the number of times a complex nonlinear expression appears in the nonlinear programming model, as was carried out in (7). For a simpler illustrative example the NCP constraints (5) are equivalent to the constraints:

$$w_i = h_i(x, y), 0 \leq w_i, 0 \leq y_i \text{ and } y_i w_i = 0, i = 1, \dots, m$$

This reformulation has an additional equality constraint, and additional variables w , but the expression h_i only appears once. There are cases when this formulation will be preferable, and the simple option `slack none|positive` controls the use of the w variables.

When there are doubly bounded variables present, these two slack options work slightly differently. For the `positive` case, the reformulation introduces two nonnegative variables w_i and v_i that take on the positive and negative parts of h_i at the solution as shown in (7). Since this is the default value of the option `slack`, the example (8) shows what ensues to both singly and doubly bounded variables under this setting.

For the case `slack none`, Scholtes proposed a way to use a multiplication to force complementarity that requires no slack variables:

$$h_i \perp a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i, (y_i - a_i)h_i \leq \mu, (y_i - b_i)h_i \leq \mu \quad (9)$$

Note that unlike the inner products in Section [Reformulation](#), we can expect that one of the inequalities in (9) is unlikely to be binding at a solution (i.e. when h_i is nonzero). Therefore, we cannot use an equality in this reformulation, and furthermore the products must not be aggregated. Thus, if you use this option, the reformulation automatically enforces the additional options `constraint inequality` and `aggregate none` on the doubly bounded variables, even if the user specifies a conflicting option. Thus the option file

```
reftype mult
slack none
```

results in the model

$$\begin{array}{ll} \min_{x_1, x_2, y_1, y_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & x_1 - y_1 + y_2 - 1 \geq 0, y_1 \geq 0 \\ & (x_1 - y_1 + y_2 - 1)y_1 = \mu \\ & y_2 \in [-1, 1], (y_2 + 1)(x_2 + y_2) \leq \mu, (y_2 - 1)(x_2 + y_2) \leq \mu \end{array}$$

Note that the complementarity constraint associated with y_1 is an equality (the default) while the constraints associated with y_2 are inequalities for the reasons outlined above.

In the case of doubly bounded variables, a third option is available for the slack variables, namely `slack one`. In this case, only one slack is introduced, and this slack removes the need to write the function h_i twice in the reformulated model as follows:

$$h_i(x, y) \perp a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i, w_i = h_i(x, y), (y_i - a_i)w_i \leq \mu, (y_i - b_i)w_i \leq \mu$$

Note that the slack variable w that is introduced is a free variable. It is not known before solving the problem whether w_i will be positive or negative at the solution.

We take this opportunity to introduce a simple extension to our option mechanism, namely the ability to set the options for singly and doubly bounded variables differently. For example, the option file

```
reftype mult
slack positive one
```

sets the option `slack positive` for the singly bounded variables and the option `slack one` for the doubly bounded variables resulting in the model

$$\begin{array}{ll} \min_{x_1, x_2, y_1, y_2, w_1, w_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\ & w_1 y_1 = \mu_1 \\ & w_2 = x_2 + y_2, y_2 \in [-1, 1], (y_2 + 1)w_2 \leq \mu_2, (y_2 - 1)w_2 \leq \mu_2 \end{array}$$

Additional options such as

```
initmu 1.0 3.0
numsolves 2
updatefac 0.1 0.2
```

allow the values of μ for the singly and doubly bounded variables to be controlled separately. In this case μ_1 takes on values of 1, 0.1 and 0.01, while μ_2 takes on values 3.0, 0.6 and 0.12 in each of the three nonlinear programming models generated.

5.31.3.2 NCP functions

An NCP-function is a function $\phi(r, s)$ with the following property:

$$\phi(r, s) = 0 \iff r \geq 0, s \geq 0, rs = 0$$

Clearly, finding a zero of an NCP-function solves a complementarity problem in (r, s) . We can replace the inner products of nonnegative vectors in (7) with a vector of NCP functions whose arguments are complementary pairs, e.g. $(y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} = 0$ becomes $\phi(y_i - a_i, w_i) = 0, i \in \mathcal{L}$ and arrive at another way to treat the complementarity conditions. Note that an NCP function forces both nonnegativity and complementarity, so constraints to explicitly force nonnegativity are not required, though they can be included.

Examples of NCP functions include the min function, $\min(\mathbf{r}, \mathbf{s})$, and the Fischer-Burmeister function

$$\phi(r, s) = \sqrt{r^2 + s^2} - r - s$$

There is no requirement that an NCP function be nonnegative everywhere (it may be strictly negative at some points), so there is little point in setting the option `constraint`; it will automatically take on the value `constraint equality`. NCP functions cannot be aggregated, so the `aggregate` option will always be set to `none`.

Since the arguments to the NCP functions are going to be nonnegative at solution, we cannot use the functions h_i directly in the case of doubly-bounded variables. We must use slacks $w - v = h_i$ to separate h_i into its positive and negative parts (but see Section [Doubly bounded variables](#) below). The slacks can be **positive** or **free**, since the NCP function will force positivity at solution. For the singly-bounded variables, slacks are optional, and can also be **positive** or **free**.

Both of the NCP functions mentioned above suffer from being non-differentiable at the origin (and at points where $r = s$ for the min function). Various smoothed NCP-functions have been proposed that are differentiable. These smooth functions are parameterized by μ , and approach the true NCP-function as the smoothing parameter approaches zero. For example, the Fischer-Burmeister function includes a perturbation μ that guarantees differentiability:

$$\phi_{FB}(r, s) := \sqrt{r^2 + s^2 + 2\mu} - (r + s). \quad (10)$$

You can choose these particular NCP functions using option **RefType** `min|FB|fFB`. The difference between the last two is that **RefType** `FB` writes out GAMS code to compute the function ϕ_{FB} , while **RefType** `fFB` makes use of the GAMS intrinsic function `NCPFB(r,s,mu)` that computes ϕ_{FB} internally. In general, using the GAMS intrinsic function should work better since the intrinsic can guard against overflow, scale the arguments before computing the function, and use alternative formulas that give more accurate results for certain input ranges.

As an example, the option file

```
reftype fFB
slack free
initmu 1e-2
```

generates the reformulation

$$\begin{array}{ll} \min_{x_1, x_2, y_1, y_2, w_1, w_2, v_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1 \\ & \phi_{FB}(w_1, y_1, \mu) = 0 \\ & w_2 - v_2 = x_2 + y_2 \\ & \phi_{FB}(y_2 + 1, w_2, \mu) = 0, \phi_{FB}(1 - y_2, v_2, \mu) = 0 \end{array}$$

with a value of $\mu = 0.01$. Following a path of solutions for decreasing values of μ is possible using the options discussed above.

Each of the two arguments to the NCP function will be nonnegative at solution, but for each argument we have the option of including a nonnegativity constraint explicitly as well. This results in the 4 values for the option **NCPBounds** `none|all|function|variable`. When no slacks are present, this option controls whether to bound the function h_i as well as including it in the NCP function, e.g. $h_i \geq 0$, $\phi(h_i, y_i - a_i) = 0$. When slacks are present, we require that the slack setting be consistent with the bound setting for the function argument to the NCP function, where **NCPBounds** `none|variable` is consistent with free slack variables and **NCPBounds** `all|function` is consistent with positive slack variables.

Thus, the option file

```
reftype min
slack positive
NCPBounds function
```

generates the reformulation

$$\begin{aligned}
 & \min_{x_1, x_2, y_1, y_2, w_1, w_2, v_2} && x_1 + x_2 \\
 & \text{subject to} && x_1^2 + x_2^2 \leq 1 \\
 & && w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0 \\
 & && \min(w_1, y_1) = \mu \\
 & && w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0 \\
 & && \min(y_2 + 1, w_2) = \mu, \min(1 - y_2, v_2) = \mu
 \end{aligned}$$

The `NCPBounds` function option means that the variable argument to the NCP function (in this case y) does not have its bounds explicitly enforced. It should be noted that this nonlinear program has nondifferentiable constraints for every value of μ . For this reason, the model is constructed as a `dnlp` model (instead of an `nlp` model) in GAMS.

A smoothed version of the min function was proposed by Chen & Mangasarian:

$$\phi_{CM}(r, s) := r - \mu \log(1 + \exp((r - s)/\mu)). \quad (11)$$

This function is not symmetric in its two arguments, so $\phi_{CM}(r, s) \neq \phi_{CM}(s, r)$. For this reason, we distinguish between the two cases. Unlike the Fischer-Burmeister function ϕ_{FB} , ϕ_{CM} is not defined in the limit (i.e. for $\mu = 0$) if you use GAMS code to compute it. However, the GAMS intrinsic `NCPCM(r,s,mu)` handles this limit case internally. The option `RefType CMxf|CMfx|fCMxf|fCMfx` chooses a reformulation based on the function ϕ_{CM} . Again, the last two choices use the GAMS intrinsic function.

5.31.3.2.1 Doubly bounded variables Like the mult reformulation (7), reformulations using NCP functions are appropriate as long as we split the function h_i matching a doubly-bounded variable into its positive and negative parts $w_i - v_i = h_i$. To avoid this, Billups has proposed using a composition of NCP functions to treat the doubly-bounded case:

$$h_i \perp a_i \leq y_i \leq b_i \iff \phi_{FB}(y_i - a_i, \phi_{FB}(b_i - y_i, -h_i)) = 0 \quad (12)$$

Use option `RefType Bill|fBill` to choose such a reformulation for the doubly-bounded variables. The first option value writes out the function in explicit GAMS code, while the second writes it out using the GAMS intrinsic function `NCPFB`.

5.31.3.3 Penalty functions

All of the reformulations discussed so far have reformulated the complementarity conditions as constraints. It is also possible to treat these by moving them into the objective function with a penalty parameter $1/\mu$: as μ goes to zero, the relative weight placed on complementarity increases. Ignoring the NLP constraints, we can rewrite the original MPEC problem as

$$\min_{x \in \mathbf{R}^n, y \in \mathbf{R}^m} f(x, y) + \frac{1}{\mu} ((y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} + (b_{\mathcal{U}} - y_{\mathcal{U}})^T v_{\mathcal{U}} + (y_{\mathcal{B}} - a_{\mathcal{B}})^T w_{\mathcal{B}} + (b_{\mathcal{B}} - y_{\mathcal{B}})^T v_{\mathcal{B}}) \quad (13)$$

subject to the constraints

$$\begin{aligned}
 & g(x, y) \leq 0 \\
 & w_{\mathcal{L}} = h_{\mathcal{L}}(x, y), a_{\mathcal{L}} \leq y_{\mathcal{L}}, w_{\mathcal{L}} \geq 0 \\
 & v_{\mathcal{U}} = -h_{\mathcal{U}}(x, y), y_{\mathcal{U}} \leq b_{\mathcal{U}}, v_{\mathcal{U}} \geq 0 \\
 & w_{\mathcal{B}} - v_{\mathcal{B}} = h_{\mathcal{B}}(x, y) a_{\mathcal{B}} \leq y_{\mathcal{B}} \leq b_{\mathcal{B}}, w_{\mathcal{B}} \geq 0, v_{\mathcal{B}} \geq 0
 \end{aligned} \quad (14)$$

Choose this treatment using option `refType penalty`. The options `aggregate` and `constraint` are ignored, since the inner products here are all aggregated and there are no relevant constraints. It is possible to do a similar reformulation without using slacks, so the options `slack none|positive` can be used in conjunction with this reformulation type.

The following option file shows the use of the `penalty` reformulation, but also indicates how to use a different reformulation for the singly and doubly bounded variables:

```
reftype penalty mult
slack none *
initmu 1.0
numsolves 2
updatefac 0.1 0.2
```

The "*" value allows the `slack` option to take on its existing value, in this case `positive`. Applied to our simple example given above, such an option file generates the nonlinear programming model:

$$\begin{array}{ll} \min_{x_1, x_2, y_1, y_2, w_2, v_2} & x_1 + x_2 + \frac{1}{\mu_1} y_1 (x_1 - y_1 + y_2 - 1) \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & x_1 - y_1 + y_2 - 1 \geq 0, y_1 \geq 0 \\ & w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1] \\ & (y_2 + 1)w_2 \leq \mu_2, (1 - y_2)v_2 \leq \mu_2 \end{array}$$

The penalty parameter μ_1 is controlled separately from the doubly bounded constraint parameter μ_2 . For consistency with other options, the penalty parameter in the objective is $1/\mu$ meaning that as μ_1 tends to zero, the penalty increases. The option `initmu` has only one value, so both the singly and doubly bounded μ values are initialized to 1. In the above example, three solves are performed with $\mu_1 = 1, 0.1$ and 0.01 and $\mu_2 = 1, 0.2$ and 0.04 .

5.31.3.4 Testing for complementarity

In some cases a solution to the reformulated model may not satisfy the complementarity constraints of the original MPEC, e.g. if a large penalty parameter is used in the reformulation. It can also happen that the solution tolerances used in the NLP solver allow solutions with small error in the NLP model but large error in the original MPEC. For example if $x = f(x) = .001$ then the NLP constraint $xf(x) = 0$ may satisfy the NLP feasibility tolerance but it's not so easy to claim that either x or $f(x)$ is zero. The NLPEC solver includes a check that the proposed solution does in fact satisfy the complementarity constraints. The complementarity gap is computed using the definition common to all GAMS MCP solvers in computing the `objval` model attribute for an MCP model. The tolerance used for this complementarity gap can be adjusted using the `testtol` option.

5.31.4 Options

For details on how to create and use an option file, see the introductory chapter on [solver usage](#).

For most GAMS solvers, the use of an options file is discouraged, at least for those unfamiliar with the solver. For NLPEC, however, we expect that most users will want to use an options file from the very beginning. NLPEC is as much a tool for experimentation as it is a solver, and as such use of the options file is encouraged.

Option values can take many different types (e.g. strings, integers, or reals). Perhaps the most important option to remember is one with no value at all: the `help` option. `Help` prints a list of the available options, along with their possible values and some helpful text. The options file is read sequentially, so in case an option value is set twice, the latter value takes precedence. However, any consistency checks performed on the options values (e.g. `RefType fBill` cannot be used with `aggregate full`) are made after the entire options file is read in, so the order in which different options appear is not important, provided the options are not specified twice.

5.31.4.1 Setting the Reformulation Options

While NLPEC has many options, there is a small set of five options that, taken together, serve to define the type of reformulation used. Listed in order of importance (highest priority items first), these *reformulation options* are the `RefType`, `slack`, `constraint`, `aggregate` and `NCPBounds` options. In some cases, setting the highest-priority option `RefType` is enough to completely define a reformulation (e.g. `RefType penalty` in the case of doubly-bounded variables). In most cases though, the lower-priority options play a role in defining or modifying a reformulation. It's useful to consider the reformulation options in priority order when creating option files to define reformulations.

Some of the combinations of the reformulation options don't make sense. For example, the use of an NCP function to force complementarity between its two input arguments requires a separate function for each complementary pair, so setting both `RefType min` and `aggregate full` is inconsistent. NLPEC implements consistency checks on the reformulation options using the priority order: Given a consistent setting of the higher priority options, the next-highest priority option is checked and, if necessary, reset to be consistent with the items of higher priority. The end result is a set of consistent options that will result in a working reformulation. NLPEC prints out the pre- and post-checked sets of reformulation options, as well as warning messages about changes made. In case you want to use an option that NLPEC doesn't think is consistent, you can use the `NoCheck` option: this suppresses the consistency checks.

Each of the reformulation options in the table below takes two values - one for the singly-bounded variables in $\mathcal{L} \cup \mathcal{U}$ and another for the doubly-bounded variables in \mathcal{B} . If one option value appears, it sets both option values. When setting both option values, use an asterisk "*" to indicate no change. So for example, an option file

```
RefType fCMxf
RefType * fBill
```

first sets the `RefType` to `fCMxf` for all variable types, and then resets the `RefType` to `fBill` for doubly-bounded variables.

5.31.4.2 Reformulation Options

Option	Description	Default
aggregate	controls constraint aggregation Determines if certain constraints are aggregated or not. E.g. to force $\mathbf{w} \geq 0$ and $\mathbf{y} \geq 0$ to be complementary we can write either $\mathbf{w}^T \mathbf{y} \leq 0$ or $\mathbf{w}_i^T \mathbf{y}_i \leq 0$, for all i . none : use no aggregation partial : aggregate doubly-bounded variables separately from others full : use maximum aggregation possible	none
constraint	controls use of equality/inequality Determines if certain constraints are written down using equalities or inequalities. E.g. to force $\mathbf{w} \geq 0$ and $\mathbf{y} \geq 0$ to be complementary we can write either $\mathbf{w}^T \mathbf{y} \leq 0$ or $\mathbf{w}^T \mathbf{y} = 0$. This option only plays a role when bounding a quantity whose sign cannot be both positive and negative and which must be 0 at a solution. equality : use =E= constraints inequality : use =L= constraints	equality
NCPBounds	sets explicit bounds on arguments of NCP functions Determines which of the two arguments to an NCP function $\Phi(\mathbf{r}, \mathbf{s})$ are explicitly constrained to be nonnegative. The explicit constraints are in addition to those imposed by the constraint $\Phi(\mathbf{r}, \mathbf{s}) = 0$, which implies nonnegativity of \mathbf{r} and \mathbf{s} . none : no explicit bounds	none
	function : explicit bound on function/slack argument variable : explicit bound on variable argument all : explicit bound on both function and variable arguments	

Option	Description	Default
refType	<p>reformulation type</p> <p>Determines the type of reformulation used. Our notation and descriptions are taken from a special case of the MPEC, the NCP: find $\mathbf{x} \geq 0$, $\mathbf{f}(\mathbf{x}) \geq 0$, $\mathbf{x}^T \mathbf{f}(\mathbf{x}) = 0$.</p> <p>mult: inner product $\langle \mathbf{x}, \mathbf{f} \rangle = 0$</p> <p>min: NCP function $\min(\mathbf{x}, \mathbf{f})$</p> <p>CMxf: Chen-Mangasarian NCP function, explicit</p> <p>CMfx: Chen-Mangasarian NCP function, explicit</p> <p>fCMxf: Chen-Mangasarian NCP function, intrinsic</p> <p>fCMfx: Chen-Mangasarian NCP function, intrinsic</p> <p>FB: Fischer-Burmeister NCP function, explicit</p> <p>fFB: Fischer-Burmeister NCP function, intrinsic</p> <p>FB_neg: Fischer-Burmeister NCP function negated, explicit</p> <p>fFB_neg: Fischer-Burmeister NCP function negated, intrinsic</p> <p>Bill: Billups function for doubly-bounded variables, explicit</p> <p>fBill: Billups function for doubly-bounded variables, intrinsic</p> <p>penalty: weighted penalization of non-complementarity in objective</p> <p>median: median function for doubly-bounded variables, explicit</p> <p>fVUsin: Veelken-Ulbrich NCP function (smoothed min), intrinsic</p> <p>fVUpow: Veelken-Ulbrich NCP function (smoothed min), intrinsic</p>	mult
slack	<p>control use of slacks for function values</p> <p>Determines if slacks are used to treat the functions h.i. For single-bounded variables, we use at most one slack (either free or positive) for each h.i. For doubly-bounded variables, we can have no slacks, one slack (necessarily free), or two slacks (either free or positive) for each h.i.</p> <p>none: no slacks will be used</p> <p>free: free slacks will be used</p> <p>positive: non-negative slacks will be used</p> <p>one: one free slack will be used for each h.i. in the doubly bounded case</p>	positive

5.31.4.3 General Options

Option	Description	Default
allSolves	<p>do all solves in a loop regardless of previous failure</p> <p>In case multiple (looped) solves are specified, the default is to skip subsequent solves when any solve terminates without getting a solution. Setting this flag removes the check and all solves are done, regardless of previous failures.</p>	0
dotGams	name of gams source file for scalar model	auto
dumpValid	dump valid reformulation options to a GDX file and exit	0
equReform	<p>outdated and deprecated</p> <p>Range: $\{0, \dots, 33\}$</p>	0
finalMu	<p>final value of parameter mu</p> <p>If specified, an extra solve is carried out with mu set to this value. Can be set independently for singly and doubly bounded variables.</p>	none
initMu	<p>initial value of parameter mu</p> <p>A single solve of the nonlinear program is carried out for this value. Note that mu must be positive for some settings of refType, e.g. penalty. Can be set independently for singly and doubly bounded variables.</p>	0
initSLo	<p>lower bound for artificials added to the problem</p> <p>Range: $[-\infty, \infty]$</p>	0
initSUp	<p>upper bound for artificials added to the problem</p> <p>Range: $[-\infty, \infty]$</p>	+inf

Option	Description	Default
noCheck	do not check consistency of reformulation options	0
numSolves	number of looped solves This should be set in conjunction with the <code>updateFac</code> option, so that the <code>mu</code> values are lowered successively.	0
parmFile	extra GAMS options for running scalar model	
subSolver	controls what subsolver to run If this option is not specified, the usual GAMS rules for selecting the solver to run are used.	auto
subSolverOpt	optfile value to pass to the subsolver	0
terminate	terminate after generating scalar GAMS source code	0
testTol	tolerance for complementarity check in MPEC/MCP	1e-005
updateFac	update factor for <code>mu</code> The factor that multiplies <code>mu</code> before each of the extra solves triggered by the <code>numsolves</code> option. Can be set independently for singly and doubly bounded variables. Range: [1e-280, 1.0]	1e-1

5.31.4.4 The Outdated `equreform` Option

In the early versions of NLPEC the only way to set the reform type was via the `equreform` option. Each valid `equreform` value represented a preselected combination of the options from Section [Setting the Reformulation Options](#). This made it difficult to experiment with combinations not preselected, so the options in Section [Setting the Reformulation Options](#) were added. By default, the `equreform` option has value 0 and is not used. To get the old behavior, set `equreform` to a positive value - this will force the options in Section [Setting the Reformulation Options](#) to be ignored. The general options in Section [General Options](#) are used no matter how the reformulation type is selected - via `RefType` or `equreform`.

Option	Description	Default
<code>equreform</code>	Old way to set the type of reformulation used.	0

The values allowed for `equreform` and their implications are given by the following table.

equiref	L/U				B			
	reftype	sign	slacks	free-y	reftype	sign	slacks	free-y
1	\langle, \rangle_i	$= \mu$	bnd		\langle, \rangle_i	$= \mu$	bnd	
2	\langle, \rangle_i	$\leq \mu$	bnd		\langle, \rangle_i	$\leq \mu$	bnd	
3	\langle, \rangle_i	$= \mu$	bnd		Scholtes	$\leq \mu$	one	
4	\langle, \rangle_{L+U+B}	$= \mu$	bnd		\langle, \rangle_{L+U+B}	$= \mu$	bnd	
5	\langle, \rangle_{L+U+B}	$= \mu$	none		\langle, \rangle_{L+U+B}	$= \mu$	bnd	
6	\langle, \rangle_{L+U}	$= \mu$	none		Scholtes	$\leq \mu$	one	
7	\langle, \rangle_{L+U}	$\leq \mu$	none		Scholtes	$\leq \mu$	none	
8	\langle, \rangle_i	$= \mu$	none		Scholtes	$\leq \mu$	none	
9	\langle, \rangle_{obj}		bnd		\langle, \rangle_{obj}		bnd	
10	\langle, \rangle_{obj}		none		\langle, \rangle_{obj}		bnd	
11	\langle, \rangle_i	$= \mu$	none		\langle, \rangle_i	$= \mu$	bnd	
12	F-B	$= 0$	none	free	F-B	$= 0$	free	free
13	F-B	$= 0$	none	free	Billups	$= 0$	none	free
14	min	$= \mu$	free	free	min	$= \mu$	free	free
15	min	$\leq \mu$	bnd		min	$\leq \mu$	bnd	
16	C-M(x, f)	$= 0$	free	free	C-M(x, f)	$= 0$	free	free
17	C-M(x, f)	$= 0$	bnd		C-M(x, f)	$= 0$	bnd	
18	$\langle, \rangle_{L,U}$	$\leq \mu$	none		\langle, \rangle_B	$\leq \mu$	bnd	
19	\langle, \rangle_i	$\leq \mu$	none		\langle, \rangle_i	$\leq \mu$	bnd	
20	$\langle, \rangle_{L,U}$	$\leq \mu$	bnd		\langle, \rangle_B	$\leq \mu$	bnd	
21	\langle, \rangle_{L+U+B}	$\leq \mu$	bnd		\langle, \rangle_{L+U+B}	$\leq \mu$	bnd	
22	F-B	$= 0$	bnd		F-B	$= 0$	bnd	
23	F-B	$= 0$	free	free	F-B	$= 0$	free	free
24	C-M(f, x)	$= 0$	none	free	C-M(f, x)	$= 0$	free	free
25	C-M(f, x)	$= 0$	none		C-M(f, x)	$= 0$	bnd	
26	NCPF	$= 0$	none	free	NCPF	$= 0$	free	
27	NCPF	$= 0$	none	free	Billups†	$= 0$	none	free
28	NCPF	$= 0$	bnd		NCPF	$= 0$	bnd	
29	NCPF	$= 0$	free	free	NCPF	$= 0$	free	free
30	NCPCM(x, f)	$= 0$	free	free	C-M(x, f)	$= 0$	free	free
31	NCPCM(x, f)	$= 0$	bnd		C-M(x, f)	$= 0$	bnd	
32	NCPCM(f, x)	$= 0$	none	free	NCPCM(f, x)	$= 0$	free	free
33	NCPCM(f, x)	$= 0$	none		NCPCM(f, x)	$= 0$	bnd	

Table 1: Values for `equireform` option.

5.31.5 Open Architecture

In this section we describe the architecture of the NLPEC solver, i.e. the way the solver is put together. This should be useful to anybody using NLPEC for experiments or to those wanting to know the details of how NLPEC works.

The foundation for the NLPEC solver is the software library (also used in the GAMS/CONVERT solver) that allows us to write out a scalar GAMS model that is mathematically equivalent to the original, or to write out selected pieces of such a model. Using this software, NLPEC creates a GAMS NLP model using one of the reformulation strategies from Section [Reformulation](#). This model may contain many new variables and/or equations, but it will surely contain the (non)linear expressions defining the original model as well. Once the scalar model has been created, NLPEC calls GAMS to solve this model, using the current NLP solver. The option `parmFile` can be used to pass on additional options to this GAMS job. After the model has solved, NLPEC reads the NLP solution, extracts the MPEC solution from it, and passes this MPEC solution back to GAMS as it terminates.

There are a number of advantages to this architecture. First, its openness makes it easy to see exactly what reformulation is being done. The intermediate scalar GAMS NLP model can be made available after the run by either saving the scratch directory (i.e. run with `keep=1`) or using the `dotGams` option to select an alternate file name. This intermediate model contains all the details of the reformulation. It can be used for debugging in case things didn't work out as expected. It is also possible to modify this file to do some quick and dirty experiments with similar reformulation strategies. Another advantage is the variety of NLP solvers that can be plugged in to solve the reformulated model. There is no need to program (and debug) an interface to an NLP package to run experiments with an NLP solver - the existing GAMS link is all that is needed. It is also easy to experiment with non-default solver options that may be more appropriate for reformulated MPEC models or for a particular choice of reformulation.

5.32 Octeract Engine

Octeract Engine is a deterministic solver to find globally optimal solutions for mixed-integer nonlinear programs (MINLPs). Distinguishing highlights of Octeract are its powerful and flexible symbolic reformulation engine and its parallelism capabilities. For more detailed information, we refer to the [Octeract Knowledge Base](#).

5.32.1 Usage

The following statement can be used inside your GAMS program to specify that Octeract should be used:

```
Option SOLVER = OCTERACT;
```

The above statement should appear before the Solve statement. If Octeract was specified as the default solver during GAMS installation, the above statement is not necessary.

GAMS/Octeract by default uses CLP/CBC to solve LP/MIP problems. By setting options `LP_SOLVER` or `MILP_SOLVER`, other solvers can be selected:

- If a license for GAMS/CPLEX, GAMS/OsiCPLEX, GAMS/CPLEX-link is available, then CPLEX can be used.
- If a Gurobi license is installed on the machine, then Gurobi can be used.
- If a FICO Xpress license is installed on the machine, then Xpress can be used. A GAMS/XPRESS license is currently **not** sufficient.

5.32.1.1 Specification of Octeract Options

GAMS/OCTERACT supports the GAMS parameters `reslim`, `nodlim`, `optcr`, and `threads`. The interpretation of `threads` differs from its [original meaning](#) in the sense that also on systems with hyperthreading enabled only the number of actual processor cores is taken into account. Further, GAMS/OCTERACT is limited to the use of at most 16 cores and distributed parallelization is not available.

Options can be specified by an **Octeract options file**. An Octeract options file consists of one option or comment per line. A pound sign (`#`) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (`=`) and any amount of white space. Note that **options are case-sensitive**.

A small example for an `octeract.opt` file is:

```
LP_SOLVER = CPLEX
MILP_SOLVER = CPLEX
STARTING_POINT_IPOPT = VARIABLE_MID_POINT
```

It causes Octeract to use CPLEX to solve LP or MIP problems and to use a different starting point strategy for calls of `Ipopt`.

5.32.2 List of Octeract Options

See https://docs.octeract.com/so1007-all_available_options.

5.33 ODHCPLEX

5.33.1 Introduction

GAMS/ODHCPLEX is a solver from Optimization Direct Inc. that implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models that uses IBM CPLEX as its underlying solver engine. It is designed for large-scale models which a MIP solver would find intractable: either by it being unable to find feasible solutions at all or; more usually, by being unable to find feasible solutions of adequate quality in the time available to its user.

It is intended for users who are familiar with MIP modelling and have some knowledge of using the GAMS/CPLEX solver. GAMS/ODHCPLEX does not demand expert specialism in this field.

ODHCPLEX can be used in two ways: it is implemented as a stand-alone ODHeuristic engine, which can be used on its own (`ODHeuristicMethod=STANDALONE`); and also within the CPLEX optimizer, within which it can supply and receive solutions from the main CPLEX caller (`ODHeuristicMethod=ODH-CPLEX` (default)) thereby accelerating optimization compared with GAMS/CPLEX run on its own.

The ODHeuristic engine has a heuristic method for finding an initial feasible solution that it designed to complement, those of CPLEX. Since its main algorithmic procedure works by improving an incumbent feasible solution, getting an initial one is important and may consume a significant part of its total runtime. When used on its own (i.e. `ODHeuristicMethod=STANDALONE`), users should experiment to discover whether ODHeuristics' or CPLEX's initial feasible solution methods work best, but within ODH-CPLEX (i.e. `ODHeuristicMethod=ODH-CPLEX`) both methods are run in parallel and the winner is chosen automatically.

ODHeuristics' principal algorithm works by solving a sequence of sub-models. An innovative aspect of this process is its ability to use the model's symbolic structure to achieve the sub-model decomposition. It does this by analyzing the symbolic names that the user gives to the decision variables and careful specification of how this should be done this is worthwhile. ODHCPLEX can work without this analysis, but it usually takes about twice as much runtime.

5.33.2 Specifying Model Structure

The ODHeuristic method needs to break the model down into sub-models. It can do this in one of three ways:

1. Automatically using its decomposition heuristic;
 2. Using information specified by the user in the `IndexKey` parameter;
 3. By simply assigning each variable to a different block (or *key*); or
 4. By using the `dot option` notation with the option `.key`.
-

By default, the program will use information specified by the [IndexKey](#) parameter if it is set and its automatic decomposition heuristic otherwise. This may be overridden by the [Decomposition](#) parameter. If it is set to 0 (zero), option 3 above is selected. If it is set to 1, its automatic decomposition method is used, and if it is set to 2, option 4 above is selected.

Whilst the automatic decomposition method often works well, there may be an advantage to specifying decomposition through the [IndexKey](#) parameter. After performing the decomposition in whatever way, the program analyses the decomposition and displays statistics showing the maximum and minimum number of variables in each key or block and showing a percentage score to the decomposition as a whole. A typical display is of the form:

```
Variables/key 205.58 (+/-304.79), max/min variables/key 933(32) / 60(113).
There are 227 keys (4149 keys were dropped) with 46872 values.
Decomposition score 13.66%, graph score 2074/3135232.
```

Other things (such as the distribution of variables in keys and the number of keys) being equal, the smaller the percentage decomposition score, the better the decomposition is and the more effective the program will be.

5.33.2.1 Using the [IndexKey](#) parameter

The program needs to associate sets of variables with distinct values of a single index. The user can specify this association with a pattern to which some or all of the variables conform. The pattern is in standard C scanf format (see, for example, Kernighan and Ritchie's 2nd edition of *The C Programming Language*, section B1.3 *Formatted Input*). Currently allowable index values must be non-negative integers, so the pattern must include *d*. For example, if we have variables *x* whose first index names starts with a number of letters then an underscore followed by a numeric index value (like `x(firstone_1)`, `x(another_1)`, `x(firstone_2)`, `x(another_2)`, ..) the pattern

```
x(%*[a-z]_%d)
```

associates those variables whose name ends in `_1` with index value 1, those whose name ends in `_2` with index value 2 and so on. The pattern is called an *index key* referred to by the program as the option parameter [IndexKey](#), for example

```
IndexKey=%*[xy](t_%d)
```

It may, however, be desirable to consider variables whose names are, say, `x(t_2)` and `y(t_2)`, to belong to different index values, i.e. to belong to different groups. One way of doing this is to identify them with separate index keys. These can be supplied to [IndexKey](#) as two fields separated by a semi-colon, for example

```
IndexKey=x(t_%d);y(t_%d)
```

Up to 10 fields can be specified in this way.

On the other hand, it may be desirable to consider such variables as having the same index key and their nomenclature may not permit their identification by a single key field. For example, suppose there are variables `john(t_1)`, `john(t_2)`, .., `jane(t_1)`, `jane(t_2)`, .. and `johnny(t_1)`, `johnny(t_2)`, .. and we want to associate `john(t_x)` and `jane(t_x)` as belonging to key value *x*, but want to ignore `johnny(t_x)`.

Two key fields can be used to do this by

```
INDEXKEY=john(t_%d);jane(t_%d)
```

By default `john(t_2)` and `jane(t_2)` would not share the same index value, but if the option parameter `KeyType`, is set to 1, the heuristic will group them together so as to share the same index.

If `IndexKey` is not specified, the program uses a default decomposition.

The program divides the model up into parts associated with different values of the `IndexKey` (if specified), using an integer interval divisor. Initially this is a number not less than 2 and it is increased as the search progresses. When no improved solution is found after a number, `MaxRepeat`, of attempts with the maximum interval divisor, `MaxInterDiv`, the program terminates. Default values are provided for `MaxRepeat` and `MaxInterDiv`, so these do not have to be specified by the user.

5.33.3 Heuristic Parameters

There are a number of other parameters which control the behaviour of the heuristic program. These may be left at their default values or specified on the GAMS/ODHCPLEX option file. In addition, many GAMS/CPLEX options can be supplied in the GAMS/ODHCPLEX option file to tweak the CPLEX behavior, see tables below. Note however that - although they can be technically set - these GAMS/CPLEX options may not have any influence on a GAMS/ODHCPLEX solve. For detailed descriptions of the GAMS/CPLEX options, see [Detailed Descriptions of CPLEX Options](#).

Parameter names and their meanings are summarized in the table below.

5.33.3.1 GAMS/ODHCPLEX: General Options

Option	Description	Default
<code>cpxpresolve</code>	Applies CPLEX presolve to full model	0
<code>decompdensity</code>	Matrix density above which automatic decomposition assigns each variable to a separate key	0.3
<code>decomposition</code>	Model decomposition method.	-1
<code>deterministic</code>	Specifies whether the solution improvement heuristic is run in deterministic or opportunistic (i.e. non-deterministic) mode	1
<code>divisor</code>	Initial divisor for sub models	automatic
<code>dynamicsearch</code>	Search strategy for CPLEX caller and sub-model solves	-1
<code>extracplexlog</code>	Write addition CPLEX output to log	0
<code>feastol</code>	Feasibility tolerance	1e-6
<code>firstfeas</code>	Use first feasible heuristic for finding an initial feasible solution	-1
<code>firstfeascontinue</code>	Whether first feasible heuristic continues when it achieves feasibility	0
<code>firstfeaseffort</code>	Effort limit on first feasible heuristic	-500
<code>firstfeasshift</code>	First feasible heuristic variable shifting in found solutions	1
<code>globalbounds</code>	Use of global bounds from CPLEX caller	2
<code>indexkey</code>	Pattern used to match variable names for grouping into sub-models discussed above	
<code>integeronly</code>	Variables to include in INDEXKEY	-1

Option	Description	Default
integertol	Integrality tolerance for variable values	1e-5
interdiv	Initial divisor value	4
.key	Variable block or key number	0
keytype	Treatment of multiple INDEXKEYs	0
maxbacktrack	The maximum number of backtracks permitted in sub-model solves	-1
maxbound	The largest(smallest) non infinite bound value ODH will accept for upper(lower) bounds	1e+9
maxinfrepeat	Maximum divisor value when solution is infeasible	0
maxinterdiv	Maximum divisor value	0
maxrepeat	Maximum number of sub-model repeat solves for each divisor value	0
newcallback	CPLEX call-back type used	1
objtarget	Target objective value	0
odheuristicsmethod	ODHeuristic method section	ODH-CPLEX
odhfeasopt	Optimization method for sub-models in phaseI	0
odhpresolve	Indicator for the ODHeuristics engine using a separate presolve within ODH-CPLEX	1
odhthreads	The number of heuristic threads used by ODH-CPLEX or STAN-DALONE	-1
odhtimelimit	Elapsed time limit in seconds	GAMS ResLim
penalty	The objective function coefficient value for penalties	-1
penperturb	Perturbation tolerance for penalties coefficients	0
phase12	Specifies whether to use a phaseI/phaseII method to remove infeasibilities	1
processorlock	Thread allocation	0
quickfirstsolve	Accelerate initial CPLEX solve	0
recurse	Recurse using heuristic to solve sub-models when a feasible solution has been obtained	0
recursedecom	Recursed model decomposition method	0
recurseiterlim	Recursed heuristic iteration limit for sub-solves	40
recurselog	Write thread log files for recursed sub-solves	0
recurseminterlim	Recursed heuristic minimum iterations before a solution is found in sub-solves	0
recursesoliterlim	Recursed heuristic sub-solves quit after these iterations if a solution is found	maxint
rejectinfsol	Reject infeasible solutions to sub-models	2
relaxsos2	Treatment of SOS2 members	1
seed	Initial random number seed	1234
strategy	ODH-Cplex Strategy	1

Option	Description	Default
subnodelimit	Node limit for submodel searches	-1
suborder	Use of priority order in sub-solves	1
subpresolve	Use of CPLEX presolve in sub-solves	1
sub_cpx_threads	Threads available for the solves within ODHeuristic	1
syncfreq	Thread synchronization frequency in deterministic parallel mode	1
threadlog	Write thread log files	0
threadzerosync	Which CPLEX threads to use for synchronization	0
variableclean	Clean variable values from sub-models	0
zerotol	Zero tolerance for variable values	1e-9

5.33.3.2 GAMS/CPLEX: Preprocessing and General Options

Option	Description	Default
advind	advanced basis use	1
aggfill	aggregator fill parameter	10
aggind	aggregator on/off	-1
calcqpduals	calculate the dual values of a quadratically constrained problem	1
clocktype	clock type for computation time	2
coeredind	coefficient reduction on/off	-1
cpumask	switch and mask to bind threads to processors (Linux only)	auto
cutoff	GMO cutoff	0.0
datacheck	controls data consistency checking and modeling assistance	0
depind	dependency checker on/off	-1
dettlim	deterministic time limit	1.0e+75
domlim	domain violation number	0
eprelax	relaxation for FeasOpt	1.0e-06
feasoptmode	mode of FeasOpt	0
fixoptfile	name of option file which is read just before solving the fixed problem	
folding	LP folding will be attempted during the preprocessing phase	-1
freegamsmodel	preserves memory by dumping the GAMS model instance representation temporarily to disk	0
indicoptstrict	abort in case of an error in indicator constraint in solver option file	1
lpmethod	algorithm to be used for LP problems	0
memoryemphasis	reduces use of memory	0

Option	Description	Default
multobjdisplay	level of display during multiobjective optimization	1
names	load GAMS names into Cplex	1
numeralemphasis	emphasizes precision in numerically unstable or difficult problems	0
optimalitytarget	type of optimality that Cplex targets	0
parallelmode	parallel optimization mode	0
paramdisplay	display the nondefault parameters before optimization	1
predual	give dual problem to the optimizer	0
preind	turn presolver on/off	1
prelinear	linear reduction indicator	1
prepass	number of presolve applications to perform	-1
prereform	set presolve reformulations	3
printoptions	list values of all options to GAMS listing file	0
qextractalg	quadratic extraction algorithm in GAMS interface	0
qpmethod	algorithm to be used for QP problems	0
qtolin	linearization of the quadratic terms in the objective function of a QP or MIQP model	-1
randomseed	sets the random seed differently for diversity of solutions	202009243
record	Records invocations of Callable Library routines	0
reduce	primal and dual reduction type	3
relaxfixedinfeas	accept small infeasibilities in the solve of the fixed problem	0
relaxpreind	presolve for initial relaxation on/off	-1
rerun	rerun problem if presolve infeasible or unbounded	yes
scaind	matrix scaling on/off	0
solutiontype	type of solution (basic or non basic) for an LP or QP	0
threads	global default thread count	0
tilim	overrides the GAMS ResLim option	1.0e+75
tryint	GMO tryint	0.0
tuningdettlim	tuning deterministic time limit per model or suite	1.0e+75
tuningdisplay	level of information reported by the tuning tool	1
tuningmeasure	measure for evaluating progress for a suite of models	1
tuningrepeat	number of times tuning is to be repeated on perturbed versions	1
tuningtilim	tuning time limit per model or suite	1.0e+75
usebasis	GMO usebasis	0

Option	Description	Default
warninglimit	determines how many times warnings of a specific type (datacheck=2) will be displayed	10
workdir	directory for working files	.
workmem	memory available for working storage	2048.0

5.33.3.3 GAMS/CPLEX: Simplex Algorithmic Options

Option	Description	Default
confictalg	algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model	0
confictdisplay	decides how much information CPLEX reports when the conflict refiner is working	1
craind	crash strategy (used to obtain starting basis)	1
dpriind	dual simplex pricing	0
dynamicrows	switch for dynamic management of rows	-1
epper	perturbation constant	1.0e-06
netfind	attempt network extraction	2
netppriind	network simplex pricing	0
perind	force initial perturbation	0
perlim	number of stalled iterations before perturbation	0
ppriind	primal simplex pricing	0
pricelim	pricing candidate list	0
reinv	refactorization frequency	0
sifting	switch for sifting from simplex optimization	1

5.33.3.4 GAMS/CPLEX: Simplex Limit Options

Option	Description	Default
itlim	iteration limit	2147483647
netitlim	iteration limit for network simplex	2147483647
objllim	objective function lower limit	-1.0e+75
objulim	objective function upper limit	1.0e+75
singlim	limit on singularity repairs	10

5.33.3.5 GAMS/CPLEX: Simplex Tolerance Options

Option	Description	Default
epmrk	Markowitz pivot tolerance	0.01
epopt	optimality tolerance	1.0e-06
eprhs	feasibility tolerance	1.0e-06
netepopt	optimality tolerance for the network simplex method	1.0e-06
neteprhs	feasibility tolerance for the network simplex method	1.0e-06

5.33.3.6 GAMS/CPLEX: Barrier Specific Options

Option	Description	Default
baralg	algorithm selection	0
barcolnz	dense column handling	0
barcrossalg	barrier crossover method	0
barepcomp	convergence tolerance	1.0e-08
bargrowth	unbounded face detection	1.0e+12
baritlim	iteration limit	2147483647
barmaxcor	maximum correction limit	-1
barobjrng	maximum objective function	1.0e+20
barorder	row ordering algorithm selection	0
barqpepcomp	convergence tolerance for the barrier optimizer for QCPs	1.0e-07
barstartalg	barrier starting point algorithm	1

5.33.3.7 GAMS/CPLEX: Sifting Specific Options

Option	Description	Default
siftalg	sifting subproblem algorithm	0
siftitlim	limit on sifting iterations	2147483647

5.33.3.8 GAMS/CPLEX: MIP Algorithmic Options

Option	Description	Default
bbinterval	best bound interval	7
bendersstrategy	Benders decomposition algorithm as a strategy	0
bndstrenind	bound strengthening	-1
bqpcuts	boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality	0

Option	Description	Default
brdir	set branching direction	0
bttol	backtracking limit	1.0
cliques	clique cut generation	0
covers	cover cut generation	0
cutlo	lower cutoff for tree search	-1.0e+75
cuts	default cut generation	0
cutsfactor	cut limit	-1.0
cutup	upper cutoff for tree search	1.0e+75
disjcuts	disjunctive cuts generation	0
divetype	MIP dive strategy	0
eachcutlim	sets a limit for each type of cut	2100000000
flowcovers	flow cover cut generation	0
flowpaths	flow path cut generation	0
fpheur	feasibility pump heuristic	0
fraccuts	Gomory fractional cut generation	0
gubcovers	GUB cover cut generation	0
heurfreq	heuristic frequency	0
heuristicceffort	the effort that CPLEX spends on heuristics during a MIP solve	1.0
implbd	implied bound cut generation	0
.lazy	Lazy constraints activation	0
lazyconstraints	Indicator to use lazy constraints	0
lbheur	local branching heuristic	0
liftprojcuts	lift-and-project cuts	0
localimplied	generation of locally valid implied bound cuts	0
mfcuts	multi-commodity flow cut generation	0
mipemphasis	MIP solution tactics	0
mipkappastats	MIP kappa computation	0
mipordind	priority list on/off	1
mipordtype	priority order generation	0
mipsearch	search strategy for mixed integer programs	0
mipstart	use mip starting values	0
miqcpstrat	MIQCP relaxation choice	0
mircuts	mixed integer rounding cut generation	0

Option	Description	Default
multimipstart	use multiple mipstarts provided via.gdx files	
nodecuts	decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree	0
nodefileind	node storage file indicator	1
nodesel	node selection strategy	1
preslvnd	node presolve selector	0
probe	perform probing before solving a MIP	0
qpmakepsdind	adjust MIQP formulation to make the quadratic matrix positive-semi-definite	1
repeatpresolve	reapply presolve at root after preprocessing	-1
rinsheur	relaxation induced neighborhood search frequency	0
rltcuts	Reformulation Linearization Technique (RLT) cuts	0
solvefinal	switch to solve the problem with fixed discrete variables	1
sos1reform	automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)	0
sos2reform	automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)	0
startalg	MIP starting algorithm	0
strongcandlim	size of the candidates list for strong branching	10
strongitlim	limit on iterations per branch for strong branching	0
subalg	algorithm for subproblems	0
submipodelim	limit on number of nodes in an RINS subMIP	500
submipscale	scale the problem matrix when CPLEX solves a subMIP during MIP optimization	0
submipstartalg	starting algorithm for a subMIP of a MIP	0
submipsubalg	algorithm for subproblems of a subMIP of a MIP	0
symmetry	symmetry breaking cuts	-1
varsel	variable selection strategy at each node	0
workeralgorithm	set method for optimizing benders subproblems	0
zerohalfcuts	zero-half cuts	0

5.33.3.9 GAMS/CPLEX: MIP Limit Options

Option	Description	Default
aggcutlim	aggregation limit for cut generation	3
auxrootthreads	number of threads for auxiliary tasks at the root node	0
cutpass	maximum number of cutting plane passes	0

Option	Description	Default
fraccand	candidate limit for generating Gomory fractional cuts	200
fracpass	maximum number of passes for generating Gomory fractional cuts	0
intsollim	maximum number of integer solutions	2147483647
nodelim	maximum number of nodes to solve	2147483647
polishafterdetime	deterministic time before starting to polish a feasible solution	1.0e+75
polishafterepagap	absolute MIP gap before starting to polish a feasible solution	0.0
polishafterepgap	relative MIP gap before starting to polish a solution	0.0
polishafterintsol	MIP integer solutions to find before starting to polish a feasible solution	2147483647
polishafternode	nodes to process before starting to polish a feasible solution	2147483647
polishaftertime	time before starting to polish a feasible solution	1.0e+75
polishtime	time spent polishing a solution	0.0
probedetime	deterministic time spent probing	1.0e+75
probetime	time spent probing	1.0e+75
rampupdetlimit	limits the amount of time in deterministic ticks spent during ramp up of distributed parallel optimization	1.0e+75
rampupduration	customizes ramp up for distributed parallel optimization	0
rampuptimelimit	limits the amount of time in seconds spent during ramp up of distributed parallel optimization	1.0e+75
repairtries	try to repair infeasible MIP start	0
trelim	maximum space in memory for tree	1.0e+75

5.33.3.10 GAMS/CPLEX: MIP Solution Pool Options

Option	Description	Default
.divfft	solution pool range filter coefficients	0
divfftlo	lower bound on diversity	mindouble
divfftup	upper bound on diversity	maxdouble
populatelim	limit of solutions generated for the solution pool by populate method	20
readfft	reads Cplex solution pool filter file	
solnpool	solution pool file name	
solnpoolagap	absolute tolerance for the solutions in the solution pool	1.0e+75
solnpoolcapacity	limits of solutions kept in the solution pool	2100000000
solnpoolgap	relative tolerance for the solutions in the solution pool	1.0e+75
solnpoolintensity	solution pool intensity for ability to produce multiple solutions	0
solnpoolmerge	solution pool file name for merged solutions	

Option	Description	Default
solnpoolnumsym	maximum number of variable symbols when writing merged solutions	10
solnpoolprefix	file name prefix for GDX solution files	soln
solnpoolreplace	strategy for replacing a solution in the solution pool	0

5.33.3.11 GAMS/CPLEX: MIP Tolerance Options

Option	Description	Default
bendersfeascuttol	Tolerance for whether a feasibility cut has been violated in Benders decomposition	1.0e-06
bendersoptcuttol	Tolerance for optimality cuts in Benders decomposition	1.0e-06
epagap	absolute stopping tolerance	1.0e-06
epgap	relative stopping tolerance	1.0e-04
epint	integrality tolerance	1.0e-05
eplin	degree of tolerance used in linearization	0.001
objdif	overrides GAMS Cheat parameter	0.0
relobjdif	relative cheat parameter	0.0

5.33.3.12 GAMS/CPLEX: Output Options

Option	Description	Default
bardisplay	progress display level	1
clonelog	enable clone logs	0
mipdisplay	progress display level	2
mipinterval	progress display interval	0
mpslongnum	MPS file format precision of numeric output	1
netdisplay	network display level	2
quality	write solution quality statistics	0
siftdisplay	sifting display level	1
simdisplay	simplex display level	1
writeannotation	produce a Cplex annotation file	
writebas	produce a Cplex basis file	
writefft	produce a Cplex solution pool filter file	
writelp	produce a Cplex LP file	
writemps	produce a Cplex MPS file	

Option	Description	Default
writemst	produce a Cplex mst file	
writeord	produce a Cplex ord file	
writeparam	produce a Cplex parameter file with all active options	
writepre	produce a Cplex LP/MPS/SAV file of the presolved problem	
writeprob	produce a Cplex problem file and infers the type from the extension	
writesav	produce a Cplex binary problem file	

5.33.4 Parallel execution using multiple threads

Both [ODHeuristicMethods](#) `STANDALONE` and `ODH-CPLEX` can use multiple simultaneous threads. `ODH-CPLEX` must use separate threads for the main CPLEX solve and for the ODHeuristics engine. The `STANDALONE` just uses the ODHeuristics engine which may use multiple simultaneous threads. Thus the processing capability of multi-core hardware can be exploited effectively.

GAMS/ODHCPLEX will ignore the [GAMS threads](#) parameter and use its own default. The default ODHeuristic method (i.e. `ODH-CPLEX`) requires multiple threads to work and with the [GAMS threads](#) default of 1 this will not work.

Whilst there are good defaults for allocating available threads, it may be worthwhile to give some attention to the allocation of threads between the main CPLEX solver and the ODHeuristics engine for `ODH-CPLEX` and `STANDALONE`.

If the option [ODHThreads](#) is set to n , n threads are allocated in total, otherwise the total number of threads allocated for both `ODH-CPLEX` and `STANDALONE` is set to the number of physical processors available on the computer. If the [ODHThreads](#) option is set to a number greater than the number of available processors, multiple threads will have to share the same processor, which may severely degrade performance.

In general, the more threads allocated to the main CPLEX solver, the faster it will run, and similarly, the more allocated to the ODHeuristics engine, the faster it will run. The best balance depends on the model being solved and whether it is intended to run to optimality or to an optimality gap of (say) 0.05 or 0.1. If the GAMS/Cplex [Threads](#) is not set, `ODH-CPLEX` defaults to allocating a quarter of the threads to the ODHeuristics engine and the remainder to the main CPLEX solve. Otherwise it allocates the specified number of threads to the main CPLEX solver and the remainder to the ODHeuristics engine.

Within the ODHeuristics engine, the principal heuristic algorithm can run in parallel on multiple threads. Each algorithmic thread uses CPLEX to solve sub-models and each such instance of CPLEX can itself run on multiple threads. So some attention needs to be given to the allocation of threads between them. If [SUB_CPX_THREADS](#) is not set, the CPLEX solver will use one thread for each available logical processor to solve the sub-models. This means that only one thread will be available for the solution improvement heuristic. If the option [SUB_CPX_THREADS](#) is set, then by default the heuristic engine sets its number of algorithmic threads to

`number_of_available_processors / SUB_CPX_THREADS`

where `number_of_available_processors` is: the number of logical processors for `STANDALONE`; and for `ODH-CPLEX` it is this number less those allocated to the main CPLEX solver.

Many Intel and compatible processors support hyperthreading (where this is enabled on the computer and operating system) and if so there will be two logical processors for every physical core. Using them

can severely degrade performance, so if they are enabled it is often a good idea to set `ODHThreads` to the number of physical processors. Note that on machines with a large number of processors (cores), the principal bottleneck for large scale optimization is usually memory access. In practice it is often better to use only about half of the available cores on (say) a 24 core Intel Xeon system. This is model dependent and some experimentation is worthwhile.

Although the operating system's scheduler usually allocates threads to logical processors so that they run on separate physical cores where possible, it will have more threads to manage than those of the heuristic or CPLEX and so will change this allocation as the heuristic and CPLEX run so as to balance its workload effectively. There is a performance penalty to doing this from the perspective of the heuristic run time. For the ODHeuristics STANDALONE, this can be avoided by locking the heuristic threads to specific processors by setting the heuristic option parameter `ProcessorLock` to 1. It is not supported for ODH-CPLEX. Under Windows, beware that the threads need to be locked at an above normal priority so this may have a negative impact on other programs concurrently running on the machine.

5.33.5 Determinism

Many users require that repeated runs of their applications under the same conditions give the same results, albeit in slightly variable times. The heuristic runs in this way by default. However, there is a performance penalty that has to be paid for synchronizing the threads. On average, performance can be considerably improved performance at the expense of non-repeatable execution by setting the heuristic option parameter `Deterministic` to 0. This is often preferred by users with particularly large and difficult models.

5.33.6 Detailed Descriptions of ODHCLPEX Options

advind (*integer*): advanced basis use ↔

Default: 1

aggcutlim (*integer*): aggregation limit for cut generation ↔

Default: 3

aggfill (*integer*): aggregator fill parameter ↔

Default: 10

aggind (*integer*): aggregator on/off ↔

Default: -1

auxrootthreads (*integer*): number of threads for auxiliary tasks at the root node ↔

Default: 0

baralg (*integer*): algorithm selection ↔

Default: 0

barcolnz (*integer*): dense column handling ↔

Default: 0

barcrossalg (*integer*): barrier crossover method ↔

Default: 0

bardisplay (*integer*): progress display level [↔](#)

Default: 1

barepcomp (*real*): convergence tolerance [↔](#)

Default: 1.0e-08

bargrowth (*real*): unbounded face detection [↔](#)

Default: 1.0e+12

baritlim (*integer*): iteration limit [↔](#)

Default: 2147483647

barmaxcor (*integer*): maximum correction limit [↔](#)

Default: -1

barobjrng (*real*): maximum objective function [↔](#)

Default: 1.0e+20

barorder (*integer*): row ordering algorithm selection [↔](#)

Default: 0

barqcpepcomp (*real*): convergence tolerance for the barrier optimizer for QCPs [↔](#)

Default: 1.0e-07

barstartalg (*integer*): barrier starting point algorithm [↔](#)

Default: 1

bbinterval (*integer*): best bound interval [↔](#)

Default: 7

bendersfeascuttol (*real*): Tolerance for whether a feasibility cut has been violated in Benders decomposition [↔](#)

Default: 1.0e-06

bendersoptcuttol (*real*): Tolerance for optimality cuts in Benders decomposition [↔](#)

Default: 1.0e-06

bendersstrategy (*integer*): Benders decomposition algorithm as a strategy [↔](#)

Default: 0

bndstrenind (*integer*): bound strengthening [↔](#)

Default: -1

bqpcuts (*integer*): boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality ↔

Default: 0

brdir (*integer*): set branching direction ↔

Default: 0

bttol (*real*): backtracking limit ↔

Default: 1.0

calcqcpduals (*integer*): calculate the dual values of a quadratically constrained problem ↔

Default: 1

cliques (*integer*): clique cut generation ↔

Default: 0

clocktype (*integer*): clock type for computation time ↔

Default: 2

clonelog (*integer*): enable clone logs ↔

Default: 0

coeredind (*integer*): coefficient reduction on/off ↔

Default: -1

confictalg (*integer*): algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model ↔

Default: 0

conflictdisplay (*integer*): decides how much information CPLEX reports when the conflict refiner is working ↔

Default: 1

covers (*integer*): cover cut generation ↔

Default: 0

cpumask (*string*): switch and mask to bind threads to processors (Linux only) ↔

Default: auto

cpxpresolve (*integer*): Applies CPLEX presolve to full model ↔

Default: 0

value	meaning
-1	Do not apply
0	Automatically determined
1	Always applied

craind (*integer*): crash strategy (used to obtain starting basis) [↔](#)

Default: 1

cutlo (*real*): lower cutoff for tree search [↔](#)

Default: -1.0e+75

cutoff (*real*): GMO cutoff [↔](#)

Default: 0.0

cutpass (*integer*): maximum number of cutting plane passes [↔](#)

Default: 0

cuts (*string*): default cut generation [↔](#)

Default: 0

cutsfactor (*real*): cut limit [↔](#)

Default: -1.0

cutup (*real*): upper cutoff for tree search [↔](#)

Default: 1.0e+75

datacheck (*integer*): controls data consistency checking and modeling assistance [↔](#)

Default: 0

decompdensity (*real*): Matrix density above which automatic decomposition assigns each variable to a separate key [↔](#)

Default: 0.3

decomposition (*integer*): Model decomposition method. [↔](#)

Default: -1

value	meaning
-1	Automatically determined
0	Assign each variable to a separate key
1	Use automatic decomposition method
2	Use decomposition based on dot option .key

depend (*integer*): dependency checker on/off [↔](#)

Default: -1

deterministic (*boolean*): Specifies whether the solution improvement heuristic is run in deterministic or opportunistic (i.e. non-deterministic) mode [↔](#)

Default: 1

value	meaning
0	Opportunistic
1	Deterministic

dettlim (*real*): deterministic time limit [↔](#)

Default: 1.0e+75

disjcuts (*integer*): disjunctive cuts generation [↔](#)

Default: 0

divetype (*integer*): MIP dive strategy [↔](#)

Default: 0

.divflt (*real*): solution pool range filter coefficients [↔](#)

Default: 0

divftlo (*real*): lower bound on diversity [↔](#)

Default: mindouble

divftup (*real*): upper bound on diversity [↔](#)

Default: maxdouble

divisor (*integer*): Initial divisor for sub models [↔](#)

Initial sub model size is model_size times 1 over Divisor. Ignored if [InterDiv](#) is set.

Default: automatic

domlim (*integer*): domain violation number [↔](#)

Default: 0

dpriind (*integer*): dual simplex pricing [↔](#)

Default: 0

dynamicrows (*integer*): switch for dynamic management of rows [↔](#)

Default: -1

dynamicsearch (*integer*): Search strategy for CPLEX caller and sub-model solves [↔](#)

Default: -1

value	meaning
-1	Automatically determined
0	Use traditional branch & cut
1	Use dynamic search

eachcutlim (*integer*): sets a limit for each type of cut [↔](#)

Default: 2100000000

epagap (*real*): absolute stopping tolerance [↔](#)

Synonym: optca

Default: 1.0e-06

epgap (*real*): relative stopping tolerance [↔](#)

Synonym: optcr

Default: 1.0e-04

epint (*real*): integrality tolerance [↔](#)

Default: 1.0e-05

eplin (*real*): degree of tolerance used in linearization [↔](#)

Default: 0.001

epmrk (*real*): Markowitz pivot tolerance [↔](#)

Default: 0.01

epopt (*real*): optimality tolerance [↔](#)

Default: 1.0e-06

epper (*real*): perturbation constant [↔](#)

Default: 1.0e-06

eprelax (*real*): relaxation for feasOpt [↔](#)

Default: 1.0e-06

eprhs (*real*): feasibility tolerance [↔](#)

Default: 1.0e-06

extracplexlog (*boolean*): Write addition CPLEX output to log [↔](#)

Default: 0

value	meaning
0	Do not write extra CPLEX information
1	Write extra CPLEX information

feasoptmode (*integer*): mode of FeasOpt [↔](#)

Default: 0

feastol (*real*): Feasibility tolerance ↔

Range: [1e-9, 0.1]

Default: 1e-6

firstfeas (*integer*): Use first feasible heuristic for finding an initial feasible solution ↔

The default for ODH-CPLEX is 1 while for the heuristic engine the default is -1.

Default: -1

value	meaning
-1	Do not use
0	Use if no solution found during initial presolve
1	Always use

firstfeascontinue (*boolean*): Whether first feasible heuristic continues when it achieves feasibility ↔

Default: 0

value	meaning
0	Do not continue
1	Continue

firstfeaseffort (*integer*): Effort limit on first feasible heuristic ↔

If the option value is positive the exact value is used as the level of effort. If the value is negative no more than the absolute value of the option is used as the level of effort. The larger the effort level, the more effort is expended before giving up.

Default: -500

firstfeasshift (*integer*): First feasible heuristic variable shifting in found solutions ↔

Default: 1

value	meaning
0	Do not shift
1	Moderate shifting
2	Aggressive shifting

fixoptfile (*string*): name of option file which is read just before solving the fixed problem ↔

flowcovers (*integer*): flow cover cut generation ↔

Default: 0

flowpaths (*integer*): flow path cut generation ↔

Default: 0

folding (*integer*): LP folding will be attempted during the preprocessing phase [↔](#)

Default: -1

fpheur (*integer*): feasibility pump heuristic [↔](#)

Default: 0

fraccand (*integer*): candidate limit for generating Gomory fractional cuts [↔](#)

Default: 200

fraccuts (*integer*): Gomory fractional cut generation [↔](#)

Default: 0

fracpass (*integer*): maximum number of passes for generating Gomory fractional cuts [↔](#)

Default: 0

freegamsmodel (*boolean*): preserves memory by dumping the GAMS model instance representation temporarily to disk [↔](#)

Default: 0

globalbounds (*integer*): Use of global bounds from CPLEX caller [↔](#)

Default: 2

value	meaning
0	Never use
2	Always use
1-4	Intensity of use

gubcovers (*integer*): GUB cover cut generation [↔](#)

Default: 0

heurfreq (*integer*): heuristic frequency [↔](#)

Default: 0

heuristicseffort (*real*): the effort that CPLEX spends on heuristics during a MIP solve [↔](#)

Default: 1.0

implbd (*integer*): implied bound cut generation [↔](#)

Default: 0

indexkey (*string*): Pattern used to match variable names for grouping into sub-models discussed above [↔](#)

indicoptstrict (*boolean*): abort in case of an error in indicator constraint in solver option file [↔](#)

Default: 1

integeronly (*integer*): Variables to include in INDEXKEY [↔](#)

Default: -1

value	meaning
-1	Automatically determined
0	All variables
1	Only non-continuous variables

integertol (*real*): Integrality tolerance for variable values [↔](#)

Default: 1e-5

interdiv (*integer*): Initial divisor value [↔](#)

Default: 4

intsollim (*integer*): maximum number of integer solutions [↔](#)

Default: 2147483647

itlim (*integer*): iteration limit [↔](#)

Synonym: iterlim

Default: 2147483647

.key (*integer*): Variable block or key number [↔](#)

Default: 0

keytype (*boolean*): Treatment of multiple INDEXKEYs [↔](#)

Default: 0

value	meaning
0	Considered separately e.g. INDEXKEY=x_d;y_d means x_2 and y_2 belong to separate groups
1	Considered together e.g. INDEXKEY=x_d;y_d means x_2 and y_2 belong to the same group

.lazy (*boolean*): Lazy constraints activation [↔](#)

Default: 0

lazyconstraints (*boolean*): Indicator to use lazy constraints [↔](#)

Default: 0

lbheur (*boolean*): local branching heuristic [↔](#)

Default: 0

liftprojcuts (*integer*): lift-and-project cuts [↔](#)

Default: 0

localimplied (*integer*): generation of locally valid implied bound cuts [↔](#)

Default: 0

lpmethod (*integer*): algorithm to be used for LP problems [↔](#)

Default: 0

maxbacktrack (*integer*): The maximum number of backtracks permitted in sub-model solves [↔](#)

Default: -1

value	meaning
-1	Automatically determined
0	Infinite
>0	Use this value if a better solution is available

maxbound (*real*): The largest(smallest) non infinite bound value ODH will accept for upper(lower) bounds [↔](#)

If this value is positive, bounds exceeding MAXBOUND are reduced to MAXBOUND; if this value is negative, bounds exceeding -MAXBOUND are ignored.

Default: 1e+9

maxinfrepeat (*integer*): Maximum divisor value when solution is infeasible [↔](#)

Default: 0

value	meaning
0	Automatically determined
>0	Use this value

maxinterdiv (*integer*): Maximum divisor value [↔](#)

Default: 0

maxrepeat (*integer*): Maximum number of sub-model repeat solves for each divisor value [↔](#)

Default: 0

value	meaning
0	Automatically determined
>0	Use this value

mcfcuts (*integer*): multi-commodity flow cut generation [↔](#)

Default: 0

memoryemphasis (*boolean*): reduces use of memory [↔](#)

Default: 0

mipdisplay (*integer*): progress display level [↔](#)

Default: 2

mipemphasis (*integer*): MIP solution tactics [↔](#)

Default: 0

mipinterval (*integer*): progress display interval [↔](#)

Default: 0

mipkappastats (*integer*): MIP kappa computation [↔](#)

Default: 0

mipordind (*boolean*): priority list on/off [↔](#)

Synonym: prioropt

Default: 1

mipordtype (*integer*): priority order generation [↔](#)

Default: 0

mipsearch (*integer*): search strategy for mixed integer programs [↔](#)

Default: 0

mipstart (*integer*): use mip starting values [↔](#)

Default: 0

mipcpstrat (*integer*): MIQCP relaxation choice [↔](#)

Default: 0

mircuts (*integer*): mixed integer rounding cut generation [↔](#)

Default: 0

mpslongnum (*boolean*): MPS file format precision of numeric output [↔](#)

Default: 1

multimipstart (*string*): use multiple mipstarts provided via.gdx files [↔](#)

multobjdisplay (*integer*): level of display during multiobjective optimization [↔](#)

Default: 1

names (*boolean*): load GAMS names into Cplex [↔](#)

Default: 1

netdisplay (*integer*): network display level [↔](#)

Default: 2

netepopt (*real*): optimality tolerance for the network simplex method [↔](#)

Default: 1.0e-06

neteprhs (*real*): feasibility tolerance for the network simplex method [↔](#)

Default: 1.0e-06

netfind (*integer*): attempt network extraction [↔](#)

Default: 2

netitlim (*integer*): iteration limit for network simplex [↔](#)

Default: 2147483647

netppriind (*integer*): network simplex pricing [↔](#)

Default: 0

newcallback (*integer*): CPLEX call-back type used [↔](#)

Default: 1

value	meaning
0	Use legacy call-backs
1	Use new call-backs for main CPLEX solve
2	Use new call-backs for sub-model solves
3	Use new call-backs for main CPLEX solve and sub-model solves

nodecuts (*integer*): decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree ↔

Default: 0

nodefileind (*integer*): node storage file indicator ↔

Default: 1

nodelim (*integer*): maximum number of nodes to solve ↔

Synonym: nodlim

Default: 2147483647

nodesel (*integer*): node selection strategy ↔

Default: 1

numericalemphasis (*boolean*): emphasizes precision in numerically unstable or difficult problems ↔

Default: 0

objdif (*real*): overrides GAMS Cheat parameter ↔

Synonym: cheat

Default: 0.0

objllim (*real*): objective function lower limit ↔

Default: -1.0e+75

objtarget (*real*): Target objective value ↔

ODHeuristics terminates when this value is reached. Defaults to -infinity for minimization or +infinity for maximization models.

Default: 0

objulim (*real*): objective function upper limit ↔

Default: 1.0e+75

odheuristicmethod (*string*): ODHeuristic method section ↔

Default: ODH-CPLEX

value	meaning
ODH-CPLEX	ODHeuristic within the CPLEX optimizer
STANDALONE	Stand-alone ODHeuristic engine

odhfeasopt (*boolean*): Optimization method for sub-models in phaseI ↔

Default: 0

odhpresolve (*integer*): Indicator for the ODHeuristics engine using a separate presolve within ODH-CPLEX ↔

Default: 1

value	meaning
1	One-step presolve
2	Two-step presolve

odhthreads (*integer*): The number of heuristic threads used by ODH-CPLEX or STANDALONE ↔

Default: -1

value	meaning
-1	Automatically determined
0	Run in serial mode
>0	Use the specified number of threads

odhtimelimit (*real*): Elapsed time limit in seconds ↔

Synonym: reslim

Default: GAMS ResLim

optimalitytarget (*integer*): type of optimality that Cplex targets ↔

Default: 0

parallelmode (*integer*): parallel optimization mode ↔

Default: 0

paramdisplay (*boolean*): display the nondefault parameters before optimization ↔

Default: 1

penalty (*real*): The objective function coefficient value for penalties ↔

The objective function coefficient value for the penalties introduced to deal with infeasibilities in the solution improvement heuristic. It is set by default when required and if not specified.

Default: -1

penperturb (*real*): Perturbation tolerance for penalties coefficients ↔

Default: 0

perind (*boolean*): force initial perturbation [↔](#)

Default: 0

perlim (*integer*): number of stalled iterations before perturbation [↔](#)

Default: 0

phase12 (*boolean*): Specifies whether to use a phaseI/phaseII method to remove infeasibilities [↔](#)

Default: 1

value	meaning
0	Use composite objective method
1	Use phaseI/phaseII method

polishafterdetime (*real*): deterministic time before starting to polish a feasible solution ↔

Default: 1.0e+75

polishafterepagap (*real*): absolute MIP gap before starting to polish a feasible solution ↔

Default: 0.0

polishafterepgap (*real*): relative MIP gap before starting to polish a solution ↔

Default: 0.0

polishafterintsol (*integer*): MIP integer solutions to find before starting to polish a feasible solution ↔

Default: 2147483647

polishafternode (*integer*): nodes to process before starting to polish a feasible solution ↔

Default: 2147483647

polishaftertime (*real*): time before starting to polish a feasible solution ↔

Default: 1.0e+75

polishtime (*real*): time spent polishing a solution ↔

Default: 0.0

populatelim (*integer*): limit of solutions generated for the solution pool by populate method ↔

Default: 20

ppriind (*integer*): primal simplex pricing ↔

Default: 0

predual (*integer*): give dual problem to the optimizer ↔

Default: 0

preind (*boolean*): turn presolver on/off ↔

Default: 1

prelinear (*boolean*): linear reduction indicator ↔

Default: 1

prepass (*integer*): number of presolve applications to perform ↔

Default: -1

prereform (*integer*): set presolve reformulations ↔

Default: 3

preslvnd (*integer*): node presolve selector [↔](#)

Default: 0

pricelim (*integer*): pricing candidate list [↔](#)

Default: 0

printoptions (*boolean*): list values of all options to GAMS listing file [↔](#)

Default: 0

probe (*integer*): perform probing before solving a MIP [↔](#)

Default: 0

probedetime (*real*): deterministic time spent probing [↔](#)

Default: 1.0e+75

probetime (*real*): time spent probing [↔](#)

Default: 1.0e+75

processorlock (*boolean*): Thread allocation [↔](#)

Default: 0

value	meaning
0	Do not lock threads to processors
1	Lock threads to processors

qextractalg (*integer*): quadratic extraction algorithm in GAMS interface [↔](#)

Default: 0

qpmakepsdind (*boolean*): adjust MIQP formulation to make the quadratic matrix positive-semi-definite [↔](#)

Default: 1

qpmethod (*integer*): algorithm to be used for QP problems [↔](#)

Default: 0

qtolin (*integer*): linearization of the quadratic terms in the objective function of a QP or MIQP model [↔](#)

Default: -1

quality (*boolean*): write solution quality statistics [↔](#)

Default: 0

quickfirstsolve (*boolean*): Accelerate initial CPLEX solve [↔](#)

Default: 0

value	meaning
0	Do not unless presolve applied to full model
1	Use existing presolved model

rampupdetlimit (*real*): limits the amount of time in deterministic ticks spent during ramp up of distributed parallel optimization ↔

Default: 1.0e+75

rampupduration (*integer*): customizes ramp up for distributed parallel optimization ↔

Default: 0

rampuptimelimit (*real*): limits the amount of time in seconds spent during ramp up of distributed parallel optimization ↔

Default: 1.0e+75

randomseed (*integer*): sets the random seed differently for diversity of solutions ↔

Default: 202009243

readfit (*string*): reads Cplex solution pool filter file ↔

record (*boolean*): Records invocations of Callable Library routines ↔

Default: 0

recurse (*integer*): Recurse using heuristic to solve sub-models when a feasible solution has been obtained ↔

Default: 0

value	meaning
0	Do not recurse
1	Recurse thread 0 only
2	Recurse odd numbered threads
3	Recurse all threads
<0	Recurse when working with an infeasible solution. values are negated (e.g. -3 = recursion of all threads)

recursedecomp (*integer*): Recursed model decomposition method ↔

Default: 0

value	meaning
-1	Use initial model decomposition
0	Assign each variable to a separate key
1	Use automatic decomposition method

recurseiterlim (*integer*): Recursed heuristic iteration limit for sub-solves [↔](#)

Default: 40

recurselog (*boolean*): Write thread log files for recursed sub-solves [↔](#)

Default: 0

recurseminterlim (*integer*): Recursed heuristic minimum iterations before a solution is found in sub-solves [↔](#)

Default: 0

recursesoliterlim (*integer*): Recursed heuristic sub-solves quit after these iterations if a solution is found [↔](#)

Default: `maxint`

reduce (*integer*): primal and dual reduction type [↔](#)

Default: 3

reinv (*integer*): refactorization frequency [↔](#)

Default: 0

rejectinfosol (*integer*): Reject infeasible solutions to sub-models [↔](#)

Default: 2

value	meaning
0	Do not check feasibility or reject
1	Check feasibility and warn if infeasible, but accept
2	Check feasibility and reject if infeasible

relaxfixedinfeas (*boolean*): accept small infeasibilities in the solve of the fixed problem [↔](#)

Default: 0

relaxpreind (*integer*): presolve for initial relaxation on/off [↔](#)

Default: -1

relaxsos2 (*integer*): Treatment of SOS2 members [↔](#)

Default: 1

value	meaning
0	Aggressive use in reducing sub-model size
1	Moderate use in reducing sub-model size
2	Ignored in sub-model creation

relobjdif (*real*): relative cheat parameter [↔](#)

Default: 0.0

repairtries (*integer*): try to repair infeasible MIP start ↔

Default: 0

repeatpresolve (*integer*): reapply presolve at root after preprocessing ↔

Default: -1

rerun (*string*): rerun problem if presolve infeasible or unbounded ↔

Default: yes

rinsheur (*integer*): relaxation induced neighborhood search frequency ↔

Default: 0

rltcuts (*integer*): Reformulation Linearization Technique (RLT) cuts ↔

Default: 0

scaind (*integer*): matrix scaling on/off ↔

Default: 0

seed (*integer*): Initial random number seed ↔

Default: 1234

siftalg (*integer*): sifting subproblem algorithm ↔

Default: 0

siftdisplay (*integer*): sifting display level ↔

Default: 1

sifting (*boolean*): switch for sifting from simplex optimization ↔

Default: 1

siftitlim (*integer*): limit on sifting iterations ↔

Default: 2147483647

simdisplay (*integer*): simplex display level ↔

Default: 1

singlim (*integer*): limit on singularity repairs ↔

Default: 10

solnpool (*string*): solution pool file name ↔

solnpoolagap (*real*): absolute tolerance for the solutions in the solution pool ↔

Default: 1.0e+75

solnpoolcapacity (*integer*): limits of solutions kept in the solution pool ↔

Default: 2100000000

solnpoolgap (*real*): relative tolerance for the solutions in the solution pool ↔

Default: 1.0e+75

solnpoolintensity (*integer*): solution pool intensity for ability to produce multiple solutions ↔

Default: 0

solnpoolmerge (*string*): solution pool file name for merged solutions ↔

solnpoolnumsym (*integer*): maximum number of variable symbols when writing merged solutions ↔

Default: 10

solnpoolprefix (*string*): file name prefix for GDX solution files ↔

Default: soln

solnpoolreplace (*integer*): strategy for replacing a solution in the solution pool ↔

Default: 0

solutiontype (*integer*): type of solution (basic or non basic) for an LP or QP ↔

Default: 0

solvefinal (*boolean*): switch to solve the problem with fixed discrete variables ↔

Default: 1

sos1reform (*integer*): automatic logarithmic reformulation of special ordered sets of type 1 (SOS1) ↔

Default: 0

sos2reform (*integer*): automatic logarithmic reformulation of special ordered sets of type 2 (SOS2) ↔

Default: 0

startalg (*integer*): MIP starting algorithm ↔

Default: 0

strategy (*integer*): ODH-Cplex Strategy ↔

The aggressive setting attempt to make more progress with each sub-model solve at the cost of more expensive sub solves. Amongst other changes, it sets [InterDiv](#), [MaxInterDiv](#) and [MaxRepeat](#) if they are not explicitly set by the user.

Default: 1

value	meaning
0	Conservative
1	Normal
2	Aggressiv

strongcandlim (*integer*): size of the candidates list for strong branching ↔

Default: 10

strongitlim (*integer*): limit on iterations per branch for strong branching ↔

Default: 0

subalg (*integer*): algorithm for subproblems ↔

Default: 0

submipnodelim (*integer*): limit on number of nodes in an RINS subMIP ↔

Default: 500

submipscale (*integer*): scale the problem matrix when CPLEX solves a subMIP during MIP optimization ↔

Default: 0

submipstartalg (*integer*): starting algorithm for a subMIP of a MIP ↔

Default: 0

submipsubalg (*integer*): algorithm for subproblems of a subMIP of a MIP ↔

Default: 0

subnodelimit (*integer*): Node limit for submodel searches ↔

Default: -1

value	meaning
-1	Automatically determined
>0	Set node limit to this value

suborder (*integer*): Use of priority order in sub-solves ↔

Default: 1

value	meaning
0	Do not use any supplied priority order information in sub-solves
1	Use any supplied priority order information in sub-solves

subpresolve (*integer*): Use of CPLEX presolve in sub-solves ↔

Default: 1

value	meaning
1	Use normal presolve
2	Use two-step presolve

sub_cpx_threads (*integer*): Threads available for the solves within ODHeuristic [↔](#)

Default: 1

symmetry (*integer*): symmetry breaking cuts [↔](#)

Default: -1

syncfreq (*integer*): Thread synchronization frequency in deterministic parallel mode [↔](#)

Default: 1

value	meaning
0	Low frequency
1	High frequency

threadlog (*boolean*): Write thread log files [↔](#)

Default: 0

threads (*integer*): global default thread count [↔](#)

Synonym: gthreads

Default: 0

threadzerosync (*integer*): Which CPLEX threads to use for synchronization [↔](#)

Default: 0

value	meaning
0	Synchronize with multiple CPLEX threads
1	Only synchronize with CPLEX thread 0

tilim (*real*): overrides the GAMS ResLim option [↔](#)

Default: 1.0e+75

trelim (*real*): maximum space in memory for tree [↔](#)

Default: 1.0e+75

tryint (*real*): GMO tryint [↔](#)

Default: 0.0

tuningdettlim (*real*): tuning deterministic time limit per model or suite [↔](#)

Default: 1.0e+75

tuningdisplay (*integer*): level of information reported by the tuning tool [↔](#)

Default: 1

tuningmeasure (*integer*): measure for evaluating progress for a suite of models [↔](#)

Default: 1

tuningrepeat (*integer*): number of times tuning is to be repeated on perturbed versions [↔](#)

Default: 1

tuningtilim (*real*): tuning time limit per model or suite [↔](#)

Default: 1.0e+75

usebasis (*boolean*): GMO usebasis [↔](#)

Default: 0

variableclean (*integer*): Clean variable values from sub-models [↔](#)

Default: 0

value	meaning
0	No cleaning
1	Quick cleaning and allow feasible uncleaned solutions if unable to clean
2	Quick cleaning and disallow uncleaned solutions
3	Thorough cleaning

varsel (*integer*): variable selection strategy at each node [↔](#)

Default: 0

warninglimit (*integer*): determines how many times warnings of a specific type (datacheck=2) will be displayed [↔](#)

Default: 10

workdir (*string*): directory for working files [↔](#)

Default: .

workeralgorithm (*integer*): set method for optimizing benders subproblems [↔](#)

Default: 0

workmem (*real*): memory available for working storage [↔](#)

Default: 2048.0

writeannotation (*string*): produce a Cplex annotation file [↔](#)

writebas (*string*): produce a Cplex basis file ↔

writeflt (*string*): produce a Cplex solution pool filter file ↔

writelp (*string*): produce a Cplex LP file ↔

writemps (*string*): produce a Cplex MPS file ↔

writemst (*string*): produce a Cplex mst file ↔

writeord (*string*): produce a Cplex ord file ↔

writeparam (*string*): produce a Cplex parameter file with all active options ↔

writepre (*string*): produce a Cplex LP/MPS/SAV file of the presolved problem ↔

writeprob (*string*): produce a Cplex problem file and infers the type from the extension ↔

writesav (*string*): produce a Cplex binary problem file ↔

zerohalfcuts (*integer*): zero-half cuts ↔

Default: 0

zerotol (*real*): Zero tolerance for variable values ↔

Default: 1e-9

5.34 OSICPLEX, OSIGUROBI, OSIMOSEK, OSIXPRESS

The "bare bone" solver links GAMS/OSICPLEX, GAMS/OSIGUROBI, GAMS/OSIMOSEK, and GAMS/OSIXPRESS allow users to solve their GAMS models with a standalone license of CPLEX, GUROBI, MOSEK, or XPRESS. The links use the [COIN-OR Open Solver Interface](#) (OSI) to communicate with these solvers. The OSICPLEX link has been written primarily by Tobias Achterberg, the OSIGUROBI link has been written primarily by Stefan Vigerske, the OSIMOSEK link has been written primarily by Bo Jensen, and the OSIXPRESS link has been written primarily by John Doe. Matthew Saltzman is the COIN-OR project leader for OSI.

For more information we refer to the [OSI web site](#).

The OSI links support linear equations and continuous, binary, and integer variables. The following list provides a brief overview on features available with GAMS/Solver and GAMS/Solver-Link licenses that are *not* available with the bare bone OSI solver links:

- Nonlinear model types such as [QCP](#), [MIQCP](#), [NLP](#) and [MINLP](#)
- Variable types [SemiInt](#), [SemiCont](#), [SOS1](#) and [SOS2](#)
- certain GAMS/Solver options have no OSI counterpart (see e.g. the [Comparison of GAMS/CPLEX and GAMS/OSI](#))

5.34.1 Usage

The following statement can be used inside your GAMS program to specify using OSIGUROBI

```
Option LP = OSIGUROBI;      { or MIP or RMIP }
```

Similar statements apply to OSICPLEX, OSIMOSEK, and OSIXPRESS.

The above statement should appear before the Solve statement.

The links support the general GAMS options [reslim](#) (time limit), [iterlim](#) (iteration limit), [nodlim](#) (node limit), [optca](#) (absolute gap tolerance), [optcr](#) (relative gap tolerance), [cheat](#) (cutoff decrement, only Xpress), and [threads](#). An option file in the format required by the solver can be provided via the GAMS optfile option. See Section [Option files](#) for details.

If a MIP is solved via one of the OSI links, only primal solution values are reported by default. To receive also the dual values for the LP that is obtained from the MIP by fixing all discrete variables, the GAMS option [integer1](#) must be set to a nonzero value. Note that this may lead to solving another LP after the MIP solve has finished.

Setting the GAMS option [integer2](#) to a nonzero value makes variable and equation names available to the solver. This option may be useful for debugging purposes.

Setting the GAMS option [integer3](#) to a nonzero value leads to writing the model instance to a file in LP or MPS format before starting the solution process ([integer3=1](#) writes an MPS file, [integer3=2](#) writes an LP files, [integer3=4](#) writes a native MPS file; sum these values to write several files). The name of the MPS file is chosen to be the name of the GAMS model file with the extension [.gms](#) replaced by [.mps](#). This option may be useful for debugging purposes.

For OSICPLEX, OSIGUROBI, and OSIXPRESS, setting the GAMS option [integer4](#) to a nonzero value leads to passing the variable level values ([.1](#) suffix) to the MIP solver as initial solution. This is analog to [mipstart](#) option of the full CPLEX and GUROBI links and the [loadmipsol](#) option of the full XPRESS link.

5.34.1.1 Option files

5.34.1.1.1 OSICPLEX Options In an OSICPLEX option file, each line lists one option setting, where the option name and value are separated by space.

Example:

```
CPX_PARAM_MIPEMPHASIS      2
CPX_PARAM_HEURFREQ        42
CPX_PARAM_MIPDISPLAY      4
```

Note that GAMS/OSICPLEX will not process a [GAMS/CPLEX option](#) file. Instead, native CPLEX options (CPX...) have to be provided through an OSICPLEX option file (e.g. `osicplex.opt`) that follows the very strict syntax of a CPLEX parameter file. There is a trick to convert GAMS/CPLEX options into native CPLEX options: Create a regular GAMS/CPLEX option file `cplex.opt` with the options you would like to set for GAMS/OSICPLEX and add the option `writeparam osicplex.opt`. For example

```
* Cplex.opt
varsel 3 ! set variable selection to strong branching
writeparam osicplex.opt
```

Run this on any demo sized MIP problem (e.g. [\[MAGIC\]](#) from the GAMS Model Library) using GAMS/CPLEX. After the run you will find a file that looks as follows and can be supplied to GAMS/OSICPLEX to set the variable selection to strong branching (native CPLEX option `CPXPARAM_MIP_Strategy_VariableSelect 3`):

```
CPLEX Parameter File Version 12.10.0.0
CPXPARAM_Advance           0
CPXPARAM_Threads          1
CPXPARAM_Parallel         1
CPXPARAM_MIP_Display      4
CPXPARAM_MIP_Strategy_VariableSelect 3
CPXPARAM_MIP_Tolerances_AbsMIPGap 0
CPXPARAM_MIP_Tolerances_MIPGap 0
CPXPARAM_WorkDir          "C:\[...]\Documents\GAMS\Studio\workspace\225a\"
```

This includes some CPLEX options that have been set by the GAMS/CPLEX link and you might want to remove from this file.

Note that several GAMS/CPLEX options have no GAMS/OSICPLEX counterpart:

- [solnpool](#) (Solution Pool)
- [feasopt](#)
- [iis](#)
- [objrng, rhsrng](#) (Sensitivity Analysis)
- [indic](#) (Indicator constraints)
- [tuning](#) (Automatic Option Tuning)
- [BCH Facility Options](#)
- [quality](#) (Statistics of Solution)
- [writeXXX](#) (create some Cplex specific output files, e.g. `XXX=sav`)
- [tryInt](#)
- [interactive](#)
- [fixoptfile](#)
- [miptrace](#)

5.34.1.1.2 OSIGUROBI Options In an OSIGUROBI option file, each line lists one option setting, where the option name and value are separated by space.

Example:

```
Cuts 2
Heuristics 0.1
```

5.34.1.1.3 OSIMOSEK Options An OSIMOSEK option file begins with the line `BEGIN MOSEK` and terminates with `END MOSEK`. Comments are introduced with an `'%'`, empty lines are ignored. Each other line starts with a MOSEK parameter value, followed by space, and a value for that parameter.

Example:

```
BEGIN MOSEK
% disable probing and solve the root node by the interior point solver
MSK_IPAR_MIO_PRESOLVE_PROBING MSK_OFF
MSK_IPAR_MIO_ROOT_OPTIMIZER MSK_OPTIMIZER_INTPNT
END MOSEK
```

5.34.1.1.4 OSIXPRESS Options In an OSIXPRESS option file, each line lists one option setting, where the option name and value are separated by an equal sign.

Example:

```
MIPLLOG = 3
HEURFREQ = 2
```

5.34.1.2 Setup

5.34.1.2.1 OSICPLEX Setup The setup for GAMS/OSICPLEX is identical to the [GAMS/CPLEX-Link setup](#) but to use the bare-bone interface GAMS/OSICPLEX, you do not need a GAMS/CPLEX-Link license but instead you have to request a free of charge GAMS/OSICPLEX license from sales@gams.com.

5.34.1.2.2 OSIGUROBI Setup The setup for GAMS/OSIGUROBI is identical to the [GAMS/Gurobi-Link setup](#) but to use the bare-bone interface GAMS/OSIGUROBI, you do not need a GAMS/GUROBI-Link license.

5.34.1.2.3 OSIMOSEK Setup The setup for GAMS/OSIMOSEK is identical to the [GAMS/MOSEK-Link setup](#) but to use the bare-bone interface GAMS/OSIMOSEK, you do not need a GAMS/MOSEK-Link license.

5.34.1.2.4 OSIXPRESS Setup The setup for GAMS/OSIXPRESS is identical to the [GAMS/XPRESS-Link setup](#) but to use the bare-bone interface GAMS/OSIXPRESS, you do not need a GAMS/XPRESS-Link license.

5.35 PATHNLP

5.35.1 Introduction

This document describes the GAMS/PATHNLP solver for non-linear programs and the options unique to this solver.

PATHNLP solves an NLP by internally constructing the Karush-Kuhn-Tucker (KKT) system of first-order optimality conditions associated with the NLP and solving this system using the PATH solver for complementarity problems. The solution to the original NLP is extracted from the KKT solution and returned to GAMS. All of this takes place automatically - no special syntax or user reformulation is required.

Typically, PATHNLP works very well for convex models. It also has a comparative advantage on models whose solution via reduced gradient methods results in a large number of superbasic variables, since the PATH solver won't construct a dense reduced Hessian in the space of the superbasic variables as reduced gradient solvers do. For nonconvex models, however, PATHNLP is not as robust as the reduced gradient methods.

The theory relating NLP to their KKT systems is well-known: assuming differentiability without convexity, and assuming a constraint qualification holds, then a solution to the NLP must also be a solution to the KKT system. If we also assume convexity, then a solution to the KKT system is also a solution to the NLP - no further constraint qualification is required.

In case PATH fails to find a solution to the KKT system for the NLP, a phase I / phase II method is used in which the phase I objective is simply the feasibility error and the original objective is ignored. If a feasible point is found in phase I then phase II, an attempt to solve the KKT system for the NLP using the current feasible point, is entered.

PATHNLP is installed automatically with your GAMS system. With a demo or community license, it will solve small models only). If your GAMS license includes PATH, this size restriction is removed.

5.35.2 Usage

If you have installed the system and configured PATHNLP as the default NLP solver, all NLP models without a specific solver option will be solved with PATHNLP. If you installed another solver as the default, you can explicitly request that a particular model be solved using PATHNLP by inserting the statement

```
option NLP = pathnlp;
```

somewhere before the `solve` statement. Similar comments hold for the other model types (LP, RMINLP, QCP, etc.) PATHNLP can handle.

The standard GAMS model options `iterlim` and `reslim` can be used to control PATHNLP. A description of these options can be found in the [GAMS Options](#) section of the chapter on basic solver usage. In general this is enough to use PATHNLP effectively. In some cases, however, you may want to use some of the PATH or PATHNLP options to gain further performance improvements or for other reasons. The rules for [using an option file](#) are described in the chapter on basic solver usage. The options used to control PATH can also be used to control PATHNLP. There are also some options unique to PATHNLP.

5.35.3 Options

The tables that follow describe the options unique to PATHNLP as well as the options shared with the PATH solver for MCP models.

5.35.3.1 General options

Option	Description	Default
chen_lambda	lambda parameter for Chen-Chen-Kanzow residual Range: [0, 1]	0.8
convergence_tolerance	stopping criterion	1e-6
crash_iteration_limit	maximum iterations allowed in crash	50
crash_merit_function	merit function used in crash method normal : Use the normal map fischer : Use the Fischer function	fischer
crash_method	pnewton or none pnewton : Use projected Newton method none	pnewton
crash_minimum_dimension	minimum problem dimension to perform crash	1
crash_nbchange_limit	number of changes to the basis allowed	1
crash_perturb	perturb the problem using pnewton crash	1
crash_searchtype	search type to use in the crash method line : Use a linesearch arc : Use an arcsearch	line
cumulative_iteration_limit	maximum minor iterations allowed	10000
gradient_searchtype	search type to use on a gradient step line : Use a linesearch arc : Use an arcsearch	arc
gradient_step_limit	gradient steps allowed before restarting	5
interrupt_limit	ctrl-C's required before killing job Range: {1, ..., ∞}	5
major_iteration_limit	maximum major iterations allowed	500
merit_function	merit function to use (normal or fischer) normal : Use the normal map fischer : Use the Fischer function	fischer
minor_iteration_limit	minor iterations allowed in each major iteration	1000
nms	allow line searching, watch-dogging, and nonmonotone descent	1
nms_initial_reference_factor	controls size of initial reference value	20
nms_maximum_watchdogs	maximum number of watchdog steps allowed	5
nms_memory_size	number of reference values kept	10
nms_mstep_frequency	frequency at which m-steps are performed	10
nms_searchtype	search type to use line : Use a linesearch arc : Use an arcsearch	line
option_file	option file name for PATHLIB to read	
preprocess	turns preprocessing on/off	1
proximal_perturbation	initial perturbation	0
time_limit	number of seconds algorithm is allowed to run	
lemke_rank_deficiency_iterations	number of attempts made to fix rank-deficient basis during Lemke start	10

Option	Description	Default
lemke_start	frequency of lemke starts always: Use a Lemke start for each LCP subproblem automatic: Determined by algorithm first: Use a Lemke start for the first LCP subproblem	automatic
lemke_start_type	type of lemke start advanced: Start Lemke method using an advanced basis slack: Start Lemke method using and all-slack basis	slack

5.35.3.2 NLP-specific options

Option	Description	Default
allow_reform	substitute out objective var and equ when possible Many models have an objective variable and equation that can be substituted out of the model, e.g. $f(x) = E z$; If this option is true, PATHNLP will substitute out the objective variable and equation where possible.	1
gmo_hess_factor	maximum multiples of Jacobian size to allow Hessian storage: 0=no limit	0
nlp_lambda	linesearch factor when using the NLP objective If <code>nlp_objective</code> is true and <code>nlp_lambda</code> is positive, the PATH linesearch will be altered to take the objective function into account.	0
nlp_objective	treat NLP objective differently in PATH linesearch	0
output_memory	output breakdown of where memory is used	0
skip_kkt	go right to Phase I / Phase II method If true, PATHNLP will skip the initial attempt to solve the KKT system for the NLP and go directly into a Phase I / Phase II method that first attempts to get feasible and then attempts to solve the KKT system starting from the feasible point found in Phase I.	0

5.35.3.3 Output options

Option	Description	Default
output_crash_iterations	output information on crash iterations	1
output_crash_iterations_frequency	frequency at which crash iteration log is printed Range: $\{1, \dots, \infty\}$	1
output_errors	output error messages	1
output_final_degeneracy_statistics	print information regarding degeneracy at the solution	0
output_final_point	output final point returned from PATH	0
output_final_point_statistics	output information about the point, function, and Jacobian at the final point	1
output_final_scaling_statistics	display matrix norms on the Jacobian at the final point	0
output_final_statistics	output evaluation of available merit functions at the final point	1
output_final_summary	output summary information	1

Option	Description	Default
output_initial_point	output initial point given to PATH	0
output_initial_point_statistics	output information about the point, function, and Jacobian at the initial point	1
output_initial_scaling_statistics	display matrix norms on the Jacobian at the initial point	1
output_initial_statistics	output evaluation of available merit functions at the initial point	0
output_linear_model	output linear model at each major iteration	0
output_major_iterations	output information on major iterations	1
output_major_iterations_frequency	frequency at which major iteration log is printed Range: {1, ..., ∞ }	1
output_maximum_zero_listing	limits zero columns reported to listing file	1000
output_maximum_zero_log	limits zero columns reported to log file	10
output_minor_iterations	output information on minor iterations	1
output_minor_iterations_frequency	frequency at which minor iteration log is printed Range: {1, ..., ∞ }	500
output_options	output all options and their values	0
output	no turns all output off	1
output_preprocess_level	control output of preprocessing information	1
output_restart_log	output options during restarts	1
output_time	output breakdown of where time is spent	0
output_warnings	output warning messages	0

5.36 PATH 4.7

Author

Michael C. Ferris

Todd S. Munson

5.36.1 Complementarity

A fundamental problem of mathematics is to find a solution to a square system of nonlinear equations. Two generalizations of nonlinear equations have been developed, a constrained nonlinear system which incorporates bounds on the variables, and the complementarity problem (MCP). This document is primarily concerned with the complementarity problem.

The PATH solver for MCP models is a Newton-based solver that combines a number of the most effective variations, extensions, and enhancements of this powerful technique. See [PATH vs MILES](#) for a comparison with MILES. Algorithmic details can also be found in papers and technical reports by Dirkse, Ferris, and Munson on [Ferris' Home Page](#).

The complementarity problem adds a combinatorial twist to the classic square system of nonlinear equations, thus enabling a broader range of situations to be modeled. In its simplest form, the combinatorial problem is to choose from $2n$ inequalities a subset of n that will be satisfied as equations. These problems arise in a variety of disciplines including engineering and economics [83] where we might want to compute Wardropian and Walrasian equilibria, and optimization where we can model the first order optimality conditions for nonlinear programs [137] [151]. Other examples, such as bimatrix games [157] and options pricing [130], abound.

Our development of complementarity is done by example. We begin by looking at the optimality conditions for a transportation problem and some extensions leading to the nonlinear complementarity problem. We then discuss a Walrasian equilibrium model and use it to motivate the more general mixed complementarity problem. We conclude this chapter with information on solving the models using the PATH solver and interpreting the results.

5.36.1.1 Transportation Problem

The transportation model is a linear program where demand for a single commodity must be satisfied by suppliers at minimal transportation cost. The underlying transportation network is given as a set \mathcal{A} of arcs, where $(i, j) \in \mathcal{A}$ means that there is a route from supplier i to demand center j . The problem variables are the quantities $x_{i,j}$ shipped over each arc $(i, j) \in \mathcal{A}$. The linear program can be written mathematically as

$$\begin{aligned} \min_{x \geq 0} \quad & \sum_{(i,j) \in \mathcal{A}} c_{i,j} x_{i,j} \\ \text{subject to} \quad & \sum_{j:(i,j) \in \mathcal{A}} x_{i,j} \leq s_i, \quad \forall i \\ & \sum_{i:(i,j) \in \mathcal{A}} x_{i,j} \geq d_j, \quad \forall j. \end{aligned} \tag{1}$$

where $c_{i,j}$ is the unit shipment cost on the arc (i, j) , s_i is the available supply at i , and d_j is the demand at j .

The derivation of the optimality conditions for this linear program begins by associating with each constraint a multiplier, alternatively termed a dual variable or shadow price. These multipliers represent the marginal price on changes to the corresponding constraint. We label the prices on the supply constraint p^s and those on the demand constraint p^d . Intuitively, for each supply node i

$$0 \leq p_i^s, \quad s_i \geq \sum_{j:(i,j) \in \mathcal{A}} x_{i,j}.$$

Consider the case when $s_i > \sum_{j:(i,j) \in \mathcal{A}} x_{i,j}$, that is there is excess supply at i . Then, in a competitive marketplace, no rational person is willing to pay for more supply at node i ; it is already over-supplied. Therefore, $p_i^s = 0$. Alternatively, when $s_i = \sum_{j:(i,j) \in \mathcal{A}} x_{i,j}$, that is node i clears, we might be willing to pay for additional supply of the good. Therefore, $p_i^s \geq 0$. We write these two conditions succinctly as:

$$0 \leq p_i^s \quad \perp \quad s_i \geq \sum_{j:(i,j) \in \mathcal{A}} x_{i,j}, \quad \forall i$$

where the \perp notation is understood to mean that at least one of the adjacent inequalities must be satisfied as an equality. For example, either $0 = p_i^s$, the first case, or $s_i = \sum_{j:(i,j) \in \mathcal{A}} x_{i,j}$, the second case.

Similarly, at each node j , the demand must be satisfied in any feasible solution, that is

$$\sum_{i:(i,j) \in \mathcal{A}} x_{i,j} \geq d_j.$$

Furthermore, the model assumes all prices are nonnegative, $0 \leq p_j^d$. If there is too much of the commodity supplied, $\sum_{i:(i,j) \in \mathcal{A}} x_{i,j} > d_j$, then, in a competitive marketplace, the price p_j^d will be driven down to 0. Summing these relationships gives the following complementarity condition:

$$0 \leq p_j^d \quad \perp \quad \sum_{i:(i,j) \in \mathcal{A}} x_{i,j} \geq d_j, \quad \forall j.$$

The supply price at i plus the transportation cost $c_{i,j}$ from i to j must exceed the market price at j . That is, $p_i^s + c_{i,j} \geq p_j^d$. Otherwise, in a competitive marketplace, another producer will replicate supplier

i increasing the supply of the good in question which drives down the market price. This chain would repeat until the inequality is satisfied. Furthermore, if the cost of delivery strictly exceeds the market price, that is $p_i^s + c_{i,j} > p_j^d$, then nothing is shipped from i to j because doing so would incur a loss and $x_{i,j} = 0$. Therefore,

$$0 \leq x_{i,j} \perp p_i^s + c_{i,j} \geq p_j^d, \quad \forall (i,j) \in \mathcal{A}.$$

We combine the three conditions into a single problem,

$$\begin{aligned} 0 \leq p_i^s &\perp s_i \geq \sum_{j:(i,j) \in \mathcal{A}} x_{i,j}, & \forall i \\ 0 \leq p_j^d &\perp \sum_{i:(i,j) \in \mathcal{A}} x_{i,j} \geq d_j, & \forall j \\ 0 \leq x_{i,j} &\perp p_i^s + c_{i,j} \geq p_j^d, & \forall (i,j) \in \mathcal{A}. \end{aligned} \quad (2)$$

This model defines a linear complementarity problem that is easily recognized as the complementary slackness conditions [56] of the linear program (1). For linear programs the complementary slackness conditions are both necessary and sufficient for x to be an optimal solution of the problem (1). Furthermore, the conditions (2) are also the necessary and sufficient optimality conditions for a related problem in the variables (p^s, p^d)

$$\begin{aligned} \max_{p^s, p^d \geq 0} & \sum_j d_j p_j^d - \sum_i s_i p_i^s \\ \text{subject to} & c_{i,j} \geq p_j^d - p_i^s, \quad \forall (i,j) \in \mathcal{A} \end{aligned}$$

termed the dual linear program (hence the nomenclature "dual variables").

Looking at (2) a bit more closely we can gain further insight into complementarity problems. A solution of (2) tells us the arcs used to transport goods. A priori we do not need to specify which arcs to use, the solution itself indicates them. This property represents the key contribution of a complementarity problem over a system of equations. If we know what arcs to send flow down, we can just solve a simple system of linear equations. However, the key to the modeling power of complementarity is that it chooses which of the inequalities in (2) to satisfy as equations. In economics we can use this property to generate a model with different regimes and let the solution determine which ones are active. A regime shift could, for example, be a back stop technology like windmills that become profitable if a CO_2 tax is increased.

5.36.1.1.1 GAMS Code The GAMS code for the complementarity version of the transportation problem is given in Figure 1; the actual data for the model is assumed to be given in the file `transmcp.dat`. Note that the model written corresponds very closely to (2). In GAMS, the \perp sign is replaced in the `model` statement with a `"`. It is precisely at this point that the pairing of variables and equations shown in (2) occurs in the GAMS code. For example, the function defined by `rational` is complementary to the variable `x`. To inform a solver of the bounds, the standard GAMS statements on the variables can be used, namely (for a declared variable $z(i)$):

```
z.lo(i) = 0;
```

or alternatively

```
positive variable z;
```

Further information on the GAMS syntax can be found in [212]. Note that GAMS requires the modeler to write $F(\mathbf{z}) = g = 0$ whenever the complementary variable is lower bounded, and does not allow the alternative form $0 = l = F(\mathbf{z})$.

Figure 1: A simple MCP model in GAMS, `transmcp.gms`

```

    c(i,j)  transport cost in thousands of dollars per case ;

$include transmcp.dat

positive variables
    x(i,j)    shipment quantities in cases
    p_demand(j)  price at market j
    p_supply(i)  price at plant i;

equations
    supply(i)    observe supply limit at plant i
    demand(j)    satisfy demand at market j
    rational(i,j);

supply(i) ..    s(i) =g= sum(j, x(i,j)) ;

demand(j) ..    sum(i, x(i,j)) =g= d(j) ;

rational(i,j) .. p_supply(i) + c(i,j) =g= p_demand(j) ;

model transport / rational.x, demand.p_demand, supply.p_supply /;

solve transport using mcp;

```

5.36.1.1.2 Extension: Model Generalization While many interior point methods for linear programming exploit this complementarity framework (so-called primal-dual methods [265]), the real power of this modeling format is the new problem instances it enables a modeler to create. We now show some examples of how to extend the simple model (2) to investigate other issues and facets of the problem at hand.

Demand in the model of Figure 1 is independent of the prices p . Since the prices p are variables in the complementarity problem (2), we can easily replace the constant demand d with a function $d(p)$ in the complementarity setting. Clearly, any algebraic function of p that can be expressed in GAMS can now be added to the model given in Figure 1. For example, a linear demand function could be expressed using

$$\sum_{i:(i,j) \in \mathcal{A}} x_{i,j} \geq d_j(1 - p_j^d), \forall j.$$

Note that the demand is rather strange if p_j^d exceeds 1. Other more reasonable examples for $d(p)$ are easily derived from Cobb-Douglas or CES utilities. For those examples, the resulting complementarity problem becomes nonlinear in the variables p . Details of complementarity for more general transportation models can be found in [69], [85].

Another feature that can be added to this model are tariffs or taxes. In the case where a tax is applied at the supply point, the third general inequality in (2) is replaced by

$$p_i^s(1 + t_i) + c_{i,j} \geq p_j^d, \forall (i,j) \in \mathcal{A}.$$

The taxes can be made endogenous to the model, details are found in [212].

The key point is that with either of the above modifications, the complementarity problem is not just the optimality conditions of a linear program. In many cases, there is no optimization problem corresponding to the complementarity conditions.

5.36.1.1.3 Nonlinear Complementarity Problem We now abstract from the particular example to describe more carefully the complementarity problem in its mathematical form. All the above examples can be cast as nonlinear complementarity problems (NCPs) defined as follows:

(NCP) Given a function $F : \mathbf{R}^n \rightarrow \mathbf{R}^n$, find $z \in \mathbf{R}^n$ such that

$$0 \leq z \perp F(z) \geq 0.$$

Recall that the \perp sign signifies that one of the inequalities is satisfied as an equality, so that componentwise, $z_i F_i(z) = 0$. We frequently refer to this property as z_i is *complementary* to F_i . A special case of the NCP that has received much attention is when F is a linear function, the linear complementarity problem [61].

5.36.1.2 Walrasian Equilibrium

A Walrasian equilibrium can also be formulated as a complementarity problem (see [176]). In this case, we want to find a price $p \in \mathbf{R}^m$ and an activity level $y \in \mathbf{R}^n$ such that

$$\begin{aligned} 0 \leq y \perp L(p) &:= -A^T p \geq 0 \\ 0 \leq p \perp S(p, y) &:= b + Ay - d(p) \geq 0 \end{aligned} \quad (3)$$

where $S(p, y)$ represents the excess supply function and $L(p)$ represents the loss function. Complementarity allows us to choose the activities y_j to run (i.e. only those that do not make a loss). The second set of inequalities state that the price of a commodity can only be positive if there is no excess supply. These conditions indeed correspond to the standard exposition of Walras' law which states that supply equals demand if we assume all prices p will be positive at a solution. Formulations of equilibria as systems of equations do not allow the model to choose the activities present, but typically make an a priori assumption on this matter.

5.36.1.2.1 GAMS Code A GAMS implementation of (3) is given in Figure 2. Many large scale models of this nature have been developed. An interested modeler could, for example, see how a large scale complementarity problem was used to quantify the effects of the Uruguay round of talks [126].

Figure 2: Walrasian equilibrium as an NCP, walras1.gms

```

$include walras.dat

positive variables p(i), y(j);
equations S(i), L(j);

S(i)..  b(i) + sum(j, A(i,j)*y(j)) - c(i)*sum(k, g(k)*p(k)) / p(i)
        =g= 0;

L(j)..  -sum(i, p(i)*A(i,j)) =g= 0;

model walras / S.p, L.y /;
solve walras using mcp;

```

5.36.1.2.2 Extension: Intermediate Variables In many modeling situations, a key tool for clarification is the use of intermediate variables. As an example, the modeler may wish to define a variable corresponding to the demand function $d(p)$ in the Walrasian equilibrium (3). The syntax for carrying this out is shown in Figure 3 where we use the variables `d` to store the demand function referred to in the excess supply equation. The model `walras` now contains a mixture of equations and complementarity constraints. Since constructs of this type are prevalent in many practical models, the GAMS syntax allows such formulations.

Figure 3: Walrasian equilibrium as an MCP, `walras2.gms`

```
$include walras.dat

positive variables p(i), y(j);
variables d(i);
equations S(i), L(j), demand(i);

demand(i)..
    d(i) =e= c(i)*sum(k, g(k)*p(k)) / p(i) ;

S(i)..    b(i) + sum(j, A(i,j)*y(j)) - d(i) =g= 0 ;

L(j)..    -sum(i, p(i)*A(i,j)) =g= 0 ;

model walras / demand.d, S.p, L.y /;
solve walras using mcp;
```

Note that positive variables are paired with inequalities, while free variables are paired with equations. A crucial point misunderstood by many modelers (new and experienced alike) is that *the bounds on the variable determine the relationships satisfied by the function F* . Thus in Figure 3, d is a free variable and therefore its paired equation `demand` is an equality. Similarly, since p is nonnegative, its paired relationship `S` is a (greater-than) inequality. See the [MCP definition](#) below for details.

A simplification is allowed to the model statement in Figure 3. It is not required to match free variables explicitly to equations; we only require that there are the same number of free columns (i.e. single variables) as unmatched rows (i.e. single equations). Thus, in the example of Figure 3, the model statement could be replaced by

```
model walras / demand, S.p, L.y /;
```

This extension allows existing GAMS models consisting of a square system of nonlinear equations to be easily recast as a complementarity problem - the model statement is unchanged. GAMS generates a list of all variables appearing in the equations found in the model statement, performs explicitly defined pairings and then checks that the number of remaining equality rows equals the number of remaining free columns. However, if an explicit match is given, the PATH solver can frequently exploit the information for better solution. Note that all variables that are not free and all inequalities must be explicitly matched.

5.36.1.2.3 Mixed Complementarity Problem A mixed complementarity problem (MCP) is specified by three pieces of data, namely the lower bounds ℓ , the upper bounds u and the function F .

(MCP) Given lower bounds $\ell \in \{\mathbf{R} \cup \{-\infty\}\}^n$, upper bounds $u \in \{\mathbf{R} \cup \{\infty\}\}^n$ and a function $F : \mathbf{R}^n \rightarrow \mathbf{R}^n$, find $z \in \mathbf{R}^n$ such that *precisely* one of the following holds for each $i \in \{1, \dots, n\}$:

$$\begin{aligned} F_i(z) = 0 & \quad \text{and} \quad \ell_i \leq z_i \leq u_i \\ F_i(z) > 0 & \quad \text{and} \quad z_i = \ell_i \\ F_i(z) < 0 & \quad \text{and} \quad z_i = u_i. \end{aligned}$$

These relationships define a general MCP (sometimes termed a rectangular variational inequality [125]). We will write these conditions compactly as

$$\ell \leq x \leq u \perp F(x).$$

As the MCP model type as defined above is the one used in GAMS, there are some consequences of the definition worth emphasizing here. Firstly, the bounds on the variable determine the relationships satisfied by the function F : the constraint type (e.g. =G=, =L=) chosen plays no role in defining the problem. This being the case, it is acceptable (and perhaps advisable!) to use an =N= in the definition of all equations used in complementarity models to highlight the dependence on the variable bounds in defining the MCP. This is not required, however. The constraint types =G=, =L= and =E= are also allowed. If the variable bounds are inconsistent with the constraint type chosen, GAMS will either reject the model (e.g. an =L= row matched with a lower-bounded variable) or silently and temporarily ignore the issue (e.g. an =E= row matched with a lower-bounded variable). In the latter case, if equality does not hold at solution (allowable if the variable is at lower bound) the is marked in the listing file with a [redef](#).

Secondly, note the contrast between *complementarity conditions* like $g(z) \leq 0, z \geq 0$ and a *complementarity problem* like $F(x) \perp 0 \leq x \leq \infty$. The former requires a trivial transformation in order to fit into the MCP framework: $-g(z) \perp 0 \leq z \leq \infty$. This simple issue is a frequent source of problems and worth looking out for.

The nonlinear complementarity problem of [Nonlinear Complementarity Problem](#) is a special case of the MCP. For example, to formulate an NCP in the GAMS/MCP format we set

```
z.lo(I) = 0;
```

or declare

```
positive variable z;
```

Another special case is a square system of nonlinear equations

(NE) Given a function $F : \mathbf{R}^n \rightarrow \mathbf{R}^n$ find $z \in \mathbf{R}^n$ such that

$$F(z) = 0.$$

In order to formulate this in the GAMS/MCP format we just declare

```
free variable z;
```

In both the above cases, we *must not* modify the lower and upper bounds on the variables later (unless we wish to drastically change the problem under consideration).

An advantage of the extended formulation described above is the pairing between "fixed" variables (ones with equal upper and lower bounds) and a component of F . If a variable z_i is fixed, then $F_i(z)$ is unrestricted since precisely one of the three conditions in the MCP definition automatically holds when $z_i = \ell_i = u_i$. Thus if a variable is fixed in a GAMS model, the paired equation is completely dropped from the model. This convenient modeling trick can be used to remove particular constraints from a model at generation time. As an example, in economics, fixing a level of production will remove the zero-profit condition for that activity.

Simple bounds on the variables are a convenient modeling tool that translates into efficient mathematical programming tools. For example, specialized codes exist for the bound constrained optimization problem

$$\min f(x) \text{ subject to } \ell \leq x \leq u.$$

The first order optimality conditions for this problem class are precisely $\text{MCP}(\nabla f(x), [\ell, u])$. We can easily see this condition in a one dimensional setting. If we are at an unconstrained stationary point, then $\nabla f(x) = 0$. Otherwise, if x is at its lower bound, then the function must be increasing as x increases, so $\nabla f(x) \geq 0$. Conversely, if x is at its upper bound, then the function must be increasing as x decreases, so that $\nabla f(x) \leq 0$. The MCP allows such problems to be easily and efficiently processed.

Upper bounds can be used to extend the utility of existing models. For example, in [Figure 3](#) it may be necessary to have an upper bound on the activity level y . In this case, we simply add an upper bound to y in the model statement, and we can replace the loss equation with the following definition:

```
y.up(j) = 10;
L(j)..  -sum(i, p(i)*A(i,j)) =e 0 ;
```

Here, for bounded variables, we do not know beforehand if the constraint will be satisfied as an equation, less-than inequality or greater-than inequality, since this determination depends on the values of the solution variables. However, let us interpret the relationships that the above change generates. If $y_j = 0$, the loss function can be positive since we are not producing in the j th sector. If y_j is strictly between its bounds, then the loss function must be zero by the definition of complementarity; this is the competitive assumption. Finally, if y_j is at its upper bound, then the loss function can be negative. Of course, if the market does not allow free entry, some firms may operate at a profit (negative loss). For more examples of problems, the interested reader is referred to [\[66\]](#) , [\[82\]](#) , [\[83\]](#) .

5.36.1.3 Solution

We will assume that a file named `transmcp.gms` has been created using the GAMS syntax which defines an MCP model `transport` as developed in [Transportation Problem](#) . The modeler has a choice of the complementarity solver to use. We are going to further assume that the modeler wants to use PATH.

There are two ways to ensure that PATH is used as opposed to any other GAMS/MCP solver. These are as follows:

1. Add the following line to the `transmcp.gms` file prior to the `solve` statement

```
option mcp = path;
```

PATH will then be used instead of the default solver provided.

2. Choose PATH as the default solver for MCP (via the IDE on Windows or elsewhere by rerunning `gamsinst` from the GAMS system directory).

To solve the problem, the modeler executes the command:

```
gams transmcp
```

where `transmcp` can be replaced by any filename containing a GAMS model. Many other command line options for GAMS exist; the reader is referred to [List of Command Line Parameters](#) for further details.

At this stage, control is handed over to the solver which creates a log providing information on what the solver is doing as time elapses. See [Section PATH](#) for details about the log file. After the solver terminates, a listing file is generated containing the solution to the problem. We now describe the listing file output specifically related to complementarity problems.

5.36.1.3.1 Listing File The listing file is the standard GAMS mechanism for reporting model results. This file contains information regarding the compilation process, the form of the generated equations in the model, and a report from the solver regarding the solution process.

We now detail the last part of this output, an example of which is given in [Figure 4](#) . We use "..." to indicate where we have omitted continuing similar output.

Figure 4: Listing File for solving `transmcp.gms`

                           0      ERRORS

```

After a summary line indicating the model name and type and the solver name, the listing file shows a solver status and a model status. [Table 1](#) and [Table 2](#) display the relevant codes that are returned under different circumstances. A modeler can access these codes within the `transmcp.gms` file using `transport.solvestat` and `transport.modelstat` respectively.

Table 1: Solver Status Codes

Code	String	Meaning
1	Normal completion	Solver finished normally
2	Iteration interrupt	Solver reached the iterations limit
3	Resource interrupt	Solver reached the time limit
4	Terminated by solver	Solver reached an unspecified limit
8	User interrupt	The user interrupted the solution process

Table 2: Model Status Codes

Code	String	Meaning
1	Optimal	Solver found a solution of the problem
6	Intermediate infeasible	Solver failed to solve the problem

After this, a listing of the time and iterations used is given, along with a count on the number of evaluation errors encountered. If the number of evaluation errors is greater than zero, further information can typically be found later in the listing file, prefaced by "****". Information provided by the solver is then displayed.

Next comes the solution listing, starting with each of the equations in the model. For each equation passed to the solver, four columns are reported, namely the lower bound, level, upper bound and marginal. GAMS moves all parts of a constraint involving variables to the left hand side, and accumulates the constants on the right hand side. The lower and upper bounds correspond to the constants that GAMS generates. For equations, these should be equal, whereas for inequalities one of them should be infinite. The level value of the equation (an evaluation of the left hand side of the constraint at the current point) should be between these bounds, otherwise the solution is infeasible and the equation is marked as follows:

```
seattle .chicago    -0.153    -2.000    +INF    300.000 INFES
```

The marginal column in the equation contains the value of the variable that was matched with this equation.

For the variable listing, the lower, level and upper columns indicate the lower and upper bounds on the variables and the solution value. The level value returned by PATH will always be between these bounds. The marginal column contains the value of the slack on the equation that was paired with this variable. If a variable appears in one of the constraints in the model statement but is not explicitly paired to a constraint, the slack reported here contains the internally matched constraint slack. The definition of this slack is the minimum of $\text{equ.l} - \text{equ.lower}$ and $\text{equ.l} - \text{equ.upper}$, where equ is the paired equation.

Finally, a summary report is given that indicates how many errors were found. [Figure 4](#) is nicely-solved case; when the model has infeasibilities, these can be found by searching for the string "INFES" as described above.

5.36.1.3.2 Redefined Equations Unfortunately, this is not the end of the story. Some equations may have the following form:

```

          LOWER      LEVEL      UPPER      MARGINAL
new-york 325.000    350.000    325.000    0.225 REDEF

```

This should be construed as a warning from GAMS, as opposed to an error. In principle, the REDEF should only occur if the paired variable to the constraint has a finite lower and/or upper bound and the variable is at one of those bounds. In this case, at the solution of the complementarity problem the sense of the constraint (e.g. =E=) may not be satisfied. This occurs when GAMS constraints are used to define the function F . The bounds on each component of the function F are derived from the bounds on the matching variable component, and these bounds may be inconsistent with those implied by the constraint type used. GAMS warns the user via the REDEF label when the solution found leads to a violated "constraint". To avoid REDEF warnings the =N= can be used to define all complementarity functions.

Note that a REDEF is not an error, just a warning. The solver has solved the complementarity problem specified. GAMS gives this report to ensure that the modeler understands that the complementarity problem derives the relationships on the equations from the variable bounds, not from the equation definition.

5.36.1.4 Pitfalls

As indicated above, the ordering of an equation is important in the specification of an MCP. Since the data of the MCP is the function F and the bounds ℓ and u , it is important for the modeler to pass the solver the function F and not $-F$.

For example, if we have the optimization problem,

$$\min_{x \in [0,2]} (x - 1)^2$$

then the first order optimality conditions are

$$0 \leq x \leq 2 \quad \perp \quad 2(x - 1)$$

which has a unique solution, $x = 1$. [Figure 5](#) provides correct GAMS code for this problem.

Figure 5: First order conditions as an MCP, `first.gms`

```
variables x;
equations d_f;

x.lo = 0;
x.up = 2;

d_f.. 2*(x - 1) =e= 0;

model first / d_f.x /;
solve first using mcp;
```

However, if we accidentally write the valid equation

$$d_f.. 0 =e= 2*(x - 1);$$

the problem given to the solver is

$$0 \leq x \leq 2 \quad \perp \quad -2(x - 1)$$

which has three solutions, $x = 0$, $x = 1$, and $x = 2$. This problem is in fact the stationary conditions for the nonconvex quadratic problem,

$$\max_{x \in [0,2]} (x - 1)^2,$$

not the problem we intended to solve.

Continuing with the example, when x is a free variable, we might conclude that the ordering of the equation is irrelevant because we always have the equation, $2(x - 1) = 0$, which does not change under multiplication by -1 . In most cases, the ordering of equations (which are complementary to free variables) does not make a difference since the equation is internally "substituted out" of the model. In particular, for defining equations, such as that presented in [Figure 3](#), the choice appears to be arbitrary.

However, in difficult (singular or near singular) cases, the substitution cannot be performed, and instead a perturbation is applied to F , in the hope of "(strongly) convexifying" the problem. If the perturbation happens to be in the wrong direction because F was specified incorrectly, the perturbation actually makes the problem less convex, and hence less likely to solve. Note that determining which of the above orderings of the equations makes most sense is typically tricky. One rule of thumb is to check whether if you replace the "=e=" by "=g=", and then increase "x", is the inequality intuitively more likely to be satisfied. If so, you probably have it the right way round, if not, reorder.

Furthermore, underlying model convexity is important. For example, if we have the linear program

$$\begin{array}{ll} \min_x & c^T x \\ \text{subject to} & Ax = b, x \geq 0 \end{array}$$

we can write the first order optimality conditions as either

$$\begin{array}{ll} 0 \leq x & \perp -A^T \mu + c \\ \mu \text{ free} & \perp Ax - b \end{array}$$

or, equivalently,

$$\begin{array}{ll} 0 \leq x & \perp -A^T \mu + c \\ \mu \text{ free} & \perp b - Ax \end{array}$$

because we have an equation. The former is a linear complementarity problem with a positive semidefinite matrix, while the latter is almost certainly indefinite. Also, if we need to perturb the problem because of numerical problems, the former system will become positive definite, while the later becomes highly nonconvex and unlikely to solve. The rule of thumb here is to consider what happens when the dual multiplier μ is made non-negative in the KKT system. In the former system, the constraint becomes $Ax \geq b$, which is consistent with a minimization and a positive multiplier. In the latter system, we get $Ax \leq b$, which is backwards.

Finally, users are strongly encouraged to match equations and free variables when the matching makes sense for their application. Structure and convexity can be destroyed if it is left to the solver to perform the matching. For example, in the above example, we could lose the positive semidefinite matrix with an arbitrary matching of the free variables.

5.36.2 PATH

Newton's method, perhaps the most famous solution technique, has been extensively used in practice to solve square systems of nonlinear equations. The basic idea is to construct a local approximation of the nonlinear equations around a given point, x^k , solve the approximation to find the Newton point, x^N , update the iterate, $x^{k+1} = x^N$, and repeat until we find a solution to the nonlinear system. This method works extremely well close to a solution, but can fail to make progress when started far from a solution. To guarantee progress is made, a line search between x^k and x^N is used to enforce sufficient decrease on an appropriately defined merit function. Typically, $\frac{1}{2} \|F(x)\|^2$ is used.

PATH uses a generalization of this method on a nonsmooth reformulation of the complementarity problem. To construct the Newton direction, we use the normal map [\[207\]](#) representation

$$F(\pi(x)) + x - \pi(x)$$

associated with the MCP, where $\pi(x)$ represents the projection of x onto $[\ell, u]$ in the Euclidean norm. We note that if x is a zero of the normal map, then $\pi(x)$ solves the MCP. At each iteration, a linearization of the normal map, a linear complementarity problem, is solved using a pivotal code related to Lemke's method.

Versions of PATH prior to 4.x are based entirely on this formulation using the residual of the normal map

$$\|F(\pi(x)) + x - \pi(x)\|$$

as a merit function. However, the residual of the normal map is not differentiable, meaning that if a subproblem is not solvable then a "steepest descent" step on this function cannot be taken. PATH 4.x considers an alternative nonsmooth system [86], $\Phi(x) = 0$, where $\Phi_i(x) = \phi(x_i, F_i(x))$ and $\phi(a, b) := \sqrt{a^2 + b^2} - a - b$. The merit function, $\|\Phi(x)\|^2$, in this case is differentiable, and is used for globalization purposes. When the subproblem solver fails, a projected gradient direction for this merit function is searched. It is shown in [84] that this provides descent and a new feasible point to continue PATH, and convergence to stationary points and/or solutions of the MCP is provided under appropriate conditions.

The remainder of this chapter details the interpretation of output from PATH and ways to modify the behavior of the code. To this end, we will assume that the modeler has created a file named `transmcp.gms` which defines an MCP model `transport` as described in Section [Transportation Problem](#) and is using PATH 4.x to solve it. See Section [Solution](#) for information on changing the solver.

5.36.2.1 Log File

We will now describe the behavior of the PATH algorithm in terms of the output typically produced. An example of the log for a particular run is given in [Figure 6](#) and [Figure 7](#).

Figure 6: Log File from PATH for solving `transmcp.gms`

--- Restarting execution

The first few lines on this log file are printed by GAMS during its compilation and generation phases. The model is then passed off to PATH at the stage where the "Executing PATH" line is written out. After some basic memory allocation and problem checking, the PATH solver checks if the modeler required an option file to be read. In the example this is not the case. If PATH is directed to read an option file (see [PATH Options](#) below), then the following output is generated after the PATH banner.

```

Reading options file PATH.OPT
> output_linear_model yes;
Options: Read: Line 2 invalid: hi_there;
Read of options file complete.

```

If the option reader encounters an invalid option (as above), it reports this but carries on executing the algorithm. Following this, the algorithm starts working on the problem.

5.36.2.1.1 Diagnostic Information Some diagnostic information is initially generated by the solver at the starting point. Included is information about the initial point and function evaluation. The log file here tells the value of the largest element of the starting point and the variable where it occurs. Similarly, the maximum function value is displayed along with the row producing it. The maximum element in the gradient is also presented with the equation and variable where it is located.

The second block provides more information about the Jacobian at the starting point. This information can be used to help scale the model. See Section [Advanced Topics](#) for complete details.

5.36.2.1.2 Crash Log The first phase of the code is a crash procedure attempting to quickly determine which of the inequalities should be active. This procedure is documented fully in [68], and an example of the Crash Log can be seen in [Figure 6](#). The first column of the crash log is just a label indicating the current iteration number, the second gives an indication of how many function evaluations have been performed so far. Note that precisely one Jacobian (gradient) evaluation is performed per crash iteration. The number of changes to the active set between iterations of the crash procedure is shown under the "diff" column. The crash procedure terminates if this becomes small. Each iteration of this procedure involves a factorization of a matrix whose size is shown in the next column. The residual is a measure of how far the current iterate is from satisfying the complementarity conditions (MCP); it is zero at a solution. See [Merit Functions](#) for further information. The column "step" corresponds to the steplength taken in this iteration - ideally this should be 1. If the factorization fails, then the matrix is perturbed by an identity matrix scaled by the value indicated in the "prox" column. The "label" column indicates which row in the model is furthest away from satisfying the conditions (MCP). Typically, relatively few crash iterations are performed. Section [PATH Options](#) gives mechanisms to affect the behavior of these steps.

5.36.2.1.3 Major Iteration Log After the crash is completed, the main algorithm starts as indicated by the "Major Iteration Log" flag (see [Figure 7](#)). The columns that have the same labels as in the crash log have precisely the same meaning described above. However, there are some new columns that we now explain. Each major iteration attempts to solve a linear mixed complementarity problem using a pivotal method that is a generalization of Lemke's method [157]. The number of pivots performed per major iteration is given in the "minor" column.

The "grad" column gives the cumulative number of Jacobian evaluations used; typically one evaluation is performed per iteration. The "inorm" column gives the value of the error in satisfying the equation indicated in the "label" column.

At each iteration of the algorithm, several different step types can be taken, due to the use of nonmonotone searches [67], [79] which are used to improve robustness. In order to help the PATH user, we have added two code letters indicating the return code from the linear solver and the step type to the log file. [Table 3](#) explains the return codes for the linear solver and [Table 4](#) explains the meaning of each step type. The ideal output in this column is "SO"; "SD" and "SB" also indicate reasonable progress. Codes different from these are not catastrophic, but typically indicate the solver is having difficulties due to numerical issues or nonconvexities in the model.

Table 3: Linear Solver Codes

Code	Meaning
C	A cycle was detected.
E	An error occurred in the linear solve.
I	The minor iteration limit was reached.
N	The basis became singular.
R	An unbounded ray was encountered.
S	The linear subproblem was solved.
T	Failed to remain within tolerance after factorization was performed.

Table 4: Step Type Codes

Code	Meaning
B	A Backtracking search was performed from the current iterate to the Newton point in order to obtain sufficient decrease in the merit function.
D	The step was accepted because the Distance between the current iterate and the Newton point was small.
G	A gradient step was performed.
I	Initial information concerning the problem is displayed.
M	The step was accepted because the Merit function value is smaller than the nonmonotone reference value.
O	A step that satisfies both the distance and merit function tests.
R	A Restart was carried out.
W	A Watchdog step was performed in which we returned to the last point encountered with a better merit function value than the nonmonotone reference value (M, O, or B step), regenerated the Newton point, and performed a backtracking search.

5.36.2.1.4 Minor Iteration Log If more than 500 pivots are performed, a minor log is output that gives more details of the status of these pivots. A listing from `transmcp` model follows, where we have set the `output_minor_iteration_frequency` option to 1.

```

Minor Iteration Log
minor      t          z      w      v      art ckpts  enter  leave
  1  4.2538e-01  8      2      0      0      0 t[  0] z[ 11]
  2  9.0823e-01  8      2      0      0      0 w[ 11] w[ 10]
  3  1.0000e+00  9      2      0      0      0 z[ 10] t[  0]

```

`t` is a parameter that goes from zero to 1 for normal starts in the pivotal code. When the parameter reaches 1, we are at a solution to the subproblem. The `t` column gives the current value for this parameter. The next columns report the current number of problem variables `z` and slacks corresponding to variables at lower bound `w` and at upper bound `v`. Artificial variables are also noted in the minor log, see [80] for further details. Checkpoints are times where the basis matrix is refactorized. The number of checkpoints is indicated in the `ckpts` column. Finally, the minor iteration log displays the entering and leaving variables during the pivot sequence.

5.36.2.1.5 Restart Log The PATH code attempts to fully utilize the resources provided by the modeler to solve the problem. Versions of PATH after 3.0 have been much more aggressive in determining that a stationary point of the residual function has been encountered. When it is determined that no progress is being made, the problem is restarted from the initial point supplied in the GAMS file with a different set of options. These restarts give the flexibility to change the algorithm in the hopes that the modified algorithm leads to a solution. The ordering and nature of the restarts were determined by empirical evidence based upon tests performed on real-world problems.

The exact options set during the restart are given in the restart log, part of which is reproduced below.

```

Restart Log
proximal_perturbation 0
crash_method none
crash_perturb yes
nms_initial_reference_factor 2
proximal_perturbation 1.0000e-01

```

If a particular problem solves under a restart, a modeler can circumvent the wasted computation by setting the appropriate options as shown in the log. Note that sometimes an option is repeated in this log. In this case, it is the last option that is used.

5.36.2.1.6 Solution Log A solution report is now given by the algorithm for the point returned. The first component is an evaluation of several different merit functions. Next, a display of some statistics concerning the final point is given. This report can be used detect problems with the model and solution as detailed in Section [Advanced Topics](#) .

At the end of the log file, summary information regarding the algorithm's performance is given. The string `** EXIT - solution found`. is an indication that PATH solved the problem. Any other EXIT string indicates a termination at a point that may not be a solution. These strings give an indication of what `modelstat` and `solvestat` will be returned to GAMS. After this, the `Restarting execution` flag indicates that GAMS has been restarted and is processing the results passed back by PATH.

5.36.2.2 Status File

If for some reason the PATH solver exits without writing a solution, or the `sysout` flag is turned on, the status file generated by the PATH solver will be reported in the listing file. The status file is similar to the log file, but provides more detailed information. The modeler is typically not interested in this output.

5.36.2.3 User Interrupts

A user interrupt can be effected by typing Ctrl-C. We only check for interrupts every major iteration. If a more immediate response is wanted, repeatedly typing Ctrl-C will eventually kill the job. The number needed is controlled by the `interrupt_limit` option. In this latter case, when a kill is performed, no solution is written and an execution error will be generated in GAMS.

5.36.2.4 Preprocessing

The purpose of a preprocessor is to reduce the size and complexity of a model to achieve improved performance by the main algorithm. Another benefit of the analysis performed is the detection of some provably unsolvable problems. A comprehensive preprocessor has been incorporated into PATHC as developed in [\[81\]](#) .

The preprocessor reports its finding with some additional output to the log file. This output occurs before the initial point statistics. An example of the preprocessing on the `forcebsm` model is presented below.

```
Zero:      0 Single:   112 Double:    0 Forced:    0
Preprocessed size: 72
```

The preprocessor looks for special polyhedral structure and eliminates variables using this structure. These are indicated with the above line of text. Other special structure is also detected and reported.

On exit from the algorithm, we must generate a solution for the original problem. This is done during the postsolve. Following the postsolve, the residual using the original model is reported.

```
Postsolved residual: 1.0518e-10
```

This number should be approximately the same as the final residual reported on the presolved model.

5.36.2.4.1 Constrained Nonlinear System Modelers typically add bounds to their variables when attempting to solve nonlinear problems in order to restrict the domain of interest. For example, many square nonlinear systems are formulated as

$$F(z) = 0, \ell \leq z \leq u,$$

where typically, the bounds on z are inactive at the solution. This is *not* an MCP, but is an example of a "constrained nonlinear system" (CNS). It is important to note the distinction between MCP and CNS. The MCP uses the bounds to infer relationships on the function F . If a finite bound is active at a solution, the corresponding component of F is only constrained to be nonnegative or nonpositive in the MCP, whereas in CNS it must be zero. Thus there may be many solutions of MCP that do not satisfy $F(z) = 0$. Only if z^* is a solution of MCP with $\ell < z^* < u$ is it guaranteed that $F(z^*) = 0$.

Internally, PATHC reformulates a constrained nonlinear system of equations to an equivalent complementarity problem. The reformulation adds variables, y , with the resulting problem written as:

$$\begin{array}{rcl} \ell \leq x \leq u & \perp & -y \\ y \text{ free} & \perp & F(x). \end{array}$$

This is the MCP model passed on to the PATH solver.

5.36.3 PATH Options

The default options of PATH should be sufficient for most models. If desired, PATH-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section [The Solver Options File](#).

We give a list of the available PATH options along with their defaults and meaning below. Note that only the first three characters of every word are significant.

5.36.3.1 General options

Option	Description	Default
chen_lambda	lambda parameter for Chen-Chen-Kanzow residual Range: [0, 1]	0.8
convergence_tolerance	stopping criterion When the residual error is within this tolerance, convergence is declared.	1e-6
crash_iteration_limit	maximum iterations allowed in basis crash	50
crash_merit_function	merit function used in crash method normal : Use the normal map fischer : Use the Fischer function	fischer
crash_method	pnewton or none pnewton : Use projected Newton method none	pnewton
crash_minimum_dimension	minimum problem dimension to perform crash	1
crash_nbchange_limit	limit on crash iterations without basis change The basis crashing procedure is stopped if this many successive stagnant iterations occur.	1
crash_perturb	perturb the problem using pnewton crash	1
crash_searchtype	search type to use in the crash method line : Use a linesearch arc : Use an arcsearch	line

Option	Description	Default
cumulative_iteration_limit	maximum minor iterations allowed	GAMS iterlim
factorization_library_name	name of factorization library	
factorization_method	basis package to use lusol blu_lusol umfpack	lusol
gradient_searchtype	search type to use on a gradient step line: Use a linesearch arc: Use an arcsearch	arc
gradient_step_limit	gradient steps allowed before restarting	5
interrupt_limit	ctrl-C's required before a hard kill of the solver Range: {1, ..., ∞}	5
major_iteration_limit	maximum major iterations allowed	500
merit_function	merit function to use (normal or fischer) normal: Use the normal map fischer: Use the Fischer function	fischer
minor_iteration_limit	minor iterations allowed in each major iteration: default MIN(2n,iterlim)	auto
nms	allow line searching, watch-dogging, and nonmono- tone descent	1
nms_initial_reference_factor	controls size of initial reference value	20
nms_maximum_watchdogs	maximum number of watchdog steps allowed	5
nms_memory_size	number of reference values kept	10
nms_mstep_frequency	frequency at which m-steps are performed	10
nms_searchtype	search type to use line: Use a linesearch arc: Use an arcsearch	line
option_file	name of option file for PATHLIB to read If specified, the PATH optimizer will read this file using its internal reader, after the usual options processing is done.	none
preprocess	turns preprocessing on/off	1
proximal_perturbation	initial perturbation	0
time_limit	number of seconds algorithm is allowed to run	GAMS reslim
lemke_rank_deficiency_iterations	number of attempts made to fix rank-deficient basis during Lemke start	10
lemke_start	frequency of lemke starts always: Use a Lemke start for each LCP subprob- lem automatic: Determined by algorithm first: Use a Lemke start for the first LCP sub- problem	automatic
lemke_start_type	type of lemke start advanced: Start Lemke method using an advanced basis slack: Start Lemke method using an all-slack basis	slack

5.36.3.2 Output options

Option	Description	Default
output_crash_iterations	output information on crash iterations	1
output_crash_iterations_frequency	frequency at which crash iteration log is printed Range: {1, ..., ∞ }	1
output_errors	output error messages	1
output_final_degeneracy_statistics	print information regarding degeneracy at the solution	0
output_final_point	output final point returned from PATH	0
output_final_point_statistics	output information about the point, function, and Jacobian at the final point	1
output_final_scaling_statistics	display matrix norms on the Jacobian at the final point	0
output_final_statistics	output evaluation of available merit functions at the final point	1
output_final_summary	output summary information	1
output_initial_point	output initial point given to PATH	0
output_initial_point_statistics	output information about the point, function, and Jacobian at the initial point	1
output_initial_scaling_statistics	display matrix norms on the Jacobian at the initial point	1
output_initial_statistics	output evaluation of available merit functions at the initial point	0
output_linear_model	output linear model at each major iteration	0
output_major_iterations	output information on major iterations	1
output_major_iterations_frequency	frequency at which major iteration log is printed Range: {1, ..., ∞ }	1
output_maximum_zero_listing	limits zero columns reported to listing file	1000
output_maximum_zero_log	limits zero columns reported to log file	10
output_minor_iterations	output information on minor iterations	1
output_minor_iterations_frequency	frequency at which minor iteration log is printed Range: {1, ..., ∞ }	500
output_options	output all options and their values	0
output	turns all output off or on If output is first turned off, selected parts can be turned back on using specific output options.	1
output_preprocess_level	control output of preprocessing information Range: {-1, ..., ∞ }	1
output_restart_log	output options during restarts	1
output_time	output breakdown of where time is spent	0
output_warnings	output warning messages	0

GAMS controls the total number of pivots allowed via the `iterlim` option. If more pivots are needed for a particular model then either of the following lines should be added to the `transmcp.gms` file before the solve statement

```
option iterlim = 2000;
transport.iterlim = 2000;
```

Problems with a singular basis matrix can be overcome by using the `proximal.perturbation` option [41], and linearly dependent columns can be output with the `output.factorization.singularities` option. For more information on singularities, we refer the reader to Section [Advanced Topics](#).

As a special case, PATH can emulate Lemke's method [60], [157] for LCP with the following options:

```
crash_method none
crash_perturb no
major_iteration_limit 1
lemke_start first
nms no
```

If instead, PATH is to imitate the Successive Linear Complementarity method (SLCP, often called the Josephy Newton method) [134], [176], [175] for MCP with an Armijo style linesearch on the normal map residual, then the options to use are:

```
crash_method none
crash_perturb no
lemke_start always
nms_initial_reference_factor 1
nms_memory size 1
nms_mstep_frequency 1
nms_searchtype line
merit_function normal
```

Note that `nms_memory_size 1` and `nms_initial_reference_factor 1` turn off the nonmonotone linesearch, while `nms_mstep_frequency 1` turns off watchdogging [54]. `nms_searchtype line` forces PATH to search the line segment between the initial point and the solution to the linear model, while `merit_function normal` tell PATH to use the normal map for calculating the residual.

5.36.4 Advanced Topics

This chapter discusses some of the difficulties encountered when dealing with complementarity problems. We start off with a very formal definition of a complementarity problem (similar to the one given [previously](#)) which is used in later sections on merit functions and ill-defined, poorly-scaled, and singular models.

5.36.4.1 Formal Definition of MCP

The mixed complementarity problem is defined by a function, $F : D \rightarrow \mathbf{R}^n$ where $D \subseteq \mathbf{R}^n$ is the domain of F , and possibly infinite lower and upper bounds, ℓ and u . Let $C := \{x \in \mathbf{R}^n \mid \ell \leq x \leq u\}$, a Cartesian product of closed (possibly infinite) intervals. The problem is given as

$$MCP : \text{find } x \in C \cap D \text{ s.t. } \langle F(x), y - x \rangle \geq 0, \forall y \in C.$$

This formulation is a special case of the variational inequality problem defined by F and a (nonempty, closed, convex) set C . Special choices of ℓ and u lead to the familiar cases of a system of nonlinear equations

$$F(x) = 0$$

(generated by $\ell \equiv -\infty$, $u \equiv +\infty$) and the nonlinear complementarity problem

$$0 \leq x \perp F(x) \geq 0$$

(generated using $\ell \equiv 0$, $u \equiv +\infty$).

5.36.4.2 Algorithmic Features

We now describe some of the features of the PATH algorithm and the options affecting each.

5.36.4.2.1 Merit Functions A solver for complementarity problems typically employs a merit function to indicate the closeness of the current iterate to the solution set. The merit function is zero at a solution to the original problem and strictly positive otherwise. Numerically, an algorithm terminates when the merit function is approximately equal to zero, thus possibly introducing spurious "solutions".

The modeler needs to be able to determine with some reasonable degree of accuracy whether the algorithm terminated at solution or if it simply obtained a point satisfying the desired tolerances that is not close to the solution set. For complementarity problems, we can provide several indicators with different characteristics to help make such a determination. If one of the indicators is not close to zero, then there is some evidence that the algorithm has not found a solution. We note that if all of the indicators are close to zero, we are reasonably sure we have found a solution. However, the modeler has the final responsibility to evaluate the "solution" and check that it makes sense for their application.

For the NCP, a standard merit function is

$$\|(-x)_+, (-F(x))_+, [(x_i)_+(F_i(x))_+]_i\|$$

with the first two terms measuring the infeasibility of the current point and the last term indicating the complementarity error. In this expression, we use $(\cdot)_+$ to represent the Euclidean projection of x onto the nonnegative orthant, that is $(x)_+ = \max(x, 0)$. For the more general MCP, we can define a similar function:

$$\left\| x - \pi(x), \left[\left(\frac{x_i - \ell_i}{\|\ell_i\| + 1} \right)_+ (F_i(x))_+ \right]_i, \left[\left(\frac{u_i - x_i}{\|u_i\| + 1} \right)_+ (-F_i(x))_+ \right]_i \right\|$$

where $\pi(x)$ represents the Euclidean projection of x onto C . We can see that if we have an NCP, the function is exactly the one previously given and for nonlinear systems of equations, this becomes $\|F(x)\|$.

There are several reformulations of the MCP as a system of nonlinear (nonsmooth) equations for which the corresponding residual is a natural merit function. Some of these are as follows:

- Generalized Minimum Map: $x - \pi(x - F(x))$
- Normal Map: $F(\pi(y)) + y - \pi(y)$
- Fischer Function: $\Phi(x)$, where $\Phi_i(x) := \phi(x_i, F_i(x))$ with

$$\phi(a, b) := \sqrt{a^2 + b^2} - a - b.$$

Note that $\phi(a, b) = 0$ if and only if $0 \leq a \perp b \geq 0$. A straightforward extension of Φ to the MCP format is given for example in [84].

In the context of nonlinear complementarity problems the generalized minimum map corresponds to the classic minimum map $\min(x, F(x))$. Furthermore, for NCPs the minimum map and the Fischer function are both local error bounds and were shown to be equivalent in [243]. Figure 10 in the subsequent section plots all of these merit functions for the ill-defined example discussed therein and highlights the differences between them.

The squared norm of Φ , namely $\Psi(x) := \frac{1}{2} \sum \phi(x_i, F_i)^2$, is continuously differentiable on \mathbf{R}^n provided F itself is. Therefore, the first order optimality conditions for the unconstrained minimization of $\Psi(x)$, namely $\nabla \Psi(x) = 0$ give another indication as to whether the point under consideration is a solution of MCP.

The merit functions and the information PATH provides at the solution can be useful for diagnostic purposes. By default, PATH 4.x returns the best point with respect to the merit function because this iterate likely provides better information to the modeler. As detailed in Section [PATH Options](#), the default merit function in PATH 4.x is the Fischer function. To change this behavior the `merit_function` option can be used.

5.36.4.2.2 Crashing Method The crashing technique [68] is used to quickly identify an active set from the user-supplied starting point. At this time, a proximal perturbation scheme [39], [40] is used to overcome problems with a singular basis matrix. The proximal perturbation is introduced in the crash method, when the matrix factored is determined to be singular. The value of the perturbation is based on the current merit function value.

Even if the crash method is turned off, for example via the option `crash_method none`, perturbation can be added. This is determined by factoring the matrix that crash would have initially formed. This behavior is extremely useful for introducing a perturbation for singular models. It can be turned off by issuing the option `crash_perturb no`.

5.36.4.2.3 Nonmontone Searches The first line of defense against convergence to stationary points is the use of a nonmonotone linesearch [120], [121], [79]. In this case we define a reference value, R^k , and we use this value to test for sufficient decrease:

$$\Psi(x^k + t_k d^k) \leq R^k + t_k \nabla \Psi(x^k)^T d^k.$$

Depending upon the choice of the reference value, this allows the merit function to increase from one iteration to the next. This strategy can not only improve convergence, but can also avoid local minimizers by allowing such increases.

We now need to detail our choice of the reference value. We begin by letting $\{M_1, \dots, M_m\}$ be a finite set of values initialized to $\kappa \Psi(x^0)$, where κ is used to determine the initial set of acceptable merit function values. The value of κ defaults to 1 in the code and can be modified with the `nms_initial_reference_factor` option; $\kappa = 1$ indicates that we are not going to allow the merit function to increase beyond its initial value.

Having defined the values of $\{M_1, \dots, M_m\}$ (where the code by default uses $m = 10$), we can now calculate a reference value. We must be careful when we allow gradient steps in the code. Assuming that d^k is the Newton direction, we define $i_0 = \operatorname{argmax} M_i$ and $R^k = M_{i_0}$. After the nonmonotone linesearch rule above finds t_k , we update the memory so that $M_{i_0} = \Psi(x^k + t_k d^k)$, i.e. we remove an element from the memory having the largest merit function value.

When we decide to use a gradient step, it is beneficial to let $x^k = x^{\text{best}}$ where x^{best} is the point with the absolute best merit function value encountered so far. We then recalculate $d^k = -\nabla \Psi(x^k)$ using the best point and let $R^k = \Psi(x^k)$. That is to say that we force decrease from the best iterate found whenever a gradient step is performed. After a successful step we set $M_i = \Psi(x^k + t_k d^k)$ for all $i \in [1, \dots, m]$. This prevents future iterates from returning to the same problem area.

A watchdog strategy [54] is also available for use in the code. The method employed allows steps to be accepted when they are "close" to the current iterate. Nonmonotonic decrease is enforced every m iterations, where m is set by the `nms_mstep_frequency` option.

5.36.4.2.4 Linear Complementarity Problems PATH solves a linear complementarity problem at each major iteration. Let $M \in \mathbb{R}^{n \times n}$, $q \in \mathbb{R}^n$, and $B = [l, u]$ be given. $(\bar{z}, \bar{w}, \bar{v})$ solves the linear mixed complementarity problem defined by M , q , and B if and only if it satisfies the following constrained system of equations:

$$Mz - w + v + q = 0 \tag{4}$$

$$w^T(z - l) = 0 \tag{5}$$

$$v^T(u - z) = 0 \tag{6}$$

$$z \in B, w \in \mathfrak{R}_+^n, v \in \mathfrak{R}_+^n \quad (7)$$

where $x + \infty = \infty$ for all $x \in \mathfrak{R}$ and $0 \cdot \infty = 0$ by convention. A triple, $(\hat{z}, \hat{w}, \hat{v})$, satisfying equations (4) - (6) is called a complementary triple.

The objective of the linear model solver is to construct a path from a given complementary triple $(\hat{z}, \hat{w}, \hat{v})$ to a solution $(\bar{z}, \bar{w}, \bar{v})$. The algorithm used to solve the linear problem is identical to that given in [65]; however, artificial variables are incorporated into the model. The augmented system is then:

$$Mz - w + v + Da + \frac{(1-t)}{s}(sr) + q = 0 \quad (8)$$

$$w^T(z - l) = 0 \quad (9)$$

$$v^T(u - z) = 0 \quad (10)$$

$$z \in B, w \in \mathfrak{R}_+^n, v \in \mathfrak{R}_+^n, a \equiv 0, t \in [0, 1] \quad (11)$$

where r is the residual, t is the path parameter, and a is a vector of artificial variables. The residual is scaled by s to improve numerical stability.

The addition of artificial variables enables us to construct an initial invertible basis consistent with the given starting point even under rank deficiency. The procedure consists of two parts: constructing an initial guess as to the basis and then recovering from rank deficiency to obtain an invertible basis. The crash technique gives a good approximation to the active set. The first phase of the algorithm uses this information to construct a basis by partitioning the variables into three sets:

1. $W = \{i \in \{1, \dots, n\} \mid \hat{z}_i = l_i \text{ and } \hat{w}_i > 0\}$
2. $V = \{i \in \{1, \dots, n\} \mid \hat{z}_i = u_i \text{ and } \hat{v}_i > 0\}$
3. $Z = \{1, \dots, n\} \setminus W \cup V$

Since $(\hat{z}, \hat{w}, \hat{v})$ is a complementary triple, $Z \cap W \cap V = \emptyset$ and $Z \cup W \cup V = \{1, \dots, n\}$. Using the above guess, we can recover an invertible basis consistent with the starting point by defining D appropriately. The technique relies upon the factorization to indicate the linearly dependent rows and columns of the basis matrix. Some of the variables may be nonbasic, but not at their bounds. For such variables, the corresponding artificial will be basic.

We use a modified version of EXPAND [112] to perform the ratio test. Variables are prioritized as follows:

1. t leaving at its upper bound.
2. Any artificial variable.
3. Any z , w , or v variable.

If a choice as to the leaving variable can be made while maintaining numerical stability and sparsity, we choose the variable with the highest priority (lowest number above).

When an artificial variable leaves the basis and a z -type variable enters, we have the choice of either increasing or decreasing that entering variable because it is nonbasic but not at a bound. The determination is made such that t increases and stability is preserved.

If the code is forced to use a ray start at each iteration (`lemke_start always`), then the code carries out Lemke's method, which is known [60] not to cycle. However, by default, we use a regular start to

guarantee that the generated path emanates from the current iterate. Under appropriate conditions, this guarantees a decrease in the nonlinear residual. However, it is then possible for the pivot sequence in the linear model to cycle. To prevent this undesirable outcome, we attempt to detect the formation of a cycle with the heuristic that if a variable enters the basis more than a given number of times, we are cycling. The number of times the variable has entered is reset whenever t increases beyond its previous maximum or an artificial variable leaves the basis. If cycling is detected, we terminate the linear solver at the largest value of t and return this point.

Another heuristic is added when the linear code terminates on a ray. The returned point in this case is not the base of the ray. We move a slight distance up the ray and return this new point. If we fail to solve the linear subproblem five times in a row, a Lemke ray start will be performed in an attempt to solve the linear subproblem. Computational experience has shown this to be an effective heuristic and generally results in solving the linear model. Using a Lemke ray start is not the default mode, since typically many more pivots are required.

For times when a Lemke start is actually used in the code, an advanced ray can be used. We basically choose the "closest" extreme point of the polytope and choose a ray in the interior of the normal cone at this point. This helps to reduce the number of pivots required. However, this can fail when the basis corresponding to the cell is not invertible. We then revert to the Lemke start.

Since the EXPAND pivot rules are used, some of the variables may be nonbasic, but slightly infeasible, as the solution. Whenever the linear code finishes, the nonbasic variables are put at their bounds and the basic variables are recomputed using the current factorization. This procedure helps to find the best possible solution to the linear system.

The resulting linear solver as modified above is robust and has the desired property that we start from $(\hat{z}, \hat{w}, \hat{v})$ and construct a path to a solution.

5.36.4.2.5 Other Features Some other heuristics are incorporated into the code. During the first iteration, if the linear solver fails to find a Newton point, a Lemke start is used. Furthermore, under repeated failures during the linear solve, a Lemke start will be attempted. A gradient step can also be used when we fail repeatedly.

The proximal perturbation is reduced at each major iteration. However, when numerical difficulties are encountered, it will be increased to a fraction of the current merit function value. These are determined when the linear solver returns a Reset or Singular status.

Spacer steps are taken every major iteration, in which the iterate is chosen to be the best point for the normal map. The corresponding basis passed into the Lemke code is also updated.

Scaling is done based on the diagonal of the matrix passed into the linear solver.

We finally note, that if the merit function fails to show sufficient decrease over the last 100 iterates, a restart will be performed, as this indicates we are close to a stationary point.

5.36.4.3 Difficult Models

5.36.4.3.1 Ill-Defined Models A problem can be ill-defined for several different reasons. We concentrate on the following particular cases. We will call F well-defined at $\bar{x} \in C$ if $\bar{x} \in D$ and ill-defined at \bar{x} otherwise. Furthermore, we define F to be well-defined near $\bar{x} \in C$ if there exists an open neighborhood of \bar{x} , $\mathcal{N}(\bar{x})$, such that $C \cap \mathcal{N}(\bar{x}) \subseteq D$. By saying the function is well-defined near \bar{x} , we are simply stating that F is defined for all $x \in C$ sufficiently close to \bar{x} . A function not well-defined near \bar{x} is termed ill-defined near \bar{x} .

We will say that F has a well-defined Jacobian at $\bar{x} \in C$ if there exists an open neighborhood of \bar{x} , $\mathcal{N}(\bar{x})$, such that $\mathcal{N}(\bar{x}) \subseteq D$ and F is continuously differentiable on $\mathcal{N}(\bar{x})$. Otherwise the function has

an ill-defined Jacobian at \bar{x} . We note that a well-defined Jacobian at \bar{x} implies that the MCP has a well-defined function near \bar{x} , but the converse is not true.

PATH uses both function and Jacobian information in its attempt to solve the MCP. Therefore, both of these definitions are relevant. We discuss cases where the function and Jacobian are ill-defined in the next two subsections. We illustrate uses for the merit function information and final point statistics within the context of these problems.

Function Undefined We begin with a one-dimensional problem for which F is ill-defined at $x = 0$ as follows:

$$0 \leq x \perp \frac{1}{x} \geq 0.$$

Here x must be strictly positive because $\frac{1}{x}$ is undefined at $x = 0$. This condition implies that $F(x)$ must be equal to zero. Since $F(x)$ is strictly positive for all x strictly positive, this problem has no solution.

We are able to perform this analysis because the dimension of the problem is small. Preprocessing linear problems can be done by the solver in an attempt to detect obviously inconsistent problems, reduce problem size, and identify active components at the solution. Similar processing can be done for nonlinear models, but the analysis becomes more difficult to perform. Currently, PATH only checks the consistency of the bounds and removes fixed variables and the corresponding complementary equations from the model.

A modeler would likely not know a priori that a problem has no solution and would thus attempt to formulate and solve it. GAMS code for the model above is provided in [Figure 8](#). We must specify an initial value for x in the code. If we were to not provide one, GAMS would use $x = 0$ as the default value, notice that F is undefined at the initial point, and terminate before giving the problem to PATH. The error message indicates that the function $\frac{1}{x}$ is ill-defined at $x = 0$, but does not imply that the corresponding MCP problem has no solution.

```
positive variable x;
equations F;

F.. 1 / x =g= 0;

model simple / F.x /;

x.l = 1e-6;

solve simple using mcp;
```

After setting the starting point, GAMS generates the model, and PATH proceeds to "solve" it. A portion of the output relating statistics about the solution is given in [Figure 9](#) PATH uses the Fischer Function indicator as its termination criteria by default, but evaluates all of the merit functions given in [Section Merit Functions](#) at the final point. The Normal Map merit function, and to a lesser extent, the complementarity error, indicate that the "solution" found does not necessarily solve the MCP.

Figure 10: Merit Function Plot

To indicate the difference between the merit functions, Figure 10 plots them all for this simple example. We note that as x approaches positive infinity, numerically, we are at a solution to the problem with respect to all of the merit functions except for the complementarity error, which remains equal to one. As x approaches zero, the merit functions diverge, also indicating that $x = 0$ is not a solution.

The natural residual and Fischer function tend toward 0 as $x \downarrow 0$. From these measures, we might think $x = 0$ is the solution. However, as previously remarked F is ill-defined at $x = 0$. F and ∇F become very large, indicating that the function (and Jacobian) might not be well-defined. We might be tempted to conclude that if one of the merit function indicators is not close to zero, then we have not found a solution. This conclusion is not always warranted. When one of the indicators is non-zero, we have reservations about the solution, but we cannot eliminate the possibility that we are actually close to a solution. If we slightly perturb the original problem to

$$0 \leq x \perp \frac{1}{x+\epsilon} \geq 0$$

for a fixed $\epsilon > 0$, the function is well-defined over $C = \mathbf{R}_+^n$ and has a unique solution at $x = 0$. In this case, by starting at $x > 0$ and sufficiently small, all of the merit functions, with the exception of the Normal Map, indicate that we have solved the problem as is shown by the output in Figure 11 for $\epsilon = 1 * 10^{-6}$ and $x = 1 * 10^{-20}$.

```

In this case, the Normal Map is quite large and we might think that the function and Jacobian are undefined. When only the normal map is non-zero, we may have just mis-identified the optimal basis. By setting the `merit_function normal` option, we can resolve the problem, identify the correct basis, and solve the problem with all indicators being close to zero. This example illustrates the point that all of these tests are not infallible. The modeler still needs to do some detective work to determine if they have found a solution or if the algorithm is converging to a point where the function is ill-defined.

Jacobian Undefined Since PATH uses a Newton-like method to solve the problem, it also needs the Jacobian of F to be well-defined. One model for which the function is well-defined over C , but for which the Jacobian is undefined at the solution is: $0 \leq x \perp -\sqrt{x} \geq 0$. This model has a unique solution at $x = 0$.

Using PATH and starting from the point $x = 1 * 10^{-14}$, PATH generates the output given in [Figure 12](#).

We can see that the gradient of the Fischer Function is nonzero and the Jacobian is beginning to become large. These conditions indicate that the Jacobian is undefined at the solution. It is therefore important for a modeler to inspect the given output to guard against such problems.

If we start from $x = 0$, PATH correctly informs us that we are at the solution. The large value reported for the Jacobian is an indication that the Jacobian is undefined.

5.36.4.3.2 Poorly Scaled Models Well-defined problems can still have various numerical problems that impede the algorithm's convergence. One particular problem is a badly scaled Jacobian. In such cases, we can obtain a poor "Newton" direction because of numerical problems introduced in the linear algebra performed. This problem can also lead the code to a point from which it cannot recover.

The final model given to the solver should be scaled such that we avoid numerical difficulties in the linear algebra. The output provided by PATH can be used to iteratively refine the model so that we eventually end up with a well-scaled problem. We note that we only calculate our scaling statistics at the starting point provided. For nonlinear problems these statistics may not be indicative of the overall scaling of the model. Model specific knowledge is very important when we have a nonlinear problem because it can be used to appropriately scale the model to achieve a desired result.

We look at the `titan.gms` model in MCPLIB, that has some scaling problems. The relevant output from PATH for the original code is given in [Figure 13](#).

Figure 13: PATH Output - Poorly Scaled Model

INITIAL POINT STATISTICS

Maximum Column Norm . . . . . 9.4504e+06 var: (x2.29)
Minimum Column Norm . . . . . 1.3840e-03 var: (w.10)

```

The maximum row norm is defined as

$$\max_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}|$$

and the minimum row norm is

$$\min_{1 \leq i \leq n} \sum_{1 \leq j \leq n} |(\nabla F(x))_{ij}|.$$

Similar definitions are used for the column norm. The norm numbers for this particular example are not extremely large, but we can nevertheless improve the scaling. We first decided to reduce the magnitude of the **a1** block of equations as indicated by PATH. Using the GAMS modeling language, we can scale particular equations and variables using the `.scale` attribute. To turn the scaling on for the model we use the `.scaleopt` model attribute. After scaling the **a1** block, we re-ran PATH and found an additional block of equations that also needed scaling, **a2**. We also scaled some of the variables, **g** and **w**. The code added to the model follows:

```

titan.scaleopt = 1;
a1.scale(i) = 1000;
a2.scale(i) = 1000;
g.scale(i) = 1/1000;
w.scale(i) = 100000;

```

By scaling these equation and variable blocks, we have improved the model scaling. The statistics for the manually scaled model are given in [Figure 14](#).

```

For this particular problem PATH cannot solve the unscaled model, while it can find a solution to the scaled model. Using the scaling features of the GAMS language and the information provided by PATH we are able to remove some of the problem's difficulty and obtain better performance from PATH.

It is possible to get even more information on initial point scaling by inspecting the GAMS listing file. The equation row listing gives the values of all the entries of the Jacobian at the starting point. The row norms generated by PATH give good pointers for starting to use the row listing.

Not all of the numerical problems are directly attributable to poorly scaled models. Problems for which the Jacobian of the active constraints is singular or nearly singular can also cause numerical difficulty as illustrated next.

5.36.4.3.3 Singular Models Assuming that the problem is well-defined and properly scaled, we can still have a Jacobian for which the active constraints are singular or nearly singular (i.e. it is ill-conditioned). When problems are singular or nearly singular, we are also likely to have numerical problems. As a result the "Newton" direction obtained from the linear problem solver can be very bad. In PATH, we can use proximal perturbation or add artificial variables to attempt to remove the singularity problems from the model. However, it is most often beneficial for solver robustness to remove singularities if possible.

The easiest problems to detect are those for which the Jacobian has zero rows and columns. A simple problem for which we have zero rows and columns is:

$$-2 \leq x \leq 2 \quad \perp \quad -x^2 + 1.$$

Note that the Jacobian, $-2x$, is non-singular at all three solutions, but singular at the point $x = 0$. Output from PATH on this model starting at $x = 0$ is given in [Figure 15](#).

We display in the code the variables and equations for which the row/column in the Jacobian is close to zero. These situations are problematic and for nonlinear problems likely stem from the modeler providing an inappropriate starting point or fixing some variables resulting in some equations becoming constant. We note that the solver may perform well in the presence of zero rows and/or columns, but the modeler should make sure that these are what was intended.

Singularities in the model can also be detected by the linear solver. This in itself is a hard problem and prone to error. For matrices which are poorly scaled, we can incorrectly identify "linearly dependent" rows because of numerical problems. Setting `output_factorization_singularities yes` in an options file will inform the user which equations the linear solver thinks are linearly dependent. Typically, singularity does not cause a lot of problems and the algorithm can handle the situation appropriately. However, an excessive number of singularities are cause for concern. A further indication of possible singularities at the solution is a lack of quadratic convergence to the solution.

5.36.5 Case Study: Von Thunen Land Model

We now turn our attention towards using the diagnostic information provided by PATH to improve an actual model. The Von Thunen land model is a problem recognized in the mathematical programming literature for its computational difficulty. We attempt to understand more carefully the facets of the problem that make it difficult to solve. This will enable us to outline and identify these problems and furthermore to extend the model to a more realistic and computationally more tractable form.

5.36.5.1 Classical Model

The problem is cast in the Arrow-Debreu framework as an equilibrium problem. The basic model is a closed economy consisting of three economic agents, a landowner, a worker and a porter. There is a central market, around which concentric regions of land are located. Since the produced goods have to be delivered to the market, this is an example of a spatial price equilibrium. The key variables of the model are the prices of commodities, land, labour and transport. Given these prices, it is assumed that the agents demand certain amounts of the commodities, which are supplied so as to maximize profit in each sector. Walras' law is then a consequence of the assumed competitive paradigm, namely that supply will equal demand in the equilibrium state.

We now describe the problems that the consumers and the producers face. We first look at consumption and derive a demand function for each of the consumer agents in the economy. Each of these agents has a utility function, that they wish to maximize subject to their budgetary constraints. As is typical in such problems, the utility function is assumed to be Cobb-Douglas:

$$u_a(d) = \prod_c d_c^{\alpha_{c,a}}, \quad \alpha_{c,a} \geq 0, \sum_c \alpha_{c,a} = 1,$$

where the $\alpha_{c,a}$ are given parameters dependent only on the agent. For each agent a , the variables d_c represent quantities of the desired commodities c . In the Von Thunen model, the goods are wheat, rice, corn and barley. The agent's endowments determine their budgetary constraint as follows. Given current market prices, an agent's wealth is the value of the initial endowment of goods at those prices. The agent's problem is therefore

$$\max_d u_a(d) \text{ subject to } \langle p, d \rangle \leq \langle p, e_a \rangle, d \geq 0,$$

where e_a is the endowment bundle for agent a . A closed form solution, corresponding to demand from agent a for commodity c is thus

$$d_{c,a}(p) := \frac{\alpha_{c,a} \langle p, e_a \rangle}{p_c}.$$

Note that this assumes the prices of the commodities p_c are positive.

The supply side of the economy is similar. The worker earns a wage w_L for his labour input. The land is distributed around the market in rings with a rental rate w_r associated with each ring r of land. The area of land a_r in each ring is an increasing function of r . The model assumes that labour and land are substitutable via a constant elasticities of substitution (CES) function.

Consider the production $x_{c,r}$ of commodity c in region r . In order to maximize profit (or minimize costs), the labour y_L and land use y_r solve

$$\min w_L y_L + w_r y_r \text{ subject to } \phi_c y_L^{\beta_c} y_r^{1-\beta_c} \geq x_{c,r}, y_L, y_r \geq 0, \quad (12)$$

where ϕ_c is a given cost function scale parameter, and $\beta_c \in [0, 1]$ is the share parameter. The technology constraint is precisely the CES function allowing a suitable mix of labour and land use. Again, a closed form solution can be calculated. For example, the demand for labour in order to produce $x_{c,r}$ of commodity c in region r is given by

$$x_{c,r} \frac{\beta_c \left(\frac{w_L}{\beta_c}\right)^{\beta_c} \left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}}{\phi_c w_L}.$$

Considering all such demands, this clearly assumes the prices of inputs w_L, w_r are positive. A key point to note is that input commodity (factor) demands to produce $x_{c,r}$ can be determined by first solving (12) for unit demand $x_{c,r} \equiv 1$ and then multiplying these factor demands by the actual amount desired. Let \bar{y}_L and \bar{y}_r denote the optimal solutions of (12) with $x_{c,r} \equiv 1$. Using this fact, the *unit* production cost $\gamma_{c,r}$ for commodity c in region r can be calculated as follows:

$$\begin{aligned}
\gamma_{c,r} &= w_L \bar{y}_L + w_r \bar{y}_r \\
&= w_L \frac{\beta_c \left(\frac{w_L}{\beta_c}\right)^{\beta_c} \left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}}{\phi_c w_L} + w_r \frac{(1-\beta_c) \left(\frac{w_L}{\beta_c}\right)^{\beta_c} \left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}}{\phi_c w_r} \\
&= \frac{1}{\phi_c} \left(\frac{w_L}{\beta_c}\right)^{\beta_c} \left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}.
\end{aligned}$$

Transportation is provided by a porter, earning a wage w_p . If we denote the unit cost for transportation of commodity c by t_c , then unit transportation cost to market is

$$T_{c,r}(w_p) := t_c d_r w_p,$$

where d_r is the distance of region r to the market. Spatial price equilibrium arises from the consideration:

$$0 \leq x_{c,r} \perp \gamma_{c,r}(w_L, w_r) + T_{c,r}(w_p) \geq p_c.$$

This is intuitively clear; it states that commodity c will be produced in region r only if the combined cost of production and transportation equals the market price.

The above derivations assumed that the producers and consumers acted as price takers. Walras' law is now invoked to determine the prices so that markets clear. The resulting complementarity problem is:

$$\gamma_{c,r} = \frac{1}{\phi_c} \left(\frac{w_L}{\beta_c}\right)^{\beta_c} \left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c} \quad (13)$$

$$0 \leq x_{c,r} \perp \gamma_{c,r} + T_{c,r}(w_p) \geq p_c \quad (14)$$

$$0 \leq w_L \perp e_L \geq \sum_{r,c} x_{c,r} \frac{\beta_c \gamma_{c,r}}{w_L} \quad (15)$$

$$0 \leq w_r \perp a_r \geq \sum_c \frac{x_{c,r} (1-\beta_c) \gamma_{c,r}}{w_r} \quad (16)$$

$$0 \leq w_p \perp e_P \geq \sum_{r,c} t_c d_r x_{c,r} \quad (17)$$

$$0 \leq p_c \perp \sum_r x_{c,r} \geq \frac{\alpha_{c,P} e_P w_p + \alpha_{c,L} e_L w_L + \alpha_{c,O} \sum_r w_r a_r}{p_c} \quad (18)$$

Note that in (15), (16) and (17), the amounts of labour, land and transport are bounded from above, and hence the prices on these inputs are determined as multipliers (or shadow prices) on the corresponding constraints. The final relationship (18) in the above complementarity problem corresponds to market clearance; prices are nonnegative and can only be positive if supply equals demand. (Some modelers multiply the last inequality throughout by p_c . This removes problems where p_c becomes zero, but can also introduce spurious solutions.)

The Arrow-Debreu theory guarantees that the problem is homogeneous in prices; $(x, \lambda w, \lambda p)$ is also a solution whenever (x, w, p) solves the above. Typically this singularity in the model is removed by fixing a numeraire, that is fixing a price (for example $w_L = 1$) and dropping the corresponding complementary relationship.

Unfortunately, in this formulation even after fixing a numeraire, some of the variables p and w may go to zero, resulting in an ill-defined problem. In the case of the Von Thunen land model, the rental price of land w_r decreases as the distance to market increases, and for remote rings of land, it becomes zero. A standard modeling fix is to put artificial lower bounds on these variables. Even with this fix, the problem typically remains very hard to solve. More importantly, the homogeneity property of the prices used above to fix a numeraire no longer holds, and the corresponding complementary relationship (which was dropped from the problem) may fail to be satisfied. It therefore matters which numeraire is fixed, and many modelers run into difficulty since in many cases the solution found by a solver is invalid for the originally posed model.

In order to test our diagnostic information, we implemented a version of the above model in GAMS. The model corresponds closely to the MCPLIB model `pgvon105.gms` except we added more regions to make the problem even more difficult. The model file has been documented more fully, and the data rounded to improve clarity.

Our first trial was to solve the model without fixing a numeraire. In this case, PATH 4.x failed to find a solution. At the starting point, the indicators described in Section [Ill-Defined Models](#) are reasonable, and there are no zero rows/columns in the Jacobian. At the best point found, all indicators are still reasonable. However, the listing file indicates a large number of division by zero problems occurring in (16). We also note that a nonzero proximal perturbation is used in the first iteration of the crash method. This is an indication of singularities. We therefore added an option to output factorization singularities, and singularities appeared in the first iteration. At this point, we decided to fix a numeraire to see if this alleviated the problem.

We chose to fix the labour wage rate to 1. After increasing the iterations allowed to 100,000, PATH 4.x solved the problem. The statistics at the solution are cause for concern. In particular, the gradient of the Fischer function is 7 orders of magnitude larger than all the other residuals. Furthermore, the Jacobian is very large at the solution point. Looking further in the listing file, a large number of division by zero problems occur in (16).

To track down the problem further, we added an artificial lower bound on the variables w_r of 10^{-5} , that would not be active at the aforementioned solution. Resolving gave the same "solution", but resulted in the domain errors disappearing.

Although the problem is solved, there is concern on two fronts. Firstly, the gradient of the Fischer function should go to zero at the solution. Secondly, if a modeler happens to make the artificial lower bounds on the variables a bit larger, then they become active at the solution, and hence the constraint that has been dropped by fixing the price of labour at 1 is violated at this point. Of course, the algorithm is unable to detect this problem, since it is not part of the model that is passed to it, and the corresponding output looks satisfactory.

We are therefore led to the conclusion that the model as postulated is ill-defined. The remainder of this section outlines two possible modeling techniques to overcome the difficulties with ill-defined problems of this type.

5.36.5.2 Intervention Pricing

The principal difficulty is the fact that the rental prices on land go to zero as proximity to the market decreases, and become zero for sufficiently remote rings. Such a property is unlikely to hold in a practical setting. Typically, a landowner has a minimum rental price (for example, land in fallow increases in value). As outlined above, a fixed lower bound on the rental price violates the well-established homogeneity property. A suggestion postulated by Professor Thomas Rutherford is to allow the landowner to intervene and "purchase-back" his land whenever the rental cost gets smaller than a certain fraction of the labour wage.

The new model adds a (homogeneous in price) constraint

$$0 \leq i_r \quad \perp \quad w_r \geq 0.0001 * w_L$$

and modifies (16) and (18) as follows:

$$0 \leq w_r \perp a_r - i_r \geq \sum_c \frac{x_{c,r}(1-\beta_c)\gamma_{c,r}}{w_r}$$

$$0 \leq p_c \perp \sum_r x_{c,r} \geq \frac{\alpha_{c,PEP}w_p + \alpha_{c,LEL}w_L + \alpha_{c,O} \sum_r w_r(a_r - i_r)}{p_c}. \quad (19)$$

Given the intervention purchase, we can now add a lower bound on w_r to avoid division by zero errors. In our model we chose 10^{-5} since this will never be active at the solution and therefore will not affect the positive homogeneity. After this reformulation, PATH 4.x solves the problem. Furthermore, the gradient of the Fischer function, although slightly larger than the other residuals, is quite small, and can be made even smaller by reducing the convergence tolerance of PATH. Inspecting the listing file, the only difficulties mentioned are division by zero errors in the market clearance condition (19), that can be avoided a posteriori by imposing an artificial (inactive) lower bound on these prices. We chose not to do this however.

5.36.5.3 Nested Production and Maintenance

Another observation that can be used to overcome the land price going to zero is the fact that land typically requires some maintenance labour input to keep it usable for crop growth. Traditionally, in economics, this is carried out by providing a nested CES function as technology input to the model. The idea is that commodity c in region r is made from labour and an intermediate good, which is "maintained land". Essentially, the following production problem replaces (12):

$$\begin{aligned} \min_{y_M, y_L, y_r, g} \quad & w_L(y_M + y_L) + w_r y_r \\ \text{subject to} \quad & y_r \geq (1 - \beta_c - \epsilon)g \\ & y_M \geq \epsilon g \\ & \phi_c y_L^{\beta_c} g^{1-\beta_c} \geq 1, \\ & y_M, y_L, y_r, g \geq 0. \end{aligned}$$

Note that the variable y_M represents "maintenance labour" and g represents the amount of "maintained land" produced, an intermediate good. The process of generating maintained land uses a Leontieff production function, namely

$$\min(\lambda_r y_r, \lambda_M y_M) \geq g.$$

Here $\lambda_M = \frac{1}{\epsilon}$, ϵ small, corresponds to small amounts of maintenance labour, while $\lambda_r = \frac{1}{1-\beta_c-\epsilon}$ is chosen to calibrate the model correctly. A simple calculus exercise then generates appropriate demand and cost expressions. The resulting complementarity problem comprises (14), (17), (18) and

$$\gamma_{c,r} = \frac{w_L^{\beta_c}}{\phi_c} \left(\frac{w_L \epsilon + w_r(1-\beta_c-\epsilon)}{1-\beta_c} \right)^{1-\beta_c}$$

$$0 \leq w_L \perp e_L \geq \sum_{r,c} x_{c,r} \gamma_{c,r} \left(\frac{\beta_c}{w_L} + \frac{\epsilon(1-\beta_c)}{w_L \epsilon + w_r(1-\beta_c-\epsilon)} \right)$$

$$0 \leq w_r \perp a_r \geq \sum_c \frac{x_{c,r} \gamma_{c,r} (1-\beta_c)(1-\beta_c-\epsilon)}{w_L \epsilon + w_r(1-\beta_c-\epsilon)}$$

After making the appropriate modifications to the model file, PATH 4.x solved the problem on defaults without any difficulties. All indicators showed the problem and solution found to be well-posed.

5.37 quadMINOS

For LP (and RMIP) models that cause difficulty for the standard solvers, quadMINOS provides considerably greater reliability and accuracy than [MINOS](#) by using quadruple-precision floating-point arithmetic. Although it is slower by a factor of 20 or 30 for cold-start runs, you can use standard MINOS or another LP solver first and let them do their best. Warm-starts with quadMINOS may give greatly improved solutions at moderate cost.

To take advantage of quadMINOS, the main requirement is to set a few runtime options to non-default values in order to request higher accuracy. For example, it is reasonable to set

```
Feasibility tolerance 1e-15
Optimality tolerance  1e-15
```

because IEEE Quad floating-point has nearly 34 digits of precision. For an example of using Double and Quad MINOS together, see [\[DQQ\]](#) in the GAMS model library.

Note

GAMS/quadMINOS can only solve LPs and RMIPs at the moment because GAMS does not provide function evaluations in quad-precision.

The documentation of [MINOS](#) also refers to quadMINOS.

5.38 SBB

5.38.1 Introduction

SBB is a GAMS solver for Mixed Integer Nonlinear Programming (MINLP) models. It is based on a combination of the standard Branch and Bound (B&B) method known from Mixed Integer Linear Programming and some of the standard NLP solvers already supported by GAMS. SBB can use all GAMS NLP solvers as subsolvers but it works best with NLP solvers that can utilize a near optimal point as a starting point like Conopt, Minos, and Snoop.

SBB supports all types of discrete variables supported by GAMS, including Binary, Integer, Semicont, Semiint, Sos1, and Sos2.

5.38.2 The Branch and Bound Algorithm

The Relaxed Mixed Integer Nonlinear Programming (RMINLP) model is initially solved using the starting point provided by the modeler. SBB will stop immediately if the RMINLP model is unbounded or infeasible, or if it fails (see option `infeasseq` and `failseq` below for an exception). If all discrete variables in the RMINLP model are integer, SBB will return this solution as the optimal integer solution. Otherwise, the current solution is stored and the Branch and Bound procedure will start.

During the Branch and Bound process, the feasible region for the discrete variables is subdivided, and bounds on discrete variables are tightened to new integer values to cut off the current non-integer solutions. Each time a bound is tightened, a new, tighter NLP submodel is solved starting from the optimal solution to the previous looser submodel. The objective function values from the NLP submodel is assumed to be lower bounds on the objective in the restricted feasible space (assuming minimization), even though the local optimum found by the NLP solver may not be a global optimum. If the NLP solver returns a Locally Infeasible status for a submodel, it is usually assumed that there is no feasible solution to the submodel, even though the infeasibility only has been determined locally (see option `infeasseq` below for an exception). If the model is convex, these assumptions will be satisfied and SBB will provide correct bounds. If the model is not convex, the objective bounds may not be correct and better solutions may exist in other, unexplored parts of the search space.

5.38.3 SBB with Pseudo Costs

Over the last decades quite a number of search strategies have been successfully introduced for mixed integer linear programming (for details see e.g. J.T. Linderoth and M.W.P. Savelsbergh, A Computational Study of Search Strategies for Mixed Integer Programming, *INFORMS Journal on Computing*, 11(2), 1999). Pseudo costs are key elements of sophisticated search strategies. Using pseudo costs, we can estimate the degradation of the objective function if we move a fractional variable to a close integer value. Naturally, the variable selection can be based on pseudo costs (see SBB option `varsel`). Node selection can also make use of pseudo cost: If we can estimate the change of the objective for moving one fractional variable to the closed integer value, we can then aggregate this change for all fractional variables, to estimate the objective of the best integer solution reachable from a particular node (see SBB option `nodesel`).

Unfortunately, the computation of pseudo cost can be a substantial part of the overall computation. Models with a large number of fractional variables in the root node are **not** good candidates for search strategies which require pseudo costs (`varsel 3`, `nodesel 3,5,6`). The impact (positive or negative) of using pseudo cost depends significantly on the particular model. At this stage, general statements are difficult to make.

Selecting pseudo cost related search strategies (`varsel 3`, `nodesel 3,5,6`) may use computation time which sometimes does not pay off. However, we encourage the user to try these options for difficult models which require a large number of branch-and-bound nodes to solve.

5.38.4 The SBB Options

SBB works like other GAMS solvers, and many options can be set in the GAMS model. The most relevant GAMS options are `IterLim`, `ResLim`, `NodLim`, `OptCA`, `OptCR`, `OptfFile`, `Cheat`, and `CutOff`. A description of all available GAMS options can be found in the GAMS User's Guide [Solver related options](#). GAMS options `PriorOpt` and `TryInt` are also accepted by SBB.

SBB uses the `var.prior` information to select the fractional variable with the smallest priority during the variable selection process. SBB uses the `TryInt` information to set the branching direction in the B&B algorithm. At the beginning, SBB looks at the levels of the discrete variables provided by the user and if $\text{Abs}(\text{Round}(x.l)-x.l) < m.\text{TryInt}$, SBB will branch on that variable in the direction of `Round(x.l)`. For example, `x.l=0.9` and `m.TryInt=0.2`. We have $\text{Abs}(\text{Round}(0.9)-0.9)=0.1 < 0.2$, so when SBB decides to branch on this variable (because it is fractional, lets say with value 0.5), the node explored next will have the additional constraint $x \geq 1$ (the node with $x \leq 0$ will be explored later). If everything goes well (there is the chance that we end up in a different local optima in the subsolves for non-convex problems), SBB should reproduce a preset incumbent solution in a couple of nodes.

If you specify `<modelname>.OptFile = 1;` before the `Solve` statement in your GAMS model, SBB will then look for and read an option file with the name `sbb.opt` (see [The Solver Option File](#) for general use of solver option files). Unless explicitly specified in the SBB option file, the NLP subsolvers will not read an option file. The syntax for the SBB option file is

```
optname value
```

with one option on each line.

For example,

```
rootsolver conopt.1
subsolver snopt
loginterval 10
```

The first two lines determine the NLP subsolvers for the Branch and Bound procedure. `CONOPT` with the option file `conopt.opt` will be used for solving the root node. `SNOPT` with no option file will be used for the remaining nodes. The last option determines the frequency for log line printing. Every 10th node, and each node with a new integer solution, causes a log line to be printed. The following options are implemented:

Option	Description	Default
acceptnonopt	accepts feasible solution from subsolver	0
avgresmult	average resource multiplier	5
dfsstay	keeps DFS node selection after solution has been found	0
epint	integer feasibility tolerance	1.0e-5
failseq	solver sequence for failed nodes	
infeasseq	solver sequence for infeasible nodes	
intsollim	maximum number of integer solutions	2100000000
loginterval	progress display interval	1
loglevel	level of solver display	1
memnodes	maximum number of nodes in memory	10000
miptrace	filename of MIP trace file	
miptracetime	node interval when a trace record is written	100
miptracetime	time interval when a trace record is written	5.0
nodesel	node selection strategy	0
printbinfo	prints additional node info	0
rootsolver	solver for the root node	GAMS NLP solver
solvelink	Solverlink for GAMS NLP solver	5
subiter	iteration limit for the subsolve	GAMS iterlim
subres	resource limit for the subsolve	GAMS reslim
subsolver	solver for the subproblems	GAMS NLP solver
usercallparmfile	Command-line parameter include file used in GAMS command-line calls triggered by BCH	
usergdxname	the name of the GDX file exported from the solver with the solution at the node	bchout.gdx
usergdxnameinc	the name of the GDX file exported from the solver with the incumbent solution	bchout.i.gdx
userheurcall	the GAMS command line to call the heuristic	
userheurfirst	calls the cut generator for the first n nodes	10
userheurfreq	determines the frequency of the cut generator model calls	10
userheurinterval	determines the interval when to apply the multiplier for the frequency of the cut generator model calls	100
userheurmultip	determines the multiplier for the frequency of the cut generator model calls	2
userheurnewint	calls the heuristic if the solver found a new integer feasible solution	0
userheurobjfirst	Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement	50
varsel	variable selection strategy at each node	0

acceptnonopt (*boolean*): accepts feasible solution from subsolver ↔

If this option is set to 1 and the subsolver terminates with solver status *Terminated by Solver* and model status *Intermediate Nonoptimal* SBB takes this as a good solution and keeps on going. In default mode such a return is treated as a subsolver failure and the `failseq` is consulted.

Default: 0

avgresmult (*integer*): average resource multiplier ↔

Similar to `subres`, this option allows the user to control the time limit spend in a node. SBB keeps track of how much time is spent in the nodes, and builds an average over time. This average multiplied by the factor `avgresmult` is set as a time limit for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure: the node is ignored or the solvers in the `failseq` are called. The default multiplier `avgresmult` is 5. Setting `avgresmult` to 0 will disable the automatic time limit feature. A multiplier is not very useful for very small node solution times; therefore, independent of each node, SBB grants the solver at least 5 seconds to solve the node. The competing option `subres` overwrites the automatically generated resource limit.

Default: 5

dfsstay (*integer*): keeps DFS node selection after solution has been found ↔

If the node selection is a B*/DFS mix, SBB switches frequently to DFS node selection mode. It switches back into B* node selection mode, if no subnodes were created (new int, pruned, infeasible, fail). It can be advantageous to search the neighborhood of the last node also in a DFS manner. Setting `dfsstay` to n instructs SBB to stay in DFS mode for another n nodes.

Default: 0

epint (*real*): integer feasibility tolerance ↔

The integer infeasibility tolerance.

Range: [1e-9, 1]

Default: 1.0e-5

failseq (*string*): solver sequence for failed nodes ↔

`solver1[.n1] solver2[.n2] ...` where `solver1` is the name of a GAMS NLP solver to be used if the default solver fails, i.e., if it was not stopped by an iteration, resource, or domain limit and does not return a locally optimal or locally infeasible solution. `n1` is the value of optfile passed to the alternative NLP solver. If `.n1` is left blank it is interpreted as zero. Similarly, `solver2` is the name of a GAMS NLP solver that is used if `solver1` fails, and `n2` is the value of optfile passed to the second NLP solver. If you have a difficult model where solver failures are not unlikely, you may add more `solver.n` pairs. You can use the same solver several times with different options files. `failseq conopt conopt.2 conopt.3` means to try CONOPT with no options file. If this approach also fails, try CONOPT with options file `conopt.op2`, and if it again fails, try CONOPT with options file `conopt.op3`. If solver and options file combinations fail the node will be labeled *ignored* and the node will not be explored further. The default is to try only one solver (the `rootsolver` or `subsolver`) and to ignore nodes with a solver failure.

infeasseq (*string*): solver sequence for infeasible nodes ↔

`level solver1[.n1] solver2[.n2] ...` The purpose of `infeasseq` is to avoid cutting parts of the search tree that appear to be infeasible but really are feasible. If the NLP solver labels a node *Locally Infeasible* and the model is not convex a feasible solution may actually exist. If SBB is high in the search tree it can be very drastic to prune the node immediately. SBB is therefore directed to try the solver/option combinations in the list as long as the depth in the search tree is less than the integer value `level`. If the list is exhausted without finding a feasible solution, the node is assumed to be infeasible. The default is to trust that *Locally Infeasible* nodes are indeed infeasible and to remove them from further consideration.

intsollim (*integer*): maximum number of integer solutions ↔

Maximum number of integer solutions. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: 2100000000

loginterval (*integer*): progress display interval ↔

The interval (number of nodes) for which log lines are written.

Default: 1

loglevel (*integer*): level of solver display ↔

The level of log output.

Default: 1

value	meaning
0	only SBB log lines with one line every loginterval nodes
1	NLP solver log for the root node plus SBB loglines as 0
2	NLP solver log for all nodes plus SBB log lines as 0

memnodes (*integer*): maximum number of nodes in memory ↔

The maximum number of nodes SBB can have in memory. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: 10000

miptrace (*string*): filename of MIP trace file ↔

More info is available in chapter [Solve trace](#)

miptracenode (*integer*): node interval when a trace record is written ↔

More info is available in chapter [Solve trace](#)

Default: 100

miptracetime (*real*): time interval when a trace record is written ↔

More info is available in chapter [Solve trace](#)

Default: 5.0

nodesel (*integer*): node selection strategy ↔

Node selection scheme.

Default: 0

value	meaning
0	automatic
1	Depth First Search (DFS)
2	Best Bound (BB)
3	Best Estimate (BE)
4	DFS/BB mix
5	DFS/BE mix
6	DFS/BB/BE mix

printbbinfo (*integer*): prints additional node info ↔

Additional info of log output.

Default: 0

value	meaning
0	print no additional info
1	print variable selection letter The node and variable selection for the current node are indicated by a two letter code at the end of the log line. The first letter represents the node selection: D for DFS, B for Best Bound, and E for Best Estimate. The second letter represents the variable selection: X for maximum infeasibility, N for minimum infeasibility, and P for pseudo cost.
2	print best estimate

rootsolver (*string*): solver for the root node ↔

solver[.n] Solver is the name of the GAMS NLP solver that should be used in the root node, and **n** is the integer corresponding to optfile for the root node. If **.n** is missing, the optfile treated as zero i.e. the NLP solver will not look for an options file. This SBB option can be used to overwrite the default that uses the NLP solver specified with an **Option NLP = solver;** statement or the default GAMS solver for NLP.

Default: GAMS NLP solver

solvelink (*integer*): Solvelink for GAMS NLP solver ↔

Default: 5

value	meaning
1	Call GAMS NLP solver via script
2	Call GAMS NLP solver via module
5	Call GAMS NLP solver in memory

subiter (*integer*): iteration limit for the subsolve ↔

The default for **subiter** passed on through **iterlim**. Similar to **subres** but sets the iteration limit for solving a node in the B&B tree.

Default: GAMS iterlim

subres (*real*): resource limit for the subsolve ↔

The default for **subres** passed on through **reslim**. Sets the time limit in seconds for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure and the node is ignored, or the solvers in the failseq are called.

Default: GAMS **reslim**

subsolver (*string*): solver for the subproblems ↔

solver[.n] Similar to **rootsolver** but applied to the subnodes.

Default: GAMS NLP **solver**

usercallparmfile (*string*): Command-line parameter include file used in GAMS command-line calls triggered by BCH ↔

usergdxname (*string*): the name of the GDX file exported from the solver with the solution at the node ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: **bchout.gdx**

usergdxnameinc (*string*): the name of the GDX file exported from the solver with the incumbent solution ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: **bchout_i.gdx**

userheurcall (*string*): the GAMS command line to call the heuristic ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

userheurfirst (*integer*): calls the cut generator for the first n nodes ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 10

userheurfreq (*integer*): determines the frequency of the cut generator model calls ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 10

userheurinterval (*integer*): determines the interval when to apply the multiplier for the frequency of the cut generator model calls ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 100

userheurmultip (*integer*): determines the multiplier for the frequency of the cut generator model calls ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 2

userheurnewint (*boolean*): calls the heuristic if the solver found a new integer feasible solution ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 0

userheurobjfirst (*integer*): Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement ↔

More info is available in chapter [The GAMS Branch-and-Cut-and-Heuristic Facility](#).

Default: 50

varsel (*integer*): variable selection strategy at each node ↔

Variable selection scheme.

Default: 0

value	meaning
0	automatic
1	maximum integer infeasibility
2	minimum integer infeasibility
3	pseudo costs

5.38.5 The SBB Log File

The SBB Log file (usually directed to the screen) can be controlled with the `loginterval` and `loglevel` options in SBB. It will by default first show the iteration output from the NLP solver that solves the root node. This is followed by output from SBB describing the search tree. An example of this search tree output follows:

```

Root node solved locally optimal.
  Node  Act. Lev.  Objective  IInf  Best Int.      Best Bound  Gap (2 secs)
    0     0   0    8457.6878   3         -        8457.6878   -
    1     1   1    8491.2869   2         -        8457.6878   -
    2     2   2    8518.1779   1         -        8457.6878   -
  *    3     3   3    9338.1020   0    9338.1020    8457.6878  0.1041
    4     2   1      pruned   -    9338.1020    8491.2869  0.0997
Solution satisfies optcr
Statistics:

    # failures    0
Terminating.

```

The fields in the log are:

Field	Description
Node	The number of the current node. The root node is node 0.
Act	The number of active nodes defined as the number of subnodes that have not yet been solved.
Lev	The level in the search tree, i.e., the number of branches needed to reach this node.
Objective	The objective function value for the node. A numerical value indicates that the node was solved and the objective was good enough for the node to not be ignored. "pruned" indicates that the objective value was worse than the Best Integer value, "infeasible" indicates that the node was Infeasible or Locally Infeasible, and "ignored" indicates that the node could not be solved (see under failseq above).

Field	Description
IInf	The number of integer infeasibilities, i.e. the number of variables that are supposed to be binary or integer that do not satisfy the integrality requirement. Semi continuous variables and SOS variables may also contribute to IInf.
Best Int	The value of the best integer solution found so far. A dash (-) indicates that an integer solution has not yet been found. A star (*) in column one indicates that the node is integer and that the solution is better than the best yet found.
Best Bound	The minimum value of "Objective" for the subnodes that have not been solved yet (maximum for maximization models). For convex models, Best Bound will increase monotonically. For nonconvex models, Best Bound may decrease, indicating that the Objective value for a node was not a valid lower bound for that node.
Gap	The relative gap between the Best Integer solution and the Best Bound.

The remaining part of the Log file displays various solution statistics similar to those provided by the MIP solvers. This information can also be found in the Solver Status area of the GAMS listing file.

The following Log file shows cases where the NLP solver fails to solve a subnode. The text "ignored" in the Objective field shows the failure, and the values in parenthesis following the Gap field are the Solve and Model status returned by the NLP solver:

```

Root node solved locally optimal.
Node  Act. Lev.  Objective  IInf  Best Int.      Best Bound  Gap  (2 secs)
   0    0   0    6046.0186  12         -      6046.0186  -
   1    1   1    infeasible  -         -      6046.0186  -
   2    0   1    6042.0995  10         -      6042.0995  -
   3    1   2     ignored  -         -      6042.0995  - (4,6)
   4    0   2    5804.5856  8         -      5804.5856  -
   5    1   3     ignored  -         -      5804.5856  - (4,7)

```

The next Log file shows the effect of the `infeasseq` and `failseq` options on the model above. CONOPT with options file `conopt.opt` (the default solver and options file pair for this model) considers the first subnode to be locally infeasible. CONOPT, MINOS, and SNOPT, all with no options file, are therefore tried in sequence. In this case, they all declare the node infeasible and it is considered to be infeasible.

In node 3, CONOPT with option file fails but CONOPT without option file finds a Locally Optimal solution, and this solution is then used for further search. The SBB option file for the following run would be:

```

rootsolver conopt.1
subsolver conopt.1
failseq conopt
infeasseq 100 conopt minos snopt

```

The log looks as follows:

```

Root node solved locally optimal.
Node  Act. Lev.  Objective  IInf  Best Int.      Best Bound  Gap  (2 secs)
   0    0   0    6046.0186  12         -      6046.0186  -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos reports locally infeasible

```

```

Executing snopt
  1   1   1  infeasible  -           -           6046.0186   -
  2   0   1   6042.0995  10          -           6042.0995   -
conopt.1 failed. 4 TERMINATED BY SOLVER, 7 FEASIBLE SOLUTION
Executing conopt
  3   1   2   4790.2373   8           -           6042.0995   -
  4   2   3   4481.4156   6           -           6042.0995   -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos failed. 4 TERMINATED BY SOLVER, 6 INTERMEDIATE INFEASIBLE
Executing snopt
  5   3   4  infeasible  -           -           6042.0995   -
  6   2   4   4480.3778   4           -           6042.0995   -

```

The Log file shows a solver statistic at the end, summarizing how many times an NLP was executed and how often it failed:

```

NLP Solver Statistics
Total Number of NLP solves : 45
Total Number of NLP failures: 13
Details:      conopt      minos      snopt
# execs       34          3          8
# failures    4           3          6

```

The solutions found by the NLP solver to the subproblems in the Branch and Bound may not be the global optima. Therefore, the objective can improve even though we restrict the problem by tightening some bounds. These *jumps* of the objective in the *wrong* direction which might also have an impact on the best bound/possible are reported in a separate statistic:

```

Non convex model!
# jumps in best bound      :          2
Maximum jump in best bound : 20.626587 in node 13
# jumps to better objective :          2
Maximum jump in objective  : 20.626587 in node 13

```

5.38.6 Comparison of SBB and other MINLP Solvers

GAMS offers a variety of MINLP solvers including local and global MINLP solver. They implement different algorithms and it is usually unclear which solver performs best. Here we give a brief comparison between SBB and the well known solver DICOPT.

DICOPT is based on the outer approximation method. Initially, the RMINLP model is solved just as in SBB. The model is then linearized around this point and a linear MIP model is solved. The discrete variables are then fixed at the optimal values from the MIP model, and the resulting NLP model is solved. If the NLP model is feasible, we have an integer feasible solution.

The model is linearized again and a new MIP model with both the old and new linearized constraints is solved. The discrete variables are again fixed at the optimal values, and a new NLP model is solved.

The process stops when the MIP model becomes infeasible, when the NLP solution becomes worse, or, in some cases, when bounds derived from the MIP model indicate that it is safe to stop.

DICOPT is based on the assumption that MIP models can be solved efficiently while NLP models can be expensive and difficult to solve. The MIP models try to approximate the NLP model over a large area and solve it using much cheaper linear technology. Ideally, only a few NLPs must be solved.

DICOPT can experience difficulties solving models, if many or all the NLP submodels are infeasible. DICOPT can also have problems if the linearizations used for the MIP model create ill-conditioned models. The MIP models may become very difficult to solve, and the results from the MIP models may be poor as initial values for the NLP models. The linearized constraint used by DICOPT may also exclude certain areas of the feasible space from consideration.

SBB uses different assumptions and works very differently. Most of the work in SBB involves solving NLP models. Since the NLP submodels differ only in one or a few bounds, the assumption is that the NLP models can be solved quickly using a good restart procedure. Since the NLP models differ very little and good initial values are available, the solution process will be fairly reliable compared to the solution process in DICOPT, where initial values of good quality seldom are available. Because search space is reduced based on very different grounds than in DICOPT, other solutions may therefore be explored.

Overall, DICOPT should perform better on models that have a significant and difficult combinatorial part, while SBB may perform better on models that have fewer discrete variables but more difficult nonlinearities (and possibly also on models that are fairly non convex).

5.39 SCIP

SCIP (Solving Constraint Integer Programs) is a framework for Constraint Integer Programming oriented towards the needs of Mathematical Programming experts who want to have total control of the solution process and access detailed information down to the guts of the solver. SCIP can also be used as a pure MIP or MINLP solver or as a framework for branch-cut-and-price. Within GAMS, the MIP and MINLP solving facilities of SCIP are available.

For more detailed information, we refer to [5] [2] [3] [36] [35] [103] [170] [117] [118] [104] [37] [250] [249] [264] and the [SCIP web site](#).

GAMS/SCIP uses CPLEX, if licensed, and otherwise SOPLEX [266] as LP solver, the COIN-OR Interior Point Optimizer IPOPT [256] as nonlinear solver, and CppAD to compute derivatives of nonlinear functions.

SCIP supports continuous, binary, integer, semi-continuous, semi-integer variables, indicator constraints, special ordered sets, and branching priorities for discrete variables.

5.39.1 Usage

The following statement can be used inside your GAMS program to specify using SCIP

```
Option MIP = SCIP;      { or QCP or NLP or MIQCP or MINLP or ... }
```

The above statement should appear before the Solve statement. If SCIP was specified as the default solver during GAMS installation, the above statement is not necessary.

5.39.1.1 Specification of SCIP Options

GAMS/SCIP supports the GAMS parameters [reslim](#), [iterlim](#), [nodlim](#), [optca](#), [optcr](#), and [workspace](#). Further, the option [threads](#) can be used to control the number of threads used in the [MILP presolver](#), the [linear algebra routines of IPOPT](#), and for solving LPs if CPLEX' barrier solver is used.

Options can be specified by a SCIP options file. A SCIP options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs). Further, string values have to be enclosed in quotation marks.

A small example for a scip.opt file is:

```
propagating/probing/maxprerounds = 0
separating/maxrounds             = 0
separating/maxroundsroot         = 0
```

It causes GAMS/SCIP to disable probing during presolve and to turn off all cut generators.

5.39.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to SCIP via a separate file, see [Indicator Constraints](#) for more details on its syntax. The name of that file is specified via the option [gams/indicatorfile](#) in a SCIP option file. Currently, indicators can only be used for linear equations.

5.39.2 Special Features

5.39.2.1 SCIP interactive shell

The interactive shell in SCIP is a powerful tool that allows the user to display various information (e.g., branching statistics, presolved model), load emphasis settings, interrupt a solve to change parameters or trigger a restart, write the model in various file formats, start SCIP's solution counter, and many more things.

When setting the option [gams/interactive](#) to a nonempty string, the GAMS/SCIP interface opens the interactive shell of SCIP after having load the GAMS problem and parameters and passes the value of the [gams/interactive](#) parameter to the SCIP interactive shell.

By default, SCIP behaves as if [gams/interactive](#) has been set to "optimize write gamssol quit", that is, SCIP is requested to solve the problem, then to pass the solution back to GAMS, and to quit.

An example use of the SCIP interactive shell feature via GAMS is to add the following line to your SCIP options file:

```
gams/interactive = "write prob orig.lp presolve write transprob presol.mps opt write gamssol quit"
```

This instructs SCIP to write the original problem to the file `orig.lp` in LP format, to presolve the instance, to write the presolved problem to the file `presolved.mps` in MPS format, to solve the instance, to write the solution out to GAMS, and to finish.

By omitting the `quit` command, SCIP's interactive shell remains open and awaits user input. The command `help` prints a list of available commands. Note, that on Windows, GAMS need to be called with the option [interactivesolver](#) enabled to allow user input for the solver process.

A tutorial on using the SCIP shell is available at <https://www.scipopt.org/doc/html/SHELL.php>.

5.39.2.2 Emphasis Settings

SCIP includes various emphasis settings, which are predefined values for a set of SCIP parameters. Such predefined settings are available for setting the effort that SCIP should spend for, e.g., presolving, separation, or heuristics.

The emphasis settings are not available as single parameters, but can be set via SCIP's interactive shell. E.g., writing `set heuristics emphasis` in the shell displays the available emphasis settings for heuristics (`aggressive`, `fast`, `off`) and expects the user to input which setting to use. Further, general emphasis settings are available in the `set emphasis` menu, some of them giving predefined settings similar to the CPLEX option `mipemphasis`.

Via the `gams/interactive` option, c.f. Section [SCIP interactive shell](#), emphasis settings can be activated via a SCIP options file. For example, adding the option

```
gams/interactive = "set emphasis feasibility set loadgams optimize write gamssol quit"
```

instructs SCIP to load the emphasis setting `feasibility` prior to optimizing the model and passing the solution back to GAMS. Note, that setting one of the emphasis settings `feasibility`, `hardlp`, and `optimality` resets all previously set parameters to their default values, which includes the ones that are set by the GAMS/SCIP interface or which were loaded from a SCIP options file. Therefore, the command `set loadgams` has been used above to restore these parameter settings.

The following emphasis settings are available in SCIP:

shell command	purpose
<code>set emphasis easycip</code>	use for easy problems
<code>set emphasis feasibility</code>	emphasize finding a feasible solution
<code>set emphasis hardlp</code>	use for problems with a hard LP
<code>set emphasis optimality</code>	emphasize proving optimality
<code>set emphasis numerics</code>	increase numerical stability
<code>set heuristic emphasis aggressive</code>	use primal heuristics aggressively
<code>set heuristic emphasis fast</code>	use only fast primal heuristics
<code>set heuristic emphasis off</code>	disable all primal heuristics
<code>set presolving emphasis aggressive</code>	do aggressive presolving
<code>set presolving emphasis fast</code>	use only fast presolving steps
<code>set presolving emphasis off</code>	disable presolving
<code>set separating emphasis aggressive</code>	use cutting plane separators aggressively
<code>set separating emphasis fast</code>	use only fast cutting plane separators
<code>set separating emphasis off</code>	disable all cutting plane separators

5.39.2.3 Starting point

Using the [completesol heuristic](#), SCIP can try to find a feasible solution based on values given by the user for all or some of the variables. The values need to be specified as variable levels in the GAMS model. The heuristic solves a copy of the problem where variables for which values have been provided are restricted to be close to that value. When an integral value is specified for a binary or integer variable, the variable is fixed to that value. See also Section 2.3.2 in [170] for a more detailed description of the heuristic.

For which variables the level values are passed from GAMS to SCIP is controlled by the parameter `gams/mipstart`. The parameter values have the following meaning:

- 0: do not pass any variable values to SCIP, the heuristic will not run
- 1: pass values for all binary and integer variables to SCIP and let SCIP try to find a feasible solution in its neighborhood by using the completesol heuristic
- 2 (default): pass values for all variables to SCIP and let SCIP check feasibility of the given solution, the heuristic will not run
- 3: pass values for all variables to SCIP and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic
- 4: pass values for all binary and integer variables to SCIP which fractionality is at most the value of GAMS option `tryint` (thus, with default `tryint=0`, only for variables with integral values, the value is passed to SCIP) and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic

Note, that the completesol heuristic will not run if there are too many variables with unknown values. This behavior can be adjusted by setting parameter `heuristics/completesol/maxunknownrate`.

5.39.2.4 Decomposition Information

SCIP potentially can make use of a user-provided `problem decomposition`, e.g., in primal heuristics `PADM` or `GINS`. Note, that SCIP's Benders Decomposition is not available with GAMS at the moment. A GAMS user can inform SCIP about such a decomposition by using the `.stage variable suffix`.

In an attempt to following the same convention on interpreting the `.stage` variable suffix as the `GAMS/CPLEX link`, variables which `.stage` suffix is set to an integral value greater than 0 are assigned to a block with this number. Variables which `.stage` suffix is set to a fractional value or a value smaller than 1 are assigned to no block.

Note, that the default value for the `.stage` suffix is 1. Therefore, GAMS/SCIP only passes decomposition information to SCIP if at least one variable has its `.stage` suffix set to a value different than 1. Moreover, in order to receive the `.stage` values, `scaleOpt` and `priorOpt` must be left at their default of 0.

5.39.2.5 Solution Pool

When SCIP solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option `gams/dumpsolutions` is specified, then all alternative solutions found by SCIP are written into GDX files and an index file with the name given by the this option is written. If the option `gams/dumpsolutionsmerged` is specified, then all alternative solutions found by SCIP are written into a single GDX file, which name is given by the this option.

The GAMS testlib model `dumpsol` shows an example use for this option.

5.39.2.6 Solving process tracing

The option `gams/solvetrace/file` can be used to specify the name of a file where information about the progress of the branch-and-bound tree search in SCIP is stored. The file is created and updated during the solution process, so it may also be used to monitor the progress of SCIP while it still solves the model.

New entries are written periodically, depending on how many nodes have been processed or how much time has been elapsed since the last entry was written. Each entry contains information on the current primal and dual bound.

5.39.2.7 Notes on solving MINLPs

SCIP includes capabilities to handle nonlinear functions that are specified via algebraic expressions. Therefore, neither external/extrinsic functions nor all GAMS mathematical functions are supported.

Nonconvex MINLPs are solved via a spatial branch-and-bound algorithm using linear relaxations. The tightness of this relaxation depends heavily on the variable bounds, thus tight bounds for the nonlinear variables are crucial for SCIP.

Convex MINLPs are much easier to solve for SCIP, provided it recognizes the convexity of the model. The convexity check implemented in SCIP may not give a conclusive answer in all cases. However, setting the option `constraints/nonlinear/assumeconvex` to `TRUE` can be used to tell SCIP that it should assume all nonlinear constraints to be of convex type. This may help to improve solving times for convex MINLPs considerably in some cases. However, it can also deteriorate performance as it prevents the use of certain extended formulations.

Another feature that can be especially useful for convex MINLPs is to enable the generation of cuts in feasible solutions, since these supporting hyperplanes can be strong. At the moment, this is only enabled for purely continuous nonlinear programs (QCPs and NLPs), but can be adjusted by parameter `constraints/nonlinear/linearizeheursol`. In this connection, it may also be beneficial to set `separating/poolfreq` to 1.

5.39.3 Components

In the following, we list components that are available in SCIP together with some common properties. Many of these properties can be modified with corresponding parameters.

5.39.3.1 Branching Rules

branching rule	priority	maxdepth	maxbounddist	description
<code>relpscost</code>	10000	-1	100	reliability branching on pseudo cost values
<code>pscost</code>	2000	-1	100	branching on pseudo cost values
<code>inference</code>	1000	-1	100	inference history branching
<code>mostinf</code>	100	-1	100	most infeasible branching
<code>leastinf</code>	50	-1	100	least infeasible branching
<code>distribution</code>	0	-1	100	branching rule based on variable influence on cumulative normal distribution of row activities
<code>fullstrong</code>	0	-1	100	full strong branching
<code>cloud</code>	0	-1	100	branching rule that considers several alternative LP optima
<code>lookahead</code>	0	-1	100	full strong branching over multiple levels
<code>multaggr</code>	0	-1	100	fullstrong branching on fractional and multi-aggregated variables
<code>allfullstrong</code>	-1000	-1	100	all variables full strong branching
<code>vanillafullstrong</code>	-2000	-1	100	vanilla full strong branching
<code>random</code>	-100000	-1	100	random variable branching
<code>nodereopt</code>	-9000000	-1	100	branching rule for node reoptimization

See <https://www.scipopt.org/doc/html/BRANCH.php> for a detailed description of the branching rule properties.

5.39.3.2 Conflict Handler

conflict handler	priority	description
logicor	800000	conflict handler creating logic or constraints
setppc	700000	conflict handler creating set covering constraints
indicatorconflict	200000	replace slack variables and generate logicor constraints
linear	-1000000	conflict handler creating linear constraints
bounddisjunction	-3000000	conflict handler creating bound disjunction constraints

5.39.3.3 Constraint Handler

con- straint handler	check- prio	enfo- prio	sepa- prio	sepa- freq	propfreq	eager- freq	presol- vetim- ings	de- scrip- tion
integral	0	0	0	-1	-1	-1	always	integrality con- straint
SOS1	-10	100	1000	10	1	100	medium	SOS1 con- straint handler
SOS2	-10	100	10	0	1	100	fast	SOS2 con- straint handler
varbound	-500000	-500000	900000	0	1	100	fast medium	variable bounds lhs \leq x + c*y \leq rhs, x non- binary, y non- continuous
knapsack	-600000	-600000	600000	0	1	100	always	knapsack con- straint of the form $a^T x$ $\leq b$, x binary and a ≥ 0
setppc	-700000	-700000	700000	0	1	100	always	set parti- tioning / pack- ing / covering con- straints

constraint handler	check-prio	enfo-prio	sepa-prio	sepa-freq	propfreq	eager-freq	presolvetimings	description
and	-850100	-850100	850100	1	1	100	fast exhaustive	constraint handler for AND-constraints: $r = \text{and}(x_1, \dots, x_n)$
linear	-1000000	-1000000	100000	0	1	100	fast exhaustive	linear constraints of the form $\text{lhs} \leq a^T x \leq \text{rhs}$
orbisack	-1005200	-1005200	40100	5	5	-1	exhaustive	symmetry breaking constraint handler for orbisacks
orbitope	-1005200	-1005200	40100	-1	1	-1	medium	symmetry breaking constraint handler relying on (partitioning/packing) orbitopes
symresack	-1005200	-1005200	40100	5	5	-1	exhaustive	symmetry breaking constraint handler relying on symresacks
logicor	-2000000	-2000000	10000	0	1	100	always	logic or constraints
bounddisjunction	-3000000	-3000000	0	-1	1	100	fast	bound disjunction constraints

con- straint handler	check- prio	enfo- prio	sepa- prio	sepa- freq	propfreq	eager- freq	presol- vetim- ings	de- scrip- tion
nonlinear	-4000010	-60	10	1	1	100	always	handler for non- linear con- straints specified by al- gebraic expres- sions
indicator	-6000000	-100	10	10	1	100	fast	indicator con- straint handler
components	9999999	0	0	-1	1	-1		independent compo- nents con- straint handler

See <https://www.scipopt.org/doc/html/CONS.php> for a detailed description of the constraint handler properties.

5.39.3.4 Display Columns

display col- umn	header	position	width	priority	status	description
solfound		0	1	80000	auto	letter that indi- cates the heuris- tic which found the solution
time	time	50	5	4000	auto	total solution time
mnodes	node	100	7	100000	auto	number of pro- cessed nodes
nodesleft	left	200	7	90000	auto	number of unpro- cessed nodes
nrank1nodes	rank1	500	7	40000	off	current number of rank1 nodes left
mnodesbelowinc	nbInc	550	6	40000	off	current number of nodes with an estimate better than the current incumbent
literations	LP iter	1000	7	30000	auto	number of sim- plex iterations
lpavgiterations	LP it/n	1400	7	25000	auto	average number of LP iterations since the last output line

display column	header	position	width	priority	status	description
lpcond	LP cond	1450	7	0	auto	estimate on condition number of LP solution
memused	umem	1500	5	0	auto	total number of bytes used in block memory
memtotal	mem/heur	1500	8	20000	auto	total number of bytes in block memory or the creator name when a new incumbent solution was found
depth	depth	2000	5	500	auto	depth of current node
maxdepth	mdpt	2100	5	5000	auto	maximal depth of all processed nodes
plungedepth	pdpt	2200	5	10	auto	current plunging depth
nfrac	frac	2500	5	700	auto	number of fractional variables in the current solution
nexternbranchcand	extbr	2600	5	650	auto	number of extern branching variables in the current node
vars	vars	3000	5	3000	auto	number of variables in the problem
conss	cons	3100	5	3100	auto	number of globally valid constraints in the problem
curconss	ccons	3200	5	600	auto	number of enabled constraints in current node
curcols	cols	3300	5	800	auto	number of LP columns in current node
currows	rows	3400	5	900	auto	number of LP rows in current node
cuts	cuts	3500	5	2100	auto	total number of cuts applied to the LPs
separounds	sepa	3600	4	100	auto	number of separation rounds performed at the current node
poolsize	pool	3700	5	50	auto	number of LP rows in the cut pool

display column	header	position	width	priority	status	description
conflicts	confs	4000	5	2000	auto	total number of conflicts found in conflict analysis
strongbranches	strbr	5000	5	1000	auto	total number of strong branching calls
pseudoobj	pseudoobj	6000	14	300	auto	current pseudo objective value
lpobj	lpobj	6500	14	300	auto	current LP objective value
curdualbound	curdualbound	7000	14	400	auto	dual bound of current node
estimate	estimate	7500	14	200	auto	estimated value of feasible solution in current node
avgdualbound	avgdualbound	8000	14	40	auto	average dual bound of all unprocessed nodes
dualbound	dualbound	9000	14	70000	auto	current global dual bound
primalbound	primalbound	10000	14	80000	auto	current primal bound
cutoffbound	cutoffbound	10100	14	10	auto	current cutoff bound
gap	gap	20000	8	60000	auto	current (relative) gap using $\frac{ \text{primal-dual} }{\text{MIN}(\text{dual} , \text{primal})}$
primalgap	primgap	21000	8	20000	off	current (relative) gap using $\frac{ \text{primal-dual} }{ \text{primal} }$
nsols	nsols	30000	5	0	auto	current number of solutions found
completed	compl.	30100	8	110000	auto	completion of search in percent (based on tree size estimation)
nobjleaves	objleav	31000	7	0	auto	current number of encountered objective limit leaves
ninfeasleaves	infleav	32000	7	0	auto	number of encountered infeasible leaves
sols	sols	100000	7	110000	off	number of detected feasible solutions

display column	header	position	width	priority	status	description
feasST	feasST	110000	6	110000	off	number of detected non trivial feasible subtrees

See <https://www.scipopt.org/doc/html/DISP.php> for a detailed description of the display column properties.

5.39.3.5 Nonlinear Handler

nonlinear handler	enabled	detect priority	enforce priority	description
default	1	0	0	default handler for expressions
convex	1	50	50	handler that identifies and estimates convex expressions
concave	1	40	40	handler that identifies and estimates concave expressions
bilinear	1	-10	-10	bilinear handler for expressions
perspective	1	-20	125	perspective handler for expressions
quadratic	1	1	100	handler for quadratic expressions
quotient	1	20	20	nonlinear handler for quotient expressions
soc	1	100	100	nonlinear handler for second-order cone structures

5.39.3.6 Node Selectors

node selector	standard priority	memsave priority	description
estimate	200000	100	best estimate search
bfs	100000	0	best first search
hybridestim	50000	50	hybrid best estimate / best bound search
restartdfs	10000	50000	depth first search with periodical selection of the best node
uct	10	0	node selector which balances exploration and exploitation
dfs	0	100000	depth first search
breadthfirst	-10000	-1000000	breadth first search

See <https://www.scipopt.org/doc/html/NODESEL.php> for a detailed description of the node selector properties.

5.39.3.7 Presolvers

presolver	priority	timing	maxrounds	description
milp	9999999	medium	-1	MILP specific presolving methods
trivial	9000000	fast	-1	round fractional bounds on integers, fix variables with equal bounds
boundshift	7900000	fast	0	converts variables with domain [a,b] to variables with domain [0,b-a]
inttobinary	7000000	fast	-1	converts integer variables with domain [a,a+1] to binaries
convertinttobin	6000000	fast	0	converts integer variables to binaries
gateextraction	1000000	exhaustive	-1	presolver extracting gate(and)-constraints
qpkktrf	-1	medium	0	adds KKT conditions to (mixed-binary) quadratic programs
dualcomp	-50	exhaustive	-1	compensate single up-/downlocks by singleton continuous variables
stuffing	-100	exhaustive	0	fix redundant singleton continuous variables
domcol	-1000	exhaustive	-1	dominated column presolver
tworowbnd	-2000	exhaustive	0	do bound tightening by using two rows
dualinfer	-3000	exhaustive	0	exploit dual information for fixings and side changes
implics	-10000	medium	-1	implication graph aggregator
dualagg	-12000	exhaustive	0	aggregate variables by dual arguments
sparsify	-24000	exhaustive	-1	eliminate non-zero coefficients
dualsparsify	-240000	exhaustive	-1	eliminate non-zero coefficients
redvub	-9000000	exhaustive	0	detect redundant variable bound constraints

See <https://www.scipopt.org/doc/html/PRESOL.php> for a detailed description of the presolver properties.

5.39.3.8 Primal Heuristics

primal heuristic	type	priority	freq	freqoffset	description
actconsdiving	d	-1003700	-1	5	LP diving heuristic that chooses fixings w.r.t. the active constraints
adaptivediving	d	-70000	5	3	diving heuristic that selects adaptively between the existing, public divesets
bound	p	-1107000	-1	0	heuristic which fixes all integer variables to a bound and solves the remaining LP
clique	p	5000	0	0	LNS heuristic using a clique partition to restrict the search neighborhood
coefdiving	d	-1001000	-1	1	LP diving heuristic that chooses fixings w.r.t. the matrix coefficients
completesol	L	0	0	0	primal heuristic trying to complete given partial solutions

primal heuristic	type	priority	freq	freqoffset	description
conflictdiving	d	-1000100	10	0	LP diving heuristic that chooses fixings w.r.t. conflict locks
crossover	L	-1104000	30	0	LNS heuristic that fixes all variables that are identic in a couple of solutions
dins	L	-1105000	-1	0	distance induced neighborhood search by Ghosh
distributiondiving	d	-1003300	10	3	Diving heuristic that chooses fixings w.r.t. changes in the solution density
dps	L	75000	-1	0	primal heuristic for decomposable MIPs
dualval	L	-10	-1	0	primal heuristic using dual values
farkasdiving	d	-900000	10	0	LP diving heuristic that tries to construct a Farkas-proof
feaspump	o	-1000000	20	0	objective feasibility pump 2.0
fixandinfer	p	-500000	-1	0	iteratively fixes variables and propagates inferences
fracdiving	d	-1003000	10	3	LP diving heuristic that chooses fixings w.r.t. the fractionalities
gins	L	-1103000	20	8	gins works on k-neighborhood in a variable-constraint graph
guideddiving	d	-1007000	10	7	LP diving heuristic that chooses fixings in direction of incumbent solutions
zeroobj	L	100	-1	0	heuristic trying to solve the problem without objective
indicator	L	-20200	1	0	indicator heuristic to create feasible solutions from values for indicator variables
intdiving	d	-1003500	-1	9	LP diving heuristic that fixes binary variables with large LP value to one
intshifting	r	-10000	10	0	LP rounding heuristic with infeasibility recovering and final LP solving
linesearchdiving	d	-1006000	10	6	LP diving heuristic that chooses fixings following the line from root solution to current solution
localbranching	L	-1102000	-1	0	local branching heuristic by Fischetti and Lodi
locks	p	3000	0	0	heuristic that fixes variables based on their rounding locks
lpface	L	-1104010	15	0	LNS heuristic that searches the optimal LP face inside a sub-MIP
alns	L	-1100500	20	0	Large neighborhood search heuristic that orchestrates the popular neighborhoods Local Branching, RINS, RENS, DINS etc.
nlpdiving	d	-1003010	10	3	NLP diving heuristic that chooses fixings w.r.t. the fractionalities
mutation	L	-1103010	-1	8	mutation heuristic randomly fixing variables
multistart	L	-2100000	0	0	multistart heuristic for convex and nonconvex MINLPs

primal heuristic	type	priority	freq	freqoffset	description
mpec	d	-2050000	50	0	regularization heuristic for convex and nonconvex MINLPs
objpscostdiving	o	-1004000	20	4	LP diving heuristic that changes variable's objective values instead of bounds, using pseudo costs as guide
octane	r	-1008000	-1	0	octane primal heuristic for pure {0;1}-problems based on Balas et al.
ofins	L	60000	0	0	primal heuristic for reoptimization, objective function induced neighborhood search
oneopt	i	-20000	1	0	1-opt heuristic which tries to improve setting of single integer variables
padm	L	70000	0	0	penalty alternating direction method primal heuristic
proximity	L	-2000000	-1	0	heuristic trying to improve the incumbent by an auxiliary proximity objective function
pscostdiving	d	-1002000	10	2	LP diving heuristic that chooses fixings w.r.t. the pseudo cost values
randrounding	r	-200	20	0	fast LP rounding heuristic
rens	L	-1100000	0	0	LNS exploring fractional neighborhood of relaxation's optimum
reoptsols	p	40000	0	0	primal heuristic updating solutions found in a previous optimization round
repair	L	-20	-1	0	tries to repair a primal infeasible solution
rins	L	-1101000	25	0	relaxation induced neighborhood search by Danna, Rothberg, and Le Pape
rootsoldiving	o	-1005000	20	5	LP diving heuristic that changes variable's objective values using root LP solution as guide
rounding	r	-1000	1	0	LP rounding heuristic with infeasibility recovering
shiftandpropagate	p	1000	0	0	Pre-root heuristic to expand an auxiliary branch-and-bound tree and apply propagation techniques
shifting	r	-5000	10	0	LP rounding heuristic with infeasibility recovering also using continuous variables
simplerounding	r	-30	1	0	simple and fast LP rounding heuristic
subnlp	L	-2000010	1	0	primal heuristic that performs a local search in an NLP after fixing integer variables and presolving
trivial	t	10000	0	0	start heuristic which tries some trivial solutions
trivialnegation	p	39990	0	0	negate solution entries if an objective coefficient changes the sign, enters or leaves the objective.
trustregion	L	-1102010	-1	0	LNS heuristic for Benders' decomposition based on trust region methods

primal heuristic	type	priority	freq	freqoffset	description
trysol	t	-3000010	1	0	try solution heuristic
twoopt	i	-20100	-1	0	primal heuristic to improve incumbent solution by flipping pairs of variables
undercover	L	-1110000	0	0	solves a sub-CIP determined by a set covering approach
vbounds	p	2500	0	0	LNS heuristic uses the variable lower and upper bounds to determine the search neighborhood
veclen diving	d	-1003100	10	4	LP diving heuristic that rounds variables with long column vectors
zi rounding	r	-500	1	0	LP rounding heuristic as suggested by C. Wallace taking row slacks and bounds into account

See <https://www.scipopt.org/doc/html/HEUR.php> for a detailed description of the primal heuristic properties.

5.39.3.9 Propagators

propagator	propprio	freq	presolveprio	presolvetiming	description
rootredcost	10000000	1	0	always	reduced cost strengthening using root node reduced costs and the cutoff bound
dualfix	8000000	0	8000000	fast	roundable variables dual fixing
genvbounds	3000000	1	-2000000	fast	generalized variable bounds propagator
vbounds	3000000	1	-90000	medium exhaustive	propagates variable upper and lower bounds
pseudoobj	3000000	1	6000000	fast	pseudo objective function propagator
redcost	1000000	1	0	always	reduced cost strengthening propagator
probing	-1000000d	-1	-100000	exhaustive	probing propagator on binary variables
symmetry	-1000000	1	-10000000	exhaustive	propagator for handling symmetry
obbt	-1000000d	0	0	always	optimization-based bound tightening propagator
nlobbt	-1100000d	-1	0	always	propagator template

See <https://www.scipopt.org/doc/html/PROP.php> for a detailed description of the propagator properties.

5.39.3.10 Separators

separator	priority	freq	bounddist	description
closecuts	1000000	-1	1	closecuts meta separator
rlt	10	0	1	reformulation-linearization-technique separator
disjunctive	10d	0	0	disjunctive cut separator
gauge	0	-1	1	gauge separator
interminor	0	-1	1	intersection cuts separator to ensure that 2x2 minors of X (= xx') have determinant 0
convexproj	0d	-1	1	separate at projection of point onto convex region
minor	0	10	1	separator to ensure that 2x2 principal minors of X - xx' are positive semi-definite
impliedbounds	-50	10	1	implied bounds separator
mixing	-50	10	1	mixing inequality separator
intobj	-100	-1	0	integer objective value separator
gomory	-1000	10	1	separator for Gomory mixed-integer and strong CG cuts from LP tableau rows
cgmip	-1000	-1	0	Chvatal-Gomory cuts via MIPs separator
aggregation	-3000	10	1	aggregation heuristic for complemented mixed integer rounding cuts and flowcover cuts
clique	-5000	0	0	clique separator of stable set relaxation
zerohalf	-6000	10	1	{0,1/2}-cuts separator
mcf	-10000	0	0	multi-commodity-flow network cut separator
eccuts	-13000	-1	1	separator for edge-concave functions
oddcycle	-15000	-1	1	odd cycle separator
strongcg	-100000	10	0	separator for strong CG cuts
gomorymi	-100000	10	0	separator for Gomory mixed-integer cuts
knapsackcover	-100000	10	0	separator for knapsack cover cuts
flowcover	-100000	10	0	separator for flowcover cuts
cmir	-100000	10	0	separator for cmir cuts
rapidlearning	-1200000	5	1	rapid learning heuristic and separator

See <https://www.scipopt.org/doc/html/SEPA.php> for a detailed description of the separator properties.

5.39.4 List of SCIP Options

SCIP supports a large set of options. In the following, we give a detailed list of all SCIP options.

5.39.4.1 gams

Option	Description	Default
gams/dumpsolutions	name of solutions index.gdx file for writing all alternate solutions Range: string	
gams/dumpsolutionsmerged	name of.gdx file for writing all alternate solutions into a single file Range: string	

Option	Description	Default
gams/indicatorfile	name of GAMS options file that contains definitions on indicators Range: string	
gams/interactive	command to be issued to the SCIP shell instead of issuing a solve command Range: string	
gams/mipstart	how to handle initial variable levels, see also section Starting point Range: {0, ..., 4}	2

5.39.4.2 gams/solvetrace

Option	Description	Default
gams/solvetrace/file	name of file where to write branch-and-bound trace information too Range: string	
gams/solvetrace/nodefreq	frequency in number of nodes when to write branch-and-bound trace information, 0 to disable Range: {0, ..., ∞ }	100
gams/solvetrace/timefreq	frequency in seconds when to write branch-and-bound trace information, 0.0 to disable Range: [0, ∞]	5

5.39.4.3 branching

Option	Description	Default
branching/clamp	minimal relative distance of branching point to bounds when branching on a continuous variable Range: [0, 0.5]	0.2
branching/delaypscostupdate	should updating pseudo costs for continuous variables be delayed to the time after separation? Range: boolean	1
branching/divingpscost	should pseudo costs be updated also in diving and probing mode? Range: boolean	1
branching/lpgainnormalize	strategy for normalization of LP gain when updating pseudocosts of continuous variables (divide by movement of 'l'p value, reduction in 'd'omain width, or reduction in domain width of 's'ibling) Range: d, l, s	s
branching/midpull	fraction by which to move branching point of a continuous variable towards the middle of the domain; a value of 1.0 leads to branching always in the middle of the domain Range: [0, 1]	0.75
branching/midpullreldomtrig	multiply midpull by relative domain width if the latter is below this value Range: [0, 1]	0.5
branching/preferbinary	should branching on binary variables be preferred? Range: boolean	0
Options for expert users		

Option	Description	Default
branching/checksol	should LP solutions during strong branching with propagation be checked for feasibility? Range: boolean	1
branching/firstsbchild	child node to be regarded first during strong branching (only with propagation): 'u'p child, 'd'own child, 'h'istory-based, or 'a'utomatic Range: a, d, u, h	a
branching/forceallchildren	should all strong branching children be regarded even if one is detected to be infeasible? (only with propagation) Range: boolean	0
branching/roundsbsol	should LP solutions during strong branching with propagation be rounded? (only when checksbsol=TRUE) Range: boolean	1
branching/scorefac	branching score factor to weigh downward and upward gain prediction in sum score function Range: [0, 1]	0.167
branching/scorefunc	branching score function ('s'um, 'p'roduct, 'q'uotient) Range: s, p, q	p
branching/sumadjustscore	score adjustment near zero by adding epsilon (TRUE) or using maximum (FALSE) Range: boolean	0

5.39.4.4 branching/allfullstrong

Option	Description	Default
branching/allfullstrong/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/allfullstrong/maxdepth	maximal depth level, up to which branching rule <allfullstrong> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/allfullstrong/priority	priority of branching rule <allfullstrong> Range: {-536870912, ..., 536870911}	-1000

5.39.4.5 branching/cloud

Option	Description	Default
branching/cloud/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/cloud/maxdepth	maximal depth level, up to which branching rule <cloud> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/cloud/maxdepthunion	maximum depth for the union Range: {0, ..., 65000}	65000

Option	Description	Default
branching/cloud/maxpoints	maximum number of points for the cloud (-1 means no limit) Range: $\{-1, \dots, \infty\}$	-1
branching/cloud/minsuccessrate	minimum success rate for the cloud Range: $[0, 1]$	0
branching/cloud/minsuccessunion	minimum success rate for the union Range: $[0, 1]$	0
branching/cloud/onlyF2	should only F2 be used? Range: boolean	0
branching/cloud/priority	priority of branching rule <cloud> Range: $\{-536870912, \dots, 536870911\}$	0
branching/cloud/usecloud	should a cloud of points be used? Range: boolean	1
branching/cloud/useunion	should the union of candidates be used? Range: boolean	0

5.39.4.6 branching/distribution

Option	Description	Default
branching/distribution/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: $[0, 1]$	1
branching/distribution/maxdepth	maximal depth level, up to which branching rule <distribution> should be used (-1 for no limit) Range: $\{-1, \dots, 65534\}$	-1
branching/distribution/priority	priority of branching rule <distribution> Range: $\{-536870912, \dots, 536870911\}$	0
Options for expert users		
branching/distribution/onlyactiverows	should only rows which are active at the current node be considered? Range: boolean	0
branching/distribution/scoreparam	the score;largest 'd'ifference, 'l'owest cumulative probability, 'h'ighest c.p., 'v'otes lowest c.p., votes highest c.p.('w') Range: d, h, l, v, w	v
branching/distribution/weightedscore	should the branching score weigh up- and down-scores of a variable Range: boolean	0

5.39.4.7 branching/fullstrong

Option	Description	Default
branching/fullstrong/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: $[0, 1]$	1

Option	Description	Default
branching/fullstrong/maxdepth	maximal depth level, up to which branching rule <fullstrong> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/fullstrong/priority	priority of branching rule <fullstrong> Range: {-536870912, ..., 536870911}	0
Options for expert users		
branching/fullstrong/forcestrongbranch	should strong branching be applied even if there is just a single candidate? Range: boolean	0
branching/fullstrong/maxpropounds	maximum number of propagation rounds to be performed during strong branching before solving the LP (-1: no limit, -2: parameter settings) Range: {-3, ..., ∞ }	-2
branching/fullstrong/probingbounds	should valid bounds be identified in a probing-like fashion during strong branching (only with propagation)? Range: boolean	1
branching/fullstrong/reevalage	number of intermediate LPs solved to trigger reevaluation of strong branching value for a variable that was already evaluated at the current node Range: {0, ..., ∞ }	10

5.39.4.8 branching/inference

Option	Description	Default
branching/inference/conflictprio	priority value for using conflict weights in lex. order Range: {0, ..., ∞ }	1
branching/inference/cutoffprio	priority value for using cutoff weights in lex. order Range: {0, ..., ∞ }	1
branching/inference/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/inference/maxdepth	maximal depth level, up to which branching rule <inference> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/inference/priority	priority of branching rule <inference> Range: {-536870912, ..., 536870911}	1000
branching/inference/useweightedsum	should a weighted sum of inference, conflict and cutoff weights be used? Range: boolean	1
Options for expert users		
branching/inference/conflictweight	weight in score calculations for conflict score Range: [0, ∞]	1000
branching/inference/cutoffweight	weight in score calculations for cutoff score Range: [0, ∞]	1
branching/inference/fractionals	should branching on LP solution be restricted to the fractional variables? Range: boolean	1

Option	Description	Default
branching/inference/inferenceweight	weight in score calculations for inference score Range: real	1
branching/inference/reliablescore	weight in score calculations for conflict score Range: $[0, \infty]$	0.001

5.39.4.9 branching/leastinf

Option	Description	Default
branching/leastinf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: $[0, 1]$	1
branching/leastinf/maxdepth	maximal depth level, up to which branching rule <leastinf> should be used (-1 for no limit) Range: $\{-1, \dots, 65534\}$	-1
branching/leastinf/priority	priority of branching rule <leastinf> Range: $\{-536870912, \dots, 536870911\}$	50

5.39.4.10 branching/lookahead

Option	Description	Default
branching/lookahead/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: $[0, 1]$	1
branching/lookahead/maxdepth	maximal depth level, up to which branching rule <lookahead> should be used (-1 for no limit) Range: $\{-1, \dots, 65534\}$	-1
branching/lookahead/priority	priority of branching rule <lookahead> Range: $\{-536870912, \dots, 536870911\}$	0
Options for expert users		
branching/lookahead/abbreviated	toggles the abbreviated LAB. Range: boolean	1
branching/lookahead/abbrevpseudo	if abbreviated: Use pseudo costs to estimate the score of a candidate. Range: boolean	0
branching/lookahead/addbinconsrow	should binary constraints be added as rows to the base LP? (0: no, 1: separate, 2: as initial rows) Range: $\{0, \dots, 2\}$	0
branching/lookahead/addclique	add binary constraints with two variables found at the root node also as a clique Range: boolean	0
branching/lookahead/addnonviocons	should binary constraints, that are not violated by the base LP, be collected and added? Range: boolean	0

Option	Description	Default
branching/lookahead/applychildbounds	should bounds known for child nodes be applied? Range: boolean	0
branching/lookahead/deeperscoringfunction	scoring function to be used at deeper levels Range: d, f, s, w, l, c, r, x	x
branching/lookahead/enforcemaxdomreds	should the maximum number of domain reductions maxnviolateddomreds be enforced? Range: boolean	0
branching/lookahead/filterbymaxgain	should lookahead branching only be applied if the max gain in level 1 is not uniquely that of the best candidate? Range: boolean	0
branching/lookahead/level2avgscore	should the average score be used for uninitialized scores in level 2? Range: boolean	0
branching/lookahead/level2zeroscore	should uninitialized scores in level 2 be set to 0? Range: boolean	0
branching/lookahead/maxncands	if abbreviated: The max number of candidates to consider at the node. Range: {1, ..., ∞ }	4
branching/lookahead/maxndeepcands	if abbreviated: The max number of candidates to consider per deeper node. Range: {0, ..., ∞ }	2
branching/lookahead/maxnviolatedbincons	how many binary constraints that are violated by the base lp solution should be gathered until the rule is stopped and they are added? [0 for unrestricted] Range: {0, ..., ∞ }	0
branching/lookahead/maxnviolatedcons	how many constraints that are violated by the base lp solution should be gathered until the rule is stopped and they are added? [0 for unrestricted] Range: {0, ..., ∞ }	1
branching/lookahead/maxnviolateddomreds	how many domain reductions that are violated by the base lp solution should be gathered until the rule is stopped and they are added? [0 for unrestricted] Range: {0, ..., ∞ }	1
branching/lookahead/maxpropounds	maximum number of propagation rounds to perform at each temporary node (-1: unlimited, 0: SCIP default) Range: {-1, ..., ∞ }	0
branching/lookahead/mergedomainreductions	should domain reductions of feasible siblings should be merged? Range: boolean	0
branching/lookahead/minweight	if scoringfunction is 's', this value is used to weight the min of the gains of two child problems in the convex combination Range: [0, ∞]	0.8
branching/lookahead/onlyvioldomreds	should only domain reductions that violate the LP solution be applied? Range: boolean	0

Option	Description	Default
branching/lookahead/prefersimplebounds	should domain reductions only be applied if there are simple bound changes? Range: boolean	0
branching/lookahead/propagate	should domain propagation be executed before each temporary node is solved? Range: boolean	1
branching/lookahead/recursiondepth	the max depth of LAB. Range: {1, ..., ∞ }	2
branching/lookahead/reevalage	max number of LPs solved after which a previous prob branching results are recalculated Range: {0, ..., ∞ }	10
branching/lookahead/reevalagefsb	max number of LPs solved after which a previous FSB scoring results are recalculated Range: {0, ..., ∞ }	10
branching/lookahead/reusebasis	if abbreviated: Should the information gathered to obtain the best candidates be reused? Range: boolean	1
branching/lookahead/scoringfunction	scoring function to be used at the base level Range: d, f, s, w, p, l, c, r, a	a
branching/lookahead/scoringscoringfunction	scoring function to be used during FSB scoring Range: d, f, s, w, l, c, r	d
branching/lookahead/storeunviolatedsol	if only non violating constraints are added, should the branching decision be stored till the next call? Range: boolean	1
branching/lookahead/updatebranchingresults	should branching results (and scores) be updated w.r.t. proven dual bounds? Range: boolean	0
branching/lookahead/usedomainreduction	should domain reductions be collected and applied? Range: boolean	1
branching/lookahead/useimpliedbincons	should binary constraints be collected and applied? Range: boolean	0
branching/lookahead/uselevel2data	should branching data generated at depth level 2 be stored for re-using it? Range: boolean	1
branching/lookahead/worsefactor	if the FSB score is of a candidate is worse than the best by this factor, skip this candidate (-1: disable) Range: [-1, ∞]	-1

5.39.4.11 branching/mostinf

Option	Description	Default
branching/mostinf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1

Option	Description	Default
branching/mostinf/maxdepth	maximal depth level, up to which branching rule <mostinf> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/mostinf/priority	priority of branching rule <mostinf> Range: {-536870912, ..., 536870911}	100

5.39.4.12 branching/multaggr

Option	Description	Default
branching/multaggr/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/multaggr/maxdepth	maximal depth level, up to which branching rule <multaggr> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/multaggr/priority	priority of branching rule <multaggr> Range: {-536870912, ..., 536870911}	0
Options for expert users		
branching/multaggr/maxpropounds	maximum number of propagation rounds to be performed during multaggr branching before solving the LP (-1: no limit, -2: parameter settings) Range: {-2, ..., ∞}	0
branching/multaggr/probingbounds	should valid bounds be identified in a probing-like fashion during multaggr branching (only with propagation)? Range: boolean	1
branching/multaggr/reevalage	number of intermediate LPs solved to trigger reevaluation of strong branching value for a variable that was already evaluated at the current node Range: {0, ..., ∞}	0

5.39.4.13 branching/nodereopt

Option	Description	Default
branching/nodereopt/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/nodereopt/maxdepth	maximal depth level, up to which branching rule <nodereopt> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/nodereopt/priority	priority of branching rule <nodereopt> Range: {-536870912, ..., 536870911}	-9000000

5.39.4.14 branching/pscscost

Option	Description	Default
branching/pscost/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/pscost/maxdepth	maximal depth level, up to which branching rule <pscost> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/pscost/narymaxdepth	maximal depth where to do n-ary branching, -1 to turn off Range: {-1, ..., ∞ }	-1
branching/pscost/naryminwidth	minimal domain width in children when doing n-ary branching, relative to global bounds Range: [0, 1]	0.001
branching/pscost/narywidthfactor	factor of domain width in n-ary branching when creating nodes with increasing distance from branching value Range: [1, ∞]	2
branching/pscost/nchildren	number of children to create in n-ary branching Range: {2, ..., ∞ }	2
branching/pscost/priority	priority of branching rule <pscost> Range: {-536870912, ..., 536870911}	2000
branching/pscost/strategy	strategy for utilizing pseudo-costs of external branching candidates (multiply as in pseudo costs 'u'pdate rule, or by 'd'omain reduction, or by domain reduction of 's'ibling, or by 'v'ariable score) Range: d, s, u, v	u
Options for expert users		
branching/pscost/maxscoreweight	weight for maximum of scores of a branching candidate when building weighted sum of min/max/sum of scores Range: real	1.3
branching/pscost/minscoreweight	weight for minimum of scores of a branching candidate when building weighted sum of min/max/sum of scores Range: real	0.8
branching/pscost/sumscoreweight	weight for sum of scores of a branching candidate when building weighted sum of min/max/sum of scores Range: real	0.1

5.39.4.15 branching/random

Option	Description	Default
branching/random/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/random/maxdepth	maximal depth level, up to which branching rule <random> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1

Option	Description	Default
branching/random/priority	priority of branching rule <random> Range: {-536870912, ..., 536870911}	-100000
branching/random/seed	initial random seed value Range: {0, ..., ∞ }	41

5.39.4.16 branching/repscst

Option	Description	Default
branching/repscst/initcand	maximal number of candidates initialized with strong branching per node Range: {0, ..., ∞ }	100
branching/repscst/inititer	iteration limit for strong branching initializations of pseudo cost entries (0: auto) Range: {0, ..., ∞ }	0
branching/repscst/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/repscst/maxdepth	maximal depth level, up to which branching rule <repscst> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/repscst/priority	priority of branching rule <repscst> Range: {-536870912, ..., 536870911}	10000
branching/repscst/sbiterofs	additional number of allowed strong branching LP iterations Range: {0, ..., ∞ }	100000
branching/repscst/sbiterquot	maximal fraction of strong branching LP iterations compared to node relaxation LP iterations Range: [0, ∞]	0.5
Options for expert users		
branching/repscst/confidencelevel	the confidence level for statistical methods, between 0 (Min) and 4 (Max). Range: {0, ..., 4}	2
branching/repscst/conflictlengthweight	weight in score calculations for conflict length score Range: real	0
branching/repscst/conflictweight	weight in score calculations for conflict score Range: real	0.01
branching/repscst/cutoffweight	weight in score calculations for cutoff score Range: real	0.0001
branching/repscst/degeneracyaware	should degeneracy be taken into account to update weights and skip strong branching? (0: off, 1: after root, 2: always) Range: {0, ..., 2}	1
branching/repscst/dynamicweights	should the weights of the branching rule be adjusted dynamically during solving based on objective and infeasible leaf counters? Range: boolean	1

Option	Description	Default
branching/relpscost/filtercandssym	Use symmetry to filter branching candidates? Range: boolean	0
branching/relpscost/higherrortol	high relative error tolerance for reliability Range: $[0, \infty]$	1
branching/relpscost/inferenceweight	weight in score calculations for inference score Range: real	0.0001
branching/relpscost/lowerrortol	low relative error tolerance for reliability Range: $[0, \infty]$	0.05
branching/relpscost/maxbdchgs	maximal number of bound tightenings before the node is reevaluated (-1: unlimited) Range: $\{-1, \dots, \infty\}$	5
branching/relpscost/maxlookahead	maximal number of further variables evaluated without better score Range: $\{1, \dots, \infty\}$	9
branching/relpscost/maxpropounds	maximum number of propagation rounds to be performed during strong branching before solving the LP (-1: no limit, -2: parameter settings) Range: $\{-2, \dots, \infty\}$	-2
branching/relpscost/maxreliable	maximal value for minimum pseudo cost size to regard pseudo cost value as reliable Range: $[0, \infty]$	5
branching/relpscost/minreliable	minimal value for minimum pseudo cost size to regard pseudo cost value as reliable Range: $[0, \infty]$	1
branching/relpscost/nlscorweight	weight in score calculations for nlcount score Range: real	0.1
branching/relpscost/probingbounds	should valid bounds be identified in a probing-like fashion during strong branching (only with propagation)? Range: boolean	1
branching/relpscost/pscostweight	weight in score calculations for pseudo cost score Range: real	1
branching/relpscost/randinitorder	should candidates be initialized in randomized order? Range: boolean	0
branching/relpscost/skipbadinitcands	should branching rule skip candidates that have a low probability to be better than the best strong-branching or pseudo-candidate? Range: boolean	1
branching/relpscost/startrandseed	start seed for random number generation Range: $\{0, \dots, \infty\}$	5
branching/relpscost/storesemiinitcosts	should strong branching result be considered for pseudo costs if the other direction was infeasible? Range: boolean	0
branching/relpscost/transsympscost	Transfer pscost information to symmetric variables? Range: boolean	0

Option	Description	Default
branching/relpscost/usedynamicconfidence	should the confidence level be adjusted dynamically? Range: boolean	0
branching/relpscost/usehypptestforreliability	should the strong branching decision be based on a hypothesis test? Range: boolean	0
branching/relpscost/userelerrorreliability	should reliability be based on relative errors? Range: boolean	0
branching/relpscost/usesblocalinfo	should the scoring function use only local cutoff and inference information obtained for strong branching candidates? Range: boolean	0
branching/relpscost/usesmallweightsitlim	should smaller weights be used for pseudo cost updates after hitting the LP iteration limit? Range: boolean	0

5.39.4.17 branching/treemodel

Option	Description	Default
branching/treemodel/enable	should candidate branching variables be scored using the Treemodel branching rules? Range: boolean	0
branching/treemodel/height	estimated tree height at which we switch from using the low rule to the high rule Range: {0, ..., ∞ }	10
branching/treemodel/highrule	scoring function to use at nodes predicted to be high in the tree ('d'efault, 's'vts, 'r'atio, 't'ree sample) Range: d, s, r, t	r
branching/treemodel/lowrule	scoring function to use at nodes predicted to be low in the tree ('d'efault, 's'vts, 'r'atio, 't'ree sample) Range: d, s, r, t	r
Options for expert users		
branching/treemodel/fallbackinf	which method should be used as a fallback if the tree size estimates are infinite? ('d'efault, 'r'atio) Range: d, r	r
branching/treemodel/fallbacknoprimal	which method should be used as a fallback if there is no primal bound available? ('d'efault, 'r'atio) Range: d, r	r
branching/treemodel/filterhigh	should dominated candidates be filtered before using the high scoring function? ('a'uto, 't'rue, 'f'alse) Range: a, t, f	a
branching/treemodel/filterlow	should dominated candidates be filtered before using the low scoring function? ('a'uto, 't'rue, 'f'alse) Range: a, t, f	a
branching/treemodel/maxfpiter	maximum number of fixed-point iterations when computing the ratio Range: {1, ..., ∞ }	24

Option	Description	Default
branching/treemodel/maxsvtsheight	maximum height to compute the SVTS score exactly before approximating Range: $\{0, \dots, \infty\}$	100
branching/treemodel/smallpscost	threshold at which pseudocosts are considered small, making hybrid scores more likely to be the deciding factor in branching Range: $[0, \infty]$	0.1

5.39.4.18 branching/vanillafullstrong

Option	Description	Default
branching/vanillafullstrong/idempotent	should strong branching side-effects be prevented (e.g., domain changes, stat updates etc.)? Range: boolean	0
branching/vanillafullstrong/integralcands	should integral variables in the current LP solution be considered as branching candidates? Range: boolean	0
branching/vanillafullstrong/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: $[0, 1]$	1
branching/vanillafullstrong/maxdepth	maximal depth level, up to which branching rule <vanillafullstrong> should be used (-1 for no limit) Range: $\{-1, \dots, 65534\}$	-1
branching/vanillafullstrong/priority	priority of branching rule <vanillafullstrong> Range: $\{-536870912, \dots, 536870911\}$	-2000
Options for expert users		
branching/vanillafullstrong/collectscores	should strong branching scores be collected? Range: boolean	0
branching/vanillafullstrong/donotbranch	should candidates only be scored, but no branching be performed? Range: boolean	0
branching/vanillafullstrong/scoreall	should strong branching scores be computed for all candidates, or can we early stop when a variable has infinite score? Range: boolean	0

5.39.4.19 conflict

Option	Description	Default
conflict/conflictgraphweight	the weight the VSIDS score is weight by updating the VSIDS for a variable if it is part of a conflict graph Range: $[0, 1]$	1

Option	Description	Default
conflict/conflictweight	the weight the VSIDS score is weight by updating the VSIDS for a variable if it is part of a conflict Range: [0, 1]	0
conflict/enable	should conflict analysis be enabled? Range: boolean	1
conflict/preferbinary	should binary conflicts be preferred? Range: boolean	0
conflict/restartfac	factor to increase restartnum with after each restart Range: [0, ∞]	1.5
conflict/restartnum	number of successful conflict analysis calls that trigger a restart (0: disable conflict restarts) Range: {0, ..., ∞ }	0
conflict/sepaaltproofs	apply cut generating functions to construct alternative proofs Range: boolean	0
conflict/useboundlp	should bound exceeding LP conflict analysis be used? ('o'ff, 'c'onflict graph, 'd'ual ray, 'b'oth conflict graph and dual ray) Range: o, c, d, b	b
conflict/useinflp	should infeasible LP conflict analysis be used? ('o'ff, 'c'onflict graph, 'd'ual ray, 'b'oth conflict graph and dual ray) Range: o, c, d, b	b
conflict/useprop	should propagation conflict analysis be used? Range: boolean	1
conflict/usepseudo	should pseudo solution conflict analysis be used? Range: boolean	1
conflict/usesb	should infeasible/bound exceeding strong branching conflict analysis be used? Range: boolean	1
Options for expert users		
conflict/allowlocal	should conflict constraints be generated that are only valid locally? Range: boolean	1
conflict/cleanboundexceedings	should conflicts based on an old cutoff bound be removed from the conflict pool after improving the primal bound? Range: boolean	1
conflict/downlockscorefac	score factor for down locks in bound relaxation heuristic Range: real	0
conflict/dynamic	should the conflict constraints be subject to aging? Range: boolean	1
conflict/fuiplevels	number of depth levels up to which first UIP's are used in conflict analysis (-1: use All-FirstUIP rule) Range: {-1, ..., ∞ }	-1
conflict/fullshortenconflict	try to shorten the whole conflict set or terminate early (depending on the 'maxvarsdetectimplied-bounds' parameter) Range: boolean	1

Option	Description	Default
conflict/ignorerelaxedbd	should relaxed bounds be ignored? Range: boolean	0
conflict/interconss	maximal number of intermediate conflict constraints generated in conflict graph (-1: use every intermediate constraint) Range: $\{-1, \dots, \infty\}$	-1
conflict/keepreprop	should constraints be kept for repropagation even if they are too long? Range: boolean	1
conflict/lpiterations	maximal number of LP iterations in each LP resolving loop (-1: no limit) Range: $\{-1, \dots, \infty\}$	10
conflict/maxconss	maximal number of conflict constraints accepted at an infeasible node (-1: use all generated conflict constraints) Range: $\{-1, \dots, \infty\}$	10
conflict/maxlploops	maximal number of LP resolving loops during conflict analysis (-1: no limit) Range: $\{-1, \dots, \infty\}$	2
conflict/maxstoresize	maximal size of conflict store (-1: auto, 0: disable storage) Range: $\{-1, \dots, \infty\}$	10000
conflict/maxvarsdetectimpliedbounds	maximal number of variables to try to detect global bound implications and shorten the whole conflict set (0: disabled) Range: $\{0, \dots, \infty\}$	250
conflict/maxvarsfac	maximal fraction of variables involved in a conflict constraint Range: $[0, \infty]$	0.15
conflict/minimprove	minimal improvement of primal bound to remove conflicts based on a previous incumbent Range: $[0, 1]$	0.05
conflict/minmaxvars	minimal absolute maximum of variables involved in a conflict constraint Range: $\{0, \dots, \infty\}$	0
conflict/prefinfproof	prefer infeasibility proof to boundexceeding proof Range: boolean	1
conflict/proofscorefac	score factor for impact on activity in bound relaxation heuristic Range: real	1
conflict/reconvlevels	number of depth levels up to which UIP reconvergence constraints are generated (-1: generate reconvergence constraints in all depth levels) Range: $\{-1, \dots, \infty\}$	-1
conflict/removable	should the conflict's relaxations be subject to LP aging and cleanup? Range: boolean	1
conflict/repropagate	should earlier nodes be repropagated in order to replace branching decisions by deductions? Range: boolean	1
conflict/scorefac	factor to decrease importance of variables' earlier conflict scores Range: $[1e-06, 1]$	0.98

Option	Description	Default
conflict/separate	should the conflict constraints be separated? Range: boolean	1
conflict/settlelocal	should conflict constraints be attached only to the local subtree where they can be useful? Range: boolean	0
conflict/uplockscorefac	score factor for up locks in bound relaxation heuristic Range: real	0
conflict/uselocalrows	use local rows to construct infeasibility proofs Range: boolean	1
conflict/weightrepropdepth	weight of the repropagation depth of a conflict used in score calculation Range: [0, 1]	0.1
conflict/weightsize	weight of the size of a conflict used in score calculation Range: [0, 1]	0.001
conflict/weightvaliddepth	weight of the valid depth of a conflict used in score calculation Range: [0, 1]	1

5.39.4.20 conflict/bounddisjunction

Option	Description	Default
conflict/bounddisjunction/continuousfrac	maximal percentage of continuous variables within a conflict Range: [0, 1]	0.4
Options for expert users		
conflict/bounddisjunction/priority	priority of conflict handler <bounddisjunction> Range: {-2147483648, ..., ∞}	-3000000

5.39.4.21 conflict/graph

Option	Description	Default
Options for expert users		
conflict/graph/depthscorefac	score factor for depth level in bound relaxation heuristic Range: real	1

5.39.4.22 conflict/indicatorconflict

Option	Description	Default
Options for expert users		
conflict/indicatorconflict/priority	priority of conflict handler <indicatorconflict> Range: {-2147483648, ..., ∞}	200000

5.39.4.23 conflict/linear

Option	Description	Default
Options for expert users		
conflict/linear/priority	priority of conflict handler <linear> Range: $\{-2147483648, \dots, \infty\}$	-1000000

5.39.4.24 conflict/logicor

Option	Description	Default
Options for expert users		
conflict/logicor/priority	priority of conflict handler <logicor> Range: $\{-2147483648, \dots, \infty\}$	800000

5.39.4.25 conflict/setppc

Option	Description	Default
Options for expert users		
conflict/setppc/priority	priority of conflict handler <setppc> Range: $\{-2147483648, \dots, \infty\}$	700000

5.39.4.26 constraints

Option	Description	Default
Options for expert users		
constraints/agelimit	maximum age an unnecessary constraint can reach before it is deleted (0: dynamic, -1: keep all constraints) Range: $\{-1, \dots, \infty\}$	0
constraints/disableenfops	should enforcement of pseudo solution be disabled? Range: boolean	0
constraints/obsoleteage	age of a constraint after which it is marked obsolete (0: dynamic, -1 do not mark constraints obsolete) Range: $\{-1, \dots, \infty\}$	-1

5.39.4.27 constraints/SOS1

Option	Description	Default
constraints/SOS1/branchnonzeros	Branch on SOS constraint with most number of nonzeros? Range: boolean	0
constraints/SOS1/branchsos	Use SOS1 branching in enforcing (otherwise leave decision to branching rules)? This value can only be set to false if all SOS1 variables are binary Range: boolean	1
constraints/SOS1/branchweight	Branch on SOS cons. with highest nonzero-variable weight for branching (needs branchnonzeros = false)? Range: boolean	0

Option	Description	Default
constraints/SOS1/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/SOS1/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
constraints/SOS1/addbdsfeas	minimal feasibility value for bound inequalities in order to be added to the branching node Range: real	1
constraints/SOS1/addcomps	if TRUE then add complementarity constraints to the branching nodes (can be used in combination with neighborhood or bipartite branching) Range: boolean	0
constraints/SOS1/addcompsdepth	only add complementarity constraints to branching nodes for predefined depth (-1: no limit) Range: {-1, ..., ∞ }	30
constraints/SOS1/addcompsfeas	minimal feasibility value for complementarity constraints in order to be added to the branching node Range: real	-0.6
constraints/SOS1/addextendedbds	should added complementarity constraints be extended to SOS1 constraints to get tighter bound inequalities Range: boolean	1
constraints/SOS1/autocutsfromsos1	if TRUE then automatically switch to separating initial SOS1 constraints if the SOS1 constraints do not overlap Range: boolean	1
constraints/SOS1/autosos1branch	if TRUE then automatically switch to SOS1 branching if the SOS1 constraints do not overlap Range: boolean	1
constraints/SOS1/boundcutsdepth	node depth of separating bound cuts (-1: no limit) Range: {-1, ..., ∞ }	40
constraints/SOS1/boundcutsfreq	frequency for separating bound cuts; zero means to separate only in the root node Range: {-1, ..., 65534}	10
constraints/SOS1/boundcutsfromgraph	if TRUE separate bound inequalities from the conflict graph Range: boolean	1
constraints/SOS1/boundcutsfromsos1	if TRUE separate bound inequalities from initial SOS1 constraints Range: boolean	0
constraints/SOS1/branchingrule	which branching rule should be applied ? ('n': neighborhood, 'b': bipartite, 's': SOS1/cliq) (note: in some cases an automatic switching to SOS1 branching is possible) Range: n, b, s	n
constraints/SOS1/conflictprop	whether to use conflict graph propagation Range: boolean	1

Option	Description	Default
constraints/SOS1/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/SOS1/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/SOS1/depthimplanalysis	number of recursive calls of implication graph analysis (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
constraints/SOS1/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: $\{-1, \dots, 65534\}$	100
constraints/SOS1/fixnonzero	if neighborhood branching is used, then fix the branching variable (if positive in sign) to the value of the feasibility tolerance Range: boolean	0
constraints/SOS1/implcutsdepth	node depth of separating implied bound cuts (-1: no limit) Range: $\{-1, \dots, \infty\}$	40
constraints/SOS1/implcutsfreq	frequency for separating implied bound cuts; zero means to separate only in the root node Range: $\{-1, \dots, 65534\}$	0
constraints/SOS1/implprop	whether to use implication graph propagation Range: boolean	1
constraints/SOS1/maxaddcomps	maximal number of complementarity constraints added per branching node (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
constraints/SOS1/maxboundcuts	maximal number of bound cuts separated per branching node Range: $\{0, \dots, \infty\}$	50
constraints/SOS1/maxboundcutsroot	maximal number of bound cuts separated per iteration in the root node Range: $\{0, \dots, \infty\}$	150
constraints/SOS1/maxextensions	maximal number of extensions that will be computed for each SOS1 constraint (-1: no limit) Range: $\{-1, \dots, \infty\}$	1
constraints/SOS1/maximplcuts	maximal number of implied bound cuts separated per branching node Range: $\{0, \dots, \infty\}$	50
constraints/SOS1/maximplcutsroot	maximal number of implied bound cuts separated per iteration in the root node Range: $\{0, \dots, \infty\}$	150
constraints/SOS1/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
constraints/SOS1/maxsosadjacency	do not create an adjacency matrix if number of SOS1 variables is larger than predefined value (-1: no limit) Range: $\{-1, \dots, \infty\}$	10000
constraints/SOS1/maxtightenbds	maximal number of bound tightening rounds per presolving round (-1: no limit) Range: $\{-1, \dots, \infty\}$	5

Option	Description	Default
constraints/SOS1/nstrongiter	maximal number LP iterations to perform for each strong branching round (-2: auto, -1: no limit) Range: $\{-2, \dots, \infty\}$	10000
constraints/SOS1/nstrongrounds	maximal number of strong branching rounds to perform for each node (-1: auto); only available for neighborhood and bipartite branching Range: $\{-1, \dots, \infty\}$	0
constraints/SOS1/perfimplanalysis	if TRUE then perform implication graph analysis (might add additional SOS1 constraints) Range: boolean	0
constraints/SOS1/presolting	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{4, \dots, 60\}$	8
constraints/SOS1/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: $\{1, \dots, 15\}$	1
constraints/SOS1/sosconsprop	whether to use SOS1 constraint propagation Range: boolean	0
constraints/SOS1/strthenboundcuts	if TRUE then bound cuts are strengthened in case bound variables are available Range: boolean	1

5.39.4.28 constraints/SOS2

Option	Description	Default
constraints/SOS2/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	1
constraints/SOS2/sepafter	frequency for separating cuts (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	0
Options for expert users		
constraints/SOS2/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/SOS2/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/SOS2/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: $\{-1, \dots, 65534\}$	100
constraints/SOS2/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
constraints/SOS2/presolting	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{4, \dots, 60\}$	4

Option	Description	Default
constraints/SOS2/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.39.4.29 constraints/and

Option	Description	Default
constraints/and/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/and/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
Options for expert users		
constraints/and/aggrlinearization	should an aggregated linearization be used? Range: boolean	0
constraints/and/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/and/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/and/dualpresolving	should dual presolving be performed? Range: boolean	1
constraints/and/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/and/enforcecuts	should cuts be separated during LP enforcing? Range: boolean	1
constraints/and/linearize	should the AND-constraint get linearized and removed (in presolving)? Range: boolean	0
constraints/and/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/and/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/and/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	20
constraints/and/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/and/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

Option	Description	Default
constraints/and/upgraderesultant	should all binary resultant variables be upgraded to implicit binary variables? Range: boolean	1

5.39.4.30 constraints/bounddisjunction

Option	Description	Default
constraints/bounddisjunction/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/bounddisjunction/sepfreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
constraints/bounddisjunction/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/bounddisjunction/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/bounddisjunction/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/bounddisjunction/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/bounddisjunction/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4
constraints/bounddisjunction/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.39.4.31 constraints/components

Option	Description	Default
constraints/components/intfactor	the weight of an integer variable compared to binary variables Range: [0, ∞]	1
constraints/components/maxdepth	maximum depth of a node to run components detection (-1: disable component detection during solving) Range: {-1, ..., ∞ }	-1

Option	Description	Default
constraints/components/nodelimit	maximum number of nodes to be solved in sub-problems during presolving Range: $\{-1, \dots, \infty\}$	10000
constraints/components/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	1
constraints/components/sepaftereq	frequency for separating cuts (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	-1
Options for expert users		
constraints/components/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	1
constraints/components/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/components/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: $\{-1, \dots, 65534\}$	-1
constraints/components/feastolfactor	factor to increase the feasibility tolerance of the main SCIP in all sub-SCIPs, default value 1.0 Range: $[0, 1e+06]$	1
constraints/components/maxintvars	maximum number of integer (or binary) variables to solve a subproblem during presolving (-1: unlimited) Range: $\{-1, \dots, \infty\}$	500
constraints/components/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
constraints/components/minrelsize	minimum relative size (in terms of variables) to solve a component individually during branch-and-bound Range: $[0, 1]$	0.1
constraints/components/minsize	minimum absolute size (in terms of variables) to solve a component individually during branch-and-bound Range: $\{0, \dots, \infty\}$	50
constraints/components/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{4, \dots, 60\}$	32
constraints/components/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: $\{1, \dots, 15\}$	1

5.39.4.32 constraints/indicator

Option	Description	Default
constraints/indicator/maxsepacuts	maximal number of cuts separated per separation round Range: {0, ..., ∞ }	100
constraints/indicator/maxsepacutsroot	maximal number of cuts separated per separation round in the root node Range: {0, ..., ∞ }	2000
constraints/indicator/maxsepanonviolated	maximal number of separated non violated IISs, before separation is stopped Range: {0, ..., ∞ }	3
constraints/indicator/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/indicator/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
constraints/indicator/addcoupling	Add coupling constraints or rows if big-M is small enough? Range: boolean	1
constraints/indicator/addcouplingcons	Add initial variable upper bound constraints, if 'addcoupling' is true? Range: boolean	0
constraints/indicator/addopposite	Add opposite inequality in nodes in which the binary variable has been fixed to 0? Range: boolean	0
constraints/indicator/branchindicators	Branch on indicator constraints in enforcing? Range: boolean	0
constraints/indicator/conflictsupgrade	Try to upgrade bounddisjunction conflicts by replacing slack variables? Range: boolean	0
constraints/indicator/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/indicator/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/indicator/dualreductions	Should dual reduction steps be performed? Range: boolean	1
constraints/indicator/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/indicator/enforcecuts	In enforcing try to generate cuts (only if sepaalternatively is true)? Range: boolean	0
constraints/indicator/forcerestart	Force restart if absolute gap is 1 or enough binary variables have been fixed? Range: boolean	0

Option	Description	Default
constraints/indicator/generatebilinear	Do not generate indicator constraint, but a bilinear constraint instead? Range: boolean	0
constraints/indicator/genlogicor	Generate logicor constraints instead of cuts? Range: boolean	0
constraints/indicator/maxconditionaltlp	maximum estimated condition of the solution basis matrix of the alternative LP to be trustworthy (0.0 to disable check) Range: $[0, \infty]$	0
constraints/indicator/maxcouplingvalue	maximum coefficient for binary variable in coupling constraint Range: $[0, 1e+09]$	10000
constraints/indicator/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
constraints/indicator/nolinconscont	Decompose problem (do not generate linear constraint if all variables are continuous)? Range: boolean	0
constraints/indicator/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{4, \dots, 60\}$	4
constraints/indicator/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: $\{1, \dots, 15\}$	1
constraints/indicator/removeindicators	Remove indicator constraint if corresponding variable bound constraint has been added? Range: boolean	0
constraints/indicator/restartfrac	fraction of binary variables that need to be fixed before restart occurs (in forcerestart) Range: $[0, 1]$	0.9
constraints/indicator/scaleslackvar	Scale slack variable coefficient at construction time? Range: boolean	0
constraints/indicator/sepalternativelp	Separate using the alternative LP? Range: boolean	0
constraints/indicator/sepacouplingcuts	Should the coupling inequalities be separated dynamically? Range: boolean	1
constraints/indicator/sepacouplinglocal	Allow to use local bounds in order to separate coupling inequalities? Range: boolean	0
constraints/indicator/sepacouplingvalue	maximum coefficient for binary variable in separated coupling constraint Range: $[0, 1e+09]$	10000
constraints/indicator/sepaperspective	Separate cuts based on perspective formulation? Range: boolean	0

Option	Description	Default
constraints/indicator/sepapersplocal	Allow to use local bounds in order to separate perspective cuts? Range: boolean	1
constraints/indicator/trysolfromcover	Try to construct a feasible solution from a cover? Range: boolean	0
constraints/indicator/trysolutions	Try to make solutions feasible by setting indicator variables? Range: boolean	1
constraints/indicator/updatebounds	Update bounds of original variables for separation? Range: boolean	0
constraints/indicator/upgradelinear	Try to upgrade linear constraints to indicator constraints? Range: boolean	0
constraints/indicator/useobjectivecut	Use objective cut with current best solution to alternative LP? Range: boolean	0
constraints/indicator/useotherconss	Collect other constraints to alternative LP? Range: boolean	0

5.39.4.33 constraints/integral

Option	Description	Default
constraints/integral/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
constraints/integral/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
constraints/integral/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/integral/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/integral/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/integral/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	0
constraints/integral/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/integral/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.39.4.34 constraints/knapsack

Option	Description	Default
constraints/knapsack/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	5
constraints/knapsack/maxroundsroot	maximal number of separation rounds per node in the root node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
constraints/knapsack/maxsepacuts	maximal number of cuts separated per separation round Range: $\{0, \dots, \infty\}$	50
constraints/knapsack/maxsepacutsroot	maximal number of cuts separated per separation round in the root node Range: $\{0, \dots, \infty\}$	200
constraints/knapsack/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	1
constraints/knapsack/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	0
Options for expert users		
constraints/knapsack/cliqextractfactor	lower clique size limit for greedy clique extraction algorithm (relative to largest clique) Range: $[0, 1]$	0.5
constraints/knapsack/clqpartupdatefac	factor on the growth of global cliques to decide when to update a previous (negated) clique partition (used only if updatecliquepartitions is set to TRUE) Range: $[1, 10]$	1.5
constraints/knapsack/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/knapsack/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/knapsack/detectcutoffbound	should presolving try to detect constraints parallel to the objective function defining an upper bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/knapsack/detectlowerbound	should presolving try to detect constraints parallel to the objective function defining a lower bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/knapsack/disaggregation	should disaggregation of knapsack constraints be allowed in preprocessing? Range: boolean	1
constraints/knapsack/dualpresolving	should dual presolving steps be performed? Range: boolean	1

Option	Description	Default
constraints/knapsack/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: $\{-1, \dots, 65534\}$	100
constraints/knapsack/maxcardbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for separating knapsack cuts Range: $[0, 1]$	0
constraints/knapsack/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
constraints/knapsack/negatedclique	should negated clique information be used in solving process Range: boolean	1
constraints/knapsack/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/knapsack/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{4, \dots, 60\}$	28
constraints/knapsack/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/knapsack/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: $\{1, \dots, 15\}$	1
constraints/knapsack/sepacardfreq	multiplier on separation frequency, how often knapsack cuts are separated (-1: never, 0: only at root) Range: $\{-1, \dots, 65534\}$	1
constraints/knapsack/simplifyinequalities	should presolving try to simplify knapsacks Range: boolean	1
constraints/knapsack/updatecliquepartitions	should clique partition information be updated when old partition seems outdated? Range: boolean	0
constraints/knapsack/usegubs	should GUB information be used for separation? Range: boolean	0

5.39.4.35 constraints/linear

Option	Description	Default
constraints/linear/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	5

Option	Description	Default
constraints/linear/maxroundsroot	maximal number of separation rounds per node in the root node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
constraints/linear/maxsepacuts	maximal number of cuts separated per separation round Range: $\{0, \dots, \infty\}$	50
constraints/linear/maxsepacutsroot	maximal number of cuts separated per separation round in the root node Range: $\{0, \dots, \infty\}$	200
constraints/linear/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	1
constraints/linear/sepaftereq	frequency for separating cuts (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	0
constraints/linear/separateall	should all constraints be subject to cardinality cut generation instead of only the ones with non-zero dual value? Range: boolean	0
Options for expert users		
constraints/linear/aggregatevariables	should presolving search for aggregations in equations Range: boolean	1
constraints/linear/checkrelmaxabs	should the violation for a constraint with side 0.0 be checked relative to 1.0 (FALSE) or to the maximum absolute value in the activity (TRUE)? Range: boolean	0
constraints/linear/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/linear/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/linear/detectcutoffbound	should presolving try to detect constraints parallel to the objective function defining an upper bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/linear/detectlowerbound	should presolving try to detect constraints parallel to the objective function defining a lower bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/linear/detectpartialobjective	should presolving try to detect subsets of constraints parallel to the objective function? Range: boolean	1
constraints/linear/dualpresolving	should dual presolving steps be performed? Range: boolean	1

Option	Description	Default
constraints/linear/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/linear/extractcliques	should Cliques be extracted? Range: boolean	1
constraints/linear/maxaggrnormscale	maximal allowed relative gain in maximum norm for constraint aggregation (0.0: disable constraint aggregation) Range: [0, ∞]	0
constraints/linear/maxcardbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for separating knapsack cardinality cuts Range: [0, 1]	0
constraints/linear/maxdualmultaggrquot	maximum coefficient dynamism (ie. maxabsval / minabsval) for dual multiaggregation Range: [1, ∞]	∞
constraints/linear/maxeasyactivitydelta	maximum activity delta to run easy propagation on linear constraint (faster, but numerically less stable) Range: [0, ∞]	1e+06
constraints/linear/maxmultaggrquot	maximum coefficient dynamism (ie. maxabsval / minabsval) for primal multiaggregation Range: [1, ∞]	1000
constraints/linear/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/linear/mingainpernmincomparisons	minimal gain per minimal pairwise presolve comparisons to repeat pairwise comparison round Range: [0, 1]	1e-06
constraints/linear/multaggrremove	should multi-aggregations only be performed if the constraint can be removed afterwards? Range: boolean	0
constraints/linear/nmincomparisons	number for minimal pairwise presolve comparisons Range: {1, ..., ∞ }	200000
constraints/linear/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/linear/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	20
constraints/linear/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1

Option	Description	Default
constraints/linear/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/linear/rangedrowartcons	should presolving and propagation extract sub-constraints from ranged rows and equations? Range: boolean	1
constraints/linear/rangedrowfreq	frequency for applying ranged row propagation Range: {1, ..., 65534}	1
constraints/linear/rangedrowmaxdepth	maximum depth to apply ranged row propagation Range: {0, ..., ∞ }	∞
constraints/linear/rangedrowpropagation	should presolving and propagation try to improve bounds, detect infeasibility, and extract sub-constraints from ranged rows and equations? Range: boolean	1
constraints/linear/simplifyinequalities	should presolving try to simplify inequalities Range: boolean	1
constraints/linear/singletonstuffing	should stuffing of singleton continuous variables be performed? Range: boolean	1
constraints/linear/singlevarstuffing	should single variable stuffing be performed, which tries to fulfill constraints using the cheapest variable? Range: boolean	0
constraints/linear/sortvars	apply binaries sorting in decr. order of coeff abs value? Range: boolean	1
constraints/linear/tightenboundsfreq	multiplier on propagation frequency, how often the bounds are tightened (-1: never, 0: only at root) Range: {-1, ..., 65534}	1

5.39.4.36 constraints/linear/upgrade

Option	Description	Default
constraints/linear/upgrade/indicator	enable linear upgrading for constraint handler <indicator> Range: boolean	1
constraints/linear/upgrade/knapsack	enable linear upgrading for constraint handler <knapsack> Range: boolean	1
constraints/linear/upgrade/logicor	enable linear upgrading for constraint handler <logicor> Range: boolean	1
constraints/linear/upgrade/setppc	enable linear upgrading for constraint handler <setppc> Range: boolean	1

Option	Description	Default
constraints/linear/upgrade/varbound	enable linear upgrading for constraint handler <varbound> Range: boolean	1
constraints/linear/upgrade/xor	enable linear upgrading for constraint handler <xor> Range: boolean	1

5.39.4.37 constraints/logicor

Option	Description	Default
constraints/logicor/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/logicor/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
Options for expert users		
constraints/logicor/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/logicor/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/logicor/dualpresolving	should dual presolving steps be performed? Range: boolean	1
constraints/logicor/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/logicor/implications	should implications/cliques be used in presolving Range: boolean	1
constraints/logicor/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/logicor/negatedclique	should negated clique information be used in presolving Range: boolean	1
constraints/logicor/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/logicor/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/logicor/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/logicor/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

Option	Description	Default
constraints/logicor/strengthen	should pairwise constraint comparison try to strengthen constraints by removing superfluous non-zeros? Range: boolean	1

5.39.4.38 constraints/nonlinear

Option	Description	Default
constraints/nonlinear/assumeconvex	whether to assume that any constraint is convex Range: boolean	0
constraints/nonlinear/bilinmaxauxexprs	maximal number of auxiliary expressions per bilinear term Range: {0, ..., ∞ }	10
constraints/nonlinear/linearizeheursof	whether tight linearizations of nonlinear constraints should be added to cutpool when some heuristics finds a new solution ('o'ff, on new 'i'ncumbents, on 'e'very solution) Range: o, i, e	i if QCP or NLP, o otherwise
constraints/nonlinear/maxpropounds	limit on number of propagation rounds for a set of constraints within one round of SCIP propagation Range: {0, ..., ∞ }	10
constraints/nonlinear/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/nonlinear/reformbinprods	whether to reformulate products of binary variables during pre-solving Range: boolean	1
constraints/nonlinear/reformbinprodsand	whether to use the AND constraint handler for reformulating binary products Range: boolean	1
constraints/nonlinear/reformbinprodsfac	minimum number of terms to reformulate bilinear binary products by factorizing variables (≤ 1 : disabled) Range: {1, ..., ∞ }	50
constraints/nonlinear/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
Options for expert users		
constraints/nonlinear/checkvarlocks	whether variables contained in a single constraint should be forced to be at their lower or upper bounds ('d'isable, change 't'type, add 'b'ound disjunction) Range: b, d, t	t

Option	Description	Default
constraints/nonlinear/considerrelaxamount	by how much to relax constraint sides during bound tightening Range: [0, 1]	1e-09
constraints/nonlinear/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/nonlinear/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/nonlinear/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/nonlinear/enfoauxviolfactor	an expression will be enforced if the "auxiliary" violation is at least this factor times the "original" violation Range: [0, 1]	0.01
constraints/nonlinear/forbidmultaggrnlvar	whether to forbid multiaggregation of nonlinear variables Range: boolean	1
constraints/nonlinear/forcestrongcut	whether to force "strong" cuts in enforcement Range: boolean	0
constraints/nonlinear/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/nonlinear/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/nonlinear/propauxvars	whether to check bounds of all auxiliary variable to seed reverse propagation Range: boolean	1
constraints/nonlinear/propinenforce	whether to (re)run propagation in enforcement Range: boolean	0
constraints/nonlinear/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

Option	Description	Default
constraints/nonlinear/rownotremovable	whether to make rows to be non-removable in the node where they are added (can prevent some cycling): 'o'ff, in 'e'nforcement only, 'a'lways Range: o, e, a	o
constraints/nonlinear/strongcutefficacy	consider efficacy requirement when deciding whether a cut is "strong" Range: boolean	0
constraints/nonlinear/strongcutmaxcoef	"strong" cuts will be scaled to have their maximal coef in [1/strongcutmaxcoef,strongcutmaxcoef] Range: [1, ∞]	1000
constraints/nonlinear/tightenlpfeasol	whether to tighten LP feasibility tolerance during enforcement, if it seems useful Range: boolean	1
constraints/nonlinear/varboundrelax	strategy on how to relax variable bounds during bound tightening: relax (n)ot, relax by (a)bsolute value, relax always by a(b)solute value, relax by (r)relative value Range: n, a, b, r	r
constraints/nonlinear/varboundrelaxamount	by how much to relax variable bounds during bound tightening if strategy 'a', 'b', or 'r' Range: [0, 1]	1e-09
constraints/nonlinear/violyscale	method how to scale violations to make them comparable (not used for feasibility check): (n)one, (a)ctivity and side, norm of (g)radient Range: n, a, g	n
constraints/nonlinear/vpadjfacettresh	adjust computed facet of envelope of vertex-polyhedral function up to a violation of this value times LP feasibility tolerance Range: [0, ∞]	10
constraints/nonlinear/vpdualsimplex	whether to use dual simplex instead of primal simplex for LP that computes facet of vertex-polyhedral function Range: boolean	1
constraints/nonlinear/vpmaxperturb	maximal relative perturbation of reference point when computing facet of envelope of vertex-polyhedral function (dim>2) Range: [0, 1]	0.001
constraints/nonlinear/weakcutminviolfactor	retry enfo of constraint with weak cuts if violation is least this factor of maximal violated constraints Range: [0, 2]	0.5

Option	Description	Default
constraints/nonlinear/weakcutthreshold	threshold for when to regard a cut from an estimator as weak (lower values allow more weak cuts) Range: [0, 1]	0.2

5.39.4.39 constraints/nonlinear/branching

Option	Description	Default
constraints/nonlinear/branching/aux	from which depth on in the tree to allow branching on auxiliary variables (variables added for extended formulation) Range: {0, ..., ∞ }	∞
constraints/nonlinear/branching/domainweight	weight by how much to consider the domain width in branching score Range: [0, ∞]	0
constraints/nonlinear/branching/dualweight	weight by how much to consider the dual values of rows that contain a variable for its branching score Range: [0, ∞]	0
constraints/nonlinear/branching/external	whether to use external branching candidates and branching rules for branching Range: boolean	0
constraints/nonlinear/branching/highscorefactor	consider a variable branching score high if its branching score \geq this factor * maximal branching score among all variables Range: [0, 1]	0.9
constraints/nonlinear/branching/highviolfactor	consider a constraint highly violated if its violation is \geq this factor * maximal violation among all constraints Range: [0, 1]	0
constraints/nonlinear/branching/pscostreliable	minimum pseudo-cost update count required to consider pseudo-costs reliable Range: [0, ∞]	2
constraints/nonlinear/branching/pscostweight	weight by how much to consider the pseudo cost of a variable for its branching score Range: [0, ∞]	1
constraints/nonlinear/branching/scoreagg	how to aggregate several branching scores given for the same expression: 'a'verage, 'm'aximum, 's'um Range: a, m, s	s
constraints/nonlinear/branching/vartypeweight	weight by how much to consider variable type (continuous: 0, binary: 1, integer: 0.1, impl-integer: 0.01) in branching score Range: [0, ∞]	0.5
constraints/nonlinear/branching/violsplit	method used to split violation in expression onto variables: 'u'niform, 'm'idness of solution, 'd'omain width, 'l'ogarithmic domain width Range: u, m, d, l	m
constraints/nonlinear/branching/violweight	weight by how much to consider the violation assigned to a variable for its branching score Range: [0, ∞]	1

5.39.4.40 constraints/nonlinear/upgrade

Option	Description	Default
constraints/nonlinear/upgrade/linear	enable nonlinear upgrading for constraint handler <linear> Range: boolean	1
constraints/nonlinear/upgrade/setppc	enable nonlinear upgrading for constraint handler <setppc> Range: boolean	1

5.39.4.41 constraints/orbisack

Option	Description	Default
constraints/orbisack/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
constraints/orbisack/sepafter	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
Options for expert users		
constraints/orbisack/checkpporbisack	Upgrade orbisack constraints to packing/partitioning orbisacks? Range: boolean	1
constraints/orbisack/coeffbound	Maximum size of coefficients for orbisack inequalities Range: [0, ∞]	1e+06
constraints/orbisack/coverseparation	Separate cover inequalities for orbisacks? Range: boolean	1
constraints/orbisack/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/orbisack/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/orbisack/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/orbisack/forceconscopy	Whether orbisack constraints should be forced to be copied to sub SCIPs. Range: boolean	0
constraints/orbisack/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/orbisack/orbiSeparation	Separate orbisack inequalities? Range: boolean	0
constraints/orbisack/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

Option	Description	Default
constraints/orbisack/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.39.4.42 constraints/orbitope

Option	Description	Default
constraints/orbitope/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/orbitope/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
constraints/orbitope/checkpporbitope	Strengthen orbitope constraints to packing/partitioning orbitopes? Range: boolean	1
constraints/orbitope/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/orbitope/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/orbitope/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/orbitope/forceconscopy	Whether orbitope constraints should be forced to be copied to sub SCIPs. Range: boolean	0
constraints/orbitope/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/orbitope/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8
constraints/orbitope/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/orbitope/sepafulloorbitope	Whether we separate inequalities for full orbitopes? Range: boolean	0

5.39.4.43 constraints/setppc

Option	Description	Default
constraints/setppc/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/setppc/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
Options for expert users		
constraints/setppc/addvariablesascliques	should we try to generate extra cliques out of all binary variables to maybe fasten redundant constraint detection Range: boolean	0
constraints/setppc/cliquelifting	should we try to lift variables into other clique constraints, fix variables, aggregate them, and also shrink the amount of variables in clique constraints Range: boolean	0
constraints/setppc/cliquesthrinking	should we try to shrink the number of variables in a clique constraints, by replacing more than one variable by only one Range: boolean	1
constraints/setppc/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/setppc/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/setppc/dualpresolving	should dual presolving steps be performed? Range: boolean	1
constraints/setppc/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/setppc/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/setppc/npseudobranches	number of children created in pseudo branching (0: disable pseudo branching) Range: {0, ..., ∞ }	2
constraints/setppc/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/setppc/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/setppc/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1

Option	Description	Default
constraints/setppc/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.39.4.44 constraints/symresack

Option	Description	Default
constraints/symresack/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
constraints/symresack/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
Options for expert users		
constraints/symresack/checkmonotonicity	Check whether permutation is monotone when upgrading to packing/partioning symresacks? Range: boolean	1
constraints/symresack/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/symresack/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/symresack/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/symresack/forceconscopy	Whether symresack constraints should be forced to be copied to sub SCIPs. Range: boolean	0
constraints/symresack/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/symresack/ppsymresack	Upgrade symresack constraints to packing/partioning symresacks? Range: boolean	1
constraints/symresack/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16
constraints/symresack/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.39.4.45 constraints/varbound

Option	Description	Default
constraints/varbound/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/varbound/sepaftereq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
constraints/varbound/usebdwidening	should bound widening be used in conflict analysis? Range: boolean	1
Options for expert users		
constraints/varbound/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/varbound/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/varbound/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/varbound/maxlpcoef	maximum coefficient in varbound constraint to be added as a row into LP Range: [0, ∞]	1e+09
constraints/varbound/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
constraints/varbound/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/varbound/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	12
constraints/varbound/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.39.4.46 cutselection/hybrid

Option	Description	Default
cutselection/hybrid/dircutoffdistweight	weight of directed cutoff distance in cut score calculation Range: [0, ∞]	0
cutselection/hybrid/efficacyweight	weight of efficacy in cut score calculation Range: [0, ∞]	1
cutselection/hybrid/intsupportweight	weight of integral support in cut score calculation Range: [0, ∞]	0.1

Option	Description	Default
cutselection/hybrid/minortho	minimal orthogonality for a cut to enter the LP Range: [0, 1]	0.9
cutselection/hybrid/minorthoroot	minimal orthogonality for a cut to enter the LP in the root node Range: [0, 1]	0.9
cutselection/hybrid/objparalweight	weight of objective parallelism in cut score calculation Range: [0, ∞]	0.1
cutselection/hybrid/priority	priority of cut selection rule <hybrid> Range: {-536870912, ..., 1073741823}	8000

5.39.4.47 decomposition

Option	Description	Default
decomposition/disablemeasures	disable expensive measures Range: boolean	0
decomposition/maxgraphedge	maximum number of edges in block graph computation (-1: no limit, 0: disable block graph computation) Range: {-1, ..., ∞ }	10000

5.39.4.48 display

Option	Description	Default
display/allviols	display all violations for a given start solution / the best solution after the solving process? Range: boolean	0
display/freq	frequency for displaying node information lines Range: {-1, ..., ∞ }	100
display/headerfreq	frequency for displaying header lines (every n'th node information line) Range: {-1, ..., ∞ }	15
display/lpinfo	should the LP solver display status messages? Range: boolean	0
display/relevantstats	should the relevant statistics be displayed at the end of solving? Range: boolean	1
display/statistics	whether to print statistics on a solve and a provided decomposition Range: boolean	0
display/verblevel	verbosity level of output Range: {0, ..., 5}	4
display/width	maximal number of characters in a node information line Range: {0, ..., ∞ }	143 (80 for Windows without IDE)

5.39.4.49 display/avgdualbound

Option	Description	Default
display/avgdualbound/active	display activation status of display column <avgdualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.50 display/completed

Option	Description	Default
display/completed/active	display activation status of display column <completed> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.51 display/concdualbound

Option	Description	Default
display/concdualbound/active	display activation status of display column <concdualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.52 display/concgap

Option	Description	Default
display/concgap/active	display activation status of display column <concgap> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.53 display/concmemused

Option	Description	Default
display/concmemused/active	display activation status of display column <concmemused> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.54 display/concprimalbound

Option	Description	Default
display/concprimalbound/active	display activation status of display column <concprimalbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.55 display/concsolfound

Option	Description	Default
display/concsolfound/active	display activation status of display column <concsolfound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.56 display/conflicts

Option	Description	Default
display/conflicts/active	display activation status of display column <conflicts> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.57 display/conss

Option	Description	Default
display/conss/active	display activation status of display column <conss> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.58 display/curcols

Option	Description	Default
display/curcols/active	display activation status of display column <curcols> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.59 display/curconss

Option	Description	Default
display/curconss/active	display activation status of display column <curconss> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.60 display/curdualbound

Option	Description	Default
display/curdualbound/active	display activation status of display column <curdualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.61 display/currows

Option	Description	Default
display/currows/active	display activation status of display column <currows> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.62 display/cutoffbound

Option	Description	Default
display/cutoffbound/active	display activation status of display column <cutoffbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.63 display/cuts

Option	Description	Default
display/cuts/active	display activation status of display column <cuts> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.64 display/depth

Option	Description	Default
display/depth/active	display activation status of display column <depth> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.65 display/dualbound

Option	Description	Default
display/dualbound/active	display activation status of display column <dualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.66 display/estimate

Option	Description	Default
display/estimate/active	display activation status of display column <estimate> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.67 display/feasST

Option	Description	Default
display/feasST/active	display activation status of display column <feasST> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.39.4.68 display/gap

Option	Description	Default
display/gap/active	display activation status of display column <gap> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.69 display/lpavgiterations

Option	Description	Default
display/lpavgiterations/active	display activation status of display column <lpavgiterations> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1 (0 for Windows without IDE)

5.39.4.70 display/lpcond

Option	Description	Default
display/lpcond/active	display activation status of display column <lpcond> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.71 display/lpiterations

Option	Description	Default
display/lpiterations/active	display activation status of display column <lpiterations> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.72 display/lpobj

Option	Description	Default
display/lpobj/active	display activation status of display column <lpobj> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.73 display/maxdepth

Option	Description	Default
display/maxdepth/active	display activation status of display column <maxdepth> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1 (0 for Windows without IDE)

5.39.4.74 display/memtotal

Option	Description	Default
display/memtotal/active	display activation status of display column <memtotal> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.75 display/memused

Option	Description	Default
display/memused/active	display activation status of display column <memused> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.76 display/nexternbranchcands

Option	Description	Default
display/nexternbranchcands/active	display activation status of display column <nexternbranchcands> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.77 display/nfrac

Option	Description	Default
display/nfrac/active	display activation status of display column <nfrac> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.78 display/ninfeasleaves

Option	Description	Default
display/ninfeasleaves/active	display activation status of display column <ninfeasleaves> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.79 display/nnodes

Option	Description	Default
display/nnodes/active	display activation status of display column <nnodes> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.80 display/nnodesbelowinc

Option	Description	Default
display/nnodesbelowinc/active	display activation status of display column <nnodesbelowinc> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.39.4.81 display/nobjleaves

Option	Description	Default
display/nobjleaves/active	display activation status of display column <nobjleaves> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.82 display/nodesleft

Option	Description	Default
display/nodesleft/active	display activation status of display column <nodesleft> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.83 display/nrank1nodes

Option	Description	Default
display/nrank1nodes/active	display activation status of display column <nrank1nodes> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.39.4.84 display/nsols

Option	Description	Default
display/nsols/active	display activation status of display column <nsols> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.85 display/plungedepth

Option	Description	Default
display/plungedepth/active	display activation status of display column <plungedepth> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.86 display/poolsize

Option	Description	Default
display/poolsize/active	display activation status of display column <poolsize> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.87 display/primalbound

Option	Description	Default
display/primalbound/active	display activation status of display column <primalbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.88 display/primalgap

Option	Description	Default
display/primalgap/active	display activation status of display column <primalgap> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.39.4.89 display/pseudoobj

Option	Description	Default
display/pseudoobj/active	display activation status of display column <pseudoobj> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.90 display/separounds

Option	Description	Default
display/separounds/active	display activation status of display column <separounds> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.91 display/solfound

Option	Description	Default
display/solfound/active	display activation status of display column <solfound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.92 display/sols

Option	Description	Default
display/sols/active	display activation status of display column <sols> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.39.4.93 display/strongbranches

Option	Description	Default
display/strongbranches/active	display activation status of display column <strongbranches> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.94 display/time

Option	Description	Default
display/time/active	display activation status of display column <time> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1 (2 for Windows without IDE)

5.39.4.95 display/vars

Option	Description	Default
display/vars/active	display activation status of display column <vars> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.39.4.96 estimation

Option	Description	Default
estimation/coefmonoss	coefficient of 1 - SSG in monotone approximation of search completion Range: [0, 1]	0.6333
estimation/coefmonoweight	coefficient of tree weight in monotone approximation of search completion Range: [0, 1]	0.3667
estimation/completiontype	approximation of search tree completion: (a)uto, (g)ap, tree (w)eight, (m)onotone regression, (r)egression forest, (s)sg Range: a, g, m, r, s, w	a

Option	Description	Default
estimation/method	tree size estimation method: (c)ompletion, (e)nsemble, time series forecasts on either (g)ap, (l)eaf frequency, (o)pen nodes, tree (w)eight, (s)sg, or (t)ree profile or w(b)e Range: b, c, e, g, l, o, s, t, w	w
estimation/regforestfilename	user regression forest in RFCSV format Range: string	-
Options for expert users		
estimation/reportfreq	report frequency on estimation: -1: never, 0:always, $k \geq 1$: k times evenly during search Range: {-1, ..., 1073741823}	-1
estimation/useleaft	use leaf nodes as basic observations for time series, or all nodes? Range: boolean	1

5.39.4.97 estimation/restarts

Option	Description	Default
estimation/restarts/countonlyleaves	should only leaves count for the minnodes parameter? Range: boolean	0
estimation/restarts/hitcounterlim	limit on the number of successive samples to really trigger a restart Range: {1, ..., ∞ }	50
estimation/restarts/minnodes	minimum number of nodes before restart Range: {-1, ..., ∞ }	1000
estimation/restarts/restartactpricers	whether to apply a restart when active pricers are used Range: boolean	0
estimation/restarts/restartfactor	factor by which the estimated number of nodes should exceed the current number of nodes Range: [1, ∞]	50
estimation/restarts/restartlimit	restart limit Range: {-1, ..., ∞ }	1
estimation/restarts/restartnonlinear	whether to apply a restart when nonlinear constraints are present Range: boolean	0
estimation/restarts/restartpolicy	restart policy: (a)lways, (c)ompletion, (e)stimation, (n)ever Range: a, c, e, n	e

5.39.4.98 estimation/ssg

Option	Description	Default
estimation/ssg/nmaxsubtrees	the maximum number of individual SSG subtrees; -1: no limit Range: {-1, ..., 1073741823}	-1
estimation/ssg/nminnodeslastsplit	minimum number of nodes to process between two consecutive SSG splits Range: {0, ..., ∞ }	0

5.39.4.99 estimation/treeprofile

Option	Description	Default
estimation/treeprofile/enabled	should the event handler collect data? Range: boolean	0
estimation/treeprofile/minnodesperdepth	minimum average number of nodes at each depth before producing estimations Range: $[1, \infty]$	20

5.39.4.100 expr/log

Option	Description	Default
expr/log/minzerodistance	minimal distance from zero to enforce for child in bound tightening Range: $[0, 1]$	1e-09

5.39.4.101 expr/pow

Option	Description	Default
expr/pow/minzerodistance	minimal distance from zero to enforce for child in bound tightening Range: $[0, 1]$	1e-09

5.39.4.102 heuristics

Option	Description	Default
Options for expert users		
heuristics/useuctsubscip	should setting of common subscip parameters include the activation of the UCT node selector? Range: boolean	0

5.39.4.103 heuristics/actconsdiving

Option	Description	Default
heuristics/actconsdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/actconsdiving/freq	frequency for calling primal heuristic <actconsdiving> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	-1
heuristics/actconsdiving/freqofs	frequency offset for calling primal heuristic <actconsdiving> Range: $\{0, \dots, 65534\}$	5
heuristics/actconsdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: $[0, \infty]$	0.15

Option	Description	Default
heuristics/actconsdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞ }	0
heuristics/actconsdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1000
heuristics/actconsdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/actconsdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	1
Options for expert users		
heuristics/actconsdiving/maxdepth	maximal depth level to call primal heuristic <actconsdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/actconsdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/actconsdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	1
heuristics/actconsdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/actconsdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	1
heuristics/actconsdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/actconsdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/actconsdiving/priority	priority of heuristic <actconsdiving> Range: {-536870912, ..., 536870911}	-1003700

5.39.4.104 heuristics/adaptivediving

Option	Description	Default
heuristics/adaptivediving/bestsolweight	weight of incumbent solutions compared to other solutions in computation of LP iteration limit Range: [0, ∞]	10
heuristics/adaptivediving/epsilon	parameter that increases probability of exploration among divesets (only active if sel-type is 'e') Range: [0, ∞]	1

Option	Description	Default
heuristics/adaptivediving/freq	frequency for calling primal heuristic <adaptivediving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	5
heuristics/adaptivediving/freqofs	frequency offset for calling primal heuristic <adaptivediving> Range: {0, ..., 65534}	3
heuristics/adaptivediving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1500
heuristics/adaptivediving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.1
heuristics/adaptivediving/scoretype	score parameter for selection: minimize either average 'n'odes, LP 'i'terations,backtrack/'c'onflict ratio, 'd'e'pth, 1 / 's'o'lutions, or 1 / solutions'u'ccess Range: c, d, i, n, s, u	c
heuristics/adaptivediving/selconfidencecoeff	coefficient c to decrease initial confidence (calls + 1.0) / (calls + c) in scores Range: [1, 2.14748e+09]	10
heuristics/adaptivediving/seltype	selection strategy: (e)psilon-greedy, (w)weighted distribution, (n)ext diving Range: e, n, w	w
Options for expert users		
heuristics/adaptivediving/maxdepth	maximal depth level to call primal heuristic <adaptivediving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/adaptivediving/priority	priority of heuristic <adaptivediving> Range: {-536870912, ..., 536870911}	-70000
heuristics/adaptivediving/useadaptivecontext	should the heuristic use its own statistics, or shared statistics? Range: boolean	0

5.39.4.105 heuristics/alns

Option	Description	Default
heuristics/alns/freq	frequency for calling primal heuristic <alns> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/alns/freqofs	frequency offset for calling primal heuristic <alns> Range: {0, ..., 65534}	0
heuristics/alns/nodesofs	offset added to the nodes budget Range: {0, ..., ∞ }	500
heuristics/alns/nodesquot	fraction of nodes compared to the main SCIP for budget computation Range: [0, 1]	0.1
heuristics/alns/nodesquotmin	lower bound fraction of nodes compared to the main SCIP for budget computation Range: [0, 1]	0

Option	Description	Default
heuristics/alns/nsolslim	limit on the number of improving solutions in a sub-SCIP call Range: $\{-1, \dots, \infty\}$	3
heuristics/alns/seed	initial random seed for bandit algorithms and random decisions by neighborhoods Range: $\{0, \dots, \infty\}$	113
Options for expert users		
heuristics/alns/adjustfixingrate	should the heuristic adjust the target fixing rate based on the success? Range: boolean	1
heuristics/alns/adjustminimprove	should the factor by which the minimum improvement is bound be dynamically updated? Range: boolean	0
heuristics/alns/adjusttargetnodes	should the target nodes be dynamically adjusted? Range: boolean	1
heuristics/alns/alpha	parameter to increase the confidence width in UCB Range: $[0, 100]$	0.0016
heuristics/alns/banditalgo	the bandit algorithm: (u)pper confidence bounds, (e)xp.3, epsilon (g)reedy Range: u, e, g	u
heuristics/alns/beta	reward offset between 0 and 1 at every observation for Exp.3 Range: $[0, 1]$	0
heuristics/alns/copycuts	should cutting planes be copied to the sub-SCIP? Range: boolean	0
heuristics/alns/domorefixings	should the ALNS heuristic do more fixings by itself based on variable prioritization until the target fixing rate is reached? Range: boolean	1
heuristics/alns/eps	increase exploration in epsilon-greedy bandit algorithm Range: $[0, 1]$	0.468584
heuristics/alns/fixtol	tolerance by which the fixing rate may be missed without generic fixing Range: $[0, 1]$	0.1
heuristics/alns/gamma	weight between uniform ($\gamma \sim 1$) and weight driven ($\gamma \sim 0$) probability distribution for exp3 Range: $[0, 1]$	0.0704146
heuristics/alns/initduringroot	should the heuristic be executed multiple times during the root node? Range: boolean	0
heuristics/alns/maxcallssamesol	number of allowed executions of the heuristic on the same incumbent solution (-1: no limit, 0: number of active neighborhoods) Range: $\{-1, \dots, 100\}$	-1
heuristics/alns/maxdepth	maximal depth level to call primal heuristic <alns> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/alns/maxnodes	maximum number of nodes to regard in the subproblem Range: $\{0, \dots, \infty\}$	5000

Option	Description	Default
heuristics/alns/minimprovehigh	upper bound for the minimal improvement over the incumbent Range: [0, 1]	0.01
heuristics/alns/minimprovelow	lower threshold for the minimal improvement over the incumbent Range: [0, 1]	0.01
heuristics/alns/minnodes	minimum number of nodes required to start a sub-SCIP Range: {0, ..., ∞}	50
heuristics/alns/priority	priority of heuristic <alns> Range: {-536870912, ..., 536870911}	-1100500
heuristics/alns/resetweights	should the bandit algorithms be reset when a new problem is read? Range: boolean	1
heuristics/alns/rewardbaseline	the reward baseline to separate successful and failed calls Range: [0, 0.99]	0.5
heuristics/alns/rewardcontrol	reward control to increase the weight of the simple solution indicator and decrease the weight of the closed gap reward Range: [0, 1]	0.8
heuristics/alns/rewardfilename	file name to store all rewards and the selection of the bandit Range: string	-
heuristics/alns/scalebyeffort	should the reward be scaled by the effort? Range: boolean	1
heuristics/alns/startminimprove	initial factor by which ALNS should at least improve the incumbent Range: [0, 1]	0.01
heuristics/alns/subsciprandseeds	should random seeds of sub-SCIPs be altered to increase diversification? Range: boolean	0
heuristics/alns/targetnodefactor	factor by which target node number is eventually increased Range: [1, 100000]	1.05
heuristics/alns/unfixtol	tolerance by which the fixing rate may be exceeded without generic unfixing Range: [0, 1]	0.1
heuristics/alns/usedistances	distances from fixed variables be used for variable prioritization Range: boolean	1
heuristics/alns/uselocalredcost	should local reduced costs be used for generic (un)fixing? Range: boolean	0
heuristics/alns/usepscost	should pseudo cost scores be used for variable prioritization? Range: boolean	1
heuristics/alns/useredcost	should reduced cost scores be used for variable prioritization? Range: boolean	1
heuristics/alns/usesubscipheurs	should the heuristic activate other sub-SCIP heuristics during its search? Range: boolean	0

Option	Description	Default
heuristics/alns/waitingnodes	number of nodes since last incumbent solution that the heuristic should wait Range: $\{0, \dots, \infty\}$	25

5.39.4.106 heuristics/alns/crossover

Option	Description	Default
Options for expert users		
heuristics/alns/crossover/active	is this neighborhood active? Range: boolean	1
heuristics/alns/crossover/maxfixingrate	maximum fixing rate for this neighborhood Range: $[0, 1]$	0.9
heuristics/alns/crossover/minfixingrate	minimum fixing rate for this neighborhood Range: $[0, 1]$	0.3
heuristics/alns/crossover/nsols	the number of solutions that crossover should combine Range: $\{2, \dots, 10\}$	2
heuristics/alns/crossover/priority	positive call priority to initialize bandit algorithms Range: $[0.01, 1]$	1

5.39.4.107 heuristics/alns/dins

Option	Description	Default
Options for expert users		
heuristics/alns/dins/active	is this neighborhood active? Range: boolean	1
heuristics/alns/dins/maxfixingrate	maximum fixing rate for this neighborhood Range: $[0, 1]$	0.9
heuristics/alns/dins/minfixingrate	minimum fixing rate for this neighborhood Range: $[0, 1]$	0.3
heuristics/alns/dins/npoolsols	number of pool solutions where binary solution values must agree Range: $\{1, \dots, 100\}$	5
heuristics/alns/dins/priority	positive call priority to initialize bandit algorithms Range: $[0.01, 1]$	1

5.39.4.108 heuristics/alns/localbranching

Option	Description	Default
Options for expert users		
heuristics/alns/localbranching/active	is this neighborhood active? Range: boolean	1
heuristics/alns/localbranching/maxfixingrate	maximum fixing rate for this neighborhood Range: $[0, 1]$	0.9
heuristics/alns/localbranching/minfixingrate	minimum fixing rate for this neighborhood Range: $[0, 1]$	0.3

Option	Description	Default
heuristics/alns/localbranching/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.39.4.109 heuristics/alns/mutation

Option	Description	Default
Options for expert users		
heuristics/alns/mutation/active	is this neighborhood active? Range: boolean	1
heuristics/alns/mutation/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/mutation/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/mutation/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.39.4.110 heuristics/alns/proximity

Option	Description	Default
Options for expert users		
heuristics/alns/proximity/active	is this neighborhood active? Range: boolean	1
heuristics/alns/proximity/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/proximity/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/proximity/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.39.4.111 heuristics/alns/rens

Option	Description	Default
Options for expert users		
heuristics/alns/rens/active	is this neighborhood active? Range: boolean	1
heuristics/alns/rens/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/rens/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/rens/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.39.4.112 heuristics/alns/rins

Option	Description	Default
Options for expert users		
heuristics/alns/rins/active	is this neighborhood active? Range: boolean	1
heuristics/alns/rins/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/rins/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/rins/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.39.4.113 heuristics/alns/trustregion

Option	Description	Default
heuristics/alns/trustregion/violpenalty	the penalty for each change in the binary variables from the candidate solution Range: [0, ∞]	100
Options for expert users		
heuristics/alns/trustregion/active	is this neighborhood active? Range: boolean	0
heuristics/alns/trustregion/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/trustregion/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/trustregion/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.39.4.114 heuristics/alns/zeroobjective

Option	Description	Default
Options for expert users		
heuristics/alns/zeroobjective/active	is this neighborhood active? Range: boolean	1
heuristics/alns/zeroobjective/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/zeroobjective/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/zeroobjective/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.39.4.115 heuristics/bound

Option	Description	Default
heuristics/bound/bound	to which bound should integer variables be fixed? (l'ower, u'pper, or b'oth) Range: l, u, b	1

Option	Description	Default
heuristics/bound/freq	frequency for calling primal heuristic <bound> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/bound/freqofs	frequency offset for calling primal heuristic <bound> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/bound/maxdepth	maximal depth level to call primal heuristic <bound> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/bound/maxpropounds	maximum number of propagation rounds during probing (-1 infinity, -2 parameter settings) Range: {-1, ..., 536870911}	0
heuristics/bound/onlywithoutsol	Should heuristic only be executed if no primal solution was found, yet? Range: boolean	1
heuristics/bound/priority	priority of heuristic <bound> Range: {-536870912, ..., 536870911}	-1107000

5.39.4.116 heuristics/cliquote

Option	Description	Default
heuristics/cliquote/freq	frequency for calling primal heuristic <cliquote> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/cliquote/freqofs	frequency offset for calling primal heuristic <cliquote> Range: {0, ..., 65534}	0
heuristics/cliquote/minintfixingrate	minimum percentage of integer variables that have to be fixable Range: [0, 1]	0.65
heuristics/cliquote/minmipfixingrate	minimum percentage of fixed variables in the sub-MIP Range: [0, 1]	0.65
heuristics/cliquote/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/cliquote/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/cliquote/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/cliquote/maxbacktracks	maximum number of backtracks during the fixing process Range: {-1, ..., 536870911}	10
heuristics/cliquote/maxdepth	maximal depth level to call primal heuristic <cliquote> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/cliquote/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	5000

Option	Description	Default
heuristics/cliقة/maxpropounds	maximum number of propagation rounds during probing (-1 infinity) Range: {-1, ..., 536870911}	2
heuristics/cliقة/minimprove	factor by which clique heuristic should at least improve the incumbent Range: [0, 1]	0.01
heuristics/cliقة/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	500
heuristics/cliقة/priority	priority of heuristic <cliقة> Range: {-536870912, ..., 536870911}	5000
heuristics/cliقة/uselockfixings	should more variables be fixed based on variable locks if the fixing rate was not reached? Range: boolean	0

5.39.4.117 heuristics/coefdiving

Option	Description	Default
heuristics/coefdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/coefdiving/freq	frequency for calling primal heuristic <coefdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/coefdiving/freqofs	frequency offset for calling primal heuristic <coefdiving> Range: {0, ..., 65534}	1
heuristics/coefdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/coefdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/coefdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/coefdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/coefdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/coefdiving/maxdepth	maximal depth level to call primal heuristic <coefdiving> (-1: no limit) Range: {-1, ..., 65534}	-1

Option	Description	Default
heuristics/coefdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: $[0, \infty]$	0
heuristics/coefdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: $[0, \infty]$	0
heuristics/coefdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: $[0, 1]$	0.8
heuristics/coefdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: $[0, 1]$	0.1
heuristics/coefdiving/maxreldepth	maximal relative depth to start diving Range: $[0, 1]$	1
heuristics/coefdiving/minreldepth	minimal relative depth to start diving Range: $[0, 1]$	0
heuristics/coefdiving/priority	priority of heuristic <coefdiving> Range: $\{-536870912, \dots, 536870911\}$	-1001000

5.39.4.118 heuristics/completesol

Option	Description	Default
heuristics/completesol/beforepresol	should the heuristic run before presolving? Range: boolean	1
heuristics/completesol/freq	frequency for calling primal heuristic <completesol> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	0
heuristics/completesol/freqofs	frequency offset for calling primal heuristic <completesol> Range: $\{0, \dots, 65534\}$	0
heuristics/completesol/ignorecont	should number of continuous variables be ignored? Range: boolean	0
heuristics/completesol/maxcontvars	maximal number of continuous variables after presolving Range: $\{-1, \dots, \infty\}$	-1
heuristics/completesol/maxlpiter	maximal number of LP iterations (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
heuristics/completesol/maxpropounds	maximal number of iterations in propagation (-1: no limit) Range: $\{-1, \dots, \infty\}$	10
heuristics/completesol/maxunknownrate	maximal rate of unknown solution values Range: $[0, 1]$	0.85
heuristics/completesol/nodesofs	number of nodes added to the contingent of the total nodes Range: $\{0, \dots, \infty\}$	500

Option	Description	Default
heuristics/completesol/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/completesol/solutions	heuristic stops, if the given number of improving solutions were found (-1: no limit) Range: {-1, ..., ∞}	5
Options for expert users		
heuristics/completesol/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/completesol/boundwidening	bound widening factor applied to continuous variables (0: fix variables to given solution values, 1: relax to global bounds) Range: [0, 1]	0.1
heuristics/completesol/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/completesol/maxdepth	maximal depth level to call primal heuristic <completesol> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/completesol/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/completesol/minimprove	factor by which the incumbent should be improved at least Range: [0, 1]	0.01
heuristics/completesol/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/completesol/objweight	weight of the original objective function (1: only original objective) Range: [0.001, 1]	1
heuristics/completesol/priority	priority of heuristic <completesol> Range: {-536870912, ..., 536870911}	0

5.39.4.119 heuristics/conflictdiving

Option	Description	Default
heuristics/conflictdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/conflictdiving/freq	frequency for calling primal heuristic <conflictdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/conflictdiving/freqofs	frequency offset for calling primal heuristic <conflictdiving> Range: {0, ..., 65534}	0
heuristics/conflictdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15

Option	Description	Default
heuristics/conflictdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞ }	0
heuristics/conflictdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1000
heuristics/conflictdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.15
heuristics/conflictdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/conflictdiving/likecoef	perform rounding like coefficient diving Range: boolean	0
heuristics/conflictdiving/lockweight	weight used in a convex combination of conflict and variable locks Range: [0, 1]	0.75
heuristics/conflictdiving/maxdepth	maximal depth level to call primal heuristic <conflictdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/conflictdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/conflictdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/conflictdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/conflictdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/conflictdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/conflictdiving/maxviol	try to maximize the violation Range: boolean	1
heuristics/conflictdiving/minconflictlocks	minimal number of conflict locks per variable Range: {0, ..., ∞ }	5
heuristics/conflictdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/conflictdiving/priority	priority of heuristic <conflictdiving> Range: {-536870912, ..., 536870911}	-1000100

5.39.4.120 heuristics/crossover

Option	Description	Default
heuristics/crossover/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: $\{-1, \dots, \infty\}$	-1
heuristics/crossover/freq	frequency for calling primal heuristic <crossover> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	30
heuristics/crossover/freqofs	frequency offset for calling primal heuristic <crossover> Range: $\{0, \dots, 65534\}$	0
heuristics/crossover/minfixingrate	minimum percentage of integer variables that have to be fixed Range: $[0, 1]$	0.666
heuristics/crossover/nodesofs	number of nodes added to the contingent of the total nodes Range: $\{0, \dots, \infty\}$	500
heuristics/crossover/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: $[0, 1]$	0.1
heuristics/crossover/nusedsols	number of solutions to be taken into account Range: $\{2, \dots, \infty\}$	3
Options for expert users		
heuristics/crossover/copycuts	if useprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/crossover/dontwaitatroot	should the nwaitingnodes parameter be ignored at the root node? Range: boolean	0
heuristics/crossover/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: $[1, \infty]$	2
heuristics/crossover/maxdepth	maximal depth level to call primal heuristic <crossover> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/crossover/maxnodes	maximum number of nodes to regard in the subproblem Range: $\{0, \dots, \infty\}$	5000
heuristics/crossover/minimprove	factor by which Crossover should at least improve the incumbent Range: $[0, 1]$	0.01
heuristics/crossover/minnodes	minimum number of nodes required to start the subproblem Range: $\{0, \dots, \infty\}$	50
heuristics/crossover/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: $\{0, \dots, \infty\}$	200
heuristics/crossover/permute	should the subproblem be permuted to increase diversification? Range: boolean	0
heuristics/crossover/priority	priority of heuristic <crossover> Range: $\{-536870912, \dots, 536870911\}$	-1104000
heuristics/crossover/randomization	should the choice which sols to take be randomized? Range: boolean	1

Option	Description	Default
heuristics/crossover/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/crossover/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.39.4.121 heuristics/dins

Option	Description	Default
heuristics/dins/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: $\{-1, \dots, \infty\}$	3
heuristics/dins/freq	frequency for calling primal heuristic <dins> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	-1
heuristics/dins/freqofs	frequency offset for calling primal heuristic <dins> Range: $\{0, \dots, 65534\}$	0
heuristics/dins/minfixingrate	minimum percentage of integer variables that have to be fixable Range: $[0, 1]$	0.3
heuristics/dins/minnodes	minimum number of nodes required to start the subproblem Range: $\{0, \dots, \infty\}$	50
heuristics/dins/neighborhoodsize	radius (using Manhattan metric) of the incumbent's neighborhood to be searched Range: $\{1, \dots, \infty\}$	18
heuristics/dins/nodesofs	number of nodes added to the contingent of the total nodes Range: $\{0, \dots, \infty\}$	5000
heuristics/dins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: $[0, 1]$	0.05
heuristics/dins/solnum	number of pool-solutions to be checked for flag array update (for hard fixing of binary variables) Range: $\{1, \dots, \infty\}$	5
Options for expert users		
heuristics/dins/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/dins/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: $[1, \infty]$	1.5
heuristics/dins/maxdepth	maximal depth level to call primal heuristic <dins> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/dins/maxnodes	maximum number of nodes to regard in the subproblem Range: $\{0, \dots, \infty\}$	5000
heuristics/dins/minimprove	factor by which dins should at least improve the incumbent Range: $[0, 1]$	0.01

Option	Description	Default
heuristics/dins/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞ }	200
heuristics/dins/priority	priority of heuristic <dins> Range: {-536870912, ..., 536870911}	-1105000
heuristics/dins/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/dins/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.39.4.122 heuristics/distributiondiving

Option	Description	Default
heuristics/distributiondiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/distributiondiving/freq	frequency for calling primal heuristic <distributiondiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/distributiondiving/freqofs	frequency offset for calling primal heuristic <distributiondiving> Range: {0, ..., 65534}	3
heuristics/distributiondiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/distributiondiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞ }	0
heuristics/distributiondiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1000
heuristics/distributiondiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/distributiondiving/onlylpbranchcandidates	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	1
Options for expert users		
heuristics/distributiondiving/maxdepth	maximal depth level to call primal heuristic <distributiondiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/distributiondiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0

Option	Description	Default
heuristics/distributiondiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/distributiondiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/distributiondiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/distributiondiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/distributiondiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/distributiondiving/priority	priority of heuristic <distributiondiving> Range: {-536870912, ..., 536870911}	-1003300
heuristics/distributiondiving/scoreparam	the score;largest 'd'ifference, 'l'owest cumulative probability,'h'ighest c.p., 'v'otes lowest c.p., votes highest c.p.('w'), 'r'evolving Range: l, v, d, h, w, r	r

5.39.4.123 heuristics/dps

Option	Description	Default
heuristics/dps/freq	frequency for calling primal heuristic <dps> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/dps/freqofs	frequency offset for calling primal heuristic <dps> Range: {0, ..., 65534}	0
heuristics/dps/maxiterations	maximal number of iterations Range: {1, ..., ∞ }	50
heuristics/dps/maxlinkscore	maximal linking score of used decomposition (equivalent to percentage of linking constraints) Range: [0, 1]	1
heuristics/dps/penalty	multiplier for absolute increase of penalty parameters (0: no increase) Range: [0, ∞]	100
heuristics/dps/reoptimize	should the problem get reoptimized with the original objective function? Range: boolean	0
heuristics/dps/reuse	should solutions get reused in subproblems? Range: boolean	0
Options for expert users		
heuristics/dps/maxdepth	maximal depth level to call primal heuristic <dps> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/dps/priority	priority of heuristic <dps> Range: {-536870912, ..., 536870911}	75000

5.39.4.124 heuristics/dualval

Option	Description	Default
heuristics/dualval/dynamicdepth	says if and how the recursion depth is computed at runtime Range: {0, ..., 1}	0
heuristics/dualval/freq	frequency for calling primal heuristic <dualval> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/dualval/freqofs	frequency offset for calling primal heuristic <dualval> Range: {0, ..., 65534}	0
heuristics/dualval/heurverblevel	verblevel of the heuristic, default is 0 to display nothing Range: {0, ..., 4}	0
heuristics/dualval/lambdaobj	scaling factor for the objective function Range: [0, 1]	0
heuristics/dualval/lambdaslack	value added to objective of slack variables, must not be zero Range: [0.1, ∞]	1
heuristics/dualval/maxcalls	maximal number of recursive calls of the heuristic (if dynamicdepth is off) Range: {0, ..., ∞ }	25
heuristics/dualval/maxequalranks	maximal number of variables that may have maximal rank, quit if there are more, turn off by setting -1 Range: {-1, ..., ∞ }	50
heuristics/dualval/mingap	minimal gap for which we still run the heuristic, if gap is less we return without doing anything Range: [0, 100]	5
heuristics/dualval/nlpverblevel	verblevel of the nlp solver, can be 0 or 1 Range: {0, ..., 1}	0
heuristics/dualval/onlyleaves	disable the heuristic if it was not called at a leaf of the B&B tree Range: boolean	0
heuristics/dualval/rankvalue	number of ranks that should be displayed when the heuristic is called Range: {0, ..., ∞ }	10
heuristics/dualval/relaxcontvars	relax the continuous variables Range: boolean	0
heuristics/dualval/relaxindicators	relax the indicator variables by introducing continuous copies Range: boolean	0
Options for expert users		
heuristics/dualval/forceimprovements	exit if objective doesn't improve Range: boolean	0
heuristics/dualval/maxdepth	maximal depth level to call primal heuristic <dualval> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/dualval/onlycheaper	add constraint to ensure that discrete vars are improving Range: boolean	1

Option	Description	Default
heuristics/dualval/priority	priority of heuristic <dualval> Range: {-536870912, ..., 536870911}	-10

5.39.4.125 heuristics/farkasdiving

Option	Description	Default
heuristics/farkasdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/farkasdiving/freq	frequency for calling primal heuristic <farkasdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/farkasdiving/freqofs	frequency offset for calling primal heuristic <farkasdiving> Range: {0, ..., 65534}	0
heuristics/farkasdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/farkasdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	1
heuristics/farkasdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/farkasdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/farkasdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/farkasdiving/checkcands	should diving candidates be checked before running? Range: boolean	0
heuristics/farkasdiving/maxdepth	maximal depth level to call primal heuristic <farkasdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/farkasdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/farkasdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/farkasdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8

Option	Description	Default
heuristics/farkasdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/farkasdiving/maxobjocc	maximal occurrence factor of an objective coefficient Range: [0, 1]	1
heuristics/farkasdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/farkasdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/farkasdiving/objdynamism	minimal objective dynamism (log) to run Range: [0, ∞]	0.0001
heuristics/farkasdiving/priority	priority of heuristic <farkasdiving> Range: {-536870912, ..., 536870911}	-900000
heuristics/farkasdiving/rootsuccess	should the heuristic only run within the tree if at least one solution was found at the root node? Range: boolean	1
heuristics/farkasdiving/scalescore	should the score be scaled? Range: boolean	1
heuristics/farkasdiving/scaletype	scale score by [f]ractionality or [i]mpact on farkasproof Range: f, i	i

5.39.4.126 heuristics/feaspump

Option	Description	Default
heuristics/feaspump/alpha	initial weight of the objective function in the convex combination Range: [0, 1]	1
heuristics/feaspump/alphadiff	threshold difference for the convex parameter to perform perturbation Range: [0, 1]	1
heuristics/feaspump/beforecuts	should the feasibility pump be called at root node before cut separation? Range: boolean	1
heuristics/feaspump/freq	frequency for calling primal heuristic <feaspump> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/feaspump/freqofs	frequency offset for calling primal heuristic <feaspump> Range: {0, ..., 65534}	0
heuristics/feaspump/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1000
heuristics/feaspump/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.01
heuristics/feaspump/neighborhoodsize	radius (using Manhattan metric) of the neighborhood to be searched in stage 3 Range: {1, ..., ∞ }	18

Option	Description	Default
heuristics/feaspump/objfactor	factor by which the regard of the objective is decreased in each round, 1.0 for dynamic Range: [0, 1]	0.1
heuristics/feaspump/pertsolfound	should a random perturbation be performed if a feasible solution was found? Range: boolean	1
heuristics/feaspump/stage3	should we solve a local branching sub-MIP if no solution could be found? Range: boolean	0
heuristics/feaspump/usefp20	should an iterative round-and-propagate scheme be used to find the integral points? Range: boolean	0
Options for expert users		
heuristics/feaspump/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/feaspump/cyclelength	maximum length of cycles to be checked explicitly in each round Range: {1, ..., 100}	3
heuristics/feaspump/maxdepth	maximal depth level to call primal heuristic <feaspump> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/feaspump/maxloops	maximal number of pumping loops (-1: no limit) Range: {-1, ..., ∞}	10000
heuristics/feaspump/maxsols	total number of feasible solutions found up to which heuristic is called (-1: no limit) Range: {-1, ..., ∞}	10
heuristics/feaspump/maxstallloops	maximal number of pumping rounds without fractionality improvement (-1: no limit) Range: {-1, ..., ∞}	10
heuristics/feaspump/minflips	minimum number of random variables to flip, if a 1-cycle is encountered Range: {1, ..., ∞}	10
heuristics/feaspump/perturbfreq	number of iterations until a random perturbation is forced Range: {1, ..., ∞}	100
heuristics/feaspump/priority	priority of heuristic <feaspump> Range: {-536870912, ..., 536870911}	-1000000

5.39.4.127 heuristics/fixandinfer

Option	Description	Default
heuristics/fixandinfer/freq	frequency for calling primal heuristic <fixandinfer> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/fixandinfer/freqofs	frequency offset for calling primal heuristic <fixandinfer> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/fixandinfer/maxdepth	maximal depth level to call primal heuristic <fixandinfer> (-1: no limit) Range: {-1, ..., 65534}	-1

Option	Description	Default
heuristics/fixandinfer/minfixings	minimal number of fixings to apply before dive may be aborted Range: $\{0, \dots, \infty\}$	100
heuristics/fixandinfer/priority	priority of heuristic <fixandinfer> Range: $\{-536870912, \dots, 536870911\}$	-500000
heuristics/fixandinfer/proprounds	maximal number of propagation rounds in probing subproblems (-1: no limit, 0: auto) Range: $\{-1, \dots, \infty\}$	0

5.39.4.128 heuristics/fracdiving

Option	Description	Default
heuristics/fracdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/fracdiving/freq	frequency for calling primal heuristic <fracdiving> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	10
heuristics/fracdiving/freqofs	frequency offset for calling primal heuristic <fracdiving> Range: $\{0, \dots, 65534\}$	3
heuristics/fracdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: $[0, \infty]$	0.15
heuristics/fracdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: $\{0, \dots, \infty\}$	0
heuristics/fracdiving/maxlpiterofs	additional number of allowed LP iterations Range: $\{0, \dots, \infty\}$	1000
heuristics/fracdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: $[0, \infty]$	0.05
heuristics/fracdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/fracdiving/maxdepth	maximal depth level to call primal heuristic <fracdiving> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/fracdiving/maxdiveavgquot	maximal quotient $(\text{curlowerbound} - \text{lowerbound}) / (\text{avglowerbound} - \text{lowerbound})$ where diving is performed (0.0: no limit) Range: $[0, \infty]$	0
heuristics/fracdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: $[0, \infty]$	0

Option	Description	Default
heuristics/fracdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/fracdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/fracdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/fracdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/fracdiving/priority	priority of heuristic <fracdiving> Range: {-536870912, ..., 536870911}	-1003000

5.39.4.129 heuristics/gins

Option	Description	Default
heuristics/gins/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞ }	3
heuristics/gins/freq	frequency for calling primal heuristic <gins> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/gins/freqofs	frequency offset for calling primal heuristic <gins> Range: {0, ..., 65534}	8
heuristics/gins/maxdistance	maximum distance to selected variable to enter the subproblem, or -1 to select the distance that best approximates the minimum fixing rate from below Range: {-1, ..., ∞ }	3
heuristics/gins/minfixingrate	percentage of integer variables that have to be fixed Range: [1e-06, 0.999999]	0.66
heuristics/gins/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/gins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.15
Options for expert users		
heuristics/gins/consecutiveblocks	should blocks be treated consecutively (sorted by ascending label?) Range: boolean	1
heuristics/gins/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/gins/fixcontvars	should continuous variables outside the neighborhoods be fixed? Range: boolean	0

Option	Description	Default
heuristics/gins/maxdepth	maximal depth level to call primal heuristic <gins> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/gins/maxnodes	maximum number of nodes to regard in the sub-problem Range: {0, ..., ∞ }	5000
heuristics/gins/minimprove	factor by which gins should at least improve the incumbent Range: [0, 1]	0.01
heuristics/gins/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	50
heuristics/gins/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞ }	100
heuristics/gins/overlap	overlap of blocks between runs - 0.0: no overlap, 1.0: shift by only 1 block Range: [0, 1]	0
heuristics/gins/potential	the reference point to compute the neighborhood potential: (r)oot, (l)ocal lp, or (p)seudo solution Range: l, p, r	r
heuristics/gins/priority	priority of heuristic <gins> Range: {-536870912, ..., 536870911}	-1103000
heuristics/gins/relaxdenseconss	should dense constraints (at least as dense as 1 - minfixingrate) be ignored by connectivity graph? Range: boolean	0
heuristics/gins/rollhorizonlimfac	limiting percentage for variables already used in sub-SCIPs to terminate rolling horizon approach Range: [0, 1]	0.4
heuristics/gins/usedecomp	should user decompositions be considered, if available? Range: boolean	1
heuristics/gins/usedecomprollhorizon	should user decompositions be considered for initial selection in rolling horizon, if available? Range: boolean	0
heuristics/gins/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/gins/userollinghorizon	should the heuristic solve a sequence of sub-MIP's around the first selected variable Range: boolean	1
heuristics/gins/useselffallback	should random initial variable selection be used if decomposition was not successful? Range: boolean	1

5.39.4.130 heuristics/guideddiving

Option	Description	Default
heuristics/guideddiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1

Option	Description	Default
heuristics/guideddiving/freq	frequency for calling primal heuristic <guideddiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/guideddiving/freqofs	frequency offset for calling primal heuristic <guideddiving> Range: {0, ..., 65534}	7
heuristics/guideddiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/guideddiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞ }	0
heuristics/guideddiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1000
heuristics/guideddiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/guideddiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/guideddiving/maxdepth	maximal depth level to call primal heuristic <guideddiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/guideddiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/guideddiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	1
heuristics/guideddiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/guideddiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	1
heuristics/guideddiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/guideddiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/guideddiving/priority	priority of heuristic <guideddiving> Range: {-536870912, ..., 536870911}	-1007000

5.39.4.131 heuristics/indicator

Option	Description	Default
heuristics/indicator/freq	frequency for calling primal heuristic <indicator> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/indicator/freqofs	frequency offset for calling primal heuristic <indicator> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/indicator/improvesols	Try to improve other solutions by one-opt? Range: boolean	0
heuristics/indicator/maxdepth	maximal depth level to call primal heuristic <indicator> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/indicator/oneopt	whether the one-opt heuristic should be started Range: boolean	0
heuristics/indicator/priority	priority of heuristic <indicator> Range: {-536870912, ..., 536870911}	-20200

5.39.4.132 heuristics/intdiving

Option	Description	Default
heuristics/intdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/intdiving/freq	frequency for calling primal heuristic <intdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/intdiving/freqofs	frequency offset for calling primal heuristic <intdiving> Range: {0, ..., 65534}	9
heuristics/intdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1000
heuristics/intdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
Options for expert users		
heuristics/intdiving/maxdepth	maximal depth level to call primal heuristic <intdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/intdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/intdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/intdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8

Option	Description	Default
heuristics/intdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/intdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/intdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/intdiving/priority	priority of heuristic <intdiving> Range: {-536870912, ..., 536870911}	-1003500

5.39.4.133 heuristics/intshifting

Option	Description	Default
heuristics/intshifting/freq	frequency for calling primal heuristic <intshifting> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/intshifting/freqofs	frequency offset for calling primal heuristic <intshifting> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/intshifting/maxdepth	maximal depth level to call primal heuristic <intshifting> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/intshifting/priority	priority of heuristic <intshifting> Range: {-536870912, ..., 536870911}	-10000

5.39.4.134 heuristics/linesearchdiving

Option	Description	Default
heuristics/linesearchdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/linesearchdiving/freq	frequency for calling primal heuristic <linesearchdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/linesearchdiving/freqofs	frequency offset for calling primal heuristic <linesearchdiving> Range: {0, ..., 65534}	6
heuristics/linesearchdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/linesearchdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/linesearchdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000

Option	Description	Default
heuristics/linesearchdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: $[0, \infty]$	0.05
heuristics/linesearchdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/linesearchdiving/maxdepth	maximal depth level to call primal heuristic <linesearchdiving> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/linesearchdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: $[0, \infty]$	0
heuristics/linesearchdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: $[0, \infty]$	0
heuristics/linesearchdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: $[0, 1]$	0.8
heuristics/linesearchdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: $[0, 1]$	0.1
heuristics/linesearchdiving/maxreldepth	maximal relative depth to start diving Range: $[0, 1]$	1
heuristics/linesearchdiving/minreldepth	minimal relative depth to start diving Range: $[0, 1]$	0
heuristics/linesearchdiving/priority	priority of heuristic <linesearchdiving> Range: $\{-536870912, \dots, 536870911\}$	-1006000

5.39.4.135 heuristics/localbranching

Option	Description	Default
heuristics/localbranching/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: $\{-1, \dots, \infty\}$	3
heuristics/localbranching/freq	frequency for calling primal heuristic <localbranching> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	-1
heuristics/localbranching/freqofs	frequency offset for calling primal heuristic <localbranching> Range: $\{0, \dots, 65534\}$	0
heuristics/localbranching/neighborhoodsize	radius (using Manhattan metric) of the incumbent's neighborhood to be searched Range: $\{1, \dots, \infty\}$	18
heuristics/localbranching/nodesofs	number of nodes added to the contingent of the total nodes Range: $\{0, \dots, \infty\}$	1000

Option	Description	Default
heuristics/localbranching/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.05
Options for expert users		
heuristics/localbranching/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/localbranching/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	1.5
heuristics/localbranching/maxdepth	maximal depth level to call primal heuristic <localbranching> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/localbranching/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	10000
heuristics/localbranching/minimprove	factor by which localbranching should at least improve the incumbent Range: [0, 1]	0.01
heuristics/localbranching/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	1000
heuristics/localbranching/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	200
heuristics/localbranching/priority	priority of heuristic <localbranching> Range: {-536870912, ..., 536870911}	-1102000
heuristics/localbranching/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0

5.39.4.136 heuristics/locks

Option	Description	Default
heuristics/locks/freq	frequency for calling primal heuristic <locks> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/locks/freqofs	frequency offset for calling primal heuristic <locks> Range: {0, ..., 65534}	0
heuristics/locks/minfixingrate	minimum percentage of integer variables that have to be fixable Range: [0, 1]	0.65
heuristics/locks/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/locks/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1

Option	Description	Default
heuristics/locks/roundupprobability	probability for rounding a variable up in case of ties Range: [0, 1]	0.67
Options for expert users		
heuristics/locks/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/locks/maxdepth	maximal depth level to call primal heuristic <locks> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/locks/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	5000
heuristics/locks/maxpropounds	maximum number of propagation rounds to be performed in each propagation call (-1: no limit, -2: parameter settings) Range: {-2, ..., ∞ }	2
heuristics/locks/minfixingratelp	minimum fixing rate over all variables (including continuous) to solve LP Range: [0, 1]	0
heuristics/locks/minimprove	factor by which locks heuristic should at least improve the incumbent Range: [0, 1]	0.01
heuristics/locks/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	500
heuristics/locks/priority	priority of heuristic <locks> Range: {-536870912, ..., 536870911}	3000
heuristics/locks/updatelocks	should the locks be updated based on LP rows? Range: boolean	1
heuristics/locks/usefinalsubmip	should a final sub-MIP be solved to construct a feasible solution if the LP was not roundable? Range: boolean	1

5.39.4.137 heuristics/lpface

Option	Description	Default
heuristics/lpface/freq	frequency for calling primal heuristic <lpface> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	15
heuristics/lpface/freqofs	frequency offset for calling primal heuristic <lpface> Range: {0, ..., 65534}	0
heuristics/lpface/minfixingrate	required percentage of fixed integer variables in sub-MIP to run Range: [0, 1]	0.1
heuristics/lpface/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	200
heuristics/lpface/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1

Option	Description	Default
Options for expert users		
heuristics/lpface/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/lpface/dualbasisequations	should dually nonbasic rows be turned into equations? Range: boolean	0
heuristics/lpface/keepsubscip	should the heuristic continue solving the same sub-SCIP? Range: boolean	0
heuristics/lpface/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/lpface/maxdepth	maximal depth level to call primal heuristic <lpface> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/lpface/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/lpface/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/lpface/minpathlen	the minimum active search tree path length along which lower bound hasn't changed before heuristic becomes active Range: {0, ..., 65531}	5
heuristics/lpface/priority	priority of heuristic <lpface> Range: {-536870912, ..., 536870911}	-1104010
heuristics/lpface/subscipobjective	objective function in the sub-SCIP: (z)ero, (r)oot-LP-difference, (i)nference, LP (f)ractionality, (o)riginal Range: f, o, r, z, i	z
heuristics/lpface/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	1

5.39.4.138 heuristics/mpec

Option	Description	Default
heuristics/mpec/freq	frequency for calling primal heuristic <mpec> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	50
heuristics/mpec/freqofs	frequency offset for calling primal heuristic <mpec> Range: {0, ..., 65534}	0
heuristics/mpec/inittheta	initial regularization right-hand side value Range: [0, 0.25]	0.125
heuristics/mpec/maxiter	maximum number of iterations of the MPEC loop Range: {0, ..., ∞}	100
heuristics/mpec/maxnlpcost	maximum cost available for solving NLPs per call of the heuristic Range: [0, ∞]	1e+08

Option	Description	Default
heuristics/mpec/maxnlpiter	maximum number of NLP iterations per solve Range: $\{0, \dots, \infty\}$	500
heuristics/mpec/maxnunsucc	maximum number of consecutive calls for which the heuristic did not find an improving solution Range: $\{0, \dots, \infty\}$	10
heuristics/mpec/mingapleft	minimum amount of gap left in order to call the heuristic Range: $[0, \infty]$	0.05
heuristics/mpec/minimprove	factor by which heuristic should at least improve the incumbent Range: $[0, 1]$	0.01
heuristics/mpec/sigma	regularization update factor Range: $[0, 1]$	0.5
heuristics/mpec/subnlptrigger	maximum number of NLP iterations per solve Range: $[0, 1]$	0.001
Options for expert users		
heuristics/mpec/maxdepth	maximal depth level to call primal heuristic <mpec> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/mpec/priority	priority of heuristic <mpec> Range: $\{-536870912, \dots, 536870911\}$	-2050000

5.39.4.139 heuristics/multistart

Option	Description	Default
heuristics/multistart/freq	frequency for calling primal heuristic <multistart> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	0
heuristics/multistart/freqofs	frequency offset for calling primal heuristic <multistart> Range: $\{0, \dots, 65534\}$	0
heuristics/multistart/gradlimit	limit for gradient computations for all improve-Point() calls (0 for no limit) Range: $[0, \infty]$	5e+06
heuristics/multistart/maxboundsize	maximum variable domain size for unbounded variables Range: $[0, \infty]$	20000
heuristics/multistart/maxiter	number of iterations to reduce the maximum violation of a point Range: $\{0, \dots, \infty\}$	300
heuristics/multistart/maxncluster	maximum number of considered clusters per heuristic call Range: $\{0, \dots, \infty\}$	3
heuristics/multistart/maxreldist	maximum distance between two points in the same cluster Range: $[0, \infty]$	0.15
heuristics/multistart/minimprfac	minimum required improving factor to proceed in improvement of a single point Range: real	0.05
heuristics/multistart/minimpriter	number of iteration when checking the minimum improvement Range: $\{1, \dots, \infty\}$	10

Option	Description	Default
heuristics/multistart/nrndpoints	number of random points generated per execution call Range: {0, ..., ∞ }	100
heuristics/multistart/onlynlps	should the heuristic run only on continuous problems? Range: boolean	1
Options for expert users		
heuristics/multistart/maxdepth	maximal depth level to call primal heuristic <multistart> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/multistart/priority	priority of heuristic <multistart> Range: {-536870912, ..., 536870911}	-2100000

5.39.4.140 heuristics/mutation

Option	Description	Default
heuristics/mutation/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞ }	-1
heuristics/mutation/freq	frequency for calling primal heuristic <mutation> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/mutation/freqofs	frequency offset for calling primal heuristic <mutation> Range: {0, ..., 65534}	8
heuristics/mutation/minfixingrate	percentage of integer variables that have to be fixed Range: [1e-06, 0.999999]	0.8
heuristics/mutation/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/mutation/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/mutation/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/mutation/maxdepth	maximal depth level to call primal heuristic <mutation> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/mutation/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	5000
heuristics/mutation/minimprove	factor by which mutation should at least improve the incumbent Range: [0, 1]	0.01
heuristics/mutation/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	500
heuristics/mutation/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞ }	200

Option	Description	Default
heuristics/mutation/priority	priority of heuristic <mutation> Range: {-536870912, ..., 536870911}	-1103010
heuristics/mutation/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/mutation/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.39.4.141 heuristics/nlpdiving

Option	Description	Default
heuristics/nlpdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/nlpdiving/fixquot	percentage of fractional variables that should be fixed before the next NLP solve Range: [0, 1]	0.2
heuristics/nlpdiving/freq	frequency for calling primal heuristic <nlpdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/nlpdiving/freqofs	frequency offset for calling primal heuristic <nlpdiving> Range: {0, ..., 65534}	3
heuristics/nlpdiving/maxfeasnlps	maximal number of NLPs with feasible solution to solve during one dive Range: {1, ..., ∞ }	10
heuristics/nlpdiving/maxnlpiterabs	minimial absolute number of allowed NLP iterations Range: {0, ..., ∞ }	200
heuristics/nlpdiving/maxnlpiterrel	additional allowed number of NLP iterations relative to successfully found solutions Range: {0, ..., ∞ }	10
heuristics/nlpdiving/minsuccquot	heuristic will not run if less then this percentage of calls succeeded (0.0: no limit) Range: [0, 1]	0.1
heuristics/nlpdiving/nlpfastfail	should the NLP solver stop early if it converges slow? Range: boolean	1
heuristics/nlpdiving/prefercover	should variables in a minimal cover be preferred? Range: boolean	1
heuristics/nlpdiving/solvesubmip	should a sub-MIP be solved if all cover variables are fixed? Range: boolean	0
heuristics/nlpdiving/varselrule	which variable selection should be used? ('f'ractionality, 'c'oefficient, 'p'seudocost, 'g'uided, 'd'ouble, 'v'eclen) Range: f, c, p, g, d, v	d
Options for expert users		

Option	Description	Default
heuristics/nlpdiving/lp	should the LP relaxation be solved before the NLP relaxation? Range: boolean	0
heuristics/nlpdiving/maxdepth	maximal depth level to call primal heuristic <nlpdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/nlpdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/nlpdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/nlpdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/nlpdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/nlpdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/nlpdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/nlpdiving/nlpstart	which point should be used as starting point for the NLP solver? ('n'one, last 'f'easible, from dive's'tart) Range: f, n, s	s
heuristics/nlpdiving/preferlpfracs	prefer variables that are also fractional in LP solution? Range: boolean	0
heuristics/nlpdiving/priority	priority of heuristic <nlpdiving> Range: {-536870912, ..., 536870911}	-1003010

5.39.4.142 heuristics/objpscostdiving

Option	Description	Default
heuristics/objpscostdiving/freq	frequency for calling primal heuristic <objpscostdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/objpscostdiving/freqofs	frequency offset for calling primal heuristic <objpscostdiving> Range: {0, ..., 65534}	4
heuristics/objpscostdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/objpscostdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to total iteration number Range: [0, 1]	0.01
Options for expert users		

Option	Description	Default
heuristics/objpscostdiving/depthfac	maximal diving depth: number of binary/integer variables times depthfac Range: $[0, \infty]$	0.5
heuristics/objpscostdiving/depthfacnosol	maximal diving depth factor if no feasible solution was found yet Range: $[0, \infty]$	2
heuristics/objpscostdiving/maxdepth	maximal depth level to call primal heuristic <objpscostdiving> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/objpscostdiving/maxreldepth	maximal relative depth to start diving Range: $[0, 1]$	1
heuristics/objpscostdiving/maxsols	total number of feasible solutions found up to which heuristic is called (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
heuristics/objpscostdiving/minreldepth	minimal relative depth to start diving Range: $[0, 1]$	0
heuristics/objpscostdiving/priority	priority of heuristic <objpscostdiving> Range: $\{-536870912, \dots, 536870911\}$	-1004000

5.39.4.143 heuristics/octane

Option	Description	Default
heuristics/octane/freq	frequency for calling primal heuristic <octane> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	-1
heuristics/octane/freqofs	frequency offset for calling primal heuristic <octane> Range: $\{0, \dots, 65534\}$	0
Options for expert users		
heuristics/octane/ffirst	number of 0-1-points to be tested at first whether they violate a common row Range: $\{1, \dots, \infty\}$	10
heuristics/octane/fmax	number of 0-1-points to be tested as possible solutions by OCTANE Range: $\{1, \dots, \infty\}$	100
heuristics/octane/maxdepth	maximal depth level to call primal heuristic <octane> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/octane/priority	priority of heuristic <octane> Range: $\{-536870912, \dots, 536870911\}$	-1008000
heuristics/octane/useavgnbray	should the weighted average of the nonbasic cone be used as one ray direction? Range: boolean	1
heuristics/octane/useavgray	should the average of the basic cone be used as one ray direction? Range: boolean	1
heuristics/octane/useavgwgray	should the weighted average of the basic cone be used as one ray direction? Range: boolean	1
heuristics/octane/usediffgray	should the difference between the root solution and the current LP solution be used as one ray direction? Range: boolean	0

Option	Description	Default
heuristics/octane/usefracspace	execute OCTANE only in the space of fractional variables (TRUE) or in the full space? Range: boolean	1
heuristics/octane/useobjray	should the inner normal of the objective be used as one ray direction? Range: boolean	1

5.39.4.144 heuristics/ofins

Option	Description	Default
heuristics/ofins/freq	frequency for calling primal heuristic <ofins> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/ofins/freqofs	frequency offset for calling primal heuristic <ofins> Range: {0, ..., 65534}	0
heuristics/ofins/maxchange	maximal rate of change per coefficient to get fixed Range: [0, 1]	0.04
heuristics/ofins/maxchangerate	maximal rate of changed coefficients Range: [0, 1]	0.5
heuristics/ofins/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/ofins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/ofins/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/ofins/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/ofins/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/ofins/maxdepth	maximal depth level to call primal heuristic <ofins> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/ofins/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	5000
heuristics/ofins/minimprove	factor by which RENS should at least improve the incumbent Range: [0, 1]	0.01
heuristics/ofins/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	50
heuristics/ofins/priority	priority of heuristic <ofins> Range: {-536870912, ..., 536870911}	60000

5.39.4.145 heuristics/oneopt

Option	Description	Default
heuristics/oneopt/freq	frequency for calling primal heuristic <oneopt> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/oneopt/freqofs	frequency offset for calling primal heuristic <oneopt> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/oneopt/beforepresol	should the heuristic be called before presolving? Range: boolean	0
heuristics/oneopt/duringroot	should the heuristic be called before and during the root node? Range: boolean	1
heuristics/oneopt/forcelpconstruction	should the construction of the LP be forced even if LP solving is deactivated? Range: boolean	0
heuristics/oneopt/maxdepth	maximal depth level to call primal heuristic <oneopt> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/oneopt/priority	priority of heuristic <oneopt> Range: {-536870912, ..., 536870911}	-20000
heuristics/oneopt/useloop	should the heuristic continue to run as long as improvements are found? Range: boolean	1
heuristics/oneopt/weightedobj	should the objective be weighted with the po- tential shifting value when sorting the shifting candidates? Range: boolean	1

5.39.4.146 heuristics/padm

Option	Description	Default
heuristics/padm/assignlinking	should linking constraints be assigned? Range: boolean	1
heuristics/padm/freq	frequency for calling primal heuristic <padm> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/padm/freqofs	frequency offset for calling primal heuristic <padm> Range: {0, ..., 65534}	0
heuristics/padm/reoptimize	should the problem get reoptimized with the original objective function? Range: boolean	1
heuristics/padm/timing	should the heuristic run before or after the processing of the node? (0: before, 1: after, 2: both) Range: {0, ..., 2}	0
Options for expert users		
heuristics/padm/admiterations	maximal number of ADM iterations in each penalty loop Range: {1, ..., 100}	4
heuristics/padm/gap	mipgap at start Range: [0, 16]	2

Option	Description	Default
heuristics/padm/maxdepth	maximal depth level to call primal heuristic <padm> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/padm/maxnodes	maximum number of nodes to regard in all subproblems Range: {0, ..., ∞ }	5000
heuristics/padm/minnodes	minimum number of nodes to regard in one subproblem Range: {0, ..., ∞ }	50
heuristics/padm/nodfac	factor to control nodelimits of subproblems Range: [0, 0.99]	0.8
heuristics/padm/original	should the original problem be used? This is only for testing and not recommended! Range: boolean	0
heuristics/padm/penaltyiterations	maximal number of penalty iterations Range: {1, ..., 100000}	100
heuristics/padm/priority	priority of heuristic <padm> Range: {-536870912, ..., 536870911}	70000
heuristics/padm/scaling	enable sigmoid rescaling of penalty parameters Range: boolean	1

5.39.4.147 heuristics/proximity

Option	Description	Default
heuristics/proximity/freq	frequency for calling primal heuristic <proximity> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/proximity/freqofs	frequency offset for calling primal heuristic <proximity> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/proximity/binvarquot	threshold for percentage of binary variables required to start Range: [0, 1]	0.1
heuristics/proximity/lpittersquot	quotient of sub-MIP LP iterations with respect to LP iterations so far Range: [0, 1]	0.2
heuristics/proximity/maxdepth	maximal depth level to call primal heuristic <proximity> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/proximity/maxlpiters	maximum number of LP iterations to be performed in the subproblem Range: {-1, ..., ∞ }	100000
heuristics/proximity/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	10000
heuristics/proximity/mingap	minimum primal-dual gap for which the heuristic is executed Range: [0, ∞]	0.01
heuristics/proximity/minimprove	factor by which proximity should at least improve the incumbent Range: [0, 1]	0.02

Option	Description	Default
heuristics/proximity/minlpiters	minimum number of LP iterations performed in sub-problem Range: {0, ..., ∞ }	200
heuristics/proximity/minnodes	minimum number of nodes required to start the sub-problem Range: {0, ..., ∞ }	1
heuristics/proximity/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	50
heuristics/proximity/nodesquot	sub-MIP node limit w.r.t number of original nodes Range: [0, ∞]	0.1
heuristics/proximity/priority	priority of heuristic <proximity> Range: {-536870912, ..., 536870911}	-2000000
heuristics/proximity/restart	should the heuristic immediately run again on its newly found solution? Range: boolean	1
heuristics/proximity/usefinalp	should the heuristic solve a final LP in case of continuous objective variables? Range: boolean	0
heuristics/proximity/uselprows	should subproblem be constructed based on LP row information? Range: boolean	0
heuristics/proximity/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0
heuristics/proximity/waitingnodes	waiting nodes since last incumbent before heuristic is executed Range: {0, ..., ∞ }	100

5.39.4.148 heuristics/pscstdiving

Option	Description	Default
heuristics/pscstdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/pscstdiving/freq	frequency for calling primal heuristic <pscstdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/pscstdiving/freqofs	frequency offset for calling primal heuristic <pscstdiving> Range: {0, ..., 65534}	2
heuristics/pscstdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/pscstdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞ }	0
heuristics/pscstdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞ }	1000

Option	Description	Default
heuristics/pscostdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: $[0, \infty]$	0.05
heuristics/pscostdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	1
Options for expert users		
heuristics/pscostdiving/maxdepth	maximal depth level to call primal heuristic <pscostdiving> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/pscostdiving/maxdiveavgquot	maximal quotient $(\text{curlowerbound} - \text{lowerbound}) / (\text{avglowerbound} - \text{lowerbound})$ where diving is performed (0.0: no limit) Range: $[0, \infty]$	0
heuristics/pscostdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: $[0, \infty]$	0
heuristics/pscostdiving/maxdiveubquot	maximal quotient $(\text{curlowerbound} - \text{lowerbound}) / (\text{cutoffbound} - \text{lowerbound})$ where diving is performed (0.0: no limit) Range: $[0, 1]$	0.8
heuristics/pscostdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: $[0, 1]$	0.1
heuristics/pscostdiving/maxreldepth	maximal relative depth to start diving Range: $[0, 1]$	1
heuristics/pscostdiving/minreldepth	minimal relative depth to start diving Range: $[0, 1]$	0
heuristics/pscostdiving/priority	priority of heuristic <pscostdiving> Range: $\{-536870912, \dots, 536870911\}$	-1002000

5.39.4.149 heuristics/randrounding

Option	Description	Default
heuristics/randrounding/freq	frequency for calling primal heuristic <randrounding> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	20
heuristics/randrounding/freqofs	frequency offset for calling primal heuristic <randrounding> Range: $\{0, \dots, 65534\}$	0
Options for expert users		
heuristics/randrounding/maxdepth	maximal depth level to call primal heuristic <randrounding> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/randrounding/maxpropounds	limit of rounds for each propagation call Range: $\{-1, \dots, \infty\}$	1
heuristics/randrounding/oncepernode	should the heuristic only be called once per node? Range: boolean	0

Option	Description	Default
heuristics/randrounding/priority	priority of heuristic <randrounding> Range: {-536870912, ..., 536870911}	-200
heuristics/randrounding/propagateonlyroot	should the probing part of the heuristic be applied exclusively at the root node? Range: boolean	1
heuristics/randrounding/usesimplerounding	should the heuristic apply the variable lock strategy of simple rounding, if possible? Range: boolean	0

5.39.4.150 heuristics/rens

Option	Description	Default
heuristics/rens/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞ }	-1
heuristics/rens/freq	frequency for calling primal heuristic <rens> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/rens/freqofs	frequency offset for calling primal heuristic <rens> Range: {0, ..., 65534}	0
heuristics/rens/minfixingrate	minimum percentage of integer variables that have to be fixable Range: [0, 1]	0.5
heuristics/rens/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/rens/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/rens/startsol	solution that is used for fixing values ('lp relaxation, 'nlp relaxation) Range: n, 1	1
Options for expert users		
heuristics/rens/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/rens/binarybounds	should general integers get binary bounds [floor(.),ceil(.)] ? Range: boolean	1
heuristics/rens/copycuts	if uselprows == FALSE, should all active cuts from cut-pool be copied to constraints in subproblem? Range: boolean	1
heuristics/rens/extratime	should the RENS sub-CIP get its own full time limit? This is only for testing and not recommended! Range: boolean	0
heuristics/rens/fullscale	should the RENS sub-CIP be solved with cuts, conflicts, strong branching,... This is only for testing and not recommended! Range: boolean	0
heuristics/rens/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2

Option	Description	Default
heuristics/rens/maxdepth	maximal depth level to call primal heuristic <rens> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/rens/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	5000
heuristics/rens/minimprove	factor by which RENS should at least improve the incumbent Range: [0, 1]	0.01
heuristics/rens/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	50
heuristics/rens/priority	priority of heuristic <rens> Range: {-536870912, ..., 536870911}	-1100000
heuristics/rens/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/rens/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.39.4.151 heuristics/reoptsols

Option	Description	Default
heuristics/reoptsols/freq	frequency for calling primal heuristic <reoptsols> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/reoptsols/freqofs	frequency offset for calling primal heuristic <reoptsols> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/reoptsols/maxdepth	maximal depth level to call primal heuristic <reoptsols> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/reoptsols/maxruns	check solutions of the last k runs. (-1: all) Range: {-1, ..., ∞ }	-1
heuristics/reoptsols/maxsols	maximal number solutions which should be checked. (-1: all) Range: {-1, ..., ∞ }	1000
heuristics/reoptsols/priority	priority of heuristic <reoptsols> Range: {-536870912, ..., 536870911}	40000

5.39.4.152 heuristics/repair

Option	Description	Default
heuristics/repair/filename	file name of a solution to be used as infeasible starting point, [-] if not available Range: string	-
heuristics/repair/freq	frequency for calling primal heuristic <repair> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1

Option	Description	Default
heuristics/repair/freqofs	frequency offset for calling primal heuristic <repair> Range: {0, ..., 65534}	0
heuristics/repair/minfixingrate	minimum percentage of integer variables that have to be fixed Range: [0, 1]	0.3
heuristics/repair/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/repair/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/repair/roundit	True : fractional variables which are not fractional in the given solution are rounded, FALSE : solving process of this heuristic is stopped. Range: boolean	1
heuristics/repair/useobjfactor	should a scaled objective function for original variables be used in repair subproblem? Range: boolean	0
heuristics/repair/useslackvars	should slack variables be used in repair subproblem? Range: boolean	0
heuristics/repair/usevarfix	should variable fixings be used in repair subproblem? Range: boolean	1
Options for expert users		
heuristics/repair/alpha	factor for the potential of var fixings Range: [0, 100]	2
heuristics/repair/maxdepth	maximal depth level to call primal heuristic <repair> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/repair/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	5000
heuristics/repair/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	50
heuristics/repair/priority	priority of heuristic <repair> Range: {-536870912, ..., 536870911}	-20

5.39.4.153 heuristics/rins

Option	Description	Default
heuristics/rins/freq	frequency for calling primal heuristic <rins> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	25
heuristics/rins/freqofs	frequency offset for calling primal heuristic <rins> Range: {0, ..., 65534}	0
heuristics/rins/minfixingrate	minimum percentage of integer variables that have to be fixed Range: [0, 1]	0.3
heuristics/rins/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500

Option	Description	Default
heuristics/rins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.3
Options for expert users		
heuristics/rins/copycuts	if uselprows == FALSE, should all active cuts from cut-pool be copied to constraints in subproblem? Range: boolean	1
heuristics/rins/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/rins/maxdepth	maximal depth level to call primal heuristic <rins> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/rins/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/rins/minimprove	factor by which rins should at least improve the incumbent Range: [0, 1]	0.01
heuristics/rins/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/rins/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	200
heuristics/rins/priority	priority of heuristic <rins> Range: {-536870912, ..., 536870911}	-1101000
heuristics/rins/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/rins/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.39.4.154 heuristics/rootsoldiving

Option	Description	Default
heuristics/rootsoldiving/freq	frequency for calling primal heuristic <rootsoldiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/rootsoldiving/freqofs	frequency offset for calling primal heuristic <rootsoldiving> Range: {0, ..., 65534}	5
heuristics/rootsoldiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/rootsoldiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.01
Options for expert users		
heuristics/rootsoldiving/alpha	soft rounding factor to fade out objective coefficients Range: [0, 1]	0.9

Option	Description	Default
heuristics/rootsolving/depthfac	maximal diving depth: number of binary/integer variables times depthfac Range: $[0, \infty]$	0.5
heuristics/rootsolving/depthfacnosol	maximal diving depth factor if no feasible solution was found yet Range: $[0, \infty]$	2
heuristics/rootsolving/maxdepth	maximal depth level to call primal heuristic <rootsolving> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/rootsolving/maxreldepth	maximal relative depth to start diving Range: $[0, 1]$	1
heuristics/rootsolving/maxsols	total number of feasible solutions found up to which heuristic is called (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
heuristics/rootsolving/minreldepth	minimal relative depth to start diving Range: $[0, 1]$	0
heuristics/rootsolving/priority	priority of heuristic <rootsolving> Range: $\{-536870912, \dots, 536870911\}$	-1005000

5.39.4.155 heuristics/rounding

Option	Description	Default
heuristics/rounding/freq	frequency for calling primal heuristic <rounding> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	1
heuristics/rounding/freqofs	frequency offset for calling primal heuristic <rounding> Range: $\{0, \dots, 65534\}$	0
Options for expert users		
heuristics/rounding/maxdepth	maximal depth level to call primal heuristic <rounding> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/rounding/oncepernode	should the heuristic only be called once per node? Range: boolean	0
heuristics/rounding/priority	priority of heuristic <rounding> Range: $\{-536870912, \dots, 536870911\}$	-1000
heuristics/rounding/successfactor	number of calls per found solution that are considered as standard success, a higher factor causes the heuristic to be called more often Range: $\{-1, \dots, \infty\}$	100

5.39.4.156 heuristics/shiftandpropagate

Option	Description	Default
heuristics/shiftandpropagate/freq	frequency for calling primal heuristic <shiftandpropagate> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	0

Option	Description	Default
heuristics/shiftandpropagate/freqofs	frequency offset for calling primal heuristic <shiftandpropagate> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/shiftandpropagate/binlocksfirst	should binary variables with no locks be preferred in the ordering? Range: boolean	0
heuristics/shiftandpropagate/collectstats	should variable statistics be collected during probing? Range: boolean	1
heuristics/shiftandpropagate/cutoffbreaker	The number of cutoffs before heuristic stops Range: {-1, ..., 1000000}	15
heuristics/shiftandpropagate/fixbinlocks	should binary variables with no locks in one direction be fixed to that direction? Range: boolean	1
heuristics/shiftandpropagate/impliscontinuous	should implicit integer variables be treated as continuous variables? Range: boolean	1
heuristics/shiftandpropagate/maxcutoffquot	maximum percentage of allowed cutoffs before stopping the heuristic Range: [0, 2]	0
heuristics/shiftandpropagate/maxdepth	maximal depth level to call primal heuristic <shiftandpropagate> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/shiftandpropagate/minfixingratelp	minimum fixing rate over all variables (including continuous) to solve LP Range: [0, 1]	0
heuristics/shiftandpropagate/normalize	should coefficients and left/right hand sides be normalized by max row coeff? Range: boolean	1
heuristics/shiftandpropagate/nozerofixing	should variables with a zero shifting value be delayed instead of being fixed? Range: boolean	0
heuristics/shiftandpropagate/npropounds	The number of propagation rounds used for each propagation Range: {-1, ..., 1000}	10
heuristics/shiftandpropagate/onlywithoutsol	Should heuristic only be executed if no primal solution was found, yet? Range: boolean	1
heuristics/shiftandpropagate/preferbinaries	Should binary variables be shifted first? Range: boolean	1
heuristics/shiftandpropagate/priority	priority of heuristic <shiftandpropagate> Range: {-536870912, ..., 536870911}	1000
heuristics/shiftandpropagate/probing	Should domains be reduced by probing? Range: boolean	1
heuristics/shiftandpropagate/relax	Should continuous variables be relaxed? Range: boolean	1
heuristics/shiftandpropagate/selectbest	should the heuristic choose the best candidate in every round? (set to FALSE for static order)? Range: boolean	0

Option	Description	Default
heuristics/shiftandpropagate/sortkey	the key for variable sorting: (n)orms down, norms (u)p, (v)iolations down, viola(t)ions up, or (r)andom Range: n, r, t, u, v	v
heuristics/shiftandpropagate/sortvars	Should variables be sorted for the heuristic? Range: boolean	1
heuristics/shiftandpropagate/stopafterfeasible	Should the heuristic stop calculating optimal shift values when no more rows are violated? Range: boolean	1
heuristics/shiftandpropagate/updateweights	should row weight be increased every time the row is violated? Range: boolean	0

5.39.4.157 heuristics/shifting

Option	Description	Default
heuristics/shifting/freq	frequency for calling primal heuristic <shifting> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/shifting/freqofs	frequency offset for calling primal heuristic <shifting> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/shifting/maxdepth	maximal depth level to call primal heuristic <shifting> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/shifting/priority	priority of heuristic <shifting> Range: {-536870912, ..., 536870911}	-5000

5.39.4.158 heuristics/simplerounding

Option	Description	Default
heuristics/simplerounding/freq	frequency for calling primal heuristic <simplerounding> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/simplerounding/freqofs	frequency offset for calling primal heuristic <simplerounding> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/simplerounding/maxdepth	maximal depth level to call primal heuristic <simplerounding> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/simplerounding/oncepernode	should the heuristic only be called once per node? Range: boolean	0
heuristics/simplerounding/priority	priority of heuristic <simplerounding> Range: {-536870912, ..., 536870911}	-30

5.39.4.159 heuristics/subnlp

Option	Description	Default
heuristics/subnlp/expectinfeas	percentage of NLP solves with infeasible status required to tell NLP solver to expect an infeasible NLP Range: [0, 1]	0
heuristics/subnlp/feastolfactor	factor on SCIP feasibility tolerance for NLP solves if resolving when NLP solution not feasible in CIP Range: [0, 1]	0.1
heuristics/subnlp/forbidfixings	whether to add constraints that forbid specific fixings that turned out to be infeasible Range: boolean	0
heuristics/subnlp/freq	frequency for calling primal heuristic <subnlp> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/subnlp/freqofs	frequency offset for calling primal heuristic <subnlp> Range: {0, ..., 65534}	0
heuristics/subnlp/iterinit	number of iterations used for initial NLP solves Range: {0, ..., ∞ }	300
heuristics/subnlp/itermin	minimal number of iterations for NLP solves Range: {0, ..., ∞ }	20
heuristics/subnlp/maxpresolverounds	limit on number of presolve rounds in sub-SCIP (-1 for unlimited, 0 for no presolve) Range: {-1, ..., ∞ }	-1
heuristics/subnlp/ninitsolves	number of successful NLP solves until switching to iterlimit guess and using success rate Range: {0, ..., ∞ }	2
heuristics/subnlp/nlpverblevel	verbosity level of NLP solver Range: {0, ..., 65535}	0
heuristics/subnlp/nodesfactor	factor on number of nodes in SCIP (plus nodesoffset) to compute itercontingent (higher value runs heuristics more frequently) Range: [0, ∞]	0.3
heuristics/subnlp/nodesoffset	number of nodes added to the current number of nodes when computing itercontingent (higher value runs heuristic more often in early search) Range: {0, ..., ∞ }	1600
heuristics/subnlp/presolveemphasis	presolve emphasis in sub-SCIP (0: default, 1: aggressive, 2: fast, 3: off) Range: {0, ..., 3}	2
heuristics/subnlp/setcutoff	whether to set cutoff in sub-SCIP to current primal bound Range: boolean	1
heuristics/subnlp/successrateexp	exponent for power of success rate to be multiplied with itercontingent (lower value decreases impact of success rate) Range: [0, ∞]	1
Options for expert users		
heuristics/subnlp/keepcopy	whether to keep SCIP copy or to create new copy each time heuristic is applied Range: boolean	1

Option	Description	Default
heuristics/subnlp/maxdepth	maximal depth level to call primal heuristic <subnlp> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/subnlp/opttol	absolute optimality tolerance to use for NLP solves Range: [0, 1]	1e-07
heuristics/subnlp/priority	priority of heuristic <subnlp> Range: {-536870912, ..., 536870911}	-2000010

5.39.4.160 heuristics/trivial

Option	Description	Default
heuristics/trivial/freq	frequency for calling primal heuristic <trivial> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/trivial/freqofs	frequency offset for calling primal heuristic <trivial> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/trivial/maxdepth	maximal depth level to call primal heuristic <trivial> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/trivial/priority	priority of heuristic <trivial> Range: {-536870912, ..., 536870911}	10000

5.39.4.161 heuristics/trivialnegation

Option	Description	Default
heuristics/trivialnegation/freq	frequency for calling primal heuristic <trivialnegation> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/trivialnegation/freqofs	frequency offset for calling primal heuristic <trivialnegation> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/trivialnegation/maxdepth	maximal depth level to call primal heuristic <trivialnegation> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/trivialnegation/priority	priority of heuristic <trivialnegation> Range: {-536870912, ..., 536870911}	39990

5.39.4.162 heuristics/trustregion

Option	Description	Default
heuristics/trustregion/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞ }	3

Option	Description	Default
heuristics/trustregion/freq	frequency for calling primal heuristic <trustregion> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/trustregion/freqofs	frequency offset for calling primal heuristic <trustregion> Range: {0, ..., 65534}	0
heuristics/trustregion/minbinvars	the number of binary variables necessary to run the heuristic Range: {1, ..., ∞ }	10
heuristics/trustregion/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	1000
heuristics/trustregion/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.05
heuristics/trustregion/objminimprove	the minimum absolute improvement in the objective function value Range: [0, ∞]	0.01
heuristics/trustregion/violpenalty	the penalty for each change in the binary variables from the candidate solution Range: [0, ∞]	100
Options for expert users		
heuristics/trustregion/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/trustregion/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	1.5
heuristics/trustregion/maxdepth	maximal depth level to call primal heuristic <trustregion> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/trustregion/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	10000
heuristics/trustregion/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	100
heuristics/trustregion/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞ }	1
heuristics/trustregion/priority	priority of heuristic <trustregion> Range: {-536870912, ..., 536870911}	-1102010
heuristics/trustregion/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0

5.39.4.163 heuristics/trysol

Option	Description	Default
heuristics/trysol/freq	frequency for calling primal heuristic <trysol> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/trysol/freqofs	frequency offset for calling primal heuristic <trysol> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/trysol/maxdepth	maximal depth level to call primal heuristic <trysol> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/trysol/priority	priority of heuristic <trysol> Range: {-536870912, ..., 536870911}	-3000010

5.39.4.164 heuristics/twoopt

Option	Description	Default
heuristics/twoopt/freq	frequency for calling primal heuristic <twoopt> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/twoopt/freqofs	frequency offset for calling primal heuristic <twoopt> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/twoopt/intopt	Should Integer-2-Optimization be applied or not? Range: boolean	0
heuristics/twoopt/matchingrate	parameter to determine the percentage of rows two variables have to share before they are considered equal Range: [0, 1]	0.5
heuristics/twoopt/maxdepth	maximal depth level to call primal heuristic <twoopt> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/twoopt/maxnslaves	maximum number of slaves for one master variable Range: {-1, ..., 1000000}	199
heuristics/twoopt/priority	priority of heuristic <twoopt> Range: {-536870912, ..., 536870911}	-20100
heuristics/twoopt/waitingnodes	user parameter to determine number of nodes to wait after last best solution before calling heuristic Range: {0, ..., 10000}	0

5.39.4.165 heuristics/undercover

Option	Description	Default
heuristics/undercover/fixingalts	prioritized sequence of fixing values used ('l'p relaxation, 'n'lp relaxation, 'i'ncumbent solution) Range: string	li
heuristics/undercover/freq	frequency for calling primal heuristic <undercover> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0

Option	Description	Default
heuristics/undercover/freqofs	frequency offset for calling primal heuristic <undercover> Range: {0, ..., 65534}	0
heuristics/undercover/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/undercover/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/undercover/onlyconvexify	should we only fix variables in order to obtain a convex problem? Range: boolean	0
heuristics/undercover/postnlp	should the NLP heuristic be called to polish a feasible solution? Range: boolean	1
Options for expert users		
heuristics/undercover/beforecuts	should the heuristic be called at root node before cut separation? Range: boolean	1
heuristics/undercover/conflictweight	weight for conflict score in fixing order Range: real	1000
heuristics/undercover/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/undercover/coverbd	should bounddisjunction constraints be covered (or just copied)? Range: boolean	0
heuristics/undercover/coveringobj	objective function of the covering problem (influenced nonlinear 'c'onstraints/'t'erns, 'd'omain size, 'l'ocks, 'm'in of up/down locks, 'u'nit penalties) Range: c, d, l, m, t, u	u
heuristics/undercover/cutoffweight	weight for cutoff score in fixing order Range: [0, ∞]	1
heuristics/undercover/fixingorder	order in which variables should be fixed (increasing 'C'onflict score, decreasing 'c'onflict score, increasing 'V'ariable index, decreasing 'v'ariable index Range: C, c, V, v	v
heuristics/undercover/fixintfirst	should integer variables in the cover be fixed first? Range: boolean	0
heuristics/undercover/inferenceweight	weight for inference score in fixing order Range: real	1
heuristics/undercover/locksrounding	shall LP values for integer vars be rounded according to locks? Range: boolean	1
heuristics/undercover/maxbacktracks	maximum number of backtracks in fix-and-propagate Range: {0, ..., ∞ }	6

Option	Description	Default
heuristics/undercover/maxcoversizeconss	maximum coversize (as ratio to the percentage of non-affected constraints) Range: $[0, \infty]$	∞
heuristics/undercover/maxcoversizevars	maximum coversize (as fraction of total number of variables) Range: $[0, 1]$	1
heuristics/undercover/maxdepth	maximal depth level to call primal heuristic <undercover> (-1: no limit) Range: $\{-1, \dots, 65534\}$	-1
heuristics/undercover/maxnodes	maximum number of nodes to regard in the subproblem Range: $\{0, \dots, \infty\}$	500
heuristics/undercover/maxrecovers	maximum number of recoverings Range: $\{0, \dots, \infty\}$	0
heuristics/undercover/maxreorders	maximum number of reorderings of the fixing order Range: $\{0, \dots, \infty\}$	1
heuristics/undercover/mincoveredabs	minimum number of nonlinear constraints in the original problem Range: $\{0, \dots, \infty\}$	5
heuristics/undercover/mincoveredrel	minimum percentage of nonlinear constraints in the original problem Range: $[0, 1]$	0.15
heuristics/undercover/minimprove	factor by which the heuristic should at least improve the incumbent Range: $[-1, 1]$	0
heuristics/undercover/minnodes	minimum number of nodes required to start the subproblem Range: $\{0, \dots, \infty\}$	500
heuristics/undercover/priority	priority of heuristic <undercover> Range: $\{-536870912, \dots, 536870911\}$	-1110000
heuristics/undercover/recoverdiv	fraction of covering variables in the last cover which need to change their value when recovering Range: $[0, 1]$	0.9
heuristics/undercover/reusecover	shall the cover be reused if a conflict was added after an infeasible subproblem? Range: boolean	0

5.39.4.166 heuristics/vbounds

Option	Description	Default
heuristics/vbounds/freq	frequency for calling primal heuristic <vbounds> (-1: never, 0: only at depth freqofs) Range: $\{-1, \dots, 65534\}$	0
heuristics/vbounds/freqofs	frequency offset for calling primal heuristic <vbounds> Range: $\{0, \dots, 65534\}$	0
heuristics/vbounds/minintfixingrate	minimum percentage of integer variables that have to be fixed Range: $[0, 1]$	0.65

Option	Description	Default
heuristics/vbounds/minmipfixingrate	minimum percentage of variables that have to be fixed within sub-SCIP (integer and continuous) Range: [0, 1]	0.65
heuristics/vbounds/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	500
heuristics/vbounds/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/vbounds/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/vbounds/feasvariant	which variants of the vbounds heuristic that try to stay feasible should be called? (0: off, 1: w/o looking at obj, 2: only fix to best bound, 4: only fix to worst bound Range: {0, ..., 7}	6
heuristics/vbounds/maxbacktracks	maximum number of backtracks during the fixing process Range: {-1, ..., 536870911}	10
heuristics/vbounds/maxdepth	maximal depth level to call primal heuristic <vbounds> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/vbounds/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	5000
heuristics/vbounds/maxpropounds	maximum number of propagation rounds during probing (-1 infinity) Range: {-1, ..., 536870911}	2
heuristics/vbounds/minimprove	factor by which vbounds heuristic should at least improve the incumbent Range: [0, 1]	0.01
heuristics/vbounds/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	500
heuristics/vbounds/priority	priority of heuristic <vbounds> Range: {-536870912, ..., 536870911}	2500
heuristics/vbounds/tightenvariant	which tightening variants of the vbounds heuristic should be called? (0: off, 1: w/o looking at obj, 2: only fix to best bound, 4: only fix to worst bound Range: {0, ..., 7}	7
heuristics/vbounds/uselockfixings	should more variables be fixed based on variable locks if the fixing rate was not reached? Range: boolean	0

5.39.4.167 heuristics/veclendingiv

Option	Description	Default
heuristics/veclendingiv/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1

Option	Description	Default
heuristics/veclending/freq	frequency for calling primal heuristic <veclending> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/veclending/freqofs	frequency offset for calling primal heuristic <veclending> Range: {0, ..., 65534}	4
heuristics/veclending/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/veclending/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/veclending/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/veclending/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/veclending/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/veclending/maxdepth	maximal depth level to call primal heuristic <veclending> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/veclending/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/veclending/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/veclending/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/veclending/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/veclending/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/veclending/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/veclending/priority	priority of heuristic <veclending> Range: {-536870912, ..., 536870911}	-1003100

5.39.4.168 heuristics/zeroobj

Option	Description	Default
heuristics/zeroobj/freq	frequency for calling primal heuristic <zeroobj> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/zeroobj/freqofs	frequency offset for calling primal heuristic <zeroobj> Range: {0, ..., 65534}	0
heuristics/zeroobj/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞ }	100
heuristics/zeroobj/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/zeroobj/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/zeroobj/maxdepth	maximal depth level to call primal heuristic <zeroobj> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/zeroobj/maxlpiters	maximum number of LP iterations to be performed in the subproblem Range: {-1, ..., ∞ }	5000
heuristics/zeroobj/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞ }	1000
heuristics/zeroobj/minimprove	factor by which zeroobj should at least improve the incumbent Range: [0, 1]	0.01
heuristics/zeroobj/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞ }	100
heuristics/zeroobj/onlywithoutsol	should heuristic only be executed if no primal solution was found, yet? Range: boolean	1
heuristics/zeroobj/priority	priority of heuristic <zeroobj> Range: {-536870912, ..., 536870911}	100
heuristics/zeroobj/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.39.4.169 heuristics/zirounding

Option	Description	Default
heuristics/zirounding/freq	frequency for calling primal heuristic <zirounding> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/zirounding/freqofs	frequency offset for calling primal heuristic <zirounding> Range: {0, ..., 65534}	0
Options for expert users		

Option	Description	Default
heuristics/zirounding/maxdepth	maximal depth level to call primal heuristic <zirounding> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/zirounding/maxroundingloops	determines maximum number of rounding loops Range: {-1, ..., ∞ }	2
heuristics/zirounding/minstopncalls	determines the minimum number of calls before percentage-based deactivation of Zirounding is applied Range: {1, ..., ∞ }	1000
heuristics/zirounding/priority	priority of heuristic <zirounding> Range: {-536870912, ..., 536870911}	-500
heuristics/zirounding/stoppercentage	if percentage of found solutions falls below this parameter, Zirounding will be deactivated Range: [0, 1]	0.02
heuristics/zirounding/stopziround	flag to determine if Zirounding is deactivated after a certain percentage of unsuccessful calls Range: boolean	1

5.39.4.170 history

Option	Description	Default
history/allowmerge	should variable histories be merged from sub-SCIPs whenever possible? Range: boolean	0
history/allowtransfer	should variable histories be transferred to initialize SCIP copies? Range: boolean	0
history/valuebased	should statistics be collected for variable domain value pairs? Range: boolean	0

5.39.4.171 limits

Option	Description	Default
limits/absgap	solving stops, if the absolute gap = primalbound - dualbound is below the given value Range: [0, ∞]	GAMS optca
limits/autorestartnodes	if solve exceeds this number of nodes for the first time, an automatic restart is triggered (-1: no automatic restart) Range: {-1, ..., ∞ }	-1
limits/bestsol	solving stops, if the given number of solution improvements were found (-1: no limit) Range: {-1, ..., ∞ }	-1

Option	Description	Default
limits/gap	solving stops, if the relative gap = $ \text{primal} - \text{dual} / \text{MIN}(\text{dual} , \text{primal})$ is below the given value, the gap is 'Infinity', if primal and dual bound have opposite signs Range: $[0, \infty]$	GAMS optcr
limits/maxorigsol	maximal number of solutions candidates to store in the solution storage of the original problem Range: $\{0, \dots, \infty\}$	10
limits/maxsol	maximal number of solutions to store in the solution storage Range: $\{1, \dots, \infty\}$	100
limits/memory	maximal memory usage in MB; reported memory usage is lower than real memory usage! Range: $[0, 8.79609\text{e}+12]$	GAMS workspace
limits/nodes	maximal number of nodes to process (-1: no limit) Range: $\{-1, \dots, \infty\}$	GAMS nodlim , if > 0 , otherwise -1
limits/restarts	solving stops, if the given number of restarts was triggered (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
limits/softtime	soft time limit which should be applied after first solution was found (-1.0: disabled) Range: $[-1, \infty]$	-1
limits/solutions	solving stops, if the given number of solutions were found (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
limits/stallnodes	solving stops, if the given number of nodes was processed since the last improvement of the primal solution value (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
limits/time	maximal time in seconds to run Range: $[0, \infty]$	GAMS reslim
limits/totalnodes	maximal number of total nodes (incl. restarts) to process (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1

5.39.4.172 lp

Option	Description	Default
lp/alwaysgetduals	should the Farkas duals always be collected when an LP is found to be infeasible? Range: boolean	0
lp/initalgorithm	LP algorithm for solving initial LP relaxations (automatic 's'implex, 'p'rimal simplex, 'd'ual simplex, 'b'arrier, barrier with 'c'rossover) Range: s, p, d, b, c	s

Option	Description	Default
lp/pricing	LP pricing strategy ('l'pi default, 'a'uto, 'f'ull pricing, 'p'artial, 's'teepest edge pricing, 'q'uickstart steepest edge pricing, 'd'evex pricing) Range: l, a, f, p, s, q, d	1
lp/resolvealgorithm	LP algorithm for resolving LP relaxations if a starting basis exists (automatic 's'implex, 'p'rimal simplex, 'd'ual simplex, 'b'arrier, barrier with 'c'rossover) Range: s, p, d, b, c	s
lp/solvedepth	maximal depth for solving LP at the nodes (-1: no depth limit) Range: {-1, ..., 65534}	-1
lp/solvefreq	frequency for solving LP at the nodes (-1: never; 0: only root LP) Range: {-1, ..., 65534}	1
lp/solver	LP solver to use (clp, cplex, soplex) Range: string	cplex, if licensed, otherwise soplex
Options for expert users		
lp/checkdualfeas	should LP solutions be checked for dual feasibility, resolving LP when numerical troubles occur? Range: boolean	1
lp/checkfarkas	should infeasibility proofs from the LP be checked? Range: boolean	1
lp/checkprimfeas	should LP solutions be checked for primal feasibility, resolving LP when numerical troubles occur? Range: boolean	1
lp/checkstability	should LP solver's return status be checked for stability? Range: boolean	1
lp/cleanupcols	should new non-basic columns be removed after LP solving? Range: boolean	0
lp/cleanupcolsroot	should new non-basic columns be removed after root LP solving? Range: boolean	0
lp/cleanuprows	should new basic rows be removed after LP solving? Range: boolean	1
lp/cleanuprowsroot	should new basic rows be removed after root LP solving? Range: boolean	1
lp/clearinitialprobinglp	should lp state be cleared at the end of probing mode when lp was initially unsolved, e.g., when called right after presolving? Range: boolean	1

Option	Description	Default
lp/colagelimit	maximum age a dynamic column can reach before it is deleted from the LP (-1: don't delete columns due to aging) Range: $\{-1, \dots, \infty\}$	10
lp/conditionlimit	maximum condition number of LP basis counted as stable (-1.0: no limit) Range: $[-1, \infty]$	-1
lp/disablecutoff	disable the cutoff bound in the LP solver? (0: enabled, 1: disabled, 2: auto) Range: $\{0, \dots, 2\}$	2
lp/fastmip	which FASTMIP setting of LP solver should be used? 0: off, 1: low Range: $\{0, \dots, 1\}$	1
lp/freesolvalbuffers	should the buffers for storing LP solution values during diving be freed at end of diving? Range: boolean	0
lp/iterlim	iteration limit for each single LP solve (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1
lp/lexdualalgo	should the lexicographic dual algorithm be used? Range: boolean	0
lp/lexdualbasic	choose fractional basic variables in lexicographic dual algorithm? Range: boolean	0
lp/lexdualmaxrounds	maximum number of rounds in the lexicographic dual algorithm (-1: unbounded) Range: $\{-1, \dots, \infty\}$	2
lp/lexdualrootonly	should the lexicographic dual algorithm be applied only at the root node Range: boolean	1
lp/lexdualstalling	turn on the lex dual algorithm only when stalling? Range: boolean	1
lp/minmarkowitz	minimal Markowitz threshold to control sparsity/stability in LU factorization Range: $[0.0001, 0.9999]$	0.01
lp/presolving	should presolving of LP solver be used? Range: boolean	1
lp/refactorinterval	LP refactorization interval (0: auto) Range: $\{0, \dots, \infty\}$	0
lp/resolveiterfac	factor of average LP iterations that is used as LP iteration limit for LP resolve (-1: unlimited) Range: $[-1, \infty]$	-1

Option	Description	Default
lp/resolveitermin	minimum number of iterations that are allowed for LP resolve Range: {1, ..., ∞ }	1000
lp/resolverestore	should the LP be resolved to restore the state at start of diving (if FALSE we buffer the solution values)? Range: boolean	0
lp/rootiterlim	iteration limit for initial root LP solve (-1: no limit) Range: {-1, ..., ∞ }	-1
lp/rowagelimit	maximum age a dynamic row can reach before it is deleted from the LP (-1: don't delete rows due to aging) Range: {-1, ..., ∞ }	10
lp/rowrepswitch	simplex algorithm shall use row representation of the basis if number of rows divided by number of columns exceeds this value (-1.0 to disable row representation) Range: [-1, ∞]	1.2
lp/scaling	LP scaling (0: none, 1: normal, 2: aggressive) Range: {0, ..., 2}	1
lp/solutionpolishing	LP solution polishing method (0: disabled, 1: only root, 2: always, 3: auto) Range: {0, ..., 3}	3
lp/threads	number of threads used for solving the LP (0: automatic) Range: {0, ..., 64}	GAMS threads

5.39.4.173 memory

Option	Description	Default
memory/savefac	fraction of maximal memory usage resulting in switch to memory saving mode Range: [0, 1]	0.8
Options for expert users		
memory/arraygrowfac	memory growing factor for dynamically allocated arrays Range: [1, 10]	1.2
memory/arraygrowinit	initial size of dynamically allocated arrays Range: {0, ..., ∞ }	4
memory/pathgrowfac	memory growing factor for path array Range: [1, 10]	2
memory/pathgrowinit	initial size of path array Range: {0, ..., ∞ }	256
memory/treegrowfac	memory growing factor for tree array Range: [1, 10]	2
memory/treegrowinit	initial size of tree array Range: {0, ..., ∞ }	65536

5.39.4.174 misc

Option	Description	Default
misc/allowstrongdualreds	should strong dual reductions be allowed in propagation and presolving? Range: boolean	1
misc/allowweakdualreds	should weak dual reductions be allowed in propagation and presolving? Range: boolean	1
misc/avoidmemout	try to avoid running into memory limit by restricting plugins like heuristics? Range: boolean	1
misc/calcingtegral	should SCIP calculate the primal dual integral value? Range: boolean	1
misc/catchctrlc	should the CTRL-C interrupt be caught by SCIP? Range: boolean	1
misc/estimexternmem	should the usage of external memory be estimated? Range: boolean	1
misc/finitesolutionstore	should SCIP try to remove infinite fixings from solutions copied to the solution store? Range: boolean	0
misc/improving sols	should only solutions be checked which improve the primal bound Range: boolean	0
misc/outputorigsol	should the best solution be transformed to the original space and be output in command line run? Range: boolean	1
misc/printreason	should the reason be printed if a given start solution is infeasible Range: boolean	0
misc/referencevalue	objective value for reference purposes Range: real	∞
misc/resetstat	should the statistics be reset if the transformed problem is freed (in case of a Benders' decomposition this parameter should be set to FALSE) Range: boolean	1
misc/scaleobj	should the objective function be scaled so that it is always integer? Range: boolean	1
misc/transorigsols	should SCIP try to transfer original solutions to the transformed space (after presolving)? Range: boolean	1
misc/transsolsorig	should SCIP try to transfer transformed solutions to the original space (after solving)? Range: boolean	1
misc/useconstable	should a hashtable be used to map from constraint names to constraints? Range: boolean	1
misc/usesmalltables	should smaller hashtables be used? yields better performance for small problems with about 100 variables Range: boolean	0

Option	Description	Default
misc/usesymmetry	bitset describing used symmetry handling technique (0: off; 1: polyhedral (orbitopes and/or symresacks); 2: orbital fixing; 3: orbitopes and orbital fixing; 4: Schreier Sims cuts; 5: Schreier Sims cuts and orbitopes); 6: Schreier Sims cuts and orbital fixing; 7: Schreier Sims cuts, orbitopes, and orbital fixing Range: {0, ..., 7}	7
misc/usevaritable	should a hashtable be used to map from variable names to variables? Range: boolean	1

5.39.4.175 nlhdlr/bilinear

Option	Description	Default
nlhdlr/bilinear/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/bilinear/maxsepdepth	maximum depth to apply separation Range: {0, ..., ∞ }	∞
nlhdlr/bilinear/maxseparounds	maximum number of separation rounds in a local node Range: {0, ..., ∞ }	1
nlhdlr/bilinear/maxseparoundsroot	maximum number of separation rounds in the root node Range: {0, ..., ∞ }	10
nlhdlr/bilinear/useinteval	whether to use the interval evaluation callback of the nlhdlr Range: boolean	1
nlhdlr/bilinear/usereverseprop	whether to use the reverse propagation callback of the nlhdlr Range: boolean	1

5.39.4.176 nlhdlr/concave

Option	Description	Default
nlhdlr/concave/detectsum	whether to run convexity detection when the root of an expression is a sum Range: boolean	0
nlhdlr/concave/enabled	should this nonlinear handler be used Range: boolean	1
Options for expert users		
nlhdlr/concave/cvxprodcomp	whether to use convexity check on product composition $f(h)*h$ Range: boolean	1
nlhdlr/concave/cvxquadratic	whether to use convexity check on quadratics Range: boolean	0
nlhdlr/concave/cvxsignomial	whether to use convexity check on signomials Range: boolean	1
nlhdlr/concave/handletrivial	whether to also handle trivial convex expressions Range: boolean	0

5.39.4.177 nlhdlr/convex

Option	Description	Default
nlhdlr/convex/detectsum	whether to run convexity detection when the root of an expression is a non-quadratic sum Range: boolean	0
nlhdlr/convex/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/convex/extendedform	whether to create extended formulations instead of looking for maximal convex expressions Range: boolean	1
Options for expert users		
nlhdlr/convex/cvxprodcomp	whether to use convexity check on product composition $f(h)*h$ Range: boolean	1
nlhdlr/convex/cvxquadratic	whether to use convexity check on quadratics Range: boolean	1
nlhdlr/convex/cvxsignomial	whether to use convexity check on signomials Range: boolean	1
nlhdlr/convex/handletrivial	whether to also handle trivial convex expressions Range: boolean	0

5.39.4.178 nlhdlr/default

Option	Description	Default
nlhdlr/default/enabled	should this nonlinear handler be used Range: boolean	1

5.39.4.179 nlhdlr/perspective

Option	Description	Default
nlhdlr/perspective/adjrefpoint	whether to adjust the reference point Range: boolean	1
nlhdlr/perspective/convexonly	whether perspective cuts are added only for convex expressions Range: boolean	0
nlhdlr/perspective/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/perspective/maxpropounds	maximal number of propagation rounds in probing Range: $\{-1, \dots, \infty\}$	1
nlhdlr/perspective/mindomreduction	minimal relative reduction in a variable's domain for applying probing Range: $[0, 1]$	0.1
nlhdlr/perspective/minviolprobing	minimal violation w.r.t. auxiliary variables for applying probing Range: $[0, \infty]$	1e-05
nlhdlr/perspective/probingfreq	probing frequency (-1 - no probing, 0 - root node only) Range: $\{-1, \dots, \infty\}$	1

Option	Description	Default
nlhdlr/perspective/probingonlyinsepa	whether to do probing only in separation Range: boolean	1
nlhdlr/perspective/tightenbounds	whether variable semicontinuity is used to tighten variable bounds Range: boolean	1

5.39.4.180 nlhdlr/quadratic

Option	Description	Default
nlhdlr/quadratic/atwhichnodes	determines at which nodes cut is used (if it's -1, it's used only at the root node, if it's $n \geq 0$, it's used at every multiple of n) Range: $\{-1, \dots, \infty\}$	1
nlhdlr/quadratic/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/quadratic/ignorebadrayrestriction	should cut be generated even with bad numerics when restricting to ray? Range: boolean	1
nlhdlr/quadratic/ignorehighre	should cut be added even when range / efficacy is large? Range: boolean	1
nlhdlr/quadratic/maxrank	maximal rank a slackvar can have Range: $\{0, \dots, \infty\}$	∞
nlhdlr/quadratic/mincutviolation	minimal cut violation the generated cuts must fulfill to be added to the LP Range: $[0, \infty]$	0.0001
nlhdlr/quadratic/minviolation	minimal violation the constraint must fulfill such that a cut is generated Range: $[0, \infty]$	0.0001
nlhdlr/quadratic/ncutslimit	limit for number of cuts generated consecutively Range: $\{0, \dots, \infty\}$	2
nlhdlr/quadratic/ncutslimitroot	limit for number of cuts generated at root node Range: $\{0, \dots, \infty\}$	20
nlhdlr/quadratic/nstrengthenlimit	limit for number of rays we do the strengthening for Range: $\{0, \dots, \infty\}$	∞
nlhdlr/quadratic/useboundsasrays	use bounds of variables in quadratic as rays for intersection cuts Range: boolean	0
nlhdlr/quadratic/useintersectioncuts	whether to use intersection cuts for quadratic constraints to separate Range: boolean	0
nlhdlr/quadratic/usestrengthening	whether the strengthening should be used Range: boolean	0

5.39.4.181 nlhdlr/quotient

Option	Description	Default
nlhdlr/quotient/enabled	should this nonlinear handler be used Range: boolean	1

5.39.4.182 nlhdlr/soc

Option	Description	Default
nlhdlr/soc/compeigenvalues	Should Eigenvalue computations be done to detect complex cases in quadratic constraints? Range: boolean	1
nlhdlr/soc/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/soc/mincutoffefficacy	Minimum efficacy which a cut needs in order to be added. Range: $[0, \infty]$	1e-05

5.39.4.183 nlp

Option	Description	Default
nlp/disable	should the NLP relaxation be always disabled (also for NLPs/MINLPs)? Range: boolean	0

5.39.4.184 nlpi/ipopt

Option	Description	Default
nlpi/ipopt/hessian_approximation	Indicates what Hessian information is to be used. Valid values if not empty: exact limited-memory Range: string	
nlpi/ipopt/hsllib	Name of library containing HSL routines for load at runtime Range: string	
nlpi/ipopt/linear_solver	Linear solver used for step computations. Valid values if not empty: ma27 ma57 ma77 ma86 ma97 pardiso pardisomkl mumps custom Range: string	ma27, if IpoptH licensed, mumps otherwise
nlpi/ipopt/linear_system_scaling	Method for scaling the linear system. Valid values if not empty: none mc19 slack-based Range: string	mc19, if IpoptH licensed, empty otherwise
nlpi/ipopt/mu_strategy	Update strategy for barrier parameter. Valid values if not empty: monotone adaptive Range: string	

Option	Description	Default
nlp/ipo/np_scaling_method	Select the technique used for scaling the NLP. Valid values if not empty: none user-scaling gradient-based equilibration-based Range: string	
nlp/ipo/optfile	name of Ipo options file Range: string	
nlp/ipo/pardisolib	Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime Range: string	
nlp/ipo/print_level	Output verbosity level. -1 to use NLPI or Ipo default. Range: {-1, ..., 12}	-1
nlp/ipo/priority	priority of NLPI <ipo> Range: {-536870912, ..., 536870911}	1000
nlp/ipo/warm_start_push	amount (relative and absolute) by which starting point is moved away from bounds in warmstarts Range: [0, 1]	1e-09

5.39.4.185 nodeselection

Option	Description	Default
nodeselection/childsel	child selection rule ('d'own, 'u'p, 'p'seudo costs, 'i'nference, 'l'p value, 'r'oot LP value difference, 'h'ybrid inference/root LP value difference) Range: d, u, p, i, l, r, h	h

5.39.4.186 nodeselection/bfs

Option	Description	Default
nodeselection/bfs/stdpriority	priority of node selection rule <bfs> in standard mode Range: {-536870912, ..., 1073741823}	100000
Options for expert users		
nodeselection/bfs/maxplungedepth	maximal plunging depth, before new best node is forced to be selected (-1 for dynamic setting) Range: {-1, ..., ∞ }	-1
nodeselection/bfs/maxplungequot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where plunging is performed Range: [0, ∞]	0.25
nodeselection/bfs/memsavepriority	priority of node selection rule <bfs> in memory saving mode Range: {-536870912, ..., 536870911}	0
nodeselection/bfs/minplungedepth	minimal plunging depth, before new best node may be selected (-1 for dynamic setting) Range: {-1, ..., ∞ }	-1

5.39.4.187 nodeselection/breadthfirst

Option	Description	Default
nodeselection/breadthfirst/stdpriority	priority of node selection rule <breadthfirst> in standard mode Range: {-536870912, ..., 1073741823}	-10000
Options for expert users		
nodeselection/breadthfirst/memsavepriority	priority of node selection rule <breadthfirst> in memory saving mode Range: {-536870912, ..., 536870911}	-1000000

5.39.4.188 nodeselection/dfs

Option	Description	Default
nodeselection/dfs/stdpriority	priority of node selection rule <dfs> in standard mode Range: {-536870912, ..., 1073741823}	0
Options for expert users		
nodeselection/dfs/memsavepriority	priority of node selection rule <dfs> in memory saving mode Range: {-536870912, ..., 536870911}	100000

5.39.4.189 nodeselection/estimate

Option	Description	Default
nodeselection/estimate/bestnodefreq	frequency at which the best node instead of the best estimate is selected (0: never) Range: {0, ..., ∞ }	10
nodeselection/estimate/breadthfirstdepth	depth until breadth-first search is applied Range: {-1, ..., ∞ }	-1
nodeselection/estimate/plungeoffset	number of nodes before doing plunging the first time Range: {0, ..., ∞ }	0
nodeselection/estimate/stdpriority	priority of node selection rule <estimate> in standard mode Range: {-536870912, ..., 1073741823}	200000
Options for expert users		
nodeselection/estimate/maxplungedepth	maximal plunging depth, before new best node is forced to be selected (-1 for dynamic setting) Range: {-1, ..., ∞ }	-1
nodeselection/estimate/maxplungequot	maximal quotient (estimate - lowerbound)/(cutoffbound - lowerbound) where plunging is performed Range: [0, ∞]	0.25
nodeselection/estimate/memsavepriority	priority of node selection rule <estimate> in memory saving mode Range: {-536870912, ..., 536870911}	100

Option	Description	Default
nodeselection/estimate/minplungedepth	minimal plunging depth, before new best node may be selected (-1 for dynamic setting) Range: $\{-1, \dots, \infty\}$	-1

5.39.4.190 nodeselection/hybridestim

Option	Description	Default
nodeselection/hybridestim/bestnodefreq	frequency at which the best node instead of the hybrid best estimate / best bound is selected (0: never) Range: $\{0, \dots, \infty\}$	1000
nodeselection/hybridestim/stdpriority	priority of node selection rule <hybridestim> in standard mode Range: $\{-536870912, \dots, 1073741823\}$	50000
Options for expert users		
nodeselection/hybridestim/estimweight	weight of estimate value in node selection score (0: pure best bound search, 1: pure best estimate search) Range: $[0, 1]$	0.1
nodeselection/hybridestim/maxplungedepth	maximal plunging depth, before new best node is forced to be selected (-1 for dynamic setting) Range: $\{-1, \dots, \infty\}$	-1
nodeselection/hybridestim/maxplungequot	maximal quotient (estimate - lowerbound)/(cutoffbound - lowerbound) where plunging is performed Range: $[0, \infty]$	0.25
nodeselection/hybridestim/memsavepriority	priority of node selection rule <hybridestim> in memory saving mode Range: $\{-536870912, \dots, 536870911\}$	50
nodeselection/hybridestim/minplungedepth	minimal plunging depth, before new best node may be selected (-1 for dynamic setting) Range: $\{-1, \dots, \infty\}$	-1

5.39.4.191 nodeselection/restartdfs

Option	Description	Default
nodeselection/restartdfs/countonlyleaves	count only leaf nodes (otherwise all nodes)? Range: boolean	1
nodeselection/restartdfs/selectbestfreq	frequency for selecting the best node instead of the deepest one Range: $\{0, \dots, \infty\}$	100
nodeselection/restartdfs/stdpriority	priority of node selection rule <restartdfs> in standard mode Range: $\{-536870912, \dots, 1073741823\}$	10000
Options for expert users		

Option	Description	Default
nodeselection/restartdfs/memsavepriority	priority of node selection rule <restartdfs> in memory saving mode Range: {-536870912, ..., 536870911}	50000

5.39.4.192 nodeselection/uct

Option	Description	Default
nodeselection/uct/stdpriority	priority of node selection rule <uct> in standard mode Range: {-536870912, ..., 1073741823}	10
Options for expert users		
nodeselection/uct/memsavepriority	priority of node selection rule <uct> in memory saving mode Range: {-536870912, ..., 536870911}	0
nodeselection/uct/nodelimit	maximum number of nodes before switching to default rule Range: {0, ..., 1000000}	31
nodeselection/uct/useestimate	should the estimate (TRUE) or lower bound of a node be used for UCT score? Range: boolean	0
nodeselection/uct/weight	weight for visit quotient of node selection rule Range: [0, 1]	0.1

5.39.4.193 numerics

Option	Description	Default
numerics/checkfeastolfac	feasibility tolerance factor; for checking the feasibility of the best solution Range: [0, ∞]	1
numerics/dualfeastol	feasibility tolerance for reduced costs in LP solution Range: [1e-17, 0.001]	1e-07
numerics/epsilon	absolute values smaller than this are considered zero Range: [1e-20, 0.001]	1e-09
numerics/feastol	feasibility tolerance for constraints Range: [1e-17, 0.001]	1e-06
numerics/lpfeastolfactor	factor w.r.t. primal feasibility tolerance that determines default (and maximal) primal feasibility tolerance of LP solver Range: [1e-06, 1]	1
numerics/sumepsilon	absolute values of sums smaller than this are considered zero Range: [1e-17, 0.001]	1e-06
Options for expert users		
numerics/barrierconvtol	LP convergence tolerance used in barrier algorithm Range: [1e-17, 0.001]	1e-10
numerics/boundstreps	minimal relative improve for strengthening bounds Range: [1e-17, ∞]	0.05
numerics/hugeval	values larger than this are considered huge and should be handled separately (e.g., in activity computation) Range: [0, ∞]	1e+15

Option	Description	Default
numerics/pseudocostdelta	minimal objective distance value to use for branching pseudo cost updates Range: $[0, \infty]$	0.0001
numerics/pseudocoststeps	minimal variable distance value to use for branching pseudo cost updates Range: $[1e-17, 1]$	0.1
numerics/recomputefac	minimal decrease factor that causes the recomputation of a value (e.g., pseudo objective) instead of an update Range: $[0, \infty]$	1e+07

5.39.4.194 presolving

Option	Description	Default
presolving/maxrestarts	maximal number of restarts (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
presolving/maxrounds	maximal number of presolving rounds (-1: unlimited, 0: off) Range: $\{-1, \dots, \infty\}$	-1
Options for expert users		
presolving/abortfac	abort presolve, if at most this fraction of the problem was changed in last presolve round Range: $[0, 1]$	0.0008
presolving/clqtablefac	limit on number of entries in clique table relative to number of problem nonzeros Range: $[0, \infty]$	2
presolving/donotaggr	should aggregation of variables be forbidden? Range: boolean	0
presolving/donotmultaggr	should multi-aggregation of variables be forbidden? Range: boolean	0
presolving/immrestartfac	fraction of integer variables that were fixed in the root node triggering an immediate restart with preprocessing Range: $[0, 1]$	0.1
presolving/restartfac	fraction of integer variables that were fixed in the root node triggering a restart with preprocessing after root node evaluation Range: $[0, 1]$	0.025
presolving/restartminred	minimal fraction of integer variables removed after restart to allow for an additional restart Range: $[0, 1]$	0.1
presolving/subrestartfac	fraction of integer variables that were globally fixed during the solving process triggering a restart with preprocessing Range: $[0, 1]$	1

5.39.4.195 presolving/boundshift

Option	Description	Default
presolving/boundshift/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	0
Options for expert users		

Option	Description	Default
presolving/boundshift/flipping	is flipping allowed (multiplying with -1)? Range: boolean	1
presolving/boundshift/integer	shift only integer ranges? Range: boolean	1
presolving/boundshift/maxshift	absolute value of maximum shift Range: {0, ..., ∞ }	∞
presolving/boundshift/priority	priority of presolver <boundshift> Range: {-536870912, ..., 536870911}	7900000
presolving/boundshift/timing	timing mask of presolver <boundshift> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.39.4.196 presolving/convertinttobin

Option	Description	Default
presolving/convertinttobin/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	0
Options for expert users		
presolving/convertinttobin/maxdomainsize	absolute value of maximum domain size for converting an integer variable to binaries variables Range: {0, ..., ∞ }	∞
presolving/convertinttobin/onlypoweroftwo	should only integer variables with a domain size of $2^p - 1$ be converted(, there we don't need an knapsack-constraint for restricting the sum of the binaries) Range: boolean	0
presolving/convertinttobin/priority	priority of presolver <convertinttobin> Range: {-536870912, ..., 536870911}	6000000
presolving/convertinttobin/samelocksinbothdirections	should only integer variables with uplocks equals downlocks be converted Range: boolean	0
presolving/convertinttobin/timing	timing mask of presolver <convertinttobin> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.39.4.197 presolving/domcol

Option	Description	Default
presolving/domcol/continuousred	should reductions for continuous variables be performed? Range: boolean	1
presolving/domcol/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
presolving/domcol/nummaxpairs	maximal number of pair comparisons Range: {1024, ..., 1000000000}	1048576

Option	Description	Default
presolving/domcol/numminpairs	minimal number of pair comparisons Range: {100, ..., 1048576}	1024
presolving/domcol/predbndstr	should predictive bound strengthening be applied? Range: boolean	0
Options for expert users		
presolving/domcol/priority	priority of presolver <domcol> Range: {-536870912, ..., 536870911}	-1000
presolving/domcol/timing	timing mask of presolver <domcol> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.198 presolving/dualagg

Option	Description	Default
presolving/dualagg/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	0
Options for expert users		
presolving/dualagg/priority	priority of presolver <dualagg> Range: {-536870912, ..., 536870911}	-12000
presolving/dualagg/timing	timing mask of presolver <dualagg> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.199 presolving/dualcomp

Option	Description	Default
presolving/dualcomp/componlydisvars	should only discrete variables be compensated? Range: boolean	0
presolving/dualcomp/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
presolving/dualcomp/priority	priority of presolver <dualcomp> Range: {-536870912, ..., 536870911}	-50
presolving/dualcomp/timing	timing mask of presolver <dualcomp> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.200 presolving/dualinfer

Option	Description	Default
presolving/dualinfer/maxdualbndloops	maximal number of dual bound strengthening loops Range: {-1, ..., ∞ }	12
presolving/dualinfer/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	0

Option	Description	Default
presolving/dualinfer/maxrowsupport	Maximum number of row's non-zeros for changing inequality to equality Range: {2, ..., ∞ }	3
presolving/dualinfer/twocolcombine	use convex combination of columns for determining dual bounds Range: boolean	1
Options for expert users		
presolving/dualinfer/maxcombinefails	maximal number of consecutive useless column combines Range: {-1, ..., ∞ }	1000
presolving/dualinfer/maxconsiderednonzeros	maximal number of considered non-zeros within one column (-1: no limit) Range: {-1, ..., ∞ }	100
presolving/dualinfer/maxhashfac	Maximum number of hashlist entries as multiple of number of columns in the problem (-1: no limit) Range: {-1, ..., ∞ }	10
presolving/dualinfer/maxpairfac	Maximum number of processed column pairs as multiple of the number of columns in the problem (-1: no limit) Range: {-1, ..., ∞ }	1
presolving/dualinfer/maxretriefails	maximal number of consecutive useless hashtable retrieves Range: {-1, ..., ∞ }	1000
presolving/dualinfer/priority	priority of presolver <dualinfer> Range: {-536870912, ..., 536870911}	-3000
presolving/dualinfer/timing	timing mask of presolver <dualinfer> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.201 presolving/dualsparsify

Option	Description	Default
presolving/dualsparsify/maxbinfillin	maximal fillin for binary variables (-1: unlimited) Range: {-1, ..., ∞ }	1
presolving/dualsparsify/maxcontfillin	maximal fillin for continuous variables (-1: unlimited) Range: {-1, ..., ∞ }	1
presolving/dualsparsify/maxintfillin	maximal fillin for integer variables including binaries (-1: unlimited) Range: {-1, ..., ∞ }	1
presolving/dualsparsify/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
presolving/dualsparsify/mineliminatednonzeros	minimal eliminated nonzeros within one column if we need to add a constraint to the problem Range: {0, ..., ∞ }	100
Options for expert users		

Option	Description	Default
presolving/dualsparsify/enablecopy	should dualsparsify presolver be copied to sub-SCIPs? Range: boolean	1
presolving/dualsparsify/maxconsiderednonzeros	maximal number of considered nonzeros within one column (-1: no limit) Range: {-1, ..., ∞ }	70
presolving/dualsparsify/maxretrievefac	limit on the number of useless vs. useful hashtable retrieves as a multiple of the number of constraints Range: [0, ∞]	100
presolving/dualsparsify/preservegoodlocks	should we preserve good locked properties of variables (at most one lock in one direction)? Range: boolean	0
presolving/dualsparsify/preserveintcoefs	should we forbid cancellations that destroy integer coefficients? Range: boolean	0
presolving/dualsparsify/priority	priority of presolver <dualsparsify> Range: {-536870912, ..., 536870911}	-240000
presolving/dualsparsify/timing	timing mask of presolver <dualsparsify> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16
presolving/dualsparsify/waitingfac	number of calls to wait until next execution as a multiple of the number of useless calls Range: [0, ∞]	2

5.39.4.202 presolving/gateextraction

Option	Description	Default
presolving/gateextraction/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
presolving/gateextraction/onlysetpart	should we only try to extract set-partitioning constraints and no and-constraints Range: boolean	0
presolving/gateextraction/priority	priority of presolver <gateextraction> Range: {-536870912, ..., 536870911}	1000000
presolving/gateextraction/searchequations	should we try to extract set-partitioning constraint out of one logicor and one corresponding set-packing constraint Range: boolean	1
presolving/gateextraction/sorting	order logicor constraints to extract big-gates before smaller ones (-1), do not order them (0) or order them to extract smaller gates at first (1) Range: {-1, ..., 1}	1
presolving/gateextraction/timing	timing mask of presolver <gateextraction> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.203 presolving/implics

Option	Description	Default
presolving/implics/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
presolving/implics/priority	priority of presolver <implics> Range: {-536870912, ..., 536870911}	-10000
presolving/implics/timing	timing mask of presolver <implics> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8

5.39.4.204 presolving/inttobinary

Option	Description	Default
presolving/inttobinary/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
presolving/inttobinary/priority	priority of presolver <inttobinary> Range: {-536870912, ..., 536870911}	7000000
presolving/inttobinary/timing	timing mask of presolver <inttobinary> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.39.4.205 presolving/milp

Option	Description	Default
presolving/milp/hugebound	absolute bound value that is considered too huge for activity based calculations Range: [0, ∞]	1e+08
presolving/milp/markowitztolerance	the markowitz tolerance used for substitutions Range: [0, 1]	0.01
presolving/milp/maxfillinpersubstitution	maximal possible fillin for substitutions to be considered Range: {-2147483648, ..., ∞ }	3
presolving/milp/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	0 on Mac OS X, -1 otherwise
presolving/milp/modifyconsfac	modify SCIP constraints when the number of nonzeros or rows is at most this factor times the number of nonzeros or rows before presolving Range: [0, 1]	0.8

Option	Description	Default
presolving/milp/randomseed	the random seed used for randomization of tie breaking Range: $\{-2147483648, \dots, \infty\}$	0
presolving/milp/threads	maximum number of threads presolving may use (0: automatic) Range: $\{0, \dots, \infty\}$	GAMS threads
Options for expert users		
presolving/milp/enabledomcol	should the dominated column presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enabledualinfer	should the dualinfer presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enablemultiaggr	should the multi-aggregation presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enableparallelrows	should the parallel rows presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enableprobing	should the probing presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enablesparsify	should the sparsify presolver be enabled within the presolve library? Range: boolean	0
presolving/milp/maxshiftperrow	maximal amount of nonzeros allowed to be shifted to make space for substitutions Range: $\{0, \dots, \infty\}$	10
presolving/milp/priority	priority of presolver <milp> Range: $\{-536870912, \dots, 536870911\}$	9999999
presolving/milp/probfilename	filename to store the problem before MILP presolving starts Range: string	-
presolving/milp/timing	timing mask of presolver <milp> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{4, \dots, 60\}$	8

5.39.4.206 presolving/qpkktref

Option	Description	Default
presolving/qpkktref/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	0

Option	Description	Default
Options for expert users		
presolving/qpkktrf/addkktbinary	if TRUE then allow binary variables for KKT update Range: boolean	0
presolving/qpkktrf/priority	priority of presolver <qpkktrf> Range: {-536870912, ..., 536870911}	-1
presolving/qpkktrf/timing	timing mask of presolver <qpkktrf> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8
presolving/qpkktrf/updatequadbounded	if TRUE then only apply the update to QPs with bounded variables; if the variables are not bounded then a finite optimal solution might not exist and the KKT conditions would then be invalid Range: boolean	1
presolving/qpkktrf/updatequadindef	if TRUE then apply quadratic constraint update even if the quadratic constraint matrix is known to be indefinite Range: boolean	0

5.39.4.207 presolving/redvub

Option	Description	Default
presolving/redvub/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	0
Options for expert users		
presolving/redvub/priority	priority of presolver <redvub> Range: {-536870912, ..., 536870911}	-9000000
presolving/redvub/timing	timing mask of presolver <redvub> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.208 presolving/sparsify

Option	Description	Default
presolving/sparsify/maxbinfillin	maximal fillin for binary variables (-1: unlimited) Range: {-1, ..., ∞ }	0
presolving/sparsify/maxcontfillin	maximal fillin for continuous variables (-1: unlimited) Range: {-1, ..., ∞ }	0
presolving/sparsify/maxintfillin	maximal fillin for integer variables including binaries (-1: unlimited) Range: {-1, ..., ∞ }	0
presolving/sparsify/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1

Option	Description	Default
Options for expert users		
presolving/sparsify/cancellinear	should we cancel nonzeros in constraints of the linear constraint handler? Range: boolean	1
presolving/sparsify/enablecopy	should sparsify presolver be copied to sub-SCIPs? Range: boolean	1
presolving/sparsify/maxconsiderednonzeros	maximal number of considered non-zeros within one row (-1: no limit) Range: {-1, ..., ∞}	70
presolving/sparsify/maxnonzeros	maximal support of one equality to be used for cancelling (-1: no limit) Range: {-1, ..., ∞}	-1
presolving/sparsify/maxretrievefac	limit on the number of useless vs. useful hashtable retrieves as a multiple of the number of constraints Range: [0, ∞]	100
presolving/sparsify/preserveintcoefs	should we forbid cancellations that destroy integer coefficients? Range: boolean	1
presolving/sparsify/priority	priority of presolver <sparsify> Range: {-536870912, ..., 536870911}	-24000
presolving/sparsify/rowsort	order in which to process inequalities ('n'o sorting, 'i'ncreasing nonzeros, 'd'ecreasing nonzeros) Range: n, i, d	d
presolving/sparsify/timing	timing mask of presolver <sparsify> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16
presolving/sparsify/waitingfac	number of calls to wait until next execution as a multiple of the number of useless calls Range: [0, ∞]	2

5.39.4.209 presolving/stuffing

Option	Description	Default
presolving/stuffing/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		
presolving/stuffing/priority	priority of presolver <stuffing> Range: {-536870912, ..., 536870911}	-100
presolving/stuffing/timing	timing mask of presolver <stuffing> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.210 presolving/trivial

Option	Description	Default
presolving/trivial/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
presolving/trivial/priority	priority of presolver <trivial> Range: {-536870912, ..., 536870911}	9000000
presolving/trivial/timing	timing mask of presolver <trivial> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.39.4.211 presolving/tworowbnd

Option	Description	Default
presolving/tworowbnd/maxcombinefails	maximal number of consecutive useless row combines Range: {-1, ..., ∞ }	1000
presolving/tworowbnd/maxconsiderednonzeros	maximal number of considered non-zeros within one row (-1: no limit) Range: {-1, ..., ∞ }	100
presolving/tworowbnd/maxhashfac	Maximum number of hashlist entries as multiple of number of rows in the problem (-1: no limit) Range: {-1, ..., ∞ }	10
presolving/tworowbnd/maxpairfac	Maximum number of processed row pairs as multiple of the number of rows in the problem (-1: no limit) Range: {-1, ..., ∞ }	1
presolving/tworowbnd/maxretrievefails	maximal number of consecutive useless hashtable retrieves Range: {-1, ..., ∞ }	1000
presolving/tworowbnd/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞ }	0
Options for expert users		
presolving/tworowbnd/enablecopy	should tworowbnd presolver be copied to sub-SCIPs? Range: boolean	1
presolving/tworowbnd/priority	priority of presolver <tworowbnd> Range: {-536870912, ..., 536870911}	-2000
presolving/tworowbnd/timing	timing mask of presolver <tworowbnd> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.39.4.212 propagating

Option	Description	Default
propagating/abortoncutoff	should propagation be aborted immediately? setting this to FALSE could help conflict analysis to produce more conflict constraints Range: boolean	1
propagating/maxrounds	maximal number of propagation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	100
propagating/maxroundsroot	maximal number of propagation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	1000

5.39.4.213 propagating/dualfix

Option	Description	Default
propagating/dualfix/freq	frequency for calling propagator <dualfix> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
propagating/dualfix/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
propagating/dualfix/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/dualfix/presolpriority	presolving priority of propagator <dualfix> Range: {-536870912, ..., 536870911}	8000000
propagating/dualfix/presoltiming	timing mask of the presolving method of propagator <dualfix> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	4
propagating/dualfix/priority	priority of propagator <dualfix> Range: {-536870912, ..., 536870911}	8000000
propagating/dualfix/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	1

5.39.4.214 propagating/genvbounds

Option	Description	Default
propagating/genvbounds/freq	frequency for calling propagator <genvbounds> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/genvbounds/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		

Option	Description	Default
propagating/genvbounds/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/genvbounds/global	apply global propagation? Range: boolean	1
propagating/genvbounds/presolpriority	presolving priority of propagator <genvbounds> Range: {-536870912, ..., 536870911}	-2000000
propagating/genvbounds/presoltiming	timing mask of the presolving method of propagator <genvbounds> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	4
propagating/genvbounds/priority	priority of propagator <genvbounds> Range: {-536870912, ..., 536870911}	3000000
propagating/genvbounds/propasconss	should genvbounds be transformed to (linear) constraints? Range: boolean	0
propagating/genvbounds/propinrootnode	apply genvbounds in root node if no new incumbent was found? Range: boolean	1
propagating/genvbounds/sort	sort genvbounds and wait for bound change events? Range: boolean	1
propagating/genvbounds/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	15

5.39.4.215 propagating/nlobbt

Option	Description	Default
propagating/nlobbt/addlprows	should non-initial LP rows be used? Range: boolean	1
propagating/nlobbt/freq	frequency for calling propagator <nlobbt> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
propagating/nlobbt/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
propagating/nlobbt/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	1
propagating/nlobbt/feastolfac	factor for NLP feasibility tolerance Range: [0, 1]	0.01
propagating/nlobbt/itlimitfactor	LP iteration limit for nlobbt will be this factor times total LP iterations in root node Range: [0, ∞]	2
propagating/nlobbt/minlinearfrac	minimum (convex nlrows)/(linear nlrows) threshold to apply propagator Range: [0, ∞]	0.02

Option	Description	Default
propagating/nlobbt/minnonconvexfrac	(convex nlrows)/(nonconvex nlrows) threshold to apply propagator Range: $[0, \infty]$	0.2
propagating/nlobbt/nlpiterlimit	iteration limit of NLP solver; 0 for no limit Range: $\{0, \dots, \infty\}$	500
propagating/nlobbt/nlptimelimit	time limit of NLP solver; 0.0 for no limit Range: $[0, \infty]$	0
propagating/nlobbt/nlpverblevel	verbosity level of NLP solver Range: $\{0, \dots, 5\}$	0
propagating/nlobbt/presolpriority	presolving priority of propagator <nlobbt> Range: $\{-536870912, \dots, 536870911\}$	0
propagating/nlobbt/presoltiming	timing mask of the presolving method of propagator <nlobbt> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{2, \dots, 60\}$	28
propagating/nlobbt/priority	priority of propagator <nlobbt> Range: $\{-536870912, \dots, 536870911\}$	-1100000
propagating/nlobbt/relobjtofac	factor for NLP relative objective tolerance Range: $[0, 1]$	0.01
propagating/nlobbt/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AF-TERLPLOOP, 15:ALWAYS)) Range: $\{1, \dots, 15\}$	4

5.39.4.216 propagating/obbt

Option	Description	Default
propagating/obbt/boundstreps	minimal relative improve for strengthening bounds Range: $[0, 1]$	0.001
propagating/obbt/conditionlimit	maximum condition limit used in LP solver (-1.0: no limit) Range: $[-1, \infty]$	-1
propagating/obbt/dualfeastol	feasibility tolerance for reduced costs used in obbt; this value is used if SCIP's dual feastol is greater Range: $[0, \infty]$	1e-09
propagating/obbt/freq	frequency for calling propagator <obbt> (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	0
propagating/obbt/itlimitfactor	multiple of root node LP iterations used as total LP iteration limit for obbt (≤ 0 : no limit) Range: real	10
propagating/obbt/itlimitfactorbilin	multiple of OBBT LP limit used as total LP iteration limit for solving bilinear inequality LPs (< 0 for no limit) Range: real	3
propagating/obbt/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: $\{-1, \dots, \infty\}$	-1

Option	Description	Default
propagating/obbt/minitlimit	minimum LP iteration limit Range: $\{0, \dots, \infty\}$	5000
propagating/obbt/minnonconvexity	minimum absolute value of nonconvex eigenvalues for a bilinear term Range: $[0, \infty]$	0.1
Options for expert users		
propagating/obbt/applyfilterrounds	try to filter bounds in so-called filter rounds by solving auxiliary LPs? Range: boolean	0
propagating/obbt/applytrivialfilter	try to filter bounds with the LP solution after each solve? Range: boolean	1
propagating/obbt/createbilineqs	solve auxiliary LPs in order to find valid inequalities for bilinear terms? Range: boolean	1
propagating/obbt/creategenvbounds	should obbt try to provide genvbounds if possible? Range: boolean	1
propagating/obbt/createlincons	create linear constraints from inequalities for bilinear terms? Range: boolean	0
propagating/obbt/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	1
propagating/obbt/genvbsduringfilter	should we try to generate genvbounds during trivial and aggressive filtering? Range: boolean	1
propagating/obbt/genvbsduringsepa	try to create genvbounds during separation process? Range: boolean	1
propagating/obbt/minfilter	minimal number of filtered bounds to apply another filter round Range: $\{1, \dots, \infty\}$	2
propagating/obbt/normalize	should coefficients in filtering be normalized w.r.t. the domains sizes? Range: boolean	1
propagating/obbt/onlynonconvexvars	only apply obbt on non-convex variables Range: boolean	1
propagating/obbt/orderingalgo	select the type of ordering algorithm which should be used (0: no special ordering, 1: greedy, 2: greedy reverse) Range: $\{0, \dots, 2\}$	1
propagating/obbt/presolpriority	presolving priority of propagator <obbt> Range: $\{-536870912, \dots, 536870911\}$	0
propagating/obbt/presoltiming	timing mask of the presolving method of propagator <obbt> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: $\{2, \dots, 60\}$	28
propagating/obbt/priority	priority of propagator <obbt> Range: $\{-536870912, \dots, 536870911\}$	-1000000
propagating/obbt/propagatefreq	trigger a propagation round after that many bound tightenings (0: no propagation) Range: $\{0, \dots, \infty\}$	0

Option	Description	Default
propagating/obbt/sepamaxiter	maximum number of iteration spend to separate an obbt LP solution Range: {0, ..., ∞ }	10
propagating/obbt/sepaminiter	minimum number of iteration spend to separate an obbt LP solution Range: {0, ..., ∞ }	0
propagating/obbt/separatesol	should the obbt LP solution be separated? Range: boolean	0
propagating/obbt/tightcontboundsprobing	should continuous bounds be tightened during the probing mode? Range: boolean	0
propagating/obbt/tightintboundsprobing	should integral bounds be tightened during the probing mode? Range: boolean	1
propagating/obbt/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AF-TERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	4

5.39.4.217 propagating/probing

Option	Description	Default
propagating/probing/freq	frequency for calling propagator <probing> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
propagating/probing/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
propagating/probing/maxruns	maximal number of runs, probing participates in (-1: no limit) Range: {-1, ..., ∞ }	1
Options for expert users		
propagating/probing/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	1
propagating/probing/maxdepth	maximal depth until propagation is executed(-1: no limit) Range: {-1, ..., ∞ }	-1
propagating/probing/maxfixings	maximal number of fixings found, until probing is interrupted (0: don't interrupt) Range: {0, ..., ∞ }	25
propagating/probing/maxsumuseless	maximal number of probings without fixings, until probing is aborted (0: don't abort) Range: {0, ..., ∞ }	0
propagating/probing/maxtotaluseless	maximal number of successive probings without fixings, bound changes, and implications, until probing is aborted (0: don't abort) Range: {0, ..., ∞ }	50
propagating/probing/maxuseless	maximal number of successive probings without fixings, until probing is aborted (0: don't abort) Range: {0, ..., ∞ }	1000

Option	Description	Default
propagating/probing/presolpriority	presolving priority of propagator <probing> Range: {-536870912, ..., 536870911}	-100000
propagating/probing/presoltiming	timing mask of the presolving method of propagator <probing> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	16
propagating/probing/priority	priority of propagator <probing> Range: {-536870912, ..., 536870911}	-100000
propagating/probing/proprounds	maximal number of propagation rounds in probing subproblems (-1: no limit, 0: auto) Range: {-1, ..., ∞ }	-1
propagating/probing/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	4

5.39.4.218 propagating/pseudoobj

Option	Description	Default
propagating/pseudoobj/freq	frequency for calling propagator <pseudoobj> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/pseudoobj/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
propagating/pseudoobj/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/pseudoobj/force	should the propagator be forced even if active pricer are present? Range: boolean	0
propagating/pseudoobj/maximplvars	maximum number of binary variables the implications are used if turned on (-1: unlimited)? Range: {-1, ..., ∞ }	50000
propagating/pseudoobj/maxnewvars	number of variables added after the propagator is reinitialized? Range: {0, ..., ∞ }	1000
propagating/pseudoobj/maxvarsfrac	maximal fraction of non-binary variables with non-zero objective without a bound reduction before aborted Range: [0, 1]	0.1
propagating/pseudoobj/minuseless	minimal number of successive non-binary variable propagations without a bound reduction before aborted Range: {0, ..., ∞ }	100
propagating/pseudoobj/presolpriority	presolving priority of propagator <pseudoobj> Range: {-536870912, ..., 536870911}	6000000

Option	Description	Default
propagating/pseudoobj/presoltiming	timing mask of the presolving method of propagator <pseudoobj> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	4
propagating/pseudoobj/priority	priority of propagator <pseudoobj> Range: {-536870912, ..., 536870911}	3000000
propagating/pseudoobj/propcutoffbound	propagate new cutoff bound directly globally Range: boolean	1
propagating/pseudoobj/propfullinroot	whether to propagate all non-binary variables when we are propagating the root node Range: boolean	1
propagating/pseudoobj/propuseimplics	use implications to strengthen the propagation of binary variable (increasing the objective change)? Range: boolean	1
propagating/pseudoobj/respropuseimplics	use implications to strengthen the resolve propagation of binary variable (increasing the objective change)? Range: boolean	1
propagating/pseudoobj/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	7

5.39.4.219 propagating/redcost

Option	Description	Default
propagating/redcost/continuous	should reduced cost fixing be also applied to continuous variables? Range: boolean	0
propagating/redcost/freq	frequency for calling propagator <redcost> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/redcost/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
propagating/redcost/useimplics	should implications be used to strength the reduced cost for binary variables? Range: boolean	0
Options for expert users		
propagating/redcost/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/redcost/force	should the propagator be forced even if active pricer are present? Range: boolean	0
propagating/redcost/presolpriority	presolving priority of propagator <redcost> Range: {-536870912, ..., 536870911}	0
propagating/redcost/presoltiming	timing mask of the presolving method of propagator <redcost> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	28

Option	Description	Default
propagating/redcost/priority	priority of propagator <redcost> Range: {-536870912, ..., 536870911}	1000000
propagating/redcost/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	6

5.39.4.220 propagating/rootredcost

Option	Description	Default
propagating/rootredcost/freq	frequency for calling propagator <rootredcost> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/rootredcost/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
Options for expert users		
propagating/rootredcost/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/rootredcost/force	should the propagator be forced even if active pricer are present? Range: boolean	0
propagating/rootredcost/onlybinary	should only binary variables be propagated? Range: boolean	0
propagating/rootredcost/presolpriority	presolving priority of propagator <rootredcost> Range: {-536870912, ..., 536870911}	0
propagating/rootredcost/presoltiming	timing mask of the presolving method of propagator <rootredcost> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	28
propagating/rootredcost/priority	priority of propagator <rootredcost> Range: {-536870912, ..., 536870911}	10000000
propagating/rootredcost/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	5

5.39.4.221 propagating/symmetry

Option	Description	Default
propagating/symmetry/freq	frequency for calling propagator <symmetry> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/symmetry/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞ }	-1

Option	Description	Default
Options for expert users		
propagating/symmetry/addconflictcuts	Should Schreier Sims constraints be added if we use a conflict based rule? Range: boolean	1
propagating/symmetry/addconsstiming	timing of adding constraints (0 = before presolving, 1 = during presolving, 2 = after presolving) Range: {0, ..., 2}	2
propagating/symmetry/addstrongsbcs	Should strong SBCs for enclosing orbit of symmetric subgroups be added if orbitopes are not used? Range: boolean	0
propagating/symmetry/addsymresacks	Add inequalities for symresacks for each generator? Range: boolean	0
propagating/symmetry/addweaksbcs	Should we add weak SBCs for enclosing orbit of symmetric subgroups? Range: boolean	1
propagating/symmetry/checksymmetries	Should all symmetries be checked after computation? Range: boolean	0
propagating/symmetry/compresssymmetries	Should non-affected variables be removed from permutation to save memory? Range: boolean	1
propagating/symmetry/compressthreshold	Compression is used if percentage of moved vars is at most the threshold. Range: [0, 1]	0.5
propagating/symmetry/conssaddlp	Should the symmetry breaking constraints be added to the LP? Range: boolean	1
propagating/symmetry/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/symmetry/detectorbitopes	Should we check whether the components of the symmetry group can be handled by orbitopes? Range: boolean	1
propagating/symmetry/detectsubgroups	Should we try to detect symmetric subgroups of the symmetry group on binary variables? Range: boolean	1
propagating/symmetry/displaynorbitvars	Should the number of variables affected by some symmetry be displayed? Range: boolean	0
propagating/symmetry/doubleequations	Double equations to positive/negative version? Range: boolean	0
propagating/symmetry/maxgenerators	limit on the number of generators that should be produced within symmetry detection (0 = no limit) Range: {0, ..., ∞ }	1500

Option	Description	Default
propagating/symmetry/maxnconssubgroup	maximum number of constraints up to which subgroup structures are detected Range: {0, ..., ∞ }	500000
propagating/symmetry/ofsymcomptiming	timing of symmetry computation for orbital fixing (0 = before presolving, 1 = during presolving, 2 = at first call) Range: {0, ..., 2}	2
propagating/symmetry/onlybinarysymmetry	Is only symmetry on binary variables used? Range: boolean	1
propagating/symmetry/performpresolving	run orbital fixing during presolving? Range: boolean	0
propagating/symmetry/preferlessrows	Shall orbitopes with less rows be preferred in detection? Range: boolean	1
propagating/symmetry/presolpriority	presolving priority of propagator <symmetry> Range: {-536870912, ..., 536870911}	-10000000
propagating/symmetry/presoltiming	timing mask of the presolving method of propagator <symmetry> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	16
propagating/symmetry/priority	priority of propagator <symmetry> Range: {-536870912, ..., 536870911}	-1000000
propagating/symmetry/recomputerestart	recompute symmetries after a restart has occurred? (0 = never, 1 = always, 2 = if OF found reduction) Range: {0, ..., 2}	0
propagating/symmetry/sstaddcuts	Should Schreier Sims constraints be added? Range: boolean	1
propagating/symmetry/sstleaderrule	rule to select the leader in an orbit (0: first var; 1: last var; 2: var having most conflicting vars in orbit; 3: var having most conflicting vars in problem) Range: {0, ..., 3}	0
propagating/symmetry/sstleadervartype	bitset encoding which variable types can be leaders (1: binary; 2: integer; 4: impl. int; 8: continuous);if multiple types are allowed, take the one with most affected vars Range: {1, ..., 15}	14
propagating/symmetry/sstmixedcomponents	Should Schreier Sims constraints be added if a symmetry component contains variables of different types? Range: boolean	1
propagating/symmetry/ssttiebreakrule	rule to select the orbit in Schreier Sims inequalities (variable in 0: minimum size orbit; 1: maximum size orbit; 2: orbit with most variables in conflict with leader) Range: {0, ..., 2}	1
propagating/symmetry/symfixnonbinaryvars	Whether all non-binary variables shall be not affected by symmetries if OF is active? Range: boolean	0

Option	Description	Default
propagating/symmetry/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AF-TERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	1
propagating/symmetry/usecolumnsparsity	Should the number of cons a variable is contained in be exploited in symmetry detection? Range: boolean	0
propagating/symmetry/usedynamicprop	whether dynamic propagation should be used for full orbitopes Range: boolean	1

5.39.4.222 propagating/vbounds

Option	Description	Default
propagating/vbounds/detectcycles	should cycles in the variable bound graph be identified? Range: boolean	0
propagating/vbounds/dotoposort	should the bounds be topologically sorted in advance? Range: boolean	1
propagating/vbounds/freq	frequency for calling propagator <vbounds> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/vbounds/maxcliquesexhaustive	maximum number of cliques per variable to run clique table analysis in exhaustive presolving Range: [0, ∞]	100
propagating/vbounds/maxcliquesmedium	maximum number of cliques per variable to run clique table analysis in medium presolving Range: [0, ∞]	50
propagating/vbounds/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞ }	-1
propagating/vbounds/minnewcliques	minimum percentage of new cliques to trigger another clique table analysis Range: [0, 1]	0.1
propagating/vbounds/usebdwidening	should bound widening be used to initialize conflict analysis? Range: boolean	1
Options for expert users		
propagating/vbounds/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/vbounds/presolpriority	presolving priority of propagator <vbounds> Range: {-536870912, ..., 536870911}	-90000
propagating/vbounds/presoltiming	timing mask of the presolving method of propagator <vbounds> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	24

Option	Description	Default
propagating/vbounds/priority	priority of propagator <vbounds> Range: {-536870912, ..., 536870911}	3000000
propagating/vbounds/sortcliques	should cliques be regarded for the topological sort? Range: boolean	0
propagating/vbounds/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	5
propagating/vbounds/usecliques	should cliques be propagated? Range: boolean	0
propagating/vbounds/useimplics	should implications be propagated? Range: boolean	0
propagating/vbounds/usevbounds	should vbounds be propagated? Range: boolean	1

5.39.4.223 randomization

Option	Description	Default
randomization/lpseed	random seed for LP solver, e.g. for perturbations in the simplex (0: LP default) Range: {0, ..., ∞ }	0
randomization/permutationseed	seed value for permuting the problem after reading/transformation (0: no permutation) Range: {0, ..., ∞ }	0
randomization/randomseedshift	global shift of all random seeds in the plugins and the LP random seed Range: {0, ..., ∞ }	0
Options for expert users		
randomization/permuteconss	should order of constraints be permuted (depends on permutationseed)? Range: boolean	1
randomization/permutevars	should order of variables be permuted (depends on permutationseed)? Range: boolean	0

5.39.4.224 separating

Option	Description	Default
separating/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separation (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/maxcoefratio	maximal ratio between coefficients in strongcg, cmir, and flowcover cuts Range: [1, ∞]	10000
separating/maxcoefratiofacrowprep	maximal ratio between coefficients (as factor of 1/feastol) to ensure in rowprep cleanup Range: [0, ∞]	10

Option	Description	Default
separating/maxcuts	maximal number of cuts separated per separation round (0: disable local separation) Range: {0, ..., ∞ }	100
separating/maxcutsroot	maximal number of separated cuts at the root node (0: disable root node separation) Range: {0, ..., ∞ }	2000
separating/maxlocalbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying local separation (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/maxstallrounds	maximal number of consecutive separation rounds without objective or integrality improvement in local nodes (-1: no additional restriction) Range: {-1, ..., ∞ }	1
separating/maxstallroundsroot	maximal number of consecutive separation rounds without objective or integrality improvement in the root node (-1: no additional restriction) Range: {-1, ..., ∞ }	10
separating/minactivityquot	minimum cut activity quotient to convert cuts into constraints during a restart (0.0: all cuts are converted) Range: [0, 1]	0.8
separating/minefficacy	minimal efficacy for a cut to enter the LP Range: [0, ∞]	0.0001
separating/minefficacyroot	minimal efficacy for a cut to enter the LP in the root node Range: [0, ∞]	0.0001
separating/poolfreq	separation frequency for the global cut pool (-1: disable global cut pool, 0: only separate pool at the root) Range: {-1, ..., 65534}	10
Options for expert users		
separating/cutagelimit	maximum age a cut can reach before it is deleted from the global cut pool, or -1 to keep all cuts Range: {-1, ..., ∞ }	80
separating/cutselrestart	cut selection during restart ('a'ge, activity 'q'quotient) Range: a, q	a
separating/cutselsubscip	cut selection for sub SCIPs ('a'ge, activity 'q'quotient) Range: a, q	a
separating/efficacynorm	row norm to use for efficacy calculation ('e'uclidean, 'm'aximum, 's'um, 'd'iscrete) Range: e, m, s, d	e
separating/filtercutpoolrel	should cutpool separate only cuts with high relative efficacy? Range: boolean	1

Option	Description	Default
separating/maxaddrounds	maximal additional number of separation rounds in subsequent price-and-cut loops (-1: no additional restriction) Range: $\{-1, \dots, \infty\}$	1
separating/maxroundsrootsubrun	maximal number of separation rounds in the root node of a subsequent run (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
separating/maxruns	maximal number of runs for which separation is enabled (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
separating/orthofunc	function used for calc. scalar prod. in orthogonality test ('e'uclidean, 'd'iscrete) Range: e, d	e

5.39.4.225 separating/aggregation

Option	Description	Default
separating/aggregation/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/aggregation/freq	frequency for calling separator <aggregation> (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	10
separating/aggregation/maxrounds	maximal number of cmir separation rounds per node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
separating/aggregation/maxroundsroot	maximal number of cmir separation rounds in the root node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
separating/aggregation/maxsepacuts	maximal number of cmir cuts separated per separation round Range: $\{0, \dots, \infty\}$	100
separating/aggregation/maxsepacutsroot	maximal number of cmir cuts separated per separation round in the root node Range: $\{0, \dots, \infty\}$	500
Options for expert users		
separating/aggregation/aggrtol	tolerance for bound distances used to select continuous variable in current aggregated constraint to be eliminated Range: $[0, \infty]$	0.01
separating/aggregation/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/aggregation/densityoffset	additional number of variables allowed in row on top of density Range: $\{0, \dots, \infty\}$	100
separating/aggregation/densityscore	weight of row density in the aggregation scoring of the rows Range: $[0, \infty]$	0.0001

Option	Description	Default
separating/aggregation/expbackoff	base for exponential increase of frequency at which separator <aggregation> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/aggregation/fixintegralrhs	should an additional variable be complemented if $f_0 = 0$? Range: boolean	1
separating/aggregation/maxaggdensity	maximal density of aggregated row Range: [0, 1]	0.2
separating/aggregation/maxaggrs	maximal number of aggregations for each row per separation round Range: {0, ..., ∞ }	3
separating/aggregation/maxaggrsroot	maximal number of aggregations for each row per separation round in the root node Range: {0, ..., ∞ }	6
separating/aggregation/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <aggregation> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/aggregation/maxfails	maximal number of consecutive unsuccessful aggregation tries (-1: unlimited) Range: {-1, ..., ∞ }	20
separating/aggregation/maxfailsroot	maximal number of consecutive unsuccessful aggregation tries in the root node (-1: unlimited) Range: {-1, ..., ∞ }	100
separating/aggregation/maxrowdensity	maximal density of row to be used in aggregation Range: [0, 1]	0.05
separating/aggregation/maxrowfac	maximal row aggregation factor Range: [0, ∞]	10000
separating/aggregation/maxslack	maximal slack of rows to be used in aggregation Range: [0, ∞]	0
separating/aggregation/maxslackroot	maximal slack of rows to be used in aggregation in the root node Range: [0, ∞]	0.1
separating/aggregation/maxtestdelta	maximal number of different deltas to try (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/aggregation/maxtries	maximal number of rows to start aggregation with per separation round (-1: unlimited) Range: {-1, ..., ∞ }	200
separating/aggregation/maxtriesroot	maximal number of rows to start aggregation with per separation round in the root node (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/aggregation/priority	priority of separator <aggregation> Range: {-536870912, ..., 536870911}	-3000

Option	Description	Default
separating/aggregation/slackscore	weight of slack in the aggregation scoring of the rows Range: $[0, \infty]$	0.001
separating/aggregation/trynegscaling	should negative values also be tested in scaling? Range: boolean	1

5.39.4.226 separating/cgmip

Option	Description	Default
separating/cgmip/addviolationcons	add constraint to subscip that only allows violated cuts (otherwise add obj. limit)? Range: boolean	0
separating/cgmip/addviolconshdlr	add constraint handler to filter out violated cuts? Range: boolean	0
separating/cgmip/cmirownbounds	tell CMIR-generator which bounds to used in rounding? Range: boolean	0
separating/cgmip/conshdlrusenorm	should the violation constraint handler use the norm of a cut to check for feasibility? Range: boolean	1
separating/cgmip/contconvert	Convert some integral variables to be continuous to reduce the size of the sub-MIP? Range: boolean	0
separating/cgmip/contconvfrac	fraction of integral variables converted to be continuous (if contconvert) Range: $[0, 1]$	0.1
separating/cgmip/contconvmin	minimum number of integral variables before some are converted to be continuous Range: $\{-1, \dots, \infty\}$	100
separating/cgmip/decisiontree	Use decision tree to turn separation on/off? Range: boolean	0
separating/cgmip/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/cgmip/earlyterm	terminate separation if a violated (but possibly sub-optimal) cut has been found? Range: boolean	1
separating/cgmip/freq	frequency for calling separator <cgmip> (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	-1
separating/cgmip/genprimalsols	Try to generate primal solutions from Gomory cuts? Range: boolean	0
separating/cgmip/intconvert	Convert some integral variables attaining fractional values to have integral value? Range: boolean	0
separating/cgmip/intconvfrac	fraction of frac. integral variables converted to have integral value (if intconvert) Range: $[0, 1]$	0.1
separating/cgmip/intconvmin	minimum number of integral variables before some are converted to have integral value Range: $\{-1, \dots, \infty\}$	100

Option	Description	Default
separating/cgmip/maxdepth	maximal depth at which the separator is applied (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
separating/cgmip/maxodelimit	maximum number of nodes considered for sub-MIP (-1: unlimited) Range: $\{-1, \dots, \infty\}$	5000
separating/cgmip/maxrounds	maximal number of cgmip separation rounds per node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	5
separating/cgmip/maxroundsroot	maximal number of cgmip separation rounds in the root node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	50
separating/cgmip/maxrowage	maximal age of rows to consider if onlyactiverows is false Range: $\{-1, \dots, \infty\}$	-1
separating/cgmip/minodelimit	minimum number of nodes considered for sub-MIP (-1: unlimited) Range: $\{-1, \dots, \infty\}$	500
separating/cgmip/objlone	Should the objective of the sub-MIP minimize the l1-norm of the multipliers? Range: boolean	0
separating/cgmip/objweightsize	Weight each row by its size? Range: boolean	1
separating/cgmip/onlyactiverows	Use only active rows to generate cuts? Range: boolean	0
separating/cgmip/onlyintvars	Generate cuts for problems with only integer variables? Range: boolean	0
separating/cgmip/onlyrankone	Separate only rank 1 inequalities w.r.t. CG-MIP separator? Range: boolean	0
separating/cgmip/output	Should information about the sub-MIP and cuts be displayed? Range: boolean	0
separating/cgmip/primalseparation	only separate cuts that are tight for the best feasible solution? Range: boolean	1
separating/cgmip/skipmultbounds	Skip the upper bounds on the multipliers in the sub-MIP? Range: boolean	1
separating/cgmip/subscipfast	Should the settings for the sub-MIP be optimized for speed? Range: boolean	1
separating/cgmip/usecmir	use CMIR-generator (otherwise add cut directly)? Range: boolean	1
separating/cgmip/usecutpool	use cutpool to store CG-cuts even if the are not efficient? Range: boolean	1
separating/cgmip/useobjlb	Use lower bound on objective function (via primal solution)? Range: boolean	0

Option	Description	Default
separating/cgmip/useobjub	Use upper bound on objective function (via primal solution)? Range: boolean	0
separating/cgmip/usestrongcg	use strong CG-function to strengthen cut? Range: boolean	0
Options for expert users		
separating/cgmip/cutcoefbnd	bounds on the values of the coefficients in the CG-cut Range: $[0, \infty]$	1000
separating/cgmip/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/cgmip/expbackoff	base for exponential increase of frequency at which separator <cgmip> is called (1: call at each multiple of frequency) Range: $\{1, \dots, 100\}$	4
separating/cgmip/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <cgmip> (0.0: only on current best node, 1.0: on all nodes) Range: $[0, 1]$	0
separating/cgmip/memorylimit	memory limit for sub-MIP Range: $[0, \infty]$	∞
separating/cgmip/objweight	weight used for the row combination coefficient in the sub-MIP objective Range: $[0, \infty]$	0.001
separating/cgmip/priority	priority of separator <cgmip> Range: $\{-536870912, \dots, 536870911\}$	-1000
separating/cgmip/timelimit	time limit for sub-MIP Range: $[0, \infty]$	∞

5.39.4.227 separating/cliquote

Option	Description	Default
separating/cliquote/freq	frequency for calling separator <cliquote> (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	0
separating/cliquote/maxsepacuts	maximal number of clique cuts separated per separation round (-1: no limit) Range: $\{-1, \dots, \infty\}$	10
Options for expert users		
separating/cliquote/backtrackfreq	frequency for premature backtracking up to tree level 1 (0: no backtracking) Range: $\{0, \dots, \infty\}$	1000
separating/cliquote/cliquedensity	minimal density of cliques to use a dense clique table Range: $[0, 1]$	0
separating/cliquote/cliquetablemem	maximal memory size of dense clique table (in kb) Range: $[0, 2.09715e+06]$	20000
separating/cliquote/delay	should separator be delayed, if other separators found cuts? Range: boolean	0

Option	Description	Default
separating/cliue/expbackoff	base for exponential increase of frequency at which separator <cliue> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/cliue/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <cliue> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/cliue/maxtreenodes	maximal number of nodes in branch and bound tree (-1: no limit) Range: {-1, ..., ∞}	10000
separating/cliue/maxzeroextensions	maximal number of zero-valued variables extending the cliue (-1: no limit) Range: {-1, ..., ∞}	1000
separating/cliue/priority	priority of separator <cliue> Range: {-536870912, ..., 536870911}	-5000
separating/cliue/scaleval	factor for scaling weights Range: [1, ∞]	1000

5.39.4.228 separating/closecuts

Option	Description	Default
separating/closecuts/freq	frequency for calling separator <closecuts> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
separating/closecuts/closethres	threshold on number of generated cuts below which the ordinary separation is started Range: {-1, ..., ∞}	50
separating/closecuts/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/closecuts/expbackoff	base for exponential increase of frequency at which separator <closecuts> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/closecuts/inclobjcutoff	include an objective cutoff when computing the relative interior? Range: boolean	0
separating/closecuts/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <closecuts> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/closecuts/maxlpiterfactor	factor for maximal LP iterations in relative interior computation compared to node LP iterations (negative for no limit) Range: [-1, ∞]	10
separating/closecuts/maxunsuccessful	turn off separation in current node after unsuccessful calls (-1 never turn off) Range: {-1, ..., ∞}	0

Option	Description	Default
separating/closecuts/priority	priority of separator <closecuts> Range: {-536870912, ..., 536870911}	1000000
separating/closecuts/recomputerelint	recompute relative interior point in each separation call? Range: boolean	0
separating/closecuts/sepacombvalue	convex combination value for close cuts Range: [0, 1]	0.3
separating/closecuts/separelint	generate close cuts w.r.t. relative interior point (best solution otherwise)? Range: boolean	1

5.39.4.229 separating/cmir

Option	Description	Default
separating/cmir/freq	frequency for calling separator <cmir> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/cmir/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/cmir/expbackoff	base for exponential increase of frequency at which separator <cmir> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/cmir/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <cmir> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/cmir/priority	priority of separator <cmir> Range: {-536870912, ..., 536870911}	-100000

5.39.4.230 separating/convexproj

Option	Description	Default
separating/convexproj/freq	frequency for calling separator <convexproj> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/convexproj/maxdepth	maximal depth at which the separator is applied (-1: unlimited) Range: {-1, ..., ∞ }	-1
Options for expert users		
separating/convexproj/delay	should separator be delayed, if other separators found cuts? Range: boolean	1
separating/convexproj/expbackoff	base for exponential increase of frequency at which separator <convexproj> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4

Option	Description	Default
separating/convexproj/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <convexproj> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/convexproj/nlpiterlimit	iteration limit of NLP solver; 0 for no limit Range: {0, ..., ∞ }	250
separating/convexproj/priority	priority of separator <convexproj> Range: {-536870912, ..., 536870911}	0

5.39.4.231 separating/disjunctive

Option	Description	Default
separating/disjunctive/freq	frequency for calling separator <disjunctive> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
separating/disjunctive/maxrank	maximal rank of a disj. cut that could not be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞ }	20
separating/disjunctive/maxrankintegral	maximal rank of a disj. cut that could be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞ }	-1
Options for expert users		
separating/disjunctive/delay	should separator be delayed, if other separators found cuts? Range: boolean	1
separating/disjunctive/expbackoff	base for exponential increase of frequency at which separator <disjunctive> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/disjunctive/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <disjunctive> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/disjunctive/maxconfsdelay	delay separation if number of conflict graph edges is larger than predefined value (-1: no limit) Range: {-1, ..., ∞ }	100000
separating/disjunctive/maxdepth	node depth of separating bipartite disjunctive cuts (-1: no limit) Range: {-1, ..., ∞ }	-1
separating/disjunctive/maxinvcuts	maximal number of cuts investigated per iteration in a branching node Range: {0, ..., ∞ }	50
separating/disjunctive/maxinvcutsroot	maximal number of cuts investigated per iteration in the root node Range: {0, ..., ∞ }	250

Option	Description	Default
separating/disjunctive/maxrounds	maximal number of separation rounds per iteration in a branching node (-1: no limit) Range: $\{-1, \dots, \infty\}$	25
separating/disjunctive/maxroundsroot	maximal number of separation rounds in the root node (-1: no limit) Range: $\{-1, \dots, \infty\}$	100
separating/disjunctive/maxweightrange	maximal valid range $\max(weights)/\min(weights)$ of row weights Range: $[1, \infty]$	1000
separating/disjunctive/priority	priority of separator <disjunctive> Range: $\{-536870912, \dots, 536870911\}$	10
separating/disjunctive/strengthen	strengthen cut if integer variables are present. Range: boolean	1

5.39.4.232 separating/eccuts

Option	Description	Default
separating/eccuts/cutmaxrange	maximal coef. range of a cut (max coef. divided by min coef.) in order to be added to LP relaxation Range: $[0, \infty]$	1e+07
separating/eccuts/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/eccuts/freq	frequency for calling separator <eccuts> (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	-1
separating/eccuts/maxdepth	maximal depth at which the separator is applied (-1: unlimited) Range: $\{-1, \dots, \infty\}$	-1
separating/eccuts/maxrounds	maximal number of eccuts separation rounds per node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	10
separating/eccuts/maxroundsroot	maximal number of eccuts separation rounds in the root node (-1: unlimited) Range: $\{-1, \dots, \infty\}$	250
separating/eccuts/maxsepacuts	maximal number of edge-concave cuts separated per separation round Range: $\{0, \dots, \infty\}$	10
separating/eccuts/maxsepacutsroot	maximal number of edge-concave cuts separated per separation round in the root node Range: $\{0, \dots, \infty\}$	50
separating/eccuts/minviolation	minimal violation of an edge-concave cut to be separated Range: $[0, 0.5]$	0.3
Options for expert users		
separating/eccuts/delay	should separator be delayed, if other separators found cuts? Range: boolean	0

Option	Description	Default
separating/eccuts/expbackoff	base for exponential increase of frequency at which separator <eccuts> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/eccuts/maxaggrsize	search for edge-concave aggregations of at most this size Range: {3, ..., 5}	4
separating/eccuts/maxbilinterms	maximum number of bilinear terms allowed to be in a quadratic constraint Range: {0, ..., ∞ }	500
separating/eccuts/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <eccuts> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/eccuts/maxstallrounds	maximum number of unsuccessful rounds in the edge-concave aggregation search Range: {0, ..., ∞ }	5
separating/eccuts/minaggrsize	search for edge-concave aggregations of at least this size Range: {3, ..., 5}	3
separating/eccuts/priority	priority of separator <eccuts> Range: {-536870912, ..., 536870911}	-13000

5.39.4.233 separating/flowcover

Option	Description	Default
separating/flowcover/freq	frequency for calling separator <flowcover> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/flowcover/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/flowcover/expbackoff	base for exponential increase of frequency at which separator <flowcover> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/flowcover/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <flowcover> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/flowcover/priority	priority of separator <flowcover> Range: {-536870912, ..., 536870911}	-100000

5.39.4.234 separating/gauge

Option	Description	Default
separating/gauge/freq	frequency for calling separator <gauge> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
separating/gauge/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/gauge/expbackoff	base for exponential increase of frequency at which separator <gauge> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/gauge/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <gauge> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/gauge/nlpiterlimit	iteration limit of NLP solver; 0 for no limit Range: {0, ..., ∞ }	1000
separating/gauge/priority	priority of separator <gauge> Range: {-536870912, ..., 536870911}	0

5.39.4.235 separating/gomory

Option	Description	Default
separating/gomory/away	minimal integrality violation of a basis variable in order to try Gomory cut Range: [0.0001, 0.5]	0.01
separating/gomory/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/gomory/freq	frequency for calling separator <gomory> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/gomory/maxrank	maximal rank of a gomory cut that could not be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/gomory/maxrankintegral	maximal rank of a gomory cut that could be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/gomory/maxrounds	maximal number of gomory separation rounds per node (-1: unlimited) Range: {-1, ..., ∞ }	5
separating/gomory/maxroundsroot	maximal number of gomory separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞ }	10
separating/gomory/maxsepacuts	maximal number of gomory cuts separated per separation round Range: {0, ..., ∞ }	50
separating/gomory/maxsepacutsroot	maximal number of gomory cuts separated per separation round in the root node Range: {0, ..., ∞ }	200

Option	Description	Default
Options for expert users		
separating/gomory/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/gomory/delayedcuts	should cuts be added to the delayed cut pool? Range: boolean	0
separating/gomory/expbackoff	base for exponential increase of frequency at which separator <gomory> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/gomory/forcecuts	if conversion to integral coefficients failed still consider the cut Range: boolean	1
separating/gomory/genbothgomscg	Should both Gomory and strong CG cuts be generated (otherwise take best)? Range: boolean	1
separating/gomory/makeintegral	try to scale cuts to integral coefficients Range: boolean	0
separating/gomory/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <gomory> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/gomory/priority	priority of separator <gomory> Range: {-536870912, ..., 536870911}	-1000
separating/gomory/separaterows	separate rows with integral slack Range: boolean	1
separating/gomory/sidetypebasis	choose side types of row (lhs/rhs) based on basis information? Range: boolean	1
separating/gomory/trystrongcg	try to generate strengthened Chvatal-Gomory cuts? Range: boolean	1

5.39.4.236 separating/gomorymi

Option	Description	Default
separating/gomorymi/freq	frequency for calling separator <gomorymi> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/gomorymi/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/gomorymi/expbackoff	base for exponential increase of frequency at which separator <gomorymi> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4

Option	Description	Default
separating/gomorymi/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <gomorymi> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/gomorymi/priority	priority of separator <gomorymi> Range: {-536870912, ..., 536870911}	-100000

5.39.4.237 separating/IMPLIEDBOUNDS

Option	Description	Default
separating/IMPLIEDBOUNDS/freq	frequency for calling separator <IMPLIEDBOUNDS> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/IMPLIEDBOUNDS/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/IMPLIEDBOUNDS/expbackoff	base for exponential increase of frequency at which separator <IMPLIEDBOUNDS> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/IMPLIEDBOUNDS/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <IMPLIEDBOUNDS> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/IMPLIEDBOUNDS/priority	priority of separator <IMPLIEDBOUNDS> Range: {-536870912, ..., 536870911}	-50
separating/IMPLIEDBOUNDS/usetwosizecliques	should violated inequalities for cliques with 2 variables be separated? Range: boolean	1

5.39.4.238 separating/INTERMINOR

Option	Description	Default
separating/INTERMINOR/freq	frequency for calling separator <INTERMINOR> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/INTERMINOR/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞ }	10
separating/INTERMINOR/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/INTERMINOR/mincutviol	minimum required violation of a cut Range: [0, ∞]	0.0001

Option	Description	Default
separating/interminor/usebounds	whether to also enforce nonnegativity bounds of principle minors Range: boolean	0
separating/interminor/usestrengthening	whether to use strengthened intersection cuts to separate minors Range: boolean	0
Options for expert users		
separating/interminor/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/interminor/expbackoff	base for exponential increase of frequency at which separator <interminor> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/interminor/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <interminor> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/interminor/priority	priority of separator <interminor> Range: {-536870912, ..., 536870911}	0

5.39.4.239 separating/intobj

Option	Description	Default
separating/intobj/freq	frequency for calling separator <intobj> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
separating/intobj/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/intobj/expbackoff	base for exponential increase of frequency at which separator <intobj> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/intobj/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <intobj> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/intobj/priority	priority of separator <intobj> Range: {-536870912, ..., 536870911}	-100

5.39.4.240 separating/knapsackcover

Option	Description	Default
separating/knapsackcover/freq	frequency for calling separator <knapsackcover> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/knapsackcover/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/knapsackcover/expbackoff	base for exponential increase of frequency at which separator <knapsackcover> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/knapsackcover/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <knapsackcover> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/knapsackcover/priority	priority of separator <knapsackcover> Range: {-536870912, ..., 536870911}	-100000

5.39.4.241 separating/mcf

Option	Description	Default
separating/mcf/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/mcf/freq	frequency for calling separator <mcf> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
separating/mcf/maxsepacuts	maximal number of mcf cuts separated per separation round Range: {-1, ..., ∞ }	100
separating/mcf/maxsepacutsroot	maximal number of mcf cuts separated per separation round in the root node – default separation Range: {-1, ..., ∞ }	200
Options for expert users		
separating/mcf/checkcutshoreconnectivity	should we separate only if the cuts shores are connected? Range: boolean	1
separating/mcf/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/mcf/expbackoff	base for exponential increase of frequency at which separator <mcf> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/mcf/fixintegralrhs	should an additional variable be complemented if $f_0 = 0$? Range: boolean	1

Option	Description	Default
separating/mcf/maxarcinconsistencyratio	maximum inconsistency ratio of arcs not to be deleted Range: $[0, \infty]$	0.5
separating/mcf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <mcf> (0.0: only on current best node, 1.0: on all nodes) Range: $[0, 1]$	0
separating/mcf/maxinconsistencyratio	maximum inconsistency ratio for separation at all Range: $[0, \infty]$	0.02
separating/mcf/maxtestdelta	maximal number of different deltas to try (-1: unlimited) – default separation Range: $\{-1, \dots, \infty\}$	20
separating/mcf/maxweightrange	maximal valid range of row weights $\max(weights)/\min(weights)$ Range: $[1, \infty]$	1e+06
separating/mcf/modeltype	model type of network (0: auto, 1:directed, 2:undirected) Range: $\{0, \dots, 2\}$	0
separating/mcf/nclusters	number of clusters to generate in the shrunken network – default separation Range: $\{2, \dots, 32\}$	5
separating/mcf/priority	priority of separator <mcf> Range: $\{-536870912, \dots, 536870911\}$	-10000
separating/mcf/separateflowcutset	should we separate flowcutset inequalities on the network cuts? Range: boolean	1
separating/mcf/separateknapsack	should we separate knapsack cover inequalities on the network cuts? Range: boolean	1
separating/mcf/separatesinglenodecuts	should we separate inequalities based on single-node cuts? Range: boolean	1
separating/mcf/trynegscaling	should negative values also be tested in scaling? Range: boolean	0

5.39.4.242 separating/minor

Option	Description	Default
separating/minor/freq	frequency for calling separator <minor> (-1: never, 0: only in root node) Range: $\{-1, \dots, 65534\}$	10
separating/minor/ignorepackingconss	whether to ignore circle packing constraints during minor detection Range: boolean	1
separating/minor/maxminorsconst	constant for the maximum number of minors, i.e., $\max(const, fac * \# \text{quadratic terms})$ Range: $\{0, \dots, \infty\}$	3000

Option	Description	Default
separating/minor/maxminorsfac	factor for the maximum number of minors, i.e., max(const, fac * # quadratic terms) Range: [0, ∞]	10
separating/minor/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/minor/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/minor/mincutviol	minimum required violation of a cut Range: [0, ∞]	0.0001
Options for expert users		
separating/minor/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/minor/expbackoff	base for exponential increase of frequency at which separator <minor> is called (1: call at each mul- tiple of frequency) Range: {1, ..., 100}	4
separating/minor/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <minor> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/minor/priority	priority of separator <minor> Range: {-536870912, ..., 536870911}	0

5.39.4.243 separating/mixing

Option	Description	Default
separating/mixing/freq	frequency for calling separator <mixing> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/mixing/maxnunsuccessful	maximal number of consecutive unsuccessful iter- ations Range: {-1, ..., ∞}	10
separating/mixing/maxrounds	maximal number of mixing separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/mixing/maxroundsroot	maximal number of mixing separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
Options for expert users		
separating/mixing/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/mixing/expbackoff	base for exponential increase of frequency at which separator <mixing> is called (1: call at each mul- tiple of frequency) Range: {1, ..., 100}	4

Option	Description	Default
separating/mixing/iscutsonints	Should general integer variables be used to generate cuts? Range: boolean	0
separating/mixing/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <mixing> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/mixing/priority	priority of separator <mixing> Range: {-536870912, ..., 536870911}	-50
separating/mixing/uselocalbounds	Should local bounds be used? Range: boolean	0

5.39.4.244 separating/oddcycle

Option	Description	Default
separating/oddcycle/freq	frequency for calling separator <oddcycle> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/oddcycle/liftoddcycles	Should odd cycle cuts be lifted? Range: boolean	0
separating/oddcycle/maxrounds	maximal number of oddcycle separation rounds per node (-1: unlimited) Range: {-1, ..., ∞ }	10
separating/oddcycle/maxroundsroot	maximal number of oddcycle separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞ }	10
separating/oddcycle/maxsepacuts	maximal number of oddcycle cuts separated per separation round Range: {0, ..., ∞ }	5000
separating/oddcycle/maxsepacutsroot	maximal number of oddcycle cuts separated per separation round in the root node Range: {0, ..., ∞ }	5000
separating/oddcycle/usegls	Should the search method by Groetschel, Lovasz, Schrijver be used? Otherwise use levelgraph method by Hoffman, Padberg. Range: boolean	1
Options for expert users		
separating/oddcycle/addselfarcs	add links between a variable and its negated Range: boolean	1
separating/oddcycle/allowmultiplecuts	Even if a variable is already covered by a cut, still allow another cut to cover it too? Range: boolean	1
separating/oddcycle/cutthreshold	maximal number of other cuts s.t. separation is applied (-1 for direct call) Range: {-1, ..., ∞ }	-1
separating/oddcycle/delay	should separator be delayed, if other separators found cuts? Range: boolean	0

Option	Description	Default
separating/oddcycle/expbackoff	base for exponential increase of frequency at which separator <oddcycle> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/oddcycle/includetriangles	separate triangles found as 3-cycles or repaired larger cycles Range: boolean	1
separating/oddcycle/liftcoef	Choose lifting candidate by coef*lpvalue or only by coef? Range: boolean	0
separating/oddcycle/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <oddcycle> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/oddcycle/maxcutslevel	maximal number of oddcycle cuts generated in every level of the level graph Range: {0, ..., ∞}	50
separating/oddcycle/maxcutsroot	maximal number of oddcycle cuts generated per chosen variable as root of the level graph Range: {0, ..., ∞}	1
separating/oddcycle/maxnlevels	maximal number of levels in level graph Range: {0, ..., ∞}	20
separating/oddcycle/maxpernodeslevel	percentage of nodes allowed in the same level of the level graph [0-100] Range: {0, ..., 100}	100
separating/oddcycle/maxreference	minimal weight on an edge (in level graph or bipartite graph) Range: {0, ..., ∞}	0
separating/oddcycle/maxunsuccessfull	number of unsuccessful calls at current node Range: {0, ..., ∞}	3
separating/oddcycle/multiplecuts	Even if a variable is already covered by a cut, still try it as start node for a cycle search? Range: boolean	0
separating/oddcycle/offsetnodeslevel	offset of nodes allowed in the same level of the level graph (additional to the percentage of levelnodes) Range: {0, ..., ∞}	10
separating/oddcycle/offsettestvars	offset of variables to try the chosen method on (additional to the percentage of testvars) Range: {0, ..., ∞}	100
separating/oddcycle/percenttestvars	percentage of variables to try the chosen method on [0-100] Range: {0, ..., 100}	0
separating/oddcycle/priority	priority of separator <oddcycle> Range: {-536870912, ..., 536870911}	-15000
separating/oddcycle/recalciftcoef	Calculate lifting coefficient of every candidate in every step (or only if its chosen)? Range: boolean	1
separating/oddcycle/repaircycles	try to repair violated cycles with double appearance of a variable Range: boolean	1

Option	Description	Default
separating/oddcycle/scalingfactor	factor for scaling of the arc-weights Range: {1, ..., ∞ }	1000
separating/oddcycle/sortrootneighbors	sort level of the root neighbors by fractionality (maxfrac) Range: boolean	1
separating/oddcycle/sortswitch	use sorted variable array (unsorted(0), maxlp(1), minlp(2), maxfrac(3), minfrac(4)) Range: {0, ..., 4}	3

5.39.4.245 separating/rapidlearning

Option	Description	Default
separating/rapidlearning/freq	frequency for calling separator <rapidlearning> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
Options for expert users		
separating/rapidlearning/applybdchgs	should the found global bound deductions be applied in the original SCIP? Range: boolean	1
separating/rapidlearning/applyconflicts	should the found conflicts be applied in the original SCIP? Range: boolean	1
separating/rapidlearning/applyintervals	should the inference values be used as initialization in the original SCIP? Range: boolean	1
separating/rapidlearning/applyprimalsol	should the incumbent solution be copied to the original SCIP? Range: boolean	1
separating/rapidlearning/applysolved	should a solved status be copied to the original SCIP? Range: boolean	1
separating/rapidlearning/checkdegeneracy	should local LP degeneracy be checked? Range: boolean	1
separating/rapidlearning/checkdualbound	should the progress on the dual bound be checked? Range: boolean	0
separating/rapidlearning/checkexec	check whether rapid learning should be executed Range: boolean	1
separating/rapidlearning/checkleaves	should the ratio of leaves proven to be infeasible and exceeding the cutoff bound be checked? Range: boolean	0
separating/rapidlearning/checknsols	should the number of solutions found so far be checked? Range: boolean	1
separating/rapidlearning/checkobj	should the (local) objective function be checked? Range: boolean	0
separating/rapidlearning/contvars	should rapid learning be applied when there are continuous variables? Range: boolean	0

Option	Description	Default
separating/rapidlearning/contvarsquot	maximal portion of continuous variables to apply rapid learning Range: [0, 1]	0.3
separating/rapidlearning/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
separating/rapidlearning/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/rapidlearning/expbackoff	base for exponential increase of frequency at which separator <rapidlearning> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/rapidlearning/lpiterquot	maximal fraction of LP iterations compared to node LP iterations Range: [0, ∞]	0.2
separating/rapidlearning/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <rapidlearning> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/rapidlearning/maxcalls	maximum number of overall calls Range: {0, ..., ∞ }	100
separating/rapidlearning/maxnconss	maximum problem size (constraints) for which rapid learning will be called Range: {0, ..., ∞ }	10000
separating/rapidlearning/maxnodes	maximum number of nodes considered in rapid learning run Range: {0, ..., ∞ }	5000
separating/rapidlearning/maxnvars	maximum problem size (variables) for which rapid learning will be called Range: {0, ..., ∞ }	10000
separating/rapidlearning/mindegeneracy	minimal degeneracy threshold to allow local rapid learning Range: [0, 1]	0.7
separating/rapidlearning/mininfpratio	minimal threshold of inf/obj leaves to allow local rapid learning Range: [0, ∞]	10
separating/rapidlearning/minnodes	minimum number of nodes considered in rapid learning run Range: {0, ..., ∞ }	500
separating/rapidlearning/minvarconsratio	minimal ratio of unfixed variables in relation to basis size to allow local rapid learning Range: [1, ∞]	2
separating/rapidlearning/nwaitingnodes	number of nodes that should be processed before rapid learning is executed locally based on the progress of the dualbound Range: {0, ..., ∞ }	100
separating/rapidlearning/priority	priority of separator <rapidlearning> Range: {-536870912, ..., 536870911}	-1200000

Option	Description	Default
separating/rapidlearning/reducedinfer	should the inference values only be used when rapidlearning found other reductions? Range: boolean	0

5.39.4.246 separating/rlt

Option	Description	Default
separating/rlt/addtopool	if set to true, globally valid RLT cuts are added to the global cut pool Range: boolean	1
separating/rlt/detecthidden	if set to true, hidden products are detected and separated by McCormick cuts Range: boolean	0
separating/rlt/freq	frequency for calling separator <rlt> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
separating/rlt/hiddenrlt	whether RLT cuts (TRUE) or only McCormick inequalities (FALSE) should be added for hidden products Range: boolean	0
separating/rlt/maxncuts	maximal number of rlt-cuts that are added per round (-1: unlimited) Range: {-1, ..., ∞ }	-1
separating/rlt/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞ }	1
separating/rlt/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞ }	10
separating/rlt/maxunknownterms	maximal number of unknown bilinear terms a row is still used with (-1: unlimited) Range: {-1, ..., ∞ }	0
separating/rlt/maxusedvars	maximal number of variables used to compute rlt cuts (-1: unlimited) Range: {-1, ..., ∞ }	100
separating/rlt/onlycontrows	if set to true, only continuous rows are used for rlt cuts Range: boolean	0
separating/rlt/onlyeqrows	if set to true, only equality rows are used for rlt cuts Range: boolean	0
separating/rlt/onlyoriginal	if set to true, only original rows and variables are used Range: boolean	1
separating/rlt/useinsubscip	if set to true, rlt is also used in sub-scips Range: boolean	0
separating/rlt/useprojection	if set to true, projected rows are checked first Range: boolean	0
Options for expert users		
separating/rlt/badscore	threshold for score of cut relative to best score to be discarded Range: [0, 1]	0.5

Option	Description	Default
separating/rlt/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/rlt/dircutoffdistweight	weight of directed cutoff distance in cut score calculation Range: [0, 1]	0
separating/rlt/efficacyweight	weight of efficacy in cut score calculation Range: [0, 1]	1
separating/rlt/expbackoff	base for exponential increase of frequency at which separator <rlt> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/rlt/goodmaxparall	maximum parallelism for good cuts Range: [0, 1]	0.1
separating/rlt/goodscore	threshold for score of cut relative to best score to be considered good, so that less strict filtering is applied Range: [0, 1]	1
separating/rlt/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <rlt> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/rlt/maxparall	maximum parallelism for non-good cuts Range: [0, 1]	0.1
separating/rlt/objparalweight	weight of objective parallelism in cut score calculation Range: [0, 1]	0
separating/rlt/priority	priority of separator <rlt> Range: {-536870912, ..., 536870911}	10

5.39.4.247 separating/strongcg

Option	Description	Default
separating/strongcg/freq	frequency for calling separator <strongcg> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/strongcg/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/strongcg/expbackoff	base for exponential increase of frequency at which separator <strongcg> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/strongcg/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <strongcg> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/strongcg/priority	priority of separator <strongcg> Range: {-536870912, ..., 536870911}	-100000

5.39.4.248 separating/zerohalf

Option	Description	Default
separating/zerohalf/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/zerohalf/freq	frequency for calling separator <zerohalf> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/zerohalf/initseed	initial seed used for random tie-breaking in cut selection Range: {0, ..., ∞ }	24301
separating/zerohalf/maxcutcands	maximal number of zerohalf cuts considered per separation round Range: {0, ..., ∞ }	2000
separating/zerohalf/maxrounds	maximal number of zerohalf separation rounds per node (-1: unlimited) Range: {-1, ..., ∞ }	5
separating/zerohalf/maxroundsroot	maximal number of zerohalf separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞ }	20
separating/zerohalf/maxsepacuts	maximal number of zerohalf cuts separated per separation round Range: {0, ..., ∞ }	20
separating/zerohalf/maxsepacutsroot	maximal number of zerohalf cuts separated per separation round in the root node Range: {0, ..., ∞ }	100
Options for expert users		
separating/zerohalf/badscore	threshold for score of cut relative to best score to be discarded Range: [0, 1]	0.5
separating/zerohalf/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/zerohalf/densityoffset	additional number of variables allowed in row on top of density Range: {0, ..., ∞ }	100
separating/zerohalf/dircutoffdistweight	weight of directed cutoff distance in cut score calculation Range: [0, 1]	0
separating/zerohalf/efficacyweight	weight of efficacy in cut score calculation Range: [0, 1]	1
separating/zerohalf/expbackoff	base for exponential increase of frequency at which separator <zerohalf> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/zerohalf/goodmaxparall	maximum parallelism for good cuts Range: [0, 1]	0.1
separating/zerohalf/goodscore	threshold for score of cut relative to best score to be considered good, so that less strict filtering is applied Range: [0, 1]	1

Option	Description	Default
separating/zerohalf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <zerohalf> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/zerohalf/maxparall	maximum parallelism for non-good cuts Range: [0, 1]	0.1
separating/zerohalf/maxrowdensity	maximal density of row to be used in aggregation Range: [0, 1]	0.05
separating/zerohalf/maxslack	maximal slack of rows to be used in aggregation Range: [0, ∞]	0
separating/zerohalf/maxslackroot	maximal slack of rows to be used in aggregation in the root node Range: [0, ∞]	0
separating/zerohalf/minviol	minimal violation to generate zerohalfcut for Range: [0, ∞]	0.1
separating/zerohalf/objparalweight	weight of objective parallelism in cut score calculation Range: [0, 1]	0
separating/zerohalf/priority	priority of separator <zerohalf> Range: {-536870912, ..., 536870911}	-6000

5.39.4.249 solvingphases

Option	Description	Default
solvingphases/enabled	should the event handler adapt the solver behavior? Range: boolean	0
solvingphases/fallback	should the event handler fall back from optimal phase? Range: boolean	0
solvingphases/feassetname	settings file for feasibility phase – precedence over emphasis settings Range: string	-
solvingphases/improvesetname	settings file for improvement phase – precedence over emphasis settings Range: string	-
solvingphases/interruptoptimal	should the event handler interrupt the solving process after optimal solution was found? Range: boolean	0
solvingphases/nodeoffset	node offset for rank-1 and estimate transitions Range: {1, ..., ∞ }	50
solvingphases/optimalvalue	optimal solution value for problem Range: real	∞
solvingphases/proofsetname	settings file for proof phase – precedence over emphasis settings Range: string	-
solvingphases/testmode	should the event handler test all phase transitions? Range: boolean	0
solvingphases/transitionmethod	transition method: Possible options are 'e'stimate, 'l'ogarithmic regression, 'o'ptimal-value based, 'r'ank-1 Range: e, l, o, r	r

Option	Description	Default
solvingphases/useemphsettings	should emphasis settings for the solving phases be used, or settings files? Range: boolean	1
solvingphases/userrestart1to2	should a restart be applied between the feasibility and improvement phase? Range: boolean	0
solvingphases/userrestart2to3	should a restart be applied between the improvement and the proof phase? Range: boolean	0
solvingphases/xtype	x-type for logarithmic regression - (t)ime, (n)odes, (l)p iterations Range: l, n, t	n

5.39.4.250 table/branchrules

Option	Description	Default
table/branchrules/active	is statistics table <branchrules> active Range: boolean	1

5.39.4.251 table/compression

Option	Description	Default
table/compression/active	is statistics table <compression> active Range: boolean	1

5.39.4.252 table/concurrentsolver

Option	Description	Default
table/concurrentsolver/active	is statistics table <concurrentsolver> active Range: boolean	1

5.39.4.253 table/conflict

Option	Description	Default
table/conflict/active	is statistics table <conflict> active Range: boolean	1

5.39.4.254 table/cons_nonlinear

Option	Description	Default
table/cons_nonlinear/active	is statistics table <cons_nonlinear> active Range: boolean	0

5.39.4.255 table/constiming

Option	Description	Default
table/constiming/active	is statistics table <constiming> active Range: boolean	1

5.39.4.256 table/constraint

Option	Description	Default
table/constraint/active	is statistics table <constraint> active Range: boolean	1

5.39.4.257 table/cutsel

Option	Description	Default
table/cutsel/active	is statistics table <cutsel> active Range: boolean	1

5.39.4.258 table/estim

Option	Description	Default
table/estim/active	is statistics table <estim> active Range: boolean	1

5.39.4.259 table/exprhdlr

Option	Description	Default
table/exprhdlr/active	is statistics table <exprhdlr> active Range: boolean	1

5.39.4.260 table/heuristics

Option	Description	Default
table/heuristics/active	is statistics table <heuristics> active Range: boolean	1

5.39.4.261 table/lp

Option	Description	Default
table/lp/active	is statistics table <lp> active Range: boolean	1

5.39.4.262 table/neighborhood

Option	Description	Default
table/neighborhood/active	is statistics table <neighborhood> active Range: boolean	1

5.39.4.263 table/nlhdlr

Option	Description	Default
table/nlhdlr/active	is statistics table <nlhdlr> active Range: boolean	1

5.39.4.264 table/nlhdlr_bilinear

Option	Description	Default
table/nlhdlr_bilinear/active	is statistics table <nlhdlr_bilinear> active Range: boolean	0

5.39.4.265 table/nlhdlr_quadratic

Option	Description	Default
table/nlhdlr_quadratic/active	is statistics table <nlhdlr_quadratic> active Range: boolean	0

5.39.4.266 table/nlp

Option	Description	Default
table/nlp/active	is statistics table <nlp> active Range: boolean	1

5.39.4.267 table/nlpi

Option	Description	Default
table/nlpi/active	is statistics table <nlpi> active Range: boolean	1

5.39.4.268 table/orbitalfixing

Option	Description	Default
table/orbitalfixing/active	is statistics table <orbitalfixing> active Range: boolean	1

5.39.4.269 table/origprob

Option	Description	Default
table/origprob/active	is statistics table <origprob> active Range: boolean	1

5.39.4.270 table/presolvedprob

Option	Description	Default
table/presolvedprob/active	is statistics table <presolvedprob> active Range: boolean	1

5.39.4.271 table/presolver

Option	Description	Default
table/presolver/active	is statistics table <presolver> active Range: boolean	1

5.39.4.272 table/pricer

Option	Description	Default
table/pricer/active	is statistics table <pricer> active Range: boolean	1

5.39.4.273 table/propagator

Option	Description	Default
table/propagator/active	is statistics table <propagator> active Range: boolean	1

5.39.4.274 table/relaxator

Option	Description	Default
table/relaxator/active	is statistics table <relaxator> active Range: boolean	1

5.39.4.275 table/root

Option	Description	Default
table/root/active	is statistics table <root> active Range: boolean	1

5.39.4.276 table/separator

Option	Description	Default
table/separator/active	is statistics table <separator> active Range: boolean	1

5.39.4.277 table/solution

Option	Description	Default
table/solution/active	is statistics table <solution> active Range: boolean	1

5.39.4.278 table/status

Option	Description	Default
table/status/active	is statistics table <status> active Range: boolean	1

5.39.4.279 table/timing

Option	Description	Default
table/timing/active	is statistics table <timing> active Range: boolean	1

5.39.4.280 table/tree

Option	Description	Default
table/tree/active	is statistics table <tree> active Range: boolean	1

5.39.4.281 timing

Option	Description	Default
timing/clocktype	default clock type (1: CPU user seconds, 2: wall clock time) Range: {1, ..., 2}	2
timing/enabled	is timing enabled? Range: boolean	1
timing/nlpieval	should time for evaluation in NLP solves be measured? Range: boolean	0
timing/rareclockcheck	should clock checks of solving time be performed less frequently (note: time limit could be exceeded slightly) Range: boolean	0
timing/reading	belongs reading time to solving time? Range: boolean	0
timing/statistictiming	should timing for statistic output be performed? Range: boolean	1

5.40 SELKIE

Authors

Youngdae Kim, youngdae@anl.gov; Mathematics and Computer Science Division; Argonne National Laboratory

Michael C. Ferris; Computer Science Department; UW-Madison

Date

23 Jan 2019

5.40.1 Introduction

This document describes the GAMS/SELKIE solver for equilibrium models. This is a research code, so you should set your expectations accordingly. It doesn't come with extensive documentation or a history of continuous development and improvement. To learn more about the algorithms SELKIE implements and related topics, see Y. Kim's [Ph.D. thesis](#) or [home page](#).

5.40.2 Usage

To explicitly request that a model be solved with SELKIE, insert the statement

```
option EMP = selkie;
```

somewhere before the solve statement in the GAMS source. If SELKIE has been selected as the default EMP solver (e.g. by including `EMP=selkie` in the command line arguments of the GAMS run) the above statement is not necessary.

SELKIE-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section [The Solver Options File](#).

An example of a valid SELKIE option file is:

```
* lines starting with a star are comments
diagonalization_method  jacobi
parallel_jacobi         yes
output_group_log        yes
```

Option	Description	Default
--------	-------------	---------

5.40.3 Options

Option	Description	Default
agent_group	groups of agents	empty
convergence_tolerance	convergence tolerance of residual	1e-6
coupling_constraints	names of coupling constraints	empty
coupling_variables	names of coupling variables	empty
cumulative_iteration_limit	maximum number of cumulative iterations	5000
damping_factor	damping factor b/w old and new values	1.0
dantzig_wolfe_initial_samples	initial number of samples for DW decomposition	100
dantzig_wolfe_master_subsolveropt	Subsolver option number for the master of DW	
dantzig_wolfe_subproblem_subsolveropt	Subsolver option number for the sub of DW	
decomposition_method	decomposition method to apply diagonalization: Diagonalization dantzig_wolfe: Dantzig-Wolfe	diagonalization
delay_residual_check	delay residual checking	0
detect_independent_groups	detect independent groups of agents	0
deviation_agent_list	agents whose deviations are computed	empty
deviation_convergence_tolerance	convergence tolerance of deviation	1e-10
deviation_delay_tolerance	deviation tolerance until residual is not checked	1e-8
diagonalization_method	see the values below gauss_seidel: Gauss-Seidel gauss_seidel_random: Randomized Gauss-Seidel gauss_seidel_random_sweep: Randomized Gauss-Seidel with sweep gauss_southwell: Residual-based Gauss-Seidel jacobi: Jacobi	gauss_seidel
epsilon	ignored if abs is less than this	1e-8
major_iteration_limit	maximum number of major iterations	100
minor_iteration_limit	maximum number of minor iterations	1000

Option	Description	Default
nlp_solver	NLP solver antigone: Antigone baron: Baron conopt: Conopt conopt4: Conopt4 ipopt: Ipopt knitro: Knitro lindo: Lindo lindoglobal: Lindoglobal minos: Minos mosek: Mosek scip: Scip snopt: Snopt	conopt
output	whether to output logs	1
output_group_log	whether to output group logs	0
output_iteration_log	whether to output iteration logs	1
output_subsolver_log	whether to output subsolver logs	0
parallel_agent_generation	generate agents problems in parallel	0
parallel_jacobi	run jacobi in parallel	0
proximal_increase_factor	increasing factor for proximal term	
proximal_initial_maximum	initial maximum value of proximal term	
proximal_maximum	maximum of proximal term	
proximal_merit_factor	factor that is multiplied to residual	
proximal_minimum	minimum value of proximal term	
proximal_perturbation	penalty value of proximal term	
proximal_perturbation_dual	penalty value of dual proximal term	
proximal_perturbation_primal	penalty value of primal proximal term	
proximal_residual_change	ratio of residual change	
proximal_shrink_factor	shrinking factor for proximal term	
proximal_use	determine the proximal mode	empty
record_ownership_within_group	record ownership of agents within group	0
remove_isolated_implvar	omit isolated implicit variables	1
shared_equation	allow shared equation	0
stop_on_subsolver_failure	stop selkie if subsolver fails to solve	1
subsolveropt	subsolver option file number Range: {1, ..., 999}	1
time_limit	maximum running time in seconds	3600
use_mcpopt	use MCP to solve optimization agent	0

Option	Description	Default
write_agent_model	write agent model into file	1

5.41 SHOT

SHOT (Supporting Hyperplane Optimization Toolkit) is a deterministic solver for mixed-integer nonlinear programming problems (MINLPs).

Originally, SHOT was intended for convex MINLP problems only, but now also has functionality to solve nonconvex MINLP problems as a heuristic method without providing any guarantees of global optimality. SHOT can solve certain nonconvex problem types to global optimality as well.

SHOT has mainly been developed by Andreas Lundell (Åbo Akademi University, Finland) and Jan Kronqvist (Imperial College London, UK). For more details, see [169] [165] [149] [150] [164].

SHOT supports GAMS equations that use the following **intrinsic functions**: abs, cos, cvPower, div, exp, log, log10, log2, pi, power, rPower, sin, sqr, sqrt, vcPower.

5.41.1 Algorithm

SHOT is based on iteratively creating a tighter polyhedral approximation of the nonlinear feasible set by generating supporting hyperplanes or cutting planes. These linearized problems are then solved with a mixed-integer linear programming (MIP) solver. GAMS/SHOT uses CPLEX, if a GAMS/CPLEX license is available, and otherwise CBC. Users with a license from Gurobi can also **select** Gurobi as MIP solver. If CPLEX or Gurobi is used, the subproblems can also include quadratic and bilinear nonlinearities directly.

The solution to the outer approximation problem provides a dual bound (i.e., a lower bound when solving a minimization problem) to the optimal value of the original problem if it is convex. If the problem is nonconvex, convergence to the global optimal solution cannot be guaranteed (but might be achieved for certain classes of problems, cf. [165]).

To get a primal bound (i.e., an upper bound when solving a minimization problem) on the optimal value, SHOT utilizes the following heuristics:

- Solving nonlinear programming (NLP) problems where the integer variables have been fixed to valid values. This is done by calling an **NLP solver**, which is either Ipopt, one of the **GAMS NLP solvers**, or SHOT itself.
- By checking solutions from the MIP solver's solution pool for points that fulfill also the nonlinear constraints in the original MINLP problem.
- By performing root searches.

When a **termination criterion** like a tolerance on the relative or absolute objective gap or a time limit is fulfilled, SHOT terminates and returns the current primal solution to GAMS. If the original problem is convex and SHOT could close the objective gap, then this is a global optimal solution to the problem. If it is nonconvex, then there is normally no guarantee that such a solution can be found. However, SHOT will always, in addition to a primal solution, return a valid dual bound on the solution in model attribute **object**, unless **Model.Convexity.AssumeConvex** has been enabled.

5.41.2 Usage

The following statement can be used inside your GAMS program to specify using SHOT

```
Option MINLP = SHOT;      { or MIQCP }
```

The above statement should appear before the Solve statement. If SHOT was specified as the default MINLP or MIQCP solver during GAMS installation, the above statement is not necessary.

5.41.2.1 Specification of SHOT Options

GAMS/SHOT supports the GAMS parameters [reslim](#), [iterlim](#), [nodlim](#), [optcr](#), [optca](#), [cutoff](#), and [threads](#).

Options can be specified by a SHOT options file. A SHOT options file consists of one option or comment per line. An asterik (*) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs).

A small example for a shot.opt file is:

```
Dual.CutStrategy = 1
Dual.MIP.Solver = 2
Output.Console.DualSolver.Show = true
```

It causes GAMS/SHOT to use the Extended Cutting Plane (ECP) method instead of the Extended Supporting Hyperplane (EHP) method, changes the MIP solver to CBC, and enables showing the output of the solver that computes dual bounds (typically the MIP solver).

Attention

SHOT requires options to be specified using exactly the names as specified in the documentation. That is, also casing matters.

5.41.3 List of SHOT Options

In the following, we give a detailed list of all SHOT options.

Option	Description	Default
--------	-------------	---------

5.41.3.1 Solver output

These settings control how much and what output is shown to the user from the solver.

Option	Description	Default
Output.Debug.Path	The folder where to save the debug information Range: string	
Output.GAMS.AlternateSolutionsFile	Name of GAMS GDX file to write alternative solutions to Range: string	
Output.Console.Iteration.Detail	When should the fixed strategy be used 0: Full 1: On objective gap update 2: On objective gap update and all primal NLP calls	1
Output.Console.LogLevel	Log level for console output 0: Trace 1: Debug 2: Info 3: Warning 4: Error 5: Critical 6: Off	2
Output.Console.DualSolver.Show	Show output from dual solver on console Range: boolean	0
Output.Console.PrimalSolver.Show	Show output from primal solver on console Range: boolean	0
Output.Debug.Enable	Use debug functionality Range: boolean	0

5.41.3.2 Subsolver functionality

These settings allow for more direct control of the different subsolvers utilized in SHOT.

Option	Description	Default
Subsolver.Cplex.WorkDirectory	Directory for swap file Range: string	
Subsolver.GAMS.NLP.OptionsFilename	Options file for the NLP solver in GAMS Range: string	
Subsolver.GAMS.NLP.Solver	NLP solver to use in GAMS (auto: SHOT chooses) Range: string	auto
Subsolver.Cbc.NodeStrategy	Node strategy 0: depth 1: downdepth 2: downfewest 3: fewest 4: hybrid 5: updepth 6: upfewest	4

Option	Description	Default
Subsolver.Cbc.Scaling	Whether to scale problem 0: automatic 1: dynamic 2: equilibrium 3: geometric 4: off 5: rowsonly	4
Subsolver.Cbc.Strategy	This turns on newer features 0: easy problems 1: default 2: aggressive	1
Subsolver.Cplex.FeasOptMode	Strategy to use for the feasibility repair 0: Minimize the sum of all required relaxations in first phase only 1: Minimize the sum of all required relaxations in first phase and execute second phase to find optimum among minimal relaxations 2: Minimize the number of constraints and bounds requiring relaxation in first phase only 3: Minimize the sum of squares of required relaxations in first phase only 4: Minimize the sum of squares of required relaxations in first phase and execute second phase to find optimum among minimal relaxations	0
Subsolver.Cplex.MIPEmphasis	Sets the MIP emphasis 0: Balanced 1: Feasibility 2: Optimality 3: Best bound 4: Hidden feasible	1
Subsolver.Cplex.MemoryEmphasis	Try to conserve memory when possible Range: {0, ..., 1}	0
Subsolver.Cplex.NodeFile	Where to store the node file 0: No file 1: Compressed in memory 2: On disk 3: Compressed on disk	1
Subsolver.Cplex.NumericalEmphasis	Emphasis on numerical stability Range: {0, ..., 1}	1
Subsolver.Cplex.OptimalityTarget	Specifies how CPLEX treats nonconvex quadratics 0: Automatic 1: Searches for a globally optimal solution to a convex model 2: Searches for a solution that satisfies first-order optimality conditions, but is not necessarily globally optimal 3: Searches for a globally optimal solution to a nonconvex model	0

Option	Description	Default
Subsolver.Cplex.ParallelMode	Controls how much time and memory should be used when filling the solution pool -1: Opportunistic 0: Automatic 1: Deterministic	0
Subsolver.Cplex.Probe	Sets the MIP probing level -1: No probing 0: Automatic 1: Moderate 2: Aggressive 3: Very aggressive	0
Subsolver.Cplex.SolutionPoolIntensity	Controls how much time and memory should be used when filling the solution pool 0: Automatic 1: Mild 2: Moderate 3: Aggressive 4: Very aggressive	0
Subsolver.Cplex.SolutionPoolReplace	How to replace solutions in the solution pool when full 0: Replace oldest 1: Replace worst 2: Find diverse	0
Subsolver.Gurobi.MIPFocus	MIP focus 0: Automatic 1: Feasibility 2: Optimality 3: Best bound	0
Subsolver.Gurobi.NumericFocus	MIP focus 0: Automatic 1: Mild 2: Moderate 3: Aggressive	1
Subsolver.Gurobi.PoolSearchMode	Finds extra solutions 0: No extra effort 1: Try to find solutions 2: Find n best solutions	0
Subsolver.Gurobi.PoolSolutions	Determines how many MIP solutions are stored Range: {1, ..., 2000000000}	10
Subsolver.Gurobi.ScaleFlag	Controls model scaling -1: Automatic 0: Off 1: Mild 2: Moderate 3: Aggressive	-1
Subsolver.Ipopt.LinearSolver	Ipopt linear subsolver 0: Default 1: MA27 2: MA57 3: MA86 4: MA97 5: MUMPS	5
Subsolver.Ipopt.MaxIterations	Maximum number of iterations Range: {0, ..., ∞ }	1000

Option	Description	Default
Subsolver.Rootsearch.MaxIterations	Maximal root search iterations Range: {0, ..., ∞ }	100
Subsolver.Rootsearch.Method	Root search method to use 0: TOMS748 1: Bisection	0
Subsolver.Cplex.SolutionPoolGap	Sets the relative gap filter on objective values in the solution pool Range: [0, 1e+75]	1e+75
Subsolver.Cplex.WorkMemory	Memory limit for when to start swapping to disk Range: [0, 1e+75]	0
Subsolver.Gurobi.Heuristics	The relative amount of time spent in MIP heuristics. Range: [0, 1]	0.05
Subsolver.Ipopt.ConstraintViolationTolerance	Constraint violation tolerance in Ipopt Range: real	1e-08
Subsolver.Ipopt.RelativeConvergenceTolerance	Relative convergence tolerance Range: real	1e-08
Subsolver.Rootsearch.ActiveConstraintTolerance	Epsilon constraint tolerance for root search Range: [0, ∞]	0
Subsolver.Rootsearch.TerminationTolerance	Epsilon lambda tolerance for root search Range: [0, ∞]	1e-16
Subsolver.SHOT.ReuseHyperplanes.Fraction	The fraction of generated hyperplanes to reuse. Range: [0, 1]	0.1
Subsolver.Cbc.AutoScale	Whether to scale objective, rhs and bounds of problem if they look odd (experimental) Range: boolean	0
Subsolver.Cbc.DeterministicParallelMode	Run Cbc with multiple threads in deterministic mode Range: boolean	0
Subsolver.Cplex.AddRelaxedLazyConstraintsAsLocal	Whether to add lazy constraints generated in relaxed points as local or global Range: boolean	0
Subsolver.Cplex.UseGenericCallback	Use the new generic callback in the single-tree strategy Range: boolean	0
Subsolver.SHOT.ReuseHyperplanes.Use	Reuse valid generated hyperplanes in main dual model. Range: boolean	1
Subsolver.SHOT.UseFBBT	Do FBBT on NLP problem. Range: boolean	1

5.41.3.3 Dual strategy

These settings control the various functionality of the dual strategy in SHOT, i.e., the polyhedral outer approximation utilizing the ESH or ECP algorithms.

Option	Description	Default
Dual.CutStrategy	Dual cut strategy 0: ESH 1: ECP	0

Option	Description	Default
Dual.ESH.InteriorPoint.CuttingPlane.IterationLimit	Iteration limit for minimax cutting plane solver Range: {1, ..., ∞ }	100
Dual.ESH.InteriorPoint.CuttingPlane.IterationLimitSubsolver	Iteration limit for minimization subsolver Range: {0, ..., ∞ }	100
Dual.ESH.InteriorPoint.UsePrimalSolution	Utilize primal solution as interior point 0: No 1: Add as new 2: Replace old 3: Use average	1
Dual.HyperplaneCuts.MaxPerIteration	Maximal number of hyperplanes to add per iteration Range: {0, ..., ∞ }	200
Dual.HyperplaneCuts.ObjectiveRootSearch	When to use the objective root search 0: Always 1: IfConvex 2: Never	1
Dual.MIP.InfeasibilityRepair.IterationLimit	Max number of infeasible problems repaired without primal objective value improvement Range: {0, ..., ∞ }	100
Dual.MIP.NumberOfThreads	Number of threads to use in MIP solver: 0: Automatic Range: {0, ..., 999}	GAMS threads
Dual.MIP.Presolve.Frequency	When to call the MIP presolve 0: Never 1: Once 2: Always	1
Dual.MIP.SolutionLimit.ForceOptimalIteration	Iterations without dual bound updates for forcing optimal MIP solution Range: {0, ..., ∞ }	10000
Dual.MIP.SolutionLimit.IncreaseIterations	Max number of iterations between MIP solution limit increases Range: {0, ..., ∞ }	50
Dual.MIP.SolutionLimit.Initial	Initial MIP solution limit Range: {1, ..., ∞ }	1
Dual.MIP.SolutionPool.Capacity	The maximum number of solutions in the solution pool Range: {0, ..., ∞ }	100
Dual.MIP.Solver	Which MIP solver to use 0: Cplex 1: Gurobi 2: Cbc	Cplex, if licensed, otherwise Cbc
Dual.ReductionCut.MaxIterations	Max number of primal cut reduction without primal improvement Range: {0, ..., ∞ }	5

Option	Description	Default
Dual.Relaxation.Frequency	The frequency to solve an LP problem: 0: Disable Range: {0, ..., ∞ }	0
Dual.Relaxation.IterationLimit	The max number of relaxed LP problems to solve initially Range: {0, ..., ∞ }	200
Dual.Relaxation.MaxLazyConstraints	Max number of lazy constraints to add in relaxed solutions in single-tree strategy Range: {0, ..., ∞ }	0
Dual.TreeStrategy	The main strategy to use 0: Multi-tree 1: Single-tree	1
Dual.ESH.InteriorPoint.CuttingPlane.ConstraintSelectionFactor	The fraction of violated constraints to generate cutting planes for Range: [0, 1]	0.25
Dual.ESH.InteriorPoint.CuttingPlane.TerminationToleranceAbs	Absolute termination tolerance between LP and insearch objective Range: [0, ∞]	1
Dual.ESH.InteriorPoint.CuttingPlane.TerminationToleranceRel	Relative termination tolerance between LP and insearch objective Range: [0, ∞]	1
Dual.ESH.InteriorPoint.CuttingPlane.TimeLimit	Time limit for minimax solver Range: [0, ∞]	10
Dual.ESH.InteriorPoint.MinimaxObjectiveLowerBound	Lower bound for minimax objective variable Range: $[-\infty, 0]$	-1e+12
Dual.ESH.InteriorPoint.MinimaxObjectiveUpperBound	Upper bound for minimax objective variable Range: real	0.1
Dual.ESH.Rootsearch.ConstraintTolerance	Constraint tolerance for when not to add individual hyperplanes Range: [0, ∞]	1e-08
Dual.HyperplaneCuts.ConstraintSelectionFactor	The fraction of violated constraints to generate supporting hyperplanes / cutting planes for Range: [0, 1]	0.5
Dual.HyperplaneCuts.MaxConstraintFactor	Rootsearch performed on constraints with values larger than this factor times the maximum value Range: [1e-06, 1]	0.1
Dual.MIP.CutOff.InitialValue	Initial cutoff value to use Range: real	GAMS cutoff
Dual.MIP.CutOff.Tolerance	An extra tolerance for the objective cutoff value (to prevent infeasible subproblems) Range: real	1e-05

Option	Description	Default
Dual.MIP.InfeasibilityRepair.TimeLimit	Time limit when repairing infeasible problem Range: $[0, \infty]$	10
Dual.MIP.NodeLimit	Node limit to use for MIP solver in single-tree strategy Range: $[0, \infty]$	GAMS nodlim
Dual.MIP.OptimalityTolerance	The reduced-cost tolerance for optimality in the MIP solver Range: $[1e-09, 0.01]$	1e-06
Dual.MIP.SolutionLimit.ForceOptimalTime	Time (s) without dual bound updates for forcing optimal MIP solution Range: $[0, \infty]$	1000
Dual.MIP.SolutionLimit.UpdateTolerance	The constraint tolerance for when to update MIP solution limit Range: $[0, \infty]$	0.001
Dual.ReductionCut.ReductionFactor	The factor used to reduce the cutoff value Range: $[0, 1]$	0.001
Dual.Relaxation.TerminationTolerance	Time limit (s) when solving LP problems initially Range: real	0.5
Dual.Relaxation.TimeLimit	Time limit (s) when solving LP problems initially Range: $[0, \infty]$	30
Dual.ESH.InteriorPoint.CuttingPlaneReuse	Reuse valid cutting planes in main dual model Range: boolean	0
Dual.ESH.Rootsearch.UniqueConstraints	Allow only one hyperplane per constraint per iteration Range: boolean	0
Dual.ESH.Rootsearch.UseMaxFunction	Perform rootsearch on max function, otherwise on individual constraints Range: boolean	0
Dual.HyperplaneCuts.Delay	Add hyperplane cuts to model only after optimal MIP solution Range: boolean	1
Dual.HyperplaneCuts.SaveHyperplanePoints	Whether to save the points in the generated hyperplanes list Range: boolean	0
Dual.HyperplaneCuts.UseIntegerCuts	Add integer cuts for infeasible integer-combinations for binary problems Range: boolean	0
Dual.MIP.CutOff.UseInitialValue	Use the initial cutoff value Range: boolean	1, if <code>cutoff</code> is set
Dual.MIP.InfeasibilityRepair.IntegerCuts	Allow feasibility repair of integer cuts Range: boolean	1

Option	Description	Default
Dual.MIP.InfeasibilityRepair.Use	Enable the infeasibility repair strategy for nonconvex problems Range: boolean	1
Dual.MIP.Presolve.RemoveRedundantConstraints	Remove redundant constraints (as determined by presolve) Range: boolean	0
Dual.MIP.Presolve.UpdateObtainedBounds	Update bounds (from presolve) to the MIP model Range: boolean	1
Dual.MIP.UpdateObjectiveBounds	Update nonlinear objective variable bounds to primal/dual bounds Range: boolean	0
Dual.ReductionCut.Use	Enable the dual reduction cut strategy for nonconvex problems Range: boolean	1
Dual.Relaxation.Use	Initially solve continuous dual relaxations Range: boolean	1

5.41.3.4 Optimization model

These settings control various aspects of SHOT's representation for and handling of the provided optimization model.

Option	Description	Default
Model.BoundTightening.FeasibilityBased.MaxIterations	Maximal number of bound tightening iterations Range: {0, ..., ∞ }	5
Model.BoundTightening.InitialPOA.CutStrategy	Dual cut strategy 0: ESH 1: ECP	1
Model.BoundTightening.InitialPOA.IterationLimit	Iteration limit for POA Range: {0, ..., ∞ }	50
Model.BoundTightening.InitialPOA.StagnationLimit	Limit for iterations without significant progress Range: {0, ..., ∞ }	5
Model.Reformulation.Bilinear.IntegerFormulation	Reformulate integer bilinear terms 0: No 1: No if nonconvex quadratic terms allowed by MIP solver 2: Yes	1
Model.Reformulation.Bilinear.IntegerFormulationMaxDomain	Do not reformulate integer variables in bilinear terms which can assume more than this number of discrete values Range: {2, ..., ∞ }	100
Model.Reformulation.Constraint.PartitionNonlinearTerms	When to partition nonlinear sums in objective function 0: Always 1: If result is convex 2: Never	1

Option	Description	Default
Model.Reformulation.Constraint.PartitionQuadraticTerms	When to partition quadratic sums in objective function 0: Always 1: If result is convex 2: Never	1
Model.Reformulation.Monomials.Formulation	How to reformulate binary monomials 0: None 1: Simple 2: Costa and Liberti	1
Model.Reformulation.ObjectiveFunction.PartitionNonlinearTerms	When to partition nonlinear sums in objective function 0: Always 1: If result is convex 2: Never	1

5.41.3.5 Modeling system

These settings control functionality used in the interfaces to different modeling environments.

Option	Description	Default
ModelingSystem.GAMS.QExtractAlg	Extraction algorithm for quadratic equations in GAMS interface 0: automatic 1: threepass 2: doubleforward	0

5.41.3.6 Primal heuristics

These settings control the primal heuristics used in SHOT.

Option	Description	Default
Primal.FixedInteger.CallStrategy	When should the fixed strategy be used 0: Use each iteration 1: Based on iteration or time 2: Based on iteration or time, and for all feasible MIP solutions	2
Primal.FixedInteger.Frequency.Iteration	Max number of iterations between calls Range: {0, ..., ∞ }	10
Primal.FixedInteger.IterationLimit	Max number of iterations per call Range: {0, ..., ∞ }	10000000
Primal.FixedInteger.Solver	NLP solver to use 0: Ipopt 1: GAMS 2: SHOT	1
Primal.FixedInteger.Source	Source of fixed MIP solution point 0: All 1: First 2: All feasible 3: First and all feasible 4: With smallest constraint deviation	3
Primal.FixedInteger.SourceProblem	Which problem formulation to use for NLP problem 0: Original problem 1: Reformulated problem 2: Both	0
Primal.FixedInteger.DualPointGap.Relative	If the objective gap between the MIP point and dual solution is less than this the fixed strategy is activated Range: [0, ∞]	0.001
Primal.FixedInteger.Frequency.Time	Max duration (s) between calls Range: [0, ∞]	5
Primal.FixedInteger.TimeLimit	Time limit (s) per NLP problem Range: [0, ∞]	10
Primal.Tolerance.Integer	Integer tolerance for accepting primal solutions Range: real	1e-05
Primal.Tolerance.LinearConstraint	Linear constraint tolerance for accepting primal solutions Range: real	1e-06
Primal.Tolerance.NonlinearConstraint	Nonlinear constraint tolerance for accepting primal solutions Range: real	1e-05

Option	Description	Default
Primal.FixedInteger.CreateInfeasibilityCut	Create a cut from an infeasible solution point Range: boolean	0
Primal.FixedInteger.Frequency.Dynamic	Dynamically update the call frequency based on success Range: boolean	1
Primal.FixedInteger.OnlyUniqueIntegerCombinations	Whether to resolve with the same integer combination, e.g. for nonconvex problems with different continuous variable starting points Range: boolean	1
Primal.FixedInteger.Use	Use the fixed integer primal strategy Range: boolean	1
Primal.FixedInteger.Warmstart	Warm start the NLP solver Range: boolean	1
Primal.Rootsearch.Use	Use a rootsearch to find primal solutions Range: boolean	1
Primal.Tolerance.TrustLinearConstraintValues	Trust that subsolvers (NLP, MIP) give primal solutions that respect linear constraints Range: boolean	1

5.41.3.7 Termination

These settings control when SHOT will terminate the solution process.

Option	Description	Default
Termination.DualStagnation.IterationLimit	Max number of iterations without significant dual objective value improvement Range: {0, ..., ∞ }	∞
Termination.IterationLimit	Iteration limit for main strategy Range: {1, ..., ∞ }	GAMS iterlim
Termination.PrimalStagnation.IterationLimit	Max number of iterations without significant primal objective value improvement Range: {0, ..., ∞ }	50
Termination.ConstraintTolerance	Termination tolerance for nonlinear constraints Range: [0, ∞]	1e-08
Termination.DualStagnation.ConstraintTolerance	Min absolute difference between max nonlinear constraint errors in subsequent iterations for termination Range: [0, ∞]	1e-06
Termination.ObjectiveConstraintTolerance	Termination tolerance for the nonlinear objective constraint Range: [0, ∞]	1e-08
Termination.ObjectiveGap.Absolute	Absolute gap termination tolerance for objective function Range: [0, ∞]	GAMS optca
Termination.ObjectiveGap.Relative	Relative gap termination tolerance for objective function Range: [0, ∞]	GAMS opter
Termination.TimeLimit	Time limit (s) for solver Range: [0, ∞]	GAMS reslim

5.41.3.8 Strategy

Overall strategy parameters used in SHOT.

Option	Description	Default
Strategy.UseRecommendedSettings	Modifies some settings to their recommended values based on the strategy Range: boolean	1

5.42 SNOPT

5.42.1 Introduction

This section describes the GAMS interface to the general-purpose NLP solver SNOPT, (Sparse Nonlinear Optimizer) which implements a sequential quadratic programming (SQP) method for solving constrained optimization problems with smooth nonlinear functions in the objective and constraints. The optimization problem is assumed to be stated in the form

$$\begin{aligned}
 \text{NP :} \quad & \text{minimize or maximize } f_0(x) \\
 & \text{subject to } \begin{aligned} & f(x) \sim b_1 \\ & A_L x \sim b_2 \\ & l \leq x \leq u, \end{aligned} \tag{1}
 \end{aligned}$$

where $x \in \mathfrak{R}^n$, $f_0(x)$ is a linear or nonlinear smooth objective function, l and u are constant lower and upper bounds, $f(x)$ is a set of nonlinear constraint functions, A_L is a sparse matrix, \sim is a vector of relational operators (\leq , \geq or $=$), and b_1 and b_2 are right-hand side constants. $f(x) \sim b_1$ s are the nonlinear constraints of the model and $A_L x \sim b_2$ form the linear constraints.

The gradients of f_0 and f_i are automatically provided by GAMS, using its automatic differentiation engine.

The bounds may include special values -INF or +INF to indicate $l_j = -\infty$ or $u_j = +\infty$ for appropriate j . Free variables have both bounds infinite and fixed variables have $l_j = u_j$.

SNOPT uses a sequential quadratic programming (SQP) algorithm that obtains search directions from a sequence of quadratic programming subproblems. Each QP subproblem minimizes a quadratic model of a certain Lagrangian function subject to a linearization of the constraints. An augmented Lagrangian merit function is reduced along each search direction to ensure convergence from any starting point.

SNOPT is most efficient if only some of the variables enter nonlinearly, or if the number of active constraints (including simple bounds) is nearly as large as the number of variables. SNOPT requires relatively few evaluations of the problem functions.

5.42.1.1 Problem Types

If the nonlinear functions are absent, the problem is a *linear program* (LP) and SNOPT applies the primal simplex method [62]. Sparse basis factors are maintained by LUSOL [111] as in MINOS [192].

If only the objective is nonlinear, the problem is *linearly constrained* (LC) and tends to solve more easily than the general case with nonlinear constraints (NC). Note that GAMS models have an objective variable instead of an objective function. The GAMS/SNOPT link will try to substitute out the objective variable and reformulate the model such that SNOPT will see a true objective function.

For both linearly and nonlinearly constrained problems SNOPT applies a sparse sequential quadratic programming (SQP) method [114] using limited-memory quasi-Newton approximations to the Hessian of the Lagrangian. The merit function for steplength control is an augmented Lagrangian, as in the dense SQP solver NPSOL [110] [113].

In general, SNOPT requires less matrix computation than NPSOL and fewer evaluations of the functions than the nonlinear algorithms in MINOS [190] [191]. It is suitable for nonlinear problems with thousands of constraints and variables, and is most efficient if only some of the variables enter nonlinearly, or there are relatively few degrees of freedom at a solution (i.e., many constraints are active). However, unlike previous versions of SNOPT, there is no limit on the number of degrees of freedom.

5.42.1.2 Selecting the SNOPT Solver

If SNOPT is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select SNOPT:

```
option nlp=SNOPT;
```

The option statement should appear before the `solve` statement. To be complete, we mention that the solver can be also specified on the command line, as in:

```
> gams camcge nlp=snopt
```

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

If the model contains non-smooth functions like $\text{abs}(x)$, or $\text{max}(x,y)$ you can try to get it solved by SNOPT using

```
option dnlp=SNOPT;
```

These models have discontinuous derivatives however, and SNOPT was not designed for solving such models. Discontinuities in the gradients can sometimes be tolerated if they appear away from an optimum.

5.42.2 Description of the method

Here we briefly describe the main features of the SQP algorithm used in SNOPT and introduce some terminology. The SQP algorithm is fully described by Gill, Murray and Saunders [115].

5.42.2.1 Objective function reconstruction

The first step GAMS/SNOPT performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. SNOPT however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```
obj.. z =e= sum(i, sqr[r(i)]);

model m /all/;
solve m using nlp minimizing z;
```

This can be cast in form (1) by saying minimize z subject to $z = \sum_i r_i^2$ and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize the nonlinear expression $\sum_i r_i^2$ directly. This can be achieved by a simple reformulation: z can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable z is a free continuous variable (no bounds are defined on z),
- z appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- z is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by SNOPT. For instance the model `chem.gms` from the model library solves in 16 iterations. When we add the bound

```
energy.lo = 0;
```

on the objective variable `energy` and thus preventing it from being substituted out, SNOPT will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```
variables x,y,z;
equations e1,e2;
e1..z =e= y;
e2..y =e= sqr(1+x);
model m /all/;
option nlp=snopt;
solve m using nlp minimizing z;
```

will be reformulated as an *unconstrained* optimization problem

$$\min f(x) = (1 + x)^2.$$

5.42.2.2 Constraints and slack variables

Problem (1) contains n variables in x . Let m be the number of components of $f(x)$ and $A_L x$ combined. The upper and lower bounds on those terms define the general constraints of the problem. SNOPT converts the general constraints to equalities by introducing a set of slack variables $s = (s_1, s_2, \dots, s_m)^T$. For example, the linear constraint $5 \leq 2x_1 + 3x_2 \leq +\infty$ is replaced by $2x_1 + 3x_2 - s_1 = 0$ together with the bounded slack $5 \leq s_1 \leq +\infty$. Problem (1) can be written in the equivalent form

$$\begin{aligned} & \text{minimize} && f_0(x) \\ & \text{subject to} && \begin{pmatrix} f(x) \\ A_L x \end{pmatrix} - s = 0, \quad l \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u. \end{aligned}$$

where a maximization problem is cast into a minimization by multiplying the objective function by -1 .

The linear and nonlinear general constraints become equalities of the form $f(x) - s_N = 0$ and $A_L x - s_L = 0$, where s_L and s_N are known as the *linear* and *nonlinear* slacks.

5.42.2.3 Major iterations

The basic structure of SNOPT's solution algorithm involves *major* and *minor* iterations. The major iterations generate a sequence of iterates (x_k) that satisfy the linear constraints and converge to a point that satisfies the first-order conditions for optimality. At each iterate $\{x_k\}$ a QP subproblem is used to generate a search direction towards the next iterate $\{x_{k+1}\}$. The constraints of the subproblem are formed from the linear constraints $A_L x - s_L = 0$ and the nonlinear constraint linearization

$$f(x_k) + f'(x_k)(x - x_k) - s_N = 0,$$

where $f'(x_k)$ denotes the *Jacobian*: a matrix whose rows are the first derivatives of $f(x)$ evaluated at x_k . The QP constraints therefore comprise the m linear constraints

$$\begin{aligned} f'(x_k)x - s_N &= -f(x_k) + f'(x_k)x_k, \\ A_L x - s_L &= 0, \end{aligned}$$

where x and s are bounded by l and u as before. If the $m \times n$ matrix A and m -vector b are defined as

$$A = \begin{pmatrix} f'(x_k) \\ A_L \end{pmatrix} \quad \text{and} \quad b = \begin{pmatrix} -f(x_k) + f'(x_k)x_k \\ 0 \end{pmatrix},$$

then the QP subproblem can be written as

$$\begin{aligned} \text{QP}_k : \quad & \min_{x,s} && q(x, x_k) = g_k^T(x - x_k) + \frac{1}{2}(x - x_k)^T H_k(x - x_k) \\ & \text{subject to} && Ax - s = b, \quad l \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u, \end{aligned} \tag{2}$$

where $q(x, x_k)$ is a quadratic approximation to a modified Lagrangian function [114]. The matrix H_k is a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration. If some of the variables enter the Lagrangian linearly the Hessian will have some zero rows and columns. If the nonlinear variables appear first, then only the leading n_1 rows and columns of the Hessian need be approximated, where n_1 is the number of nonlinear variables.

5.42.2.4 Minor iterations

Solving the QP subproblem is itself an iterative procedure. Here, the iterations of the QP solver SQOPT [116] form the *minor* iterations of the SQP method.

SQOPT uses a reduced-Hessian active-set method implemented as a reduced-gradient method similar to that in MINOS [190].

At each minor iteration, the constraints $Ax - s = b$ are partitioned into the form

$$Bx_B + Sx_S + Nx_N = b,$$

where the *basis matrix* B is square and nonsingular and the matrices S , N are the remaining columns of $(A - I)$. The vectors x_B , x_S , x_N are the associated basic, superbasic, and nonbasic components of the variables (x, s) .

The term *active-set method* arises because the nonbasic variables x_N are temporarily frozen at their upper or lower bounds, and their bounds are considered to be active. Since the general constraints are satisfied also, the set of active constraints takes the form

$$\begin{pmatrix} B & S & N \\ & & I \end{pmatrix} \begin{pmatrix} x_B \\ x_S \\ x_N \end{pmatrix} = \begin{pmatrix} b \\ x_N \end{pmatrix},$$

where x_N represents the current values of the nonbasic variables. (In practice, nonbasic variables are sometimes frozen at values strictly between their bounds.) The reduced-gradient method chooses to move the superbasic variables in a direction that will improve the objective function. The basic variables "tag along" to keep $Ax - s = b$ satisfied, and the nonbasic variables remain unaltered until one of them is chosen to become superbasic.

At a nonoptimal feasible point (x, s) we seek a search direction p such that $(x, s) + p$ remains on the set of active constraints yet improves the QP objective. If the new point is to be feasible, we must have $Bp_B + Sp_S + Np_N = 0$ and $p_N = 0$. Once p_S is specified, p_B is uniquely determined from the system $Bp_B = -Sp_S$. It follows that the superbasic variables may be regarded as independent variables that are free to move in any desired direction. The number of superbasic variables (n_S say) therefore indicates the number of degrees of freedom remaining after the constraints have been satisfied. In broad terms, n_S is a measure of how nonlinear the problem is. In particular, n_S need not be more than one for linear problems.

5.42.2.5 The reduced Hessian and reduced gradient

The dependence of p on p_S may be expressed compactly as $p = Zp_S$, where Z is a matrix that spans the null space of the active constraints:

$$Z = P \begin{pmatrix} -B^{-1}S \\ I \\ 0 \end{pmatrix} \quad (3)$$

where P permutes the columns of $(A - I)$ into the order $(B S N)$. Minimizing $q(x, x_k)$ with respect to p_S now involves a quadratic function of p_S :

$$g^T Z p_S + \frac{1}{2} p_S^T Z^T H Z p_S, \quad (4)$$

where g and H are expanded forms of g_k and H_k defined for all variables (x, s) . This is a quadratic with Hessian $Z^T H Z$ (the reduced Hessian) and constant vector $Z^T g$ (the reduced gradient). If the reduced Hessian is nonsingular, p_S is computed from the system

$$Z^T H Z p_S = -Z^T g. \quad (5)$$

The matrix Z is used only as an operator, i.e., it is not stored explicitly. Products of the form Zv or $Z^T g$ are obtained by solving with B or B^T . The package LUSOL [111] is used to maintain sparse LU factors of B as the BSN partition changes. From the definition of Z , we see that the reduced gradient can be computed from

$$B^T \pi = g_B, \quad Z^T g = g_S - S^T \pi,$$

where π is an estimate of the *dual variables* associated with the m equality constraints $Ax - s = b$, and g_B is the basic part of g .

By analogy with the elements of $Z^T g$, we define a vector of reduced gradients (or reduced costs) for all variables in (x, s) :

$$d = g - \begin{pmatrix} A^T \\ -I \end{pmatrix} \pi, \quad \text{so that } d_S = Z^T g.$$

At a feasible point, the reduced gradients for the slacks s are the dual variables π .

The optimality conditions for subproblem QP $_k$ (2) may be written in terms of d . The current point is optimal if $d_j \geq 0$ for all nonbasic variables at their lower bounds, $d_j \leq 0$ for all nonbasic variables at their upper bounds, and $d_j = 0$ for all superbasic variables ($d_S = 0$). In practice, SNOPT requests an *approximate* QP solution $(\hat{x}_k, \hat{s}_k, \hat{\pi}_k)$ with slightly relaxed conditions on d_j .

If $d_S = 0$, no improvement can be made with the current BSN partition, and a nonbasic variable with non-optimal reduced gradient is selected to be added to S . The iteration is then repeated with n_S increased by one. At all stages, if the step $(x, s) + p$ would cause a basic or superbasic variable to violate one of its bounds, a shorter step $(x, s) + \alpha p$ is taken, one of the variables is made nonbasic, and n_S is decreased by one.

The process of computing and testing reduced gradients d_N is known as *pricing* (a term introduced in the context of the simplex method for linear programming). Pricing the j th variable means computing $d_j = g_j - a_j^T \pi$, where a_j is the j th column of $(A - I)$. If there are significantly more variables than general constraints (i.e., $n \gg m$), pricing can be computationally expensive. In this case, a strategy known as *partial pricing* can be used to compute and test only a subset of d_N .

Solving the reduced Hessian system (5) is sometimes expensive. With the option `QPSolver Cholesky`, an upper-triangular matrix R is maintained satisfying $R^T R = Z^T H Z$. Normally, R is computed from $Z^T H Z$ at the start of phase 2 and is then updated as the BSN sets change. For efficiency the dimension of R should not be excessive (say, $n_S \leq 1000$). This is guaranteed if the number of nonlinear variables is "moderate". Other `QPSolver` options are available for problems with many degrees of freedom.

5.42.2.6 The merit function

After a QP subproblem has been solved, new estimates of the NLP solution are computed using a linesearch on the augmented Lagrangian merit function

$$\mathcal{M}(x, s, \pi) = f(x) - \pi^T (F(x) - s_N) + \frac{1}{2} (F(x) - s_N)^T D (F(x) - s_N), \quad (6)$$

where D is a diagonal matrix of penalty parameters. If (x_k, s_k, π_k) denotes the current solution estimate and $(\hat{x}_k, \hat{s}_k, \hat{\pi}_k)$ denotes the optimal QP solution, the linesearch determines a step α_k ($0 < \alpha_k \leq 1$) such that the new point

$$\begin{pmatrix} x_{k+1} \\ s_{k+1} \\ \pi_{k+1} \end{pmatrix} = \begin{pmatrix} x_k \\ s_k \\ \pi_k \end{pmatrix} + \alpha_k \begin{pmatrix} \hat{x}_k - x_k \\ \hat{s}_k - s_k \\ \hat{\pi}_k - \pi_k \end{pmatrix} \quad (7)$$

gives a *sufficient decrease* in the merit function. When necessary, the penalties in D are increased by the minimum-norm perturbation that ensures descent for \mathcal{M} [113]. As in NPSOL, s_N is adjusted to minimize the merit function as a function of s prior to the solution of the QP subproblem. For more details, see [110] [75].

5.42.2.7 Treatment of constraint infeasibilities

SNOPT makes explicit allowance for infeasible constraints. Infeasible *linear* constraints are detected first by solving a problem of the form

$$\begin{aligned} \text{FLP :} \quad & \text{minimize} && e^T(v + w) \\ & \text{subject to} && \ell \leq \begin{pmatrix} x \\ A_L x - v + w \end{pmatrix} \leq u, v \geq 0, w \geq 0, \end{aligned}$$

where e is a vector of ones. This is equivalent to minimizing the sum of the general linear constraint violations subject to the simple bounds. (In the linear programming literature, the approach is often called *elastic programming*. We also describe it as minimizing the ℓ_1 norm of the infeasibilities.)

If the linear constraints are infeasible ($v \neq 0$ or $w \neq 0$), SNOPT terminates without computing the nonlinear functions.

If the linear constraints are feasible, all subsequent iterates satisfy the linear constraints. (Such a strategy allows linear constraints to be used to define a region in which the functions can be safely evaluated.) SNOPT proceeds to solve NP (1) as given, using search directions obtained from a sequence of quadratic programming subproblems (2).

If a QP subproblem proves to be infeasible or unbounded (or if the dual variables π for the nonlinear constraints become large), SNOPT enters "elastic" mode and solves the problem

$$\begin{aligned} \text{NP}(\gamma) : \quad & \text{minimize} && f_0(x) + \gamma e^T(v + w) \\ & \text{subject to} && \ell \leq \begin{pmatrix} x \\ f(x) - v + w \\ A_L x \end{pmatrix} \leq u, v \geq 0, w \geq 0, \end{aligned}$$

where γ is a nonnegative parameter (the *elastic weight*), and $f(x) + \gamma e^T(v + w)$ is called a *composite objective*. If γ is sufficiently large, this is equivalent to minimizing the sum of the nonlinear constraint violations subject to the linear constraints and bounds. A similar ℓ_1 formulation of NP is fundamental to the S ℓ_1 QP algorithm of Fletcher [87]. See also Conn [58].

The initial value of γ is controlled by the optional parameter [elastic weight](#).

5.42.3 Starting points and advanced bases

A good starting point may be essential for solving nonlinear models. We show how such a starting point can be specified in a GAMS environment, and how SNOPT will use this information.

A related issue is the use of "restart" information in case a number of related models are solved in a row. Starting from an optimal point of a previous solve statement is in such situations often beneficial. In a GAMS environment this means reusing primal and dual information, which is stored in the `.L` and `.M` fields of variables and equations.

5.42.3.1 Starting points

To specify a starting point for SNOPT use the .L level values in GAMS. For example, to set all variables $x_{i,j} := 1$ use `x.l(i,j)=1;`. The default values for level values are zero.

Setting a good starting point can be crucial for getting good results. As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points (x_i, y_i) :

$$\begin{array}{ll} \text{Example :} & \text{minimize } r \\ & \text{subject to } (x_i - a)^2 + (y_i - b)^2 \leq r^2, r \geq 0. \end{array}$$

This problem can be modeled in GAMS as follows.

```
set i points /p1*p10/;

parameters
    x(i)    x coordinates,
    y(i)    y coordinates;

* fill with random data
x(i) = uniform(1,10);
y(i) = uniform(1,10);

variables
    a        x coordinate of center of circle
    b        y coordinate of center of circle
    r        radius;

equations
    e(i)     points must be inside circle;

e(i).. sqr(x(i)-a) + sqr(y(i)-b) =l= sqr(r);

r.lo = 0;

model m /all/;
option nlp=snopt;
solve m using nlp minimizing r;
```

Without help, SNOPT will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

$$\begin{aligned} x_{\min} &= \min_i x_i, \\ y_{\min} &= \min_i y_i, \\ x_{\max} &= \max_i x_i, \\ y_{\max} &= \max_i y_i, \end{aligned}$$

then good estimates are

$$\begin{aligned} a &= (x_{\min} + x_{\max})/2, \\ b &= (y_{\min} + y_{\max})/2, \\ r &= \sqrt{(a - x_{\min})^2 + (b - y_{\min})^2}. \end{aligned}$$

Thus we include in our model:

```

parameters xmin,ymin,xmax,ymax;
xmin = smin(i, x(i));
ymin = smin(i, x(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin+xmax)/2;
b.l = (ymin+ymax)/2;
r.l = sqrt( sqrt(a.l-xmin) + sqrt(b.l-ymin) );

```

and now the model solves very easily.

Level values can also be set implicitly as a result of assigning bounds, since GAMS will project variable levels onto their bounds as part of executing a solve statement. For example, when a variable is bounded away from zero by a statement like `Y.LO = 1;` and `Y` is at its default level of zero, the `SOLVE` statement will set the level `Y.L` to 1.

Note: another way to formulate the model would be to minimize r^2 instead of r . This allows SNOPT to solve the problem even with the default starting point.

5.42.3.2 Advanced basis

GAMS automatically passes on level values and basis information from one solve to the next. Thus, when we have two solve statements in a row, with just a few changes in between SNOPT will typically need very few iterations to find an optimal solution in the second solve. For instance, when we add a second solve to the `fawley.gms` model from the model library:

```

Model Exxon /all/;
...
Solve Exxon maximizing profit using lp;
Solve Exxon maximizing profit using lp;

```

we observe the following iteration counts:

S O L V E		S U M M A R Y	
MODEL	Exxon	OBJECTIVE	profit
TYPE	LP	DIRECTION	MAXIMIZE
SOLVER	SNOPT	FROM LINE	278
**** SOLVER STATUS	1	NORMAL COMPLETION	
**** MODEL STATUS	1	OPTIMAL	
**** OBJECTIVE VALUE		2899.2528	
RESOURCE USAGE, LIMIT		0.016	1000.000
ITERATION COUNT, LIMIT		24	10000
.....			
S O L V E		S U M M A R Y	
MODEL	Exxon	OBJECTIVE	profit
TYPE	LP	DIRECTION	MAXIMIZE

```

SOLVER  SNOPT
FROM LINE 279

**** SOLVER STATUS      1 NORMAL COMPLETION
**** MODEL STATUS      1 OPTIMAL
**** OBJECTIVE VALUE    2899.2528

RESOURCE USAGE, LIMIT    0.000    1000.000
ITERATION COUNT, LIMIT  0         10000

```

The first `solve` takes 24 iterations, while the second `solve` needs exactly zero iterations.

Basis information is passed on using the marginals of the variables and equations. In general the rule is:

- $X.M = 0$: basic
- $X.M \neq 0$: nonbasic if level value is at bound, superbasic otherwise

A marginal value of EPS means that the numerical value of the marginal is zero, but that the status is nonbasic or superbasic. The user can specify a basis by assigning zero or nonzero values to the `.M` values. It is further noted that if too many `.M` values are zero, the basis is rejected. This happens for instance when two subsequent models are too different. This decision is made based on the value of the GAMS [bratio](#) option.

5.42.4 GAMS Options

The usual GAMS options (e.g. [reslim](#), [sysout](#)) can be used to control GAMS/SNOPT. For more details, see section [Controlling a Solver via GAMS Options](#). We highlight some of the details of this usage below for cases of special interest.

[iterlim](#)

Sets the *minor* iteration limit. SNOPT will stop as soon as the number of *minor iterations* exceeds the iteration limit, in which case the current solution will be reported.

[domlim](#)

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate \sqrt{x} for $x < 0$. Other examples include taking logs of negative numbers, and evaluating the real power x^y for $x < \varepsilon$ (x^y is evaluated as $\exp(y \log x)$). When such an error occurs the count of domain errors is incremented: SNOPT will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and SNOPT continues. For example, in the case of $\sqrt{x}, x < 0$ a zero is passed back for the function value and a large value for the derivative. In many cases SNOPT will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don't occur. For example, when an expression $\log(x)$ is present in the model, add a statement like `x.lo = 0.001;`.

[bratio](#)

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to SNOPT so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead *crash* a new basis. The `bratio` determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.

workfactor

By default, GAMS/SNOPT computes an estimate of the amount of workspace needed by SNOPT, and passes this workspace on to SNOPT for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeros, etc. In most cases this is sufficient to solve the model. In some rare cases SNOPT may need more memory, and the user can provide this by specifying a value of [workfactor](#) greater than 1. The computed memory estimate is multiplied by the workfactor to determine the amount of workspace made available to SNOPT for the solve.

5.42.5 SNOPT Options

The performance of GAMS/SNOPT is controlled by a number of parameters or "options." Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-default values for some or all of the options via the SNOPT option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section [The Solver Options File](#).

Note that the option file is not case sensitive. The tables below contain summary information about the SNOPT options, default values, and links to more detailed explanations.

5.42.5.1 Printing

Option	Description	Default
major print level	Amount of information printed during optimization (listing file)	1
minor print level	Amount of information printed during optimization (listing file)	1
print frequency	Number of iterations between each log line (listing file)	100
solution	Prints SNOPT solution (listing file)	NO
summary frequency	Number of iterations between each log line (log file)	100
suppress parameters	Suppress printing of parameters (listing file)	
system information	Provides additional information on the progress of the iterations (listing file)	NO
timing level	Amount of timing information (listing file)	3

5.42.5.2 Problem specification

Option	Description	Default
feasible point	Ignore objective function and find a feasible point	
infinite bound	Bounds larger than this number are considered Infinity	1.0e20

5.42.5.3 Convergence tolerances

Option	Description	Default
major feasibility tolerance	Feasibility tolerance for nonlinear constraints	1.0e-6
major optimality tolerance	Specifies the final accuracy of the dual variables	1.0e-6
minor feasibility tolerance	Feasibility tolerance for all variables and linear constraints	1.0e-6

5.42.5.4 Derivative checking

Option	Description	Default
verify level	Finite-difference checks on the derivatives	-1

5.42.5.5 Scaling

Option	Description	Default
scale option	Controls problem scaling	auto
scale print	Print scaling factors (listing file)	
scale tolerance	Scale tolerance	0.9

5.42.5.6 Other tolerances

Option	Description	Default
crash tolerance	Allow crash procedure to ignore small elements in eligible columns	0.1
linesearch tolerance	Controls accuracy of steplength selected	0.9
pivot tolerance	Used to keep the basis non-singular	3.67e-11

5.42.5.7 QP subproblems

Option	Description	Default
crash option	Controls the basis crash algorithm	auto: 0 or 3
elastic weight	Control for elastic mode	1.0e4
iterations limit	Minor iteration limit	GAMS iterlim
partial price	Number of segments in partial pricing strategy	auto
qpsolver	Controls method used for QP subproblems	Cholesky

5.42.5.8 SQP method

Option	Description	Default
central difference interval	Not applicable: GAMS provides analytic derivatives	6.0e-6

Option	Description	Default
cold start	Ignore advanced basis and use CRASH procedure	
derivative linesearch	Linesearch method (safeguarded cubic interpolation) with use of derivatives	
difference interval	Not applicable: GAMS provides analytic derivatives	1.5e-8
function precision	Relative accuracy with which the nonlinear functions are evaluated	3.00e-13
major iterations limit	Max number of major iterations	GAMS iterlim
major step limit	Limits the change in x during a linesearch	2.0
minor iterations limit	Max number of minor iterations between linearizations of nonlinear constraints	500
new superbasics limit	Limit on new superbasics when a QP subproblem is solved	99
nonderivative linesearch	Linesearch method (safeguarded quadratic interpolation) without use of derivatives	
penalty parameter	Initial penalty parameter	0
proximal point method	Controls proximal point method used for solving linear constraints	1
reduced hessian dimension	Size of Hessian matrix	auto
superbasics limit	Maximum number of superbasics	1
unbounded objective value	Determines when a problem is called unbounded	1.0e15
unbounded step size	Determines when a problem is called unbounded	1.0e18
violation limit	Limit on maximum constraint violation after the linesearch	10
warm start	Use advanced basis provided by GAMS	

5.42.5.9 Hessian approximation

Option	Description	Default
hessian frequency	How often the full Hessian is reset to the identity matrix	999999
hessian full memory	Approximate Hessian is treated as a dense matrix	
hessian limited memory	Limited-memory procedure is used to update a diagonal Hessian approximation	
hessian updates	How often the limited memory Hessian is reset	10

5.42.5.10 Frequencies

Option	Description	Default
check frequency	Controls frequency of linear constraint satisfaction test	60
expand frequency	Setting for anti-cycling mechanism	10000
factorization frequency	Number of iterations between basis factorizations	auto: 100 or 50

5.42.5.11 LUSOL options

Option	Description	Default
LU complete pivoting	LUSOL pivoting strategy	
LU density tolerance	Controls when to move to a dense factorization	0.6
LU factor tolerance	Trade-off between stability and sparsity in basis factorization	auto
LU partial pivoting	LUSOL pivoting strategy	yes
LU rook pivoting	LUSOL pivoting strategy	
LU singularity tolerance	Protection against ill-conditioned basis matrices	3.2e-11
LU update tolerance	Trade-off between stability and sparsity in basis factorization	auto

central difference interval (*real*): Not applicable: GAMS provides analytic derivatives ↔

Default: 6.0e-6

check frequency (*integer*): Controls frequency of linear constraint satisfaction test ↔

Every i^{th} minor iteration after the most recent basis factorization, a numerical test is made to see if the current solution x satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax - s = b$, where s is the set of slack variables. To perform the numerical test, the residual vector $r = b - Ax + s$ is computed. If the largest component of r is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Check frequency 1 is useful for debugging purposes, but otherwise this option should not be needed.

Range: {1, ..., ∞}

Default: 60

cold start (*no value*): Ignore advanced basis and use CRASH procedure ↔

Requests that the CRASH procedure be used to choose an initial basis. This option takes precedence over the GAMS `bratio` option.

crash option (*integer*): Controls the basis crash algorithm ↔

Except on restarts, a CRASH procedure is used to select an initial basis from certain rows and columns of the constraint matrix ($A - I$). The **Crash option** i determines which rows and columns of A are eligible initially, and how many times CRASH is called. Columns of $-I$ are used to pad the basis where necessary.

If $i \geq 1$, certain slacks on inequality rows are selected for the basis first. (If $i \geq 2$, numerical values are used to exclude slacks that are close to a bound.) CRASH then makes several passes through the columns of A , searching for a basis matrix that is essentially triangular. A column is assigned to "pivot" on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis.) For the remaining unassigned rows, slack variables are inserted to complete the basis.

By default, **crash option** 3 is used for linearly constrained problems and **crash option** 0 for problems with nonlinear constraints.

Default: auto: 0 or 3

value	meaning
0	Initial basis will be a slack basis. The initial basis contains only slack variables: $B = I$.
1	One phase CRASH. CRASH is called once, looking for a triangular basis in all rows and columns of the matrix A .
2	Two phase CRASH. CRASH is called twice (if there are nonlinear constraints). The first call looks for a triangular basis in linear rows, and the iteration proceeds with simplex iterations until the linear constraints are satisfied. The Jacobian is then evaluated for the first major iteration and CRASH is called again to find a triangular basis in the nonlinear rows (retaining the current basis for linear rows).
3	Three phase CRASH. CRASH is called up to three times (if there are nonlinear constraints). The first two calls treat <i>linear equalities</i> and <i>linear inequalities</i> separately. As before, the last call treats nonlinear rows before the first major iteration.

crash tolerance (*real*): Allow crash procedure to ignore small elements in eligible columns ↔

The **Crash tolerance** r allows the starting procedure CRASH to ignore certain small nonzeros in each column of A . If a_{\max} is the largest element in column j , other nonzeros a_{ij} in the column are ignored if $|a_{ij}| \leq a_{\max} \times r$. (To be meaningful, r should be in the range $0 \leq r < 1$.)

When $r > 0.0$, the basis obtained by CRASH may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of A and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems.

For example, suppose the first m columns of A are the matrix shown under **LU_factor_tolerance**, i.e. a tridiagonal matrix with entries $-1, 2, -1$. To help CRASH choose all m columns for the initial basis, we would specify **Crash tolerance** r for some value of $r > 0.5$.

Range: $[0, 1]$

Default: 0.1

derivative linesearch (*no value*): Linesearch method (safeguarded cubic interpolation) with use of derivatives ↔

At each major iteration a linesearch is used to improve the merit function. A **Derivative linesearch** uses safeguarded cubic interpolation and requires both function and gradient values to compute estimates of the step size α_k .

difference interval (*real*): Not applicable: GAMS provides analytic derivatives ↔

This alters the interval h_1 that is used to estimate gradients by forward differences in the following circumstances:

- In the initial ("cheap") phase of verifying the problem derivatives.
- For verifying the problem derivatives.
- For estimating missing derivatives.

In all cases, a derivative with respect to x_j is estimated by perturbing that component of x to the value $x_j + h_1(1 + |x_j|)$, and then evaluating $f_0(x)$ or $f(x)$ at the perturbed point. The resulting gradient estimates should be accurate to $O(h_1)$ unless the functions are badly scaled. Judicious alteration of h_1 may sometimes lead to greater accuracy. This option has limited use in a GAMS environment as GAMS provides analytical gradients.

Default: 1.5e-8

elastic weight (*real*): Control for elastic mode \leftrightarrow

The *elastic_weight* ω determines the initial weight γ associated with problem NP(γ).

At any given major iteration k , elastic mode is started if the QP subproblem is infeasible or if the QP dual variables are larger in magnitude than $\omega(1 + \|g(x_k)\|_2)$, where g is the objective gradient. In either case, the QP is re-solved in elastic mode with $\gamma = \omega(1 + \|g(x_k)\|_2)$.

Thereafter, γ is increased (subject to a maximum allowable value) at any point that is optimal for problem NP(γ), but not feasible for NP. After the r th such increase, $\gamma = \omega 10^r (1 + \|g(x_{k1})\|_2)$, where x_{k1} is the iterate at which γ was first needed.

Default: 1.0e4

expand frequency (*integer*): Setting for anti-cycling mechanism \leftrightarrow

This option is part of the EXPAND anti-cycling procedure [112] designed to make progress even on highly degenerate problems.

For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose that the [minor feasibility tolerance](#) is δ and the expand frequency is k . Over a period of k iterations, the tolerance actually used by SNOPT increases from 0.5δ to δ (in steps of $0.5\delta/k$).

For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced.

At least every k iterations, a resetting procedure eliminates any infeasible nonbasic variables. Increasing k helps to reduce the number of these slightly infeasible nonbasic variables. However, it also diminishes the freedom to choose a large pivot element (see [pivot tolerance](#)).

Range: {1, ..., ∞ }

Default: 10000

factorization frequency (*integer*): Number of iterations between basis factorizations \leftrightarrow

At most k basis changes will occur between factorizations of the basis matrix.

- With linear programs, the basis factors are usually updated every iteration. The default k is reasonable for typical problems. Smaller values (say $k = 75$ or $k = 50$) may be more efficient on problems that are rather dense or poorly scaled.
- When the problem is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the [check frequency](#)) to ensure that the general constraints are satisfied. If necessary the basis will be refactored before the limit of k updates is reached.

By default, the frequency is set to 100 for linear models and 50 otherwise.

Range: $\{1, \dots, \infty\}$

Default: auto: 100 or 50

feasible point (*no value*): Ignore objective function and find a feasible point \leftrightarrow

The keyword **feasible point** means "Ignore the objective function" while finding a feasible point for the linear and nonlinear constraints. It can be used to check that the nonlinear constraints are feasible.

Default: turned off.

function precision (*real*): Relative accuracy with which the nonlinear functions are evaluated \leftrightarrow

The *relative function precision* ϵ_R is intended to be a measure of the relative accuracy with which the nonlinear functions can be computed. For example, if $f(x)$ is computed as 1000.56789 for some relevant x and if the first 6 significant digits are known to be correct, the appropriate value for ϵ_R would be $1.0\text{e-}6$.

(Ideally the functions $f_0(x)$ or $f_i(x)$ should have magnitude of order 1. If all functions are substantially less than 1 in magnitude, ϵ_R should be the absolute precision. For example, if $f(x) = 1.23456789\text{e-}4$ at some point and if the first 6 significant digits are known to be correct, the appropriate value for ϵ_R would be $1.0\text{e-}10$.)

- The default value of ϵ_R is appropriate for simple analytic functions.
- In some cases the function values will be the result of extensive computation, possibly involving an iterative procedure that can provide rather few digits of precision at reasonable cost. Specifying an appropriate **Function precision** may lead to savings, by allowing the linesearch procedure to terminate when the difference between function values along the search direction becomes as small as the absolute error in the values.

Default: $3.00\text{e-}13$

hessian frequency (*integer*): How often the full Hessian is reset to the identity matrix \leftrightarrow

This option sets the frequency i for resetting the full memory Hessian. For example, if **hessian full memory** is selected and i BFGS updates have already been carried out, the Hessian approximation is reset to the identity matrix. (For certain problems, occasional resets may improve convergence, but in general they should not be necessary.)

Hessian Full Memory and **Hessian Frequency = 20** have a similar effect to **Hessian Limited Memory** and **Hessian Updates = 20**, except that the latter retains the current diagonal during resets.

Default: 999999

hessian full memory (*no value*): Approximate Hessian is treated as a dense matrix \leftrightarrow

This option selects the full storage method for storing and updating the approximate Hessian. (SNOPT uses a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration.)

If **Hessian Full Memory** is specified, the approximate Hessian is treated as a dense matrix and the BFGS updates are applied explicitly. This option is most efficient when the number of nonlinear variables n_1 is not too large. In this case, the storage requirement is fixed and one can expect Q-superlinear convergence to the solution.

By default, this storage method is chosen when the number of nonlinear variables $n_1 \leq 75$.

hessian limited memory (*no value*): Limited-memory procedure is used to update a diagonal Hessian approximation ↔

This option selects the limited memory storage method for storing and updating the approximate Hessian. (SNOPT uses a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration.)

Hessian Limited Memory should be used on problems where the number of nonlinear variables n_1 is large. In this case a limited-memory procedure is used to update a diagonal Hessian approximation \$H_L\$ a limited number of times. (Updates are accumulated as a list of vector pairs. They are discarded at regular intervals after H_r has been reset to their diagonal.)

By default, this storage method is chosen when the number of nonlinear variables $n_1 > 75$.

hessian updates (*integer*): How often the limited memory Hessian is reset ↔

If **hessian limited memory** is selected and i BFGS updates have already been carried out, all but the diagonal elements of the accumulated updates are discarded and the updating process starts again.

Broadly speaking, the more updates stored, the better the quality of the approximate Hessian. However, the cost of each QP iteration also increases with the number of updates. The default value is likely to give a robust algorithm without significant expense, but faster convergence can sometimes be obtained with significantly fewer updates (e.g., $i = 5$).

Default: 10

infinite bound (*real*): Bounds larger than this number are considered Infinity ↔

If $r > 0$, r defines the "infinite" bound **infBnd** in the definition of the problem constraints. Any upper bound greater than or equal to **infBnd** will be regarded as plus infinity (and similarly for a lower bound less than or equal to **-infBnd**). If $r \leq 0$, the default value is used.

Default: 1.0e20

iterations limit (*integer*): Minor iteration limit ↔

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the QP algorithm), summed over all major iterations. This option, if set, overrides the GAMS **iterlim** specification.

Default: GAMS **iterlim**

linesearch tolerance (*real*): Controls accuracy of steplength selected ↔

This controls the accuracy with which a steplength will be located along the direction of search at each iteration. At the start of each linesearch a target directional derivative for the merit function is identified. The **linesearch tolerance** t determines the accuracy to which this target value is approximated.

- Larger values like $t = 0.9$ request just moderate accuracy in the linesearch.
 - If the nonlinear functions are cheap to evaluate, as is usually the case for GAMS models, a more accurate search may be appropriate; try $t = 0.1$, 0.01 or 0.001. The number of major iterations might decrease.
 - If the nonlinear functions are expensive to evaluate, a less accurate search may be appropriate. In the case of running under GAMS where all gradients are known, try $t = 0.99$. The number of major iterations might increase, but the total number of function evaluations may decrease enough to compensate.
-

Range: [0, 1]

Default: 0.9

LU complete pivoting (*no value*): LUSOL pivoting strategy [↔](#)

See [LU_partial_pivoting](#).

LU density tolerance (*real*): Controls when to move to a dense factorization [↔](#)

The density tolerance r_1 is used during LUSOL's basis factorization $B = LU$. Columns of L and rows of U are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds r_1 , the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense LU procedure. Raising the density tolerance towards 1.0 may give slightly sparser LU factors, with a slight increase in factorization time.

See also [LU_singularity_tolerance](#).

Range: [0, 1]

Default: 0.6

LU factor tolerance (*real*): Trade-off between stability and sparsity in basis factorization [↔](#)

LU factor tolerance r_1

LU update tolerance r_2

These tolerances affect the stability and sparsity of the basis factorization $B = LU$ during refactorization and updating, respectively. They must satisfy $r_1, r_2 \geq 1.0$. The matrix L is a product of matrices of the form

$$\begin{pmatrix} 1 & \\ \mu & 1 \end{pmatrix},$$

where the multipliers μ satisfy $|\mu| \leq r_i$. Smaller values of r_i favor stability, while larger values favor sparsity.

- For large and relatively dense problems, smaller values of r_1 (e.g. $r_1 = 3.0$) may give a useful improvement in stability without impairing sparsity to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to reduce r_1 and/or r_2 in order to achieve stability. For example, if the columns of A include a submatrix of the form

$$\begin{pmatrix} 2 & -1 & & & & \\ -1 & 2 & -1 & & & \\ & -1 & 2 & -1 & & \\ & & \ddots & \ddots & \ddots & \\ & & & -1 & 2 & -1 \\ & & & & -1 & 2 \end{pmatrix},$$

both r_1 and r_2 should be in the range $1.0 \leq r_i < 2.0$.

For linear models, the defaults are $r_1 = 100$ and $r_2 = 10$, while for nonlinear models both tolerances default to 3.99.

See also [LU_update_tolerance](#).

Range: [1, ∞]

Default: auto

LU partial pivoting (*no value*): LUSOL pivoting strategy ↔

The LUSOL factorization implements a Markowitz-type search for pivots that locally minimizes fill-in subject to a threshold pivoting stability criterion. The **rook pivoting** and **complete pivoting** options are more expensive than **partial pivoting** but are more stable and better at revealing rank, as long as the **LU_factor_tolerance** is not too large (say $r_1 < 2.0$).

When numerical difficulties are encountered, SNOPT automatically reduces the *LU* tolerances toward 1.0 and switches (if necessary) to rook or complete pivoting before reverting to the default or specified options at the next refactorization. (With **sysout** on and **system information** enabled, relevant messages are output to the listing file.)

Default: **yes**

LU rook pivoting (*no value*): LUSOL pivoting strategy ↔

See **LU_partial_pivoting**.

LU singularity tolerance (*real*): Protection against ill-conditioned basis matrices ↔

The singularity tolerance r_2 helps guard against ill-conditioned basis matrices. After B is refactorized, the diagonal elements of U are tested as follows: if $|U_{jj}| \leq r_2$ or $|U_{jj}| < r_2 \max_i |U_{ij}|$, the j th column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart.)

See also **LU_density_tolerance**.

Default: **3.2e-11**

LU update tolerance (*real*): Trade-off between stability and sparsity in basis factorization ↔

See **LU_factor_tolerance** for details.

Range: **[1, ∞]**

Default: **auto**

major feasibility tolerance (*real*): Feasibility tolerance for nonlinear constraints ↔

This tolerance ϵ_r specifies how accurately the nonlinear constraints should be satisfied. The default value of **1.0e-6** is appropriate when the constraints are expected to have at least that accuracy.

Let **rowerr** be the maximum nonlinear constraint violation, normalized by the size of the solution. It is required to satisfy

$$\text{rowerr} = \max_i \text{viol}_i / \|x\| \leq \epsilon_r, \quad (8)$$

where viol_i is the violation of the i th nonlinear constraint.

In the GAMS/SNOPT iteration log, **rowerr** appears as the quantity labeled "Feasibl". If some of the problem functions are known to be of low accuracy, a larger **Major feasibility tolerance** may be appropriate.

Default: **1.0e-6**

major iterations limit (*integer*): Max number of major iterations ↔

This is the maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the constraints. By default it is set to $\max(1000, m)$.

Default: GAMS iterlim

major optimality tolerance (*real*): Specifies the final accuracy of the dual variables \leftrightarrow

This tolerance ϵ_d specifies the final accuracy of the dual variables. On successful termination, SNOPT will have computed a solution (x, s, π) such that

$$\maxComp = \max_j Comp_j / \|\pi\| \leq \epsilon_d, \quad (9)$$

where $Comp_j$ is an estimate of the complementarity slackness for variable j . The values $Comp_j$ are computed from the final QP solution using the reduced gradients $d_j = g_j - \pi^T a_j$ (where g_j is the j th component of the objective gradient, a_j is the associated column of the constraint matrix $(A \ -I)$ and π is the set of QP dual variables):

$$Comp_j = \begin{cases} d_j \min\{x_j - l_j, 1\} & \text{if } d_j \geq 0; \\ -d_j \min\{u_j - x_j, 1\} & \text{if } d_j < 0. \end{cases}$$

In the GAMS/SNOPT iteration log, *maxComp* appears as the quantity labeled "Optimal".

Default: 1.0e-6

major print level (*integer*): Amount of information printed during optimization (listing file) \leftrightarrow

This controls the amount of output to the GAMS listing file at each major iteration. This output is only visible if the `sysout` option is turned on. `Major print level 1` gives normal output for linear and nonlinear problems, and `Major print level 11` gives additional details of the Jacobian factorization that commences each major iteration. In general, the value specified may be thought of as a binary number of the form

`Major print level JFDXbs`

where each letter stands for a digit that is either 0 or 1 as follows:

- **s** single line that gives a summary of each major iteration. (This entry in `JFDXbs` is not strictly binary since the summary line is printed whenever `JFDXbs` \geq 1).
- **b** BASIS statistics, i.e., information relating to the basis matrix whenever it is refactorized. (This output is always provided if `JFDXbs` \geq 10).
- **X** x_k , the nonlinear variables involved in the objective function or the constraints.
- **D** π_k , the dual variables for the nonlinear constraints.
- **F** $F(x_k)$, the values of the nonlinear constraint functions.
- **J** $J(x_k)$, the Jacobian.

To obtain output of any items `JFDXbs`, set the corresponding digit to 1, otherwise to 0.

If `J=1`, the Jacobian will be output column-wise at the start of each major iteration. Column j will be preceded by the value of the corresponding variable x_j and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence if `J=1`, there is no reason to specify `X=1` unless the objective contains more nonlinear variables than the Jacobian.) A typical line of output is

3 1.250000D+01 BS 1 1.00000E+00 4 2.00000E+00

which would mean that x_3 is basic at value 12.5, and the third column of the Jacobian has elements of 1.0 and 2.0 in rows 1 and 4.

Major print level 0 suppresses most output, except for error messages.

Default: 1

major step limit (*real*): Limits the change in x during a linesearch ↔

This parameter r limits the change in x during a linesearch. It applies to all nonlinear problems, once a "feasible solution" or "feasible subproblem" has been found.

1. A linesearch determines a step α over the range $0 < \alpha \leq \beta$, where β is 1 if there are nonlinear constraints, or the step to the nearest upper or lower bound on x if all the constraints are linear. Normally, the first steplength tried is $\alpha_1 = \min(1, \beta)$.
2. In some cases, such as $f(x) = ae^{bx}$ or $f(x) = ax^b$, even a moderate change in the components of x can lead to floating-point overflow. The parameter r is therefore used to define a limit $\bar{\beta} = r(1 + \|x\|)/\|p\|$ (where p is the search direction), and the first evaluation of $f(x)$ is at the potentially smaller steplength $\alpha_1 = \min(1, \bar{\beta}, \beta)$.
3. Wherever possible, upper and lower bounds on x should be used to prevent evaluation of nonlinear functions at meaningless points. The **Major step limit** provides an additional safeguard. The default value $r = 2.0$ should not affect progress on well behaved problems, but setting $r = 0.1$ or 0.01 may be helpful when rapidly varying functions are present. A "good" starting point may be required. An important application is to the class of nonlinear least-squares problems.
4. In cases where several local optima exist, specifying a small value for r may help locate an optimum near the starting point.

Default: 2.0

minor feasibility tolerance (*real*): Feasibility tolerance for all variables and linear constraints ↔

SNOPT tries to ensure that all variables eventually satisfy their upper and lower bounds to within this tolerance t . This includes slack variables, so general linear constraints should also be satisfied to within t .

Feasibility with respect to nonlinear constraints is judged by the [major feasibility tolerance](#).

- If the bounds and linear constraints cannot be satisfied to within t , the problem is declared **infeasible**. Let **sInf** be the corresponding sum of infeasibilities. If **sInf** is quite small, it may be appropriate to raise t by a factor of 10 or 100. Otherwise, some error in the data should be suspected.
- Nonlinear functions will be evaluated only at points that satisfy the bounds and linear constraints. If there are regions where a function is undefined, every attempt should be made to eliminate these regions from the problem. For example, if $f(x) = \sqrt{x_1} + \log x_2$, it is essential to place lower bounds on both variables. If $t = 1.0e - 6$, the bounds $x_1 \geq 10^{-5}$ and $x_2 \geq 10^{-4}$ might be appropriate. (The log singularity is more serious. In general, keep x as far away from singularities as possible.)
- If the model is scaled (see [scale option](#)), feasibility is defined in terms of the scaled problem.
- In reality, SNOPT uses t as a feasibility tolerance for satisfying the bounds on x and s in each QP subproblem. If the sum of infeasibilities cannot be reduced to zero, the QP subproblem is declared infeasible. SNOPT is then in *elastic mode* thereafter (with only the linearized nonlinear constraints defined to be elastic). See [elastic weight](#) for details.

Default: 1.0e-6

minor iterations limit (*integer*): Max number of minor iterations between linearizations of nonlinear constraints ↔

Minor iterations limit k . If the number of minor iterations for the optimality phase of the QP subproblem exceeds k , then all nonbasic QP variables that have not yet moved are frozen at their current values and the reduced QP is solved to optimality. Note that more than k minor iterations may be necessary to solve the reduced QP to optimality. These extra iterations are necessary to ensure that the terminated point gives a suitable direction for the linesearch. In the major iteration log, a \mathfrak{t} at the end of a line indicates that the corresponding QP was artificially terminated using the limit k . Note that **iterations limit** defines an independent absolute limit on the total number of minor iterations (summed over all QP subproblems).

Default: 500

minor print level (*integer*): Amount of information printed during optimization (listing file) ↔

This controls the amount of output to the GAMS listing file during solution of the QP subproblems. It is only useful if the GAMS **sysout** option is turned on. The value of k has the following effect:

- 0 No minor iteration output except error messages.
- ≥ 1 A single line of output each minor iteration (controlled by **print frequency**).
- ≥ 10 Basis factorization statistics generated during the periodic refactorization of the basis (see **factorization frequency**). Statistics for the *first factorization* of each major iteration are controlled by the **major print level**.

Default: 1

new superbasics limit (*integer*): Limit on new superbasics when a QP subproblem is solved ↔

This option causes early termination of the QP subproblems if the number of free variables has increased significantly since the first feasible point. If the number of new superbasics is greater than **new superbasics limit** the nonbasic variables that have not yet moved are frozen and the resulting smaller QP is solved to optimality. In the major iteration log, a "T" at the end of a line indicates that the QP was terminated early in this way.

Default: 99

noderivative linesearch (*no value*): Linesearch method (safeguarded quadratic interpolation) without use of derivatives ↔

A **noderivative linesearch** can be slightly less robust on difficult problems, and it is recommended that the default **derivative linesearch** be used if the functions and derivatives can be computed at approximately the same cost. If the gradients are very expensive relative to the functions, a noderivative linesearch may give a significant decrease in computation time. In a GAMS environment **derivative linesearch** (the default) is more appropriate.

partial price (*integer*): Number of segments in partial pricing strategy ↔

This parameter sets the number of segments k using in partial pricing and is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each "pricing" operation (i.e. when a nonbasic variable is selected to become superbasic).

- When $k = 1$, all columns of the constraint matrix ($A - I$) are searched.

- Otherwise, A and I are partitioned to give k roughly equal segments A_j, I_j ($j = 1$ to k). If the previous pricing search was successful on A_j, I_j , the next search begins on the segments A_{j+1}, I_{j+1} . (All subscripts here are modulo k .)
- If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. If nothing is found, the search continues on the next segments A_{j+2}, I_{j+2} , and so on.
- **Partial price** t (or $t/2$ or $t/3$) may be appropriate for time-stage models having t time periods.

The default is 10 for linear models and 1 for nonlinear models.

Range: $\{1, \dots, \infty\}$

Default: auto

penalty parameter (*real*): Initial penalty parameter \leftrightarrow

After a QP subproblem has been solved, new estimates of the NLP solution are computed using a linesearch on the augmented Lagrangian merit function. This functions contains penalty parameters, which may be increased to ensure descent.

Default: 0

pivot tolerance (*real*): Used to keep the basis non-singular \leftrightarrow

During solution of QP subproblems, the pivot tolerance r is used to prevent columns entering the basis if they would cause the basis to become almost singular.

- When x changes to $x + \alpha p$ for some search direction p , a ratio test is used to determine which component of x reaches an upper or lower bound first. The corresponding element of p is called the pivot element.
- Elements of p are ignored (and therefore cannot be pivot elements) if they are smaller than the pivot tolerance r .
- It is common for two or more variables to reach a bound at essentially the same time. In such cases, the **minor feasibility tolerance** (say t) provides some freedom to maximize the pivot element and thereby improve numerical stability. Excessively small values of t should therefore not be specified.
- To a lesser extent, the **expand frequency** (say f) also provides some freedom to maximize the pivot element. Excessively *large* values of f should therefore not be specified.

Default: 3.67e-11

print frequency (*integer*): Number of iterations between each log line (listing file) \leftrightarrow

Synonym: log_frequency

When **sysout** is turned on and **minor print level** is positive, a line of the QP iteration log will be printed on the listing file every k th minor iteration.

Range: $\{1, \dots, \infty\}$

Default: 100

proximal point method (*integer*): Controls proximal point method used for solving linear constraints \leftrightarrow

Once the linear constraints are satisfied, the proximal point method chooses a linear feasible point that is closest to x_0 , the initial point for the nonlinear variables. The idea is to both satisfy the linear constraints and stay close to the starting values provided for the nonlinear variables. This option is used to disable the proximal point method or to select the norm used.

Default: 1

value	meaning
0	disable PPM Do not use the proximal point method.

| 1 | one-norm

Minimize the one-norm $\|x - x_0\|_1$. | 2 | two-norm

Minimize the two-norm $\frac{1}{2}\|x - x_0\|_2^2$.

qpsolver (*string*): Controls method used for QP subproblems \leftrightarrow

This specifies the method used to solve system (5) for the search directions in phase 2 of the QP subproblem.

- The Cholesky QP solver is the most robust, but may require a significant amount of computation if the number of superbasics is large.
- The quasi-Newton QP solver does not require the computation of the R at the start of each QP subproblem. It may be appropriate when the number of superbasics is large but relatively few major iterations are needed to reach a solution (e.g., if SNOPT is called with a [warm start](#)).
- The conjugate-gradient QP solver is appropriate for problems with many degrees of freedom (say, more than 2000 superbasics).

Default: Cholesky

value	meaning
Cholesky	full Cholesky factor QPSolver Cholesky holds the full Cholesky factor R of the reduced Hessian $Z^T H Z$. As the minor iterations proceed, the dimension of R changes with the number of superbasic variables. If the number of superbasic variables needs to increase beyond the value of reduced hessian dimension , the reduced Hessian cannot be stored and the solver switches to QPSolver CG. The Cholesky solver is reactivated if the number of superbasics stabilizes at a value less than the reduced hessian dimension .
QN	quasi-Newton method QPSolver QN solves the QP using a quasi-Newton method similar to that of MINOS. In this case, R is the factor of a quasi-Newton approximate Hessian.
CG	conjugate-gradient method QPSolver CG uses an active-set method similar to QPSolver QN, but uses the conjugate-gradient method to solve all systems involving the reduced Hessian.

reduced hessian dimension (*integer*): Size of Hessian matrix \leftrightarrow

Synonym: hessian_dimension

This specifies that an $i \times i$ triangular matrix R is to be available for use by the QPSolver Cholesky option (to define the reduced Hessian according to $R^T R = Z^T H Z$). The value of i affects when QPSolver CG is activated. The default is computed internally by SNOPT, currently as $\min\{2000, n_1 + 1\}$.

Range: $\{1, \dots, \infty\}$

Default: auto

scale option (*integer*): Controls problem scaling \leftrightarrow

Three scale options are available. By default, option 2 is used for linear models and option 1 for nonlinear models. See also [scale tolerance](#) and [scale print](#).

Default: `auto`

value	meaning
0	No scaling This is recommended if it is known that x and the constraint matrix and Jacobian never have very large elements (say, larger than 100).
1	Scale linear variables Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see Fourer [97]). This will sometimes improve the performance of the solution procedures.
2	Scale linear + nonlinear variables All constraints and variables are scaled by the iterative procedure. Also, an additional scaling is performed that takes into account columns of $(A - I)$ that are fixed or have positive lower bounds or negative upper bounds. If nonlinear constraints are present, the scales depend on the Jacobian at the first point that satisfies the linear constraints. Scale option 2 should therefore be used only if (a) a good starting point is provided, and (b) the problem is not highly nonlinear.

scale print (*no value*): Print scaling factors (listing file) \leftrightarrow

Scale print causes the row-scales $r(i)$ and column-scales $c(j)$ to be printed. The scaled matrix coefficients are $\bar{a}_{ij} = a_{ij}c(j)/r(i)$, and the scaled bounds on the variables and slacks are $\bar{l}_j = l_j/c(j)$, $\bar{u}_j = u_j/c(j)$, where $c(j) \equiv r(j - n)$ if $j > n$.

The listing file will only show these values if the `sysout` option is turned on. See also [scale option](#) and [scale tolerance](#).

scale tolerance (*real*): Scale tolerance \leftrightarrow

The scale tolerance t affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$\rho_j = \max_i |a_{ij}| / \min_i |a_{ij}| \quad (a_{ij} \neq 0).$$

If $\max_j \rho_j$ is less than r times its previous value, another scaling pass is performed to adjust the row and column scales. Raising r from 0.9 to 0.99 (say) usually increases the number of scaling passes through A . At most 10 passes are made.

See also [scale option](#) and [scale print](#).

Range: [0, 1]

Default: 0.9

solution (*string*): Prints SNOPT solution (listing file) \leftrightarrow

This option causes the SNOPT solution file to be printed to the GAMS listing file, provided the `sysout` option is also turned on.

Default: turned off.

Default: NO

value	meaning
NO	Turn off printing of solution
YES	Turn on printing of solution

summary frequency (*integer*): Number of iterations between each log line (log file) ↔

If **minor print level** is positive, a line of the QP iteration log is output every k th minor iteration.

Range: {1, ..., ∞ }

Default: 100

superbasics limit (*integer*): Maximum number of superbasics ↔

This places a limit on the storage allocated for superbasic variables. Ideally, i should be set slightly larger than the number of degrees of freedom expected at an optimal solution.

For linear programs, an optimum is normally a basic solution with no degrees of freedom. The default value of i is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the "number of independent variables".

Normally, i need not be greater than $n_1 + 1$, where n_1 is the number of nonlinear variables. For many problems, i may be considerably smaller than n_1 . This will save storage if n_1 is very large.

This parameter also sets the **reduced hessian dimension**, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, based on problem characteristics.

Range: {1, ..., ∞ }

Default: 1

suppress parameters (*no value*): Suppress printing of parameters (listing file) ↔

Normally SNOPT prints the option file as it is being read, and then prints a complete list of the available keywords and their final values. The **suppress parameters** option tells SNOPT not to print the full list. Used in conjunction with the **sysout** option.

system information (*string*): Provides additional information on the progress of the iterations (listing file) ↔

The **Yes** option provides additional information on the progress of the iterations, including basis repair details when ill-conditioned bases are encountered and the *LU* factorization parameters are strengthened.

Default: NO

value	meaning
NO	Turn off additional printing of information on progress of algorithm
YES	Turn on additional printing of information on progress of algorithm

timing level (*integer*): Amount of timing information (listing file) ↔

Amount of timing information written to the listing file. Used in conjunction with the [sysout](#) option.

Range: {0, ..., 3}

Default: 3

unbounded objective value (*real*): Determines when a problem is called unbounded \leftrightarrow

This parameter sets the value f_{\max} intended to detect unboundedness in nonlinear problems. See [unbounded step size](#) for the setting of α_{\max} .

During a line search, f_0 is evaluated at points of the form $x + \alpha p$, where x and p are fixed and α varies. If $|f_0|$ exceeds f_{\max} or α exceeds α_{\max} , iterations are terminated with the exit message **Problem is unbounded (or badly scaled)**.

Unboundedness in x is best avoided by placing finite upper and lower bounds on the variables.

Default: 1.0e15

unbounded step size (*real*): Determines when a problem is called unbounded \leftrightarrow

This parameter sets the value α_{\max} used in the unboundedness test: see [unbounded objective value](#) for details.

Default: 1.0e18

verify level (*integer*): Finite-difference checks on the derivatives \leftrightarrow

This option refers to finite-difference checks on the derivatives computed by the user-provided routines. Derivatives are checked at the first point that satisfies all bounds and linear constraints.

This option has limited use in a GAMS environment.

Default: -1

value	meaning
0	Cheap test
1	Check individual gradients
2	Check individual columns of the Jacobian
3	Combines verify level 1 and 2
-1	Derivative checking is disabled

violation limit (*integer*): Limit on maximum constraint violation after the linesearch \leftrightarrow

This parameter τ is used to define an absolute limit on the magnitude of the maximum constraint violation after the line search. On completion of the line search, the new iterate x_{k+1} satisfies the condition

$$v_i(x_{k+1}) \leq \tau \max\{1, v_i(x_0)\},$$

where x_0 is the point at which the nonlinear constraints are first evaluated and $v_i(x)$ is the i th nonlinear constraint violation $v_i(x) = \max(0, l_i - F_i(x), F_i(x) - u_i)$.

The effect of this violation limit is to restrict the iterates to lie in an *expanded* feasible region whose size depends on the magnitude of τ . This makes it possible to keep the iterates within a

region where the objective is expected to be well-defined and bounded below. If the objective is bounded below for all values of the variables, then τ may be any large positive value.

Default: 10

warm start (*no value*): Use advanced basis provided by GAMS \leftrightarrow

Use an advanced basis provided by GAMS. This option takes precedence over the GAMS [bratio](#) option.

5.42.6 The SNOPT log

When GAMS/SNOPT solves a linearly constrained problem the following log is visible on the screen:

```

Time for solution output	0.00 seconds
Time for constraint functions	0.01 seconds
Time for objective function	0.00 seconds

The SNOPT log shows the following columns:

Major

The current major iteration number.

Minors

The number of iterations required by both the feasibility and optimality phases of the QP subproblem. Generally, `Minor` will be 1 in the later iterations, since theoretical analysis predicts that the correct active set will be identified near the solution (see [Section Description of the method](#))

Step

The step length α taken along the current search direction p . The variables x have just been changed to $x + \alpha p$. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.

nObj

The number of times the nonlinear objective function has been evaluated. `nObj` is printed as a guide to the amount of work required for the linesearch.

nCon

The number of times SNOPT evaluated the nonlinear constraint functions.

MeritFunction

The value of the augmented Lagrangian merit function (6). This function will decrease at each iteration unless it was necessary to increase the penalty parameters (see [Section Description of the method](#)). As the solution is approached, `Merit` will converge to the value of the objective at the solution.

In elastic mode, the merit function is a composite function involving the constraint violations weighted by the elastic weight.

If the constraints are linear, this item is labeled `Objective`, the value of the objective function. It will decrease monotonically to its optimal value.

Feasible

The value of `rowerr`, the maximum component of the scaled nonlinear constraint residual. The solution is regarded as acceptably feasible if `Feasible` is less than the [Major feasibility tolerance](#).

If the constraints are linear, all iterates are feasible and this entry is not printed.

Optimal

The value of `maxgap`, the maximum complementarity gap. It is an estimate of the degree of nonoptimality of the reduced costs. The solution is considered to be optimal if `Optimal` is less than the [major optimality tolerance](#).

nS

The current number of superbasic variables.

Penalty

The Euclidean norm of the vector of penalty parameters used in the augmented Lagrangian merit function (not printed if the constraints are linear).

The summary line may include additional code characters that indicate what happened during the course of the iteration.

c Central differences have been used to compute the unknown components of the objective and constraint gradients. This should not happen in a GAMS environment.

d During the linesearch it was necessary to decrease the step in order to obtain a maximum constraint violation conforming to the value of [violation limit](#).

l The norm-wise change in the variables was limited by the value of the [major step limit](#). If this output occurs repeatedly during later iterations, it may be worthwhile increasing the value of [major step limit](#).

i If SNOPT is not in elastic mode, an "i" signifies that the QP subproblem is infeasible. This event triggers the start of nonlinear elastic mode, which remains in effect for all subsequent iterations. Once in elastic mode, the QP subproblems are associated with the elastic problem $NP(\gamma)$.

If SNOPT is already in elastic mode, an "i" indicates that the minimizer of the elastic subproblem does not satisfy the linearized constraints. (In this case, a feasible point for the usual QP subproblem may or may not exist.)

M An extra evaluation of the problem functions was needed to define an acceptable positive-definite quasi-Newton update to the Lagrangian Hessian. This modification is only done when there are nonlinear constraints.

m This is the same as "M" except that it was also necessary to modify the update to include an augmented Lagrangian term.

n No positive-definite BFGS update could be found. The approximate Hessian is unchanged from the previous iteration.

R The approximate Hessian has been reset by discarding all but the diagonal elements. This reset will be forced periodically by the [hessian frequency](#) and [hessian updates](#) keywords. However, it may also be necessary to reset an ill-conditioned Hessian from time to time.

r The approximate Hessian was reset after ten consecutive major iterations in which no BFGS update could be made. The diagonals of the approximate Hessian are retained if at least one update has been done since the last reset. Otherwise, the approximate Hessian is reset to the identity matrix.

s A self-scaled BFGS update was performed. This update is always used when the Hessian approximation is diagonal, and hence always follows a Hessian reset.

S This is the same as a "s" except that it was necessary to modify the self-scaled update to maintain positive definiteness.

t The minor iterations were terminated at the [minor iterations limit](#).

T The minor iterations were terminated at the [new superbasics limit](#).

u The QP subproblem was unbounded.

w A weak solution of the QP subproblem was found.

z The [superbasics limit](#) was reached.

Finally SNOPT prints an exit message. See Section [EXIT conditions](#).

5.42.6.1 EXIT conditions

When the solution procedure terminates, an SNOPTA EXIT and SNOPTA INFO message is printed to summarize the final result. Here we describe each message and suggest possible courses of action.

1 -- optimality conditions satisfied

The final point seems to be a solution. This means that x is feasible (it satisfies the constraints to the accuracy requested), the reduced gradient is negligible, the reduced costs are optimal, and R is nonsingular. In all cases, some caution should be exercised. For example, if the objective value is much better than expected, SNOPT may have obtained an optimal solution to the wrong problem! Almost any item of data could have that effect if it has the wrong value. Verifying that the problem has been defined correctly is one of the more difficult tasks for a model builder.

If nonlinearities exist, one must always ask the question: could there be more than one local optimum? When the constraints are linear and the objective is known to be convex (e.g., a sum of squares) then all will be well if we are *minimizing* the objective: a local minimum is a global minimum in the sense that no other point has a lower function value. (However, many points could have the *same* objective value, particularly if the objective is largely linear.) Conversely, if we are *maximizing* a convex function, a local maximum cannot be expected to be global, unless there are sufficient constraints to confine the feasible region.

Similar statements could be made about nonlinear constraints defining convex or concave regions. However, the functions of a problem are more likely to be neither convex nor concave. Our advice is always to specify a starting point that is as good an estimate as possible, and to include reasonable upper and lower bounds on all variables, in order to confine the solution to the specific region of interest. We expect modelers to *know something about their problem*, and to make use of that knowledge as they themselves know best.

One other caution about the "Optimal solution" message. Some of the variables or slacks may lie outside their bounds more than desired, especially if scaling was requested. If `sysout` is on, the listing file will contain several indicators of potential issues. `Max Primal infeas` indicates the largest bound infeasibility and which variable is involved. If it is too large, consider restarting with a smaller [minor feasibility tolerance](#) (say 10 times smaller) and perhaps a [scale option](#) of 0.

Similarly, `Max Dual infeas` indicates which variable is most likely to be at a non-optimal value. Broadly speaking, if

Max Dual infeas/Norm of pi = 10^{-d} ,

then the objective function would probably change in the d th significant digit if optimization could be continued. If d seems too large, consider restarting with smaller values of [major feasibility tolerance](#) and [minor feasibility tolerance](#).

Finally, `Nonlinear constraint violn` shows the maximum infeasibility for nonlinear rows. If it seems too large, consider restarting with a smaller [major feasibility tolerance](#).

2 -- feasible point found

Occurs only if [feasible point](#) is enabled.

3 -- requested accuracy could not be achieved

If the requested accuracy could not be achieved, a feasible solution has been found, but the requested accuracy in the dual infeasibilities could not be achieved. An abnormal termination has occurred, but SNOPT is within 10^{-2} of satisfying the [major optimality tolerance](#). Check that the [major optimality tolerance](#) is not too small.

11 -- infeasible linear constraints

12 -- infeasible linear equality constraints

When the constraints are linear, the output messages are based on a relatively reliable indicator of infeasibility. Feasibility is measured with respect to the upper and lower bounds on the variables and slacks. Among all the points satisfying the general constraints $Ax - s = 0$, there is apparently no point that satisfies the bounds on x and s . Violations as small as the [minor feasibility tolerance](#) are ignored, but at least one component of x or s violates a bound by more than the tolerance.

13 -- nonlinear infeasibilities minimized

14 -- linear infeasibilities minimized

15 -- infeasible linear constraints in QP subproblem

16 -- infeasible nonelastic constraints

When nonlinear constraints are present, infeasibility is *much* harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation, when solving each QP subproblem, SNOPT is prepared to relax the bounds on the slacks associated with nonlinear rows.

If a QP subproblem proves to be infeasible or unbounded (or if the Lagrange multiplier estimates for the nonlinear constraints become large), SNOPT enters so-called "nonlinear elastic" mode. The subproblem includes the original QP objective and the sum of the infeasibilities—suitably weighted using the [elastic weight](#) parameter. In elastic mode, the nonlinear rows are made "elastic"—i.e., they are allowed to violate their specified bounds. Variables subject to elastic bounds are known as *elastic variables*. An elastic variable is free to violate one or both of its original upper or lower bounds. If the original problem has a feasible solution and the elastic weight is sufficiently large, a feasible point eventually will be obtained for the perturbed constraints, and optimization can continue on the subproblem. If the nonlinear problem has no feasible solution, SNOPT will tend to determine a "good" infeasible point if the elastic weight is sufficiently large. (If the elastic weight were infinite, SNOPT would locally minimize the nonlinear constraint violations subject to the linear constraints and bounds.)

Unfortunately, even though SNOPT locally minimizes the nonlinear constraint violations, there may still exist other regions in which the nonlinear constraints are satisfied. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

21 -- unbounded objective

22 -- constraint violation limit reached

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased or decreased by an arbitrary amount without causing a basic variable to violate a bound. Adding a bound on the objective will allow SNOPT to find a solution, and inspection of this solution will show the variables that can become too large due to missing restrictions.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the [scale option](#).

For nonlinear problems, SNOPT monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (see [unbounded step size](#) and [unbounded objective value](#)), the problem is terminated and declared UNBOUNDED. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

The second message indicates an abnormal termination while enforcing the limit on the constraint violations. This exit implies that the objective is not bounded below in the feasible region defined by expanding the bounds by the value of the [violation limit](#).

31 -- iteration limit reached

An iteration limit was reached. Most often this is cured by increasing the GAMS [iterlim](#) option. If an SNOPT option file was used, also the [iterations limit](#) may have been set too small.

Check the iteration log to be sure that progress was being made. If so, repeat the run with higher limits. If not, consider specifying new initial values for some of the nonlinear variables.

32 -- major iteration limit reached

This indicates SNOPT was running out the limit on major iterations. This can be changed using the [major iterations limit](#).

33 -- the superbasics limit is too small

The problem appears to be more nonlinear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and a PRICE operation is necessary to continue, but there are already as many superbasics as allowed (and no room for any more).

When increasing the [superbasics limit](#), be aware that this also increases the [reduced hessian dimension](#) unless both options are set explicitly. This may increase the amount of memory required by SNOPT dramatically. Consider also increasing the amount memory available to SNOPT via the [workfactor](#) option, or setting a more moderate value for the [reduced hessian dimension](#) option and possibly getting slower convergence.

34 -- time limit reached

A time limit was hit. Increase the GAMS [reslim](#) option.

41 -- current point cannot be improved

The algorithm could not find a better solution although optimality was not achieved within the optimality tolerance. Possibly scaling can lead to better function values and derivatives. Raising the [major optimality tolerance](#) will probably make this message go away. Try better scaling, better bounds or a better starting point.

42 -- singular basis

The first factorization attempt found the basis to be structurally or numerically singular. (Some diagonals of the triangular matrix U were deemed too small.) The associated variables were replaced by slacks and the modified basis refactorized, but singularity persisted. Try better scaling, better bounds or a better starting point.

43 -- cannot satisfy the general constraints

The basic variables x_B have been recomputed, given the present values of the superbasic and nonbasic variables. A step of "iterative refinement" has also been applied to increase the accuracy of x_B , but a row check has revealed that the resulting solution does not satisfy the QP constraints $Ax - s = b$ sufficiently well. Try better scaling, better bounds or a better starting point.

44 -- ill-conditioned null-space basis

During computation of the reduced Hessian $Z^T H Z$, some column(s) of Z continued to contain very large values. Try better scaling, better bounds or a better starting point.

51 -- incorrect objective derivatives

52 -- incorrect constraint derivatives

The derivatives are not deemed to be correct. This message should not occur using a GAMS model without external equations.

53 -- irregular or badly scaled problem functions

The problem function can be badly scaled in case of DNLPs (which SNOPT was not designed for) or because of evaluations at singular points.

61 -- undefined function at the first feasible point

62 -- undefined function at the initial point

SNOPT was unable to proceed because the functions are undefined at the initial point or the first feasible point. Try to add better bounds or linear equations such that non-linear functions can be evaluated or use a better starting point.

63 -- unable to proceed into undefined region

Repeated attempts to move into a region where the functions are not defined resulted in the change in variables being unacceptably small. At the final point, it appears that the only way to decrease the merit function is to move into a region where the problem functions are not defined.

Try to add better bounds or linear equations such that non-linear functions can be evaluated or use a better starting point.

71 -- terminated during function evaluation

72 -- terminated from monitor routine

These messages indicate trouble evaluating the non-linear functions or derivatives. Usually these errors show a "Function evaluation error limit" message.

81 -- work arrays must have at least 500 elements

82 -- not enough character storage

83 -- not enough integer storage

84 -- not enough real storage

Increase the memory allocation by using `workfactor > 1`.

5.43 SoPlex

SoPlex (Sequential object-oriented **simPlex**) is an optimization package for solving linear programming problems (LPs) based on an advanced implementation of the primal and dual revised simplex algorithm. SoPlex is developed at the Zuse-Institute Berlin.

For more detailed information, we refer to [103] [170] [117] [118] [104] [266] and the [SoPlex web site](#).

5.43.1 Usage

The following statement can be used inside your GAMS program to specify using SOPLEX

```
Option LP = SOPLEX;      { or RMIP }
```

The above statement should appear before the Solve statement. If SoPlex was specified as the default solver during GAMS installation, the above statement is not necessary.

5.43.1.1 Specification of SoPlex Options

GAMS/SoPlex supports the GAMS parameters [reslim](#) and [iterlim](#).

To allow to run without an iteration limit (SoPlex default), the GAMS/SoPlex link does not pass on a setting of GAMS option [iterlim](#) to 2147483647.

Setting the GAMS option [integer1](#) to a nonzero value enables writing of detailed solution statistics to the log.

Setting the GAMS option [integer3](#) to a nonzero value leads to writing the model instance to a file in LP or MPS format before starting the solution process ([integer3=1](#) writes an MPS file, [integer3=2](#) writes an LP files, [integer3=4](#) writes SoPlex state files (.mps, .bas, .set); sum these values to write several files). The name of the output file is chosen to be the name of the GAMS model file with the extension [.gms](#) replaced. Setting the GAMS option [integer2](#) to a nonzero value makes variable and equation names available when writing the LP or MPS files. These options may be useful for debugging purposes.

Options can be specified by a SoPlex options file. A SoPlex options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs).

A small example for a soplex.opt file is:

```
bool:rowboundflips = true
int:algorithm = 0
real:feastol = 1e-5
```

It causes GAMS/SoPlex to use bound flipping also for row representations, use the primal simplex, and use a primal feasibility tolerance of 1e-5.

5.43.2 List of SoPlex Options

In the following, we give a detailed list of all SoPlex options.

5.43.2.1 soplex

Option	Description	Default
bool:acceptcycling	should cycling solutions be accepted during iterative refinement? Range: boolean	0
bool:computedegen	should the degeneracy be computed for each basis? Range: boolean	0
bool:decompositiondualsimplex	should the decomposition based dual simplex be used to solve the LP? Range: boolean	0
bool:ensureray	re-optimize the original problem to get a proof (ray) of infeasibility/unboundedness? Range: boolean	0
bool:explicitviol	Should violations of the original problem be explicitly computed in the decomposition simplex? Range: boolean	0
bool:forcebasic	try to enforce that the optimal solution is a basic solution Range: boolean	0
bool:fullperturbation	should perturbation be applied to the entire problem? Range: boolean	0
bool:lifting	should lifting be used to reduce range of nonzero matrix coefficients? Range: boolean	0
bool:persistentscaling	should persistent scaling be used? Range: boolean	1
bool:powerscaling	round scaling factors for iterative refinement to powers of two? Range: boolean	1
bool:ratfacjump	continue iterative refinement with exact basic solution if not optimal? Range: boolean	0
bool:rowboundflips	use bound flipping also for row representation? Range: boolean	0
bool:testdualinf	should dual infeasibility be tested in order to try to return a dual solution even if primal infeasible? Range: boolean	0
bool:usecompdual	should the dual of the complementary problem be used in the decomposition simplex? Range: boolean	0

Option	Description	Default
int:algorithm	type of algorithm (0 - primal, 1 - dual) Range: {0, ..., 1}	1
int:decomp_displayfreq	the frequency that the decomposition based simplex status output is displayed. Range: {1, ..., ∞ }	50
int:decomp_iterlimit	the number of iterations before the decomposition simplex initialisation solve is terminated Range: {1, ..., ∞ }	100
int:decomp_maxaddedrows	maximum number of rows that are added to the reduced problem when using the decomposition based simplex Range: {1, ..., ∞ }	500
int:decomp_verbosity	the verbosity of decomposition based simplex (0 - error, 1 - warning, 2 - debug, 3 - normal, 4 - high, 5 - full). Range: {1, ..., 5}	0
int:displayfreq	display frequency Range: {1, ..., ∞ }	200
int:factor_update_max	maximum number of LU updates without fresh factorization (0 - auto) Range: {0, ..., ∞ }	0
int:factor_update_type	type of LU update (0 - eta update, 1 - Forrest-Tomlin update) Range: {0, ..., 1}	1
int:hyperpricing	mode for hyper sparse pricing (0 - off, 1 - auto, 2 - always) Range: {0, ..., 2}	1
int:iterlimit	iteration limit (-1 - no limit) Range: {-1, ..., ∞ }	GAMS iterlim
int:leastsq_maxrounds	maximum number of conjugate gradient iterations in least square scaling Range: {0, ..., ∞ }	50
int:pricer	pricing method (0 - auto, 1 - dantzig, 2 - parmilt, 3 - devex, 4 - quicksteep, 5 - steep) Range: {0, ..., 5}	0
int:printbasismetric	print basis metric during the solve (-1 - off, 0 - condition estimate, 1 - trace, 2 - determinant, 3 - condition) Range: {-1, ..., 3}	-1
int:ratiotester	method for ratio test (0 - textbook, 1 - harris, 2 - fast, 3 - boundflipping) Range: {0, ..., 3}	3

Option	Description	Default
int:reflimit	refinement limit (-1 - no limit) Range: {-1, ..., ∞ }	-1
int:representation	type of computational form (0 - auto, 1 - column representation, 2 - row representation) Range: {0, ..., 2}	0
int:scaler	scaling (0 - off, 1 - uni-equilibrium, 2 - bi-equilibrium, 3 - geometric, 4 - iterated geometric, 5 - least squares, 6 - geometric-equilibrium) Range: {0, ..., 6}	2
int:simplifier	simplifier (0 - off, 1 - auto, 2 - PaPILO, 3 - internal) Range: {0, ..., 3}	3
int:stallreflimit	stalling refinement limit (-1 - no limit) Range: {-1, ..., ∞ }	-1
int:starter	crash basis generated when starting from scratch (0 - none, 1 - weight, 2 - sum, 3 - vector) Range: {0, ..., 3}	0
int:stattimer	measure for statistics, e.g. factorization time (0 - off, 1 - user time, 2 - wallclock time) Range: {0, ..., 2}	1
int:timer	type of timer (1 - cputime, aka. usertime, 2 - wallclock time, 0 - no timing) Range: {0, ..., 2}	2
int:verbosity	verbosity level (0 - error, 1 - warning, 2 - debug, 3 - normal, 4 - high, 5 - full) Range: {0, ..., 5}	3
real:epsilon_factorization	zero tolerance used in factorization Range: [0, 1]	1e-20
real:epsilon_pivot	pivot zero tolerance used in factorization Range: [0, 1]	1e-10
real:epsilon_update	zero tolerance used in update of the factorization Range: [0, 1]	1e-16
real:epsilon_zero	general zero tolerance Range: [0, 1]	1e-16
real:feastol	primal feasibility tolerance Range: [0, 1]	1e-06
real:fpfeastol	working tolerance for feasibility in floating-point solver during iterative refinement Range: [1e-12, 1]	1e-09

Option	Description	Default
real:fpopttol	working tolerance for optimality in floating-point solver during iterative refinement Range: [1e-12, 1]	1e-09
real:infity	infinity threshold Range: [1e+10, ∞]	∞
real:leastsq_acrcy	accuracy of conjugate gradient method in least squares scaling (higher value leads to more iterations) Range: [1, ∞]	1000
real:liftmaxval	lower threshold in lifting (nonzero matrix coefficients with smaller absolute value will be reformulated) Range: [10, ∞]	1024
real:liftminval	lower threshold in lifting (nonzero matrix coefficients with smaller absolute value will be reformulated) Range: [0, 0.1]	0.000976562
real:maxscaleincr	maximum increase of scaling factors between refinements Range: [1, ∞]	1e+25
real:min_markowitz	minimal Markowitz threshold in LU factorization Range: [0.0001, 0.9999]	0.01
real:minred	minimal reduction (sum of removed rows/cols) to continue simplification Range: [0, 1]	0.0001
real:objlimit_lower	lower limit on objective value Range: real	GAMS cutoff, if maximizing, else - ∞
real:objlimit_upper	upper limit on objective value Range: real	GAMS cutoff, if minimizing, else + ∞
real:opttol	dual feasibility tolerance Range: [0, 1]	1e-06
real:refac_basis_nnz	refactor threshold for nonzeros in last factorized basis matrix compared to updated basis matrix Range: [1, 100]	10
real:refac_mem_factor	refactor threshold for memory growth in factorization since last refactorization Range: [1, 10]	1.5
real:refac_update_fill	refactor threshold for fill-in in current factor update compared to fill-in in last factorization Range: [1, 100]	5

Option	Description	Default
real:representation_switch	threshold on number of rows vs. number of columns for switching from column to row representations in auto mode Range: $[0, \infty]$	1.2
real:simplifier_modifyrowfac	modify constraints when the number of nonzeros or rows is at most this factor times the number of nonzeros or rows before presolving Range: $[0, 1]$	1
real:sparsity_threshold	sparse pricing threshold (violations $<$ dimension * SPARSITY_THRESHOLD activates sparse pricing) Range: $[0, 1]$	0.6
real:timelimit	time limit in seconds Range: $[0, \infty]$	GAMS reslim

5.44 XA

5.44.1 Introduction

This document describes the GAMS/XA linear and mixed-integer programming solver. The GAMS/XA solver (here also simply referred to as XA) is based on Sunset Software Technology's XA Callable Library, an implementation of high performance solvers for LP and MIP problems.

XA implements primal simplex, dual simplex, and barrier algorithms for solving linear problems. The primal/dual simplex method is very robust, and in most cases you should get good performance, especially from a warm start. The barrier method is particularly efficient on large models. Both algorithms benefit from XA's presolver, which reduces the size of the model by removing redundant constraints, substituting constraints, etc.

In most cases, GAMS/XA should perform satisfactorily without using any options. However, if fine-tuning is necessary or desired, XA provides many options and parameters designed for this purpose. These options are accessible via GAMS option statements or via an XA-specific option file.

5.44.2 Usage

If you have installed the GAMS system and configured XA as the default LP, RMIP and MIP solver, all LP, RMIP and MIP models without a specific solver option will use XA. If you installed another solver as the default, you can explicitly request that a particular model be solved by XA by inserting the statement

```
option LP = xa; { or MIP or RMIP }
```

somewhere before the `solve` statement.

5.44.3 Memory Usage

By default, the GAMS/XA link computes an estimate of the amount of memory that will be required by the solver, and passes this on to the solver. The solver makes an allocation of this amount and then uses this memory during the course of program execution. Usually, this will be sufficient to solve the problem successfully. In some cases, though, the computed estimate will be too small, and GAMS/XA will indicate that a larger memory estimate is required. You will need to manually specify a larger memory estimate to solve the model.

A model-specified memory estimate can be made by adding the following line to your GAMS model before the solve statement:

```
<modelname>.workspace = xx;
```

where xx is the amount of memory in Mbytes. You can also define the environment variable XAMEMORY to be the amount of memory to use, in Mbytes. The computed memory estimate is the default, and is used only if no manual estimate is specified. The model-specified workspace limit overrides the computed estimate, and the XAMEMORY environment variable takes precedence over both of these.

In an attempt to insure that all models solve without running out of memory, XA makes one final memory check and if the user supplied memory amount is below what XA would consider reasonable for that size of problem, XA will then increase your amount to XA's minimal value.

On multi-processor machines, XA will automatically detect and use all available processors (CPU's) when solving MIP models. The memory estimate computed adds 50% more memory per processor to take full advantage of these processors, but this is sometimes not enough memory for XA to multi-process. In this case, a larger estimate must be specified manually.

5.44.4 Semi-Continuous and Semi-Integer Variables

XA supports semi-continuous and semi-integer variable types. Semi-continuous variables are variables that are either at zero or greater than or equal to their lower bound. E.g. a pump motor if operating must run between 2400 and 5400 r.p.m., but it may be switched off as well. Investment levels must exceed a specific threshold or no investment is made.

All semi-continuous variables must have a lower bound specification, e.g., `speed.lo(i) = 100`. Semi-integer variables must have an upper bound as well.

Prior to the introduction of these variable types, semi-continuous variables had to be emulated by adding one additional binary variable and one additional constraint for each semi-continuous variable. For models of any size, this approach very quickly increased the model's size beyond solvability. Now XA has implicitly defined these variables without requiring the addition of new variables and constraints to your model. This effectively increases the size of model that can be solved and does it in a very neat and clean way besides.

For example, to define variables 'a' and 'b' as semi-continuous enter:

```
SemiCont a , b ;
```

or to define semi-integer variables -

```
SemiInt y1 , y2 ;
```

Priority values (`.prior` suffix) can be associated with both semi-continuous and semi-integer variables. All the integer solving options are available for models with semi-continuous and semi-integer variables as well. For example, you can select solving strategies, `optcr` and `optca` values, etc.

The solve time complexity for semi-continuous variables is comparable with the solve times for binary models, while the semi-integer case compares to integer.

5.44.5 Branch and Bound Topics

XA is designed to solve a vast majority of LP problems using the default settings. In the integer case, however, the default settings may not result in optimal speed and reliability. By experimenting with the control parameters performance can be improved (or worsened!) dramatically.

5.44.5.1 Branching Priorities

Using priorities can significantly reduce the amount of time required to obtain a good integer solution. If your model has a natural order in time, or in space, or in any other dimension then you should consider using priority branching. For example, a multi-period production problem with inventory would use the period value as the priority setting for all variables indexed by period. In a layered chip manufacturing process, the priority assigned to binary variables would be top down or bottom up in that layer.

If priorities are given to binary, integer, or semi-continuous variables, then these are used to provide a user-specified order in which variables are branched. XA selects the variable with the highest priority (lowest numerical value) for branching and the Strategy determines the direction, up or down.

Priorities are assigned to variables using the `.prior` suffix. For example:

```
NAVY.PRIOROPT = 1 ;
...
Z.PRIOR(J,"SMALL") = 10 ;
Z.PRIOR(J,"MEDIUM") = 5 ;
Z.PRIOR(J,"LARGE" ) = 1 ;
```

The value 1 indicates the highest priority (branch first), and the value 10 the lowest priority (branch last). Valid priority values should range between -32000 and 32000. The default priority value is 16000.

5.44.5.2 Branching Strategies

Ten branch & bound strategies are provided to meet the demands of many different types of problems. Each strategy has five variations (six if you include the basic strategy, or "no variation") that affect the solve time, speed to first solution, and the search for the best integer solution. The order in which integer variables are processed during the search is important. This order is called the *branching order* of integer variables. Solution times can vary significantly with the method selected.

In general, XA will solve your MIP problems much faster when all model variables are given some kind of objective function value. This biases the basis in a specific direction and usually leads to satisfactory first integer solutions.

The strategy used can be changed by setting the `strategy` option in an XA options file.

Branch & Bound Strategy	Description of Selection Criteria
1	Proprietary method. Default value. Excellent strategy,also add priority to integer variable and try 1P for additional performance gains.
2	Minimum change in the objective function. This strategy has not been very successful at solving MIP problems.
3	Priority based upon column order. This strategy probably does not have much meaning because you typically do not set the column order in GAMS

Branch & Bound Strategy	Description of Selection Criteria
4	Column closest to its integer bound. This strategy tends to send a variable to its lower bound.
6	Column always branches up (high). Second choice after 1. Excellent choice when your model is a multi-period problem; additional performance gains when priority value is equated with period number; also try 6P if using priorities.
7	Column always branches down (low). Useful if variable branched down doesn't limit capacity or resources. One suggestion is to use priorities in the reverse order from that described in Strategy 6.
8	Column farthest from its integer bound. Next to Strategies 1 and 6 this is probably the next choice to try. Using priorities and variation P is also suggested.
9	Column randomly selected, useful when solving very large problems. Priority values helpful in multi-period models.
10	Apparent smoothest sides on the polytope. Priorities helpful.

Each XA B&B strategy has many variations. Sometimes these variations reduce the solution time but may not yield the optimal integer solution. If you are interested in obtaining a fast and 'good' integer solution (which may not be the optimal integer solution), try these variations. You should be aware, though, that using these variations will invalidate the best bound and optimality gap statistics printed by the link at the end of the solve. To choose a variation, either append its letter to the strategy number or add its offset to the strategy number. For example, to choose variations B and P of strategy 6, you could either set "strategy 6BP" or "strategy 1806".

Variation	Effect
A (+100)	This variation reduces the amount of time XA spends estimating the value of a potential integer solution. The values calculated are rough estimates and may eliminate nodes that would lead to better integer solutions. Variation A may not appear with variation B.
B	This variation spends very little time calculating estimated integer solutions at each node and is the most radical in performance and integer solution value and may eliminate nodes that would lead to better integer solutions. Variation B may not appear with variation A.
C	Each time an improving integer solution is found XA splits the remaining node list in half based upon the length of the current list. This technique allows XA to search nodes that might not normally be explored. The reported integer solution value may not be the optimal integer solution because nodes may be eliminated that would lead to this solutions. Variation C may not appear with variation D.
D	Each time an improving integer solution is found XA splits the remaining node list based upon the difference in current projected objective and the best possible objective value divided by two. This technique allows XA to search nodes that might not normally be explored. The reported integer solution value may not be the optimal integer solution because nodes may be eliminated that would lead to this solutions. Variation D may not appear with variation C.
P	Each time a node is generated XA calculates the effects of each non-integer on future objective function values, which is calculation intensive. By assigning branching priorities to your integer variables XA will only perform this calculation on the non-integer variables with the lowest branching priority. This frequently reduces the number of calculations. Variation P may appear with any variation, but to be effective you must assign integer branching priorities.

If you wish to improve your solution times, you should experiment with different Strategies to determine which is best for your problems. We have found that Strategies 1 and 6 work quite well. Also try strategies

1A, 1B, 6A, 6B, and 9. As you gain experience with these Strategies you will be able to make an informed choice.

5.44.5.3 Limitsearch Parameter

LIMITSEARCH is used to limit the number of nodes to search by implicitly or explicitly stating a bound on the value of an integer solution. The integer solution obtained, if any, will have a functional value no worse than LIMITSEARCH. The next integer solution will have a monotonically improving objective function value until an optimal integer solution is found and if verified.

If you can estimate the objective function value of a good integer solution, you can avoid nodes that lead to worse solutions and, consequently, speed up the search. However, too restrictive a value may lead to no integer solution at all, if an integer solution with an objective value better than the LIMITSEARCH value does not exist. If the search terminates with 'NO INTEGER SOLUTION', you must begin the search again with a less restrictive LIMITSEARCH value. The LIMITSEARCH command line parameter has three methods of specifying a lower limit on the objective function.

LIMITSEARCH Value	Meaning
##	Only search for integer solutions between this value and the 'optimal continuous' solution.
##%	Only search for integer solutions with #% of the 'optimal continuous' solution.
(#%)	Solve for the integer solution that is within #% of the 'optimal integer solution'. This can reduce the search time significantly, but the reported integer solution may not be the optimal integer solution: it will only be within #% of it. This is similar to the GAMS <code>optcr</code> option, but setting <code>optcr</code> reports the actual gap: this is the recommended way to run GAMS/XA.

5.44.6 The XA Option File

The option file is typically called `xa.opt`. The following line in a GAMS model signals GAMS/XA to use the option file:

```
<modelname>.optfile = 1 ;
```

where *modelname* is the name of the model specified in the model statement. For instance:

```
model m /all/ ;
m.optfile = 1 ;
option LP = XA ;
solve m using LP minimize z ;
```

For more details on using solver option files, see the section on [solver option files](#).

The XA option file allows you to solver-specific options that are not anticipated by GAMS. Where an XA option and a GAMS option both set the same thing, the setting in the XA option file takes precedence. Option file lines beginning with an asterisk * are comment lines. For example:

```

* Integer solving strategy.
  Strategy 6P
* Write log information to the screen every 5 seconds.
  Set FreqLog 00:05
* Do NOT scale the problem.
  Set Scale No

```

The contents of the option file are echoed to the screen. If no options file is found where one is expected, a warning is sent to the log file and the solve continues.

Here is a list of available XA options.

Option	Description	Default
basis	controls writing of advanced basis file for restarts After XA has solved your problem, the solution is saved for the next time the problem is solved. This can greatly reduce the number of iterations and execution time required. By default, the dual simplex algorithm is used when XA detects advanced basis restarts. You can instruct XA to not use the dual simplex algorithm for restarts with a setting of <code>set DualSimplex no</code>	never
force	force internal relaxation of bounds if infeasible If your LP model is infeasible, XA makes adjustments in column and row bounds to make the problem feasible. No adjustments are made to binary columns or RHS values of SOS sets. Depending upon how tightly constrained the problem is, XA may be prevented from making additional adjustment that would lead to an integer solution. No adjustments are made to make a column's lower bound less than zero.	0
limitsearch	limit searching of the branch-and-bound tree See Section Limitsearch Parameter .	none
matlist	display the problem for debugging Problem is displayed in equation format. This is probably the most useful command when debugging the model. The GAMS equation and variable listings perform a similar function. Var: List columns in each row Con: List rows in each column Both: Do both Var and Con None: No debugging display	none
set barrier	select the primal-dual interior point algorithm The barrier algorithm is most useful when solving large-scale LP models. Yes: Use barrier, with crossover on MIP only No: Use simplex X: Use barrier, with crossover	no
set bell	controls the XA termination bell	0
set bvpriority	set default priority of all binary variables By default, all discrete variables have priority 1600, so a value < 1600 causes binary variables to be branched on before general integer variables. A value > 1600 has the opposite affect.	1600
set crash	control basis-crashing method 0: Minimize primal infeasibility 1: Minimize dual infeasibility 2: Both 0 & 1	0
set degeniter	consecutive degenerate pivots before anti-cycling code is activated	internal

Option	Description	Default
set dualsimplex	controls when to use dual simplex method By default, XA chooses when to use dual simplex automatically, e.g. when restarting from an advanced basis.	auto
set freqlog	time frequency for printing the iteration log Frequency in time to print the iteration log line. A negative number (e.g. -00:02) overwrites the same line. This command reduces the overhead of printing too many iteration lines.	50
set intgap	Minimum objective improvement between incumbents Minimum objective function improvement between each new integer solution. Reported integer solution may not be the optimal integer solution because of premature termination.	GAMS Cheat
set intlmit	limit number of incumbents found After finding N improving integer solutions, XA terminates with the best solution found thus far. Reported integer solution may not be the optimal integer solution because of premature termination.	GAMS Integer3
set intpct	% of available integer columns to consider fixing at each node Useful on very large binary problems. If 100 is entered then all integer columns that are integer at the end of solving the relaxed LP problem are fixed at the current integer bounds. Range: [0, 100]	0
set ircuit	control rounding of integer vars when XA reports solutions XA reports either rounded or unrounded integer column primal activity.	1
set iteration	sets limit on simplex iterations XA terminates if limit is exceeded, and if solving an integer problem the best integer solution found thus far is returned. Reported integer solution may not be the optimal integer solution because of premature termination.	GAMS IterLim
set ltolerance	lower tolerance for integrality: (i-utol,i+ltol) is integral The tolerances XA uses to decide that an integer column is integral. For instance, you might consider using a UTOLERANCE of 0.02 (a boat 98% full is for all practical purposes really 100% full). But beware, these integer activities within the specified tolerances are used in calculating constraint relationships and the objective function value. For example, if LTOLERANCE = 0.001, UTOLERANCE = 0.05, and Y has a reported (rounded) activity of 4.0, then $3 * Y$ is in the range $[3 * 3.95, 3 * 4.001]$.	5e-6
set markowitz	Markowitz pivot selection control Balances numeric stability vs. sparsity in basis updating and factoring. Larger values favor sparsity over numeric stability.	10
set maxcpu	limits the number of threads to use for MIP models In general, MIP models should solve faster when running on multiple cores. Consider requesting 50% more memory per thread. This number can be greater than the number of available cores.	1
set maxnodes	estimate of the number of nodes in the branch-and-bound tree	internal
set nodelimit	limits the number of nodes in the branch-and-bound tree	GAMS NodeLim

Option	Description	Default
set perturbate	controls perturbation on highly degenerate problems A positive value allows XA to generate a uniformly distributed random variable between 0 and V. A negative value uses a constant perturbation of -V. Note: This option should not be used except when all else fails. XA has build-in routines to handle degeneracy.	GAMS Real2
set pricing	controls the variable pricing strategy Useful if XA appears to make a substantial number (rows/2) of pivots that do not move the objective function or reduce the sum of infeasibilities. This feature requires more memory because an additional set of matrix coefficients are loaded into memory. 0: Standard reduced cost pricing 1: Automatic DEVEX pricing switch over 2: Infeasible DEVEX pricing 3: Feasible DEVEX pricing (our next choice) 4: Both infeasible and feasible DEVEX pricing	0
set reducedcost	zero tolerance for the dual variables	1e-7
set reinvertfreq	set basis re-inversion frequency	40
set relaxed	relax integrality requirement in MIP models - solve as an RMIP	0
set scale	set scaling method 2: Row scaling only Yes: Column and row scaling No: Data not scaled	internal
set stickwithit	controls how XA follows branching advice from an integer basis If an integer basis (.b01) file is reloaded to indicate branching direction for the current XA solve, this branching advice is following until N infeasible branches are made. After N infeasible branches, the standard branching direction for the particular branch & bound strategy is used.	10
set tctolerance	zero tolerance for technology coefficients The smallest technological coefficient allowed in your constraint matrix. This tolerance is useful when extensive calculations are performed on these coefficients, where the results should be zero (but because of rounding errors) ends up being something like 1.0e-15.	1e-7
set timelimit	set the time limit Maximum time allowed for solving the problem. XA terminates if this limit is exceeded, and if solving an integer problem the best integer solution found thus far is returned. Wall clock time is used. If set too low, reported integer solutions may not be the optimal integer solution because of premature termination.	GAMS ResLim
set tolerance dual	dual feasibility tolerance	1e-7
set tolerance primal	primal feasibility tolerance	1e-7

Option	Description	Default
set utolerance	upper tolerance for integrality: (i-utol,i+ltol) is integral The tolerances XA uses to decide that an integer column.s value is integral. For instance, you might consider using a UTOLERANCE of 0.02 (a boat 98% full is for all practical purposes really 100% full). But beware, these integer activities within the specified tolerances are used in calculating constraint relationships and the objective function value. For example, if LTOLERANCE = 0.001, UTOLERANCE = 0.05, and Y has a reported (rounded) activity of 4.0, then 3 * Y is in the range [3 * 3.95, 3 * 4.001].	5e-6
set ypivot	zero tolerance for dual values when pivoting When selecting a column to leave the basis, columns with absolute marginal values less than ypivot are rejected. Pivoting in columns with very small values can lead to numeric instability and should be avoided when possible. Setting ypivot too large can lead to infeasible pivoting. Extreme caution should be exercised when changing this value because of the overall effect on problem feasibility.	1e-9
stopafter	post-integer-feasible time limit for MIP models Amount of time (hh:mm:ss) to continue solving after finding the first integer solution. Reported integer solution may not be the optimal integer solution because of premature termination. 0 disables this cheat.	GAMS Real3
strategy	controls the MIP search strategy	GAMS Integer1
toms	write an MPS file (gams.mps) for the problem Yes: Write problem in MPS format No: Do not write an MPS formatted file Secure: Write problem in MPS format with names C0, C1, ... and R0, R1, ...	no

5.44.7 Iteration Log Formats

The iteration log is something many users watch closely, especially when solving MIP models. Setting **Set FreqLog 0** suppresses the display of the iteration log. During LP iterations, the log format varies depending on the algorithm chosen. Its format is self-explanatory. The default MIP log looks like:

```

Node      IInf      ToGo.Map      Best.Obj      Cur.Obj      Int.Obj      # Column +/- Iter
####      ###      #####      #####      #####      #####      # ##### # ####

```

	Description
Node	Active node, the smaller the better, value increases and decreases as the branch- and-bound proceeds.
IInf	Number of discrete columns having fractional values. This number converges to 0 as XA approaches an integer solution.
ToGo.Map	A numeric picture of open nodes. The i'th digit (from the right) represents the number of open nodes in the i'th group of ten nodes. For example, 435 means: - 4 unexplored nodes between nodes 20 and 29. - 3 unexplored nodes between nodes 10 and 19. - 5 unexplored nodes between nodes 0 and 9.
Best.Obj	Best possible integer objective function. As the branch-and-bound algorithm proceeds this number bounds the Optimal Integer Solution. This number does not change very fast.

	Description
Cur.Obj	Objective function for the current node. If an integer solution is found in this node cannot be any better than this value.
Int.Obj	Objective function of the best integer solution found so far. This value improves as additional integer solutions are found.
#	Number of improving integer solutions found thus far.
Column	Column selected by the branch-and-bound process.
+/-	Branching direction: up(+) or down(-).
Iter	Cumulative total of simplex iterations used (including the relaxed LP).

Use the `Set FreqLog` option to minimize the number of lines displayed. Logging each iteration can significantly slow down the solution process.

5.45 XPRESS

5.45.1 Introduction

The GAMS/XPRESS solver is based on the XPRESS Optimization Subroutine Library, and runs only in conjunction with the GAMS modeling system. GAMS/XPRESS (also simply referred to as XPRESS) is a versatile, high-performance optimization system. The system integrates:

- a powerful simplex-based [LP](#) solver.
- a [MIP](#) module with cut generation for integer programming problems.
- a barrier module implementing a state-of-the-art interior point algorithm for very large [LP](#) problems.
- a sequential linear programming solver (SLP) for (mixed-integer) nonlinear programs [NLP](#), [CNS](#) and [MINLP](#).

The GAMS/XPRESS solver is installed automatically with your GAMS system. Without a license, it will run in student or demonstration mode (i.e. it will solve small models only). If your GAMS license includes XPRESS, there is no size or algorithm restriction imposed by the license, nor is any separate licensing procedure required. XPRESS SLP requires a GAMS license that includes XPRESS for continuous nonlinear models or for mixed-integer nonlinear models. In order to use XPRESS Knitro, the GAMS license must include GAMS/Knitro in addition to the XPRESS license for (mixed-integer) nonlinear models.

5.45.2 Usage

To explicitly request that a model be solved with XPRESS, insert the statement

```
option LP = xpress; { or MIP, RMIP, NLP, CNS, DNLP, RMINLP, MINLP, QCP, MIQCP, or RMIQCP }
```

somewhere before the solve statement. If XPRESS has been selected as the default solver (e.g. during GAMS installation) for the model type in question, the above statement is not necessary.

The standard GAMS options (e.g. [iterlim](#), [optcr](#)) can be used to control XPRESS. For more details, see section [Controlling a Solver via GAMS Options](#). Please note however that - apart from [reslim](#) - these are only used for linear and quadratic programs and not the nonlinear solves. Termination conditions for XPRESS SLP can be set in [SLP Termination Options](#).

In addition, XPRESS-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section [The Solver Options File](#).

An example of a valid XPRESS option file is:

```
* sample XPRESS options file
algorithm simplex
presolve 0
IterLim 50000
```

In general this is enough knowledge to solve your models. In some cases you may want to use some of the XPRESS options to gain further performance improvements or for other reasons.

5.45.2.1 Linear and Quadratic Programming

The options [advBasis](#), [lpFlags](#), [defaultAlg](#), [basisOut](#), [mpsOutputFile](#), [reform](#), [reRun](#), and [reslim](#) control the behavior of the GAMS/XPRESS link. The options [crash](#), [lpIterlimit](#), [presolve](#), [scaling](#), [threads](#), and [trace](#) set XPRESS library control variables, and can be used to fine-tune XPRESS. See section [General LP / MIP / QP Options](#) for more details of XPRESS general options.

5.45.2.1.1 LP See section [LP Options](#) for more details of XPRESS library control variables which can be used to fine-tune the XPRESS LP solver.

5.45.2.1.2 MIP In some cases, the branch-and-bound MIP algorithm will stop with a proven optimal solution or when unboundedness or (integer) infeasibility is detected. In most cases, however, the global search is stopped through one of the generic GAMS options:

1. [iterlim](#) (on the cumulative pivot count) or [reslim](#) (in seconds of CPU time),
2. [optca](#) & [optcr](#) (stopping criteria based on gap between best integer solution found and best possible)
or
3. [nodlim](#) (on the total number of nodes allowed in the B&B tree).

It is also possible to set the [maxNode](#) and [maxMipSol](#) options to stop the global search: see section [MIP Options](#) for XPRESS control variables for MIP. The options [loadMipSol](#), [mipCleanup](#), [mipTrace](#), [mipTraceNode](#), and [mipTraceTime](#) control the behavior of the GAMS/XPRESS link on MIP models. The other options in section [MIP Options](#) set XPRESS library control variables, and can be used to fine-tune the XPRESS MIP solver.

5.45.2.1.3 MIP Solution Pool Typically, XPRESS finds a number of integer feasible points during its global search, but only the final solution is available. The MIP solution pool capability makes it possible to store multiple integer feasible points (aka solutions) for later processing. The MIP solution pool operates in one of two modes: by default (`solnpoolPop = 1`) the global search is not altered, but with (`solnpoolPop = 2`) a selected set (potentially all) of the integer feasible solutions are enumerated.

The MIP enumeration proceeds until all MIP solutions are enumerated or cut off, or until a user-defined limit is reached. Whenever a new solution is generated by the enumerator, it is presented to the solution pool manager. If there is room in the pool, the new solution is added. If the pool is full, a *cull round* is performed to select a number of solutions to be thrown out - these solutions can be those stored in the pool and/or the new solution. Solutions can be selected for culling based on their MIP objective value and/or the overall diversity of the solutions in the pool. If neither is chosen, a default choice is made to throw out one solution based on objective values. Whenever a solution is thrown out based on its MIP objective, the enumeration space is pruned based on the cutoff defined by this objective value.

By default, the capacity of the pool is set very large, as is the number of cull rounds to perform, so selecting only `solnpoolPop = 2` will result in full enumeration. However, many different strategies can be executed by setting the solution pool options. For example, to choose the N -best solutions, simply set the solution pool capacity to N . When the pool is full, new solutions will force a cull round, and the default is to reject one solution based on its objective and update the cutoff accordingly. To generate all solutions with an objective as good as X , leave the pool capacity set at a high level but set the cutoff to X using the `mipabscutoff` option. To return the N -first solutions, set the solution pool capacity to N and `solnpoolCullRounds = 0`: as soon as the pool is full the enumeration will stop on the cull round limit.

A number of other strategies for controlling the solution pool behavior are possible by combining different options. Several working examples are provided in the GAMS Test Library in models `xpress03.gms`, `xpress04.gms`, and `xpress05.gms`.

See section [MIP Solution Pool Options](#) for XPRESS control variables for MIP Solution Pool.

5.45.2.1.4 Newton-Barrier The barrier method is invoked by default for quadratic problems, and can be selected for linear models by using one of the options

```
algorithm      barrier
defaultalg    4
```

The barrier method is likely to use more memory than the simplex method. No warm start is done, so if an advanced basis exists, you may not wish to use the barrier solver.

See section [Newton-barrier Options](#) for XPRESS control variables for the Newton-Barrier method.

5.45.2.2 Nonlinear Programming

XPRESS can solve nonlinear programs of type [NLP](#), [CNS](#) and [MINLP](#) (and its relaxed version) using the sequential linear programming solver XPRESS SLP or the interior-point / sequential quadratic programming solver [XPRESS Knitro](#). Convexity is not required, but for non-convex programs XPRESS will in general find local optimal solutions only. The [XPRESS multistart](#) can be used to increase the likelihood of finding a good solution by starting from many different initial points.

XPRESS SLP solves nonlinear programs by successive linearization of the nonlinearities. These linearizations, which can be controlled by the options in [NLP Augmentation and Linearization Options](#), are solved by the [LP or QCP solver](#). Therefore, XPRESS user options for [LP or QCP](#) are also relevant when solving nonlinear programs. Note, that the [NLP Presolve](#) is independent from the [LP presolve](#) that is executed in each XPRESS SLP iteration.

5.45.2.2.1 Termination In most cases it is sufficient to control the [termination](#) of XPRESS SLP by [xslp_iterLimit](#), [reslim](#), [xslp_validationTarget.k](#) and [xslp.ValidationTarget.r](#) as the latter two automatically control the other XPRESS SLP convergence measures on default. More experienced users may want to modify the other convergence measures, which group into:

- **Strict convergence:** Describes the numerical behaviour of convergence in the formal, mathematical sense. User options: [xslp_cTol](#), [xslp_aTol.a](#), [xslp_aTol.r](#).
- **Extended convergence:** Measures the quality of the linearization, including the effect of changes to the nonlinear terms that contribute to a variable in the linearization: User options: [xslp_mTol.a](#), [xslp_mTol.r](#), [xslp_iTol.a](#), [xslp_iTol.r](#), [xslp_sTol.a](#), [xslp_sTol.r](#).

When each variable has converged in one of the above cases, XPRESS SLP terminates based on the following stopping criteria:

- **Baseline static objective convergence measure** that compares changes in the objective over a given number of iterations relative to the average objective value. User options: [xslp_vCount](#), [xslp_vLimit](#), [xslp_vTol.a](#), [xslp_vTol.r](#).
- **Static objective convergence measure** that is applied when there are no unconverged variables in active constraints. User options: [slpOCount](#), [xslp_oTol.a](#), [xslp_oTol.r](#).
- **Static objective convergence measure** that is applied when a practical solution (all variables have converged and there are no active step bounds) has been found. User options: [xslp_xCount](#), [xslp_xLimit](#), [xslp_xTol.a](#), [xslp_xTol.r](#).
- **Extended convergence continuation** that is applied when a practical solution has been found. It checks if it is worth continuing. User options: [xslp_wCount](#), [xslp_wTol.a](#), [xslp_wTol.r](#).

The user option [slpConvergenceOps](#) enables/disables the different convergence measures and stopping conditions.

5.45.2.2.2 Output The output or logging can be controlled by the [NLP Log Options](#). The default XPRESS SLP iteration output shows:

- **It:** Iteration number.
 - **LP:** The LP status of the linearization (0: optimal; I: infeasible; U: unbounded; X: interrupted)
 - **NetObj:** The net objective of the SLP iteration.
 - **ValObj:** The original objective function value.
 - **ErrorSum:** Sum of the error delta variables. A measure of infeasibility.
 - **ErrorCost:** The value of the weighted error delta variables in the objective. A measure of the effort needed to push the model towards feasibility.
 - **Validate:** Relative feasibility measure (calculated only if convergence is likely)
 - **KKT:** Relative optimality measure (calculated only if convergence is likely)
 - **Unconv:** The number of SLP variables that are not converged.
 - **Ext:** The number of SLP variables that are converged, but only by extended criteria.
 - **Action:** Special actions (0: failed line search; B: enforcing step bounds; E: some infeasible rows were enforced; G: global variables were fixed; P: solution needed polishing, postsolve instability; P!: solution polishing failed; R: penalty error vectors removed; V: feasibility validation induces further iterations; K: optimality validation induces further iterations)
 - **T:** Time.
-

5.45.2.2.3 XPRESS Knitro Nonlinear programs can also be solved by XPRESS Knitro using the option `xslp_solver`. In this case, the nonlinear program is passed to Knitro after the `NLP Presolve`. Setting `xslp_solver` to `auto` will enable XPRESS to choose XPRESS SLP or XPRESS Knitro automatically based on the problem instance. XPRESS Knitro options can be specified in a `Knitro` solver option file, which needs to be selected in `knitroOptFile`. Note, that XPRESS Knitro does not support all `Knitro` options. Specified but unsupported options trigger a warning and are then ignored.

For more information about this nonlinear programming solver, see the [GAMS/Knitro documentation](#).

5.45.3 Summary of XPRESS Options

5.45.3.1 General LP / MIP / QP Options

Option	Description	Default
<code>advBasis</code>	Use advanced basis provided by GAMS	<code>auto</code>
<code>algorithm</code>	Choose between simplex and barrier algorithm	<code>simplex</code>
<code>basisOut</code>	Directs optimizer to output an MPS basis file	<code>none</code>
<code>clamping</code>	Allows for the adjustment of returned solution values such that they are always within bounds	<code>0</code>
<code>clamping_dual</code>	Adjust primal slack values to always be within constraint bounds	<code>0</code>
<code>clamping_primal</code>	Adjust primal solution to always be within primal bounds	<code>0</code>
<code>clamping_rdj</code>	Adjust reduced costs to always be within dual bounds implied by the primal solution	<code>0</code>
<code>clamping_slacks</code>	Adjust dual solution to always be within the dual bounds implied by the slacks	<code>0</code>
<code>cpuTime</code>	How time should be measured when timings are reported in the log and when checking against time limits	<code>0</code>
<code>extraPresolve</code>	No longer has any effect and will be removed from future releases	<code>0</code>
<code>inputTol</code>	Tolerance on input values elements	<code>0</code>
<code>ioTimeout</code>	Maximum number of seconds to wait for an I/O operation before it is cancelled	<code>30</code>
<code>lpIterLimit</code>	Maximum number of iterations that will be performed by primal simplex or dual simplex before the optimization process terminates	<code>maxint</code>
<code>lpRefineIterLimit</code>	Simplex iteration limit the solution refiner can spend in attempting to increase the accuracy of an LP solution	<code>auto</code>
<code>maxScaleFactor</code>	Determines the maximum scaling factor that can be applied during scaling	<code>64</code>
<code>maxTime</code>	Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time	<code>0</code>
<code>mpsNameLength</code>	Maximum length of MPS names in characters	<code>0</code>
<code>mpsOutputFile</code>	Name of MPS output file	<code>none</code>
<code>outputControls</code>	Toggles the printing of all control settings at the beginning of the search	<code>1</code>
<code>outputLog</code>	Controls the level of output produced by the Optimizer during optimization	<code>1</code>

Option	Description	Default
outputTol	Zero tolerance on print values	1e-05
qextractalg	quadratic extraction algorithm in GAMS interface	0
randomSeed	Sets the initial seed to use for the pseudo-random number generator in the Optimizer	1
refineOps	Specifies when the solution refiner should be executed to reduce solution infeasibilities	19
refineOps_iterativeRefiner	Apply the iterative refiner to refine the solution	0
refineOps_lpOptimal	Run the solution refiner on an optimal solution of a non-global problem	1
refineOps_lpPresolve	Run the solution refiner on an optimal solution before postsolve on a non-global problem	1
refineOps_mipFixGlobals	Refine MIP solutions such that rounding them keeps the problem feasible when reoptimized	0
refineOps_mipFixGlobalsTarget	Attempt to refine MIP solutions such that rounding them keeps the problem feasible when reoptimized, but accept integers solutions even if refinement fails	0
refineOps_mipNodeLp	Run the solution refiner on each node of the MIP search	0
refineOps_mipSolution	Run the solution refiner when a new solution is found during a global search	1
refineOps_refinerPrecision	Use higher precision in the iterative refinement	0
refineOps_refinerUseDual	If set, the iterative refiner will use the dual simplex algorithm	0
refineOps_refinerUsePrimal	If set, the iterative refiner will use the primal simplex algorithm	0
reform	Substitute out objective var and equ when possible	1
reRun	Rerun with primal simplex when not optimal/feasible	0
reslim	Overrides GAMS reslim option	
trace	Display the infeasibility diagnosis during presolve	0
writePrtSol	Directs optimizer to output a "printsol" file	0

5.45.3.2 Hardware Related Options

Option	Description	Default
barCores	If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm	auto
barOrderThreads	If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton-barrier method	auto
barThreads	If set to a positive integer it determines the number of threads implemented to run the Newton-barrier algorithm	auto
cacheSize	Newton Barrier: L2 or L3 (see notes) cache size in kB (kilobytes) of the CPU	auto
concurrentThreads	Determines the number of threads used by the concurrent solver	auto

Option	Description	Default
<code>coresPerCpu</code>	Used to override the detected value of the number of cores on a CPU	<code>auto</code>
<code>cpuPlatform</code>	Newton Barrier: Selects the AMD or Intel x86 vectorization instruction set that Barrier should run optimized code for	<code>-1</code>
<code>crossoverThreads</code>	Determines the maximum number of threads that parallel crossover is allowed to use	<code>auto</code>
<code>dualThreads</code>	Determines the maximum number of threads that dual simplex is allowed to use	<code>auto</code>
<code>heurThreads</code>	Branch and Bound: Number of threads to dedicate to running heuristics on the root node	<code>0</code>
<code>l1Cache</code>	Newton barrier: L1 cache size in kB (kilo bytes) of the CPU	<code>auto</code>
<code>maxMemoryHard</code>	Sets the maximum amount of memory in megabytes the optimizer should allocate	<code>unlimited</code>
<code>maxMemorySoft</code>	When <code>resourceStrategy</code> is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate	<code>unlimited</code>
<code>mipThreads</code>	If set to a positive integer it determines the number of threads implemented to run the parallel MIP code	<code>auto</code>
<code>relaxTreeMemoryLimit</code>	When the memory used by the branch and bound search tree exceeds the target specified by the <code>treeMemoryLimit</code> control, the optimizer will try to reduce this by writing nodes to the global file	<code>0.1</code>
<code>resourceStrategy</code>	Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve	<code>0</code>
<code>threads</code>	Default number of threads used during optimization	<code>1</code>
<code>treeCompression</code>	When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the global file on disk	<code>2</code>
<code>treeMemoryLimit</code>	Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree	<code>auto</code>
<code>treeMemorySavingTarget</code>	When the memory used by the branch-and-bound search tree exceeds the limit specified by the <code>treeMemoryLimit</code> control, the optimizer will try to save memory by writing lower-rated sections of the tree to the global file	<code>0.4</code>

5.45.3.3 Presolve Options

Option	Description	Default
<code>barPresolveOps</code>	Newton barrier: Controls the Newton-Barrier specific presolve operations	<code>0</code>
<code>dualize</code>	Whether presolve should form the dual of the problem	<code>auto</code>
<code>dualizeOps</code>	Bit-vector control for adjusting the behavior when a problem is dualized	<code>1</code>
<code>elimFillin</code>	Amount of fill-in allowed when performing an elimination in presolve	<code>10</code>
<code>elimTol</code>	Markowitz tolerance for the elimination phase of the presolve	<code>0.001</code>
<code>indLinBigM</code>	During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough	<code>100000</code>

Option	Description	Default
indPreLinBigM	During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough	100
lpFolding	Simplex and barrier: Whether to fold an LP problem before solving it	auto
maxImpliedBound	Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than maxImpliedBound will be applied to the problem	1e+08
mipPresolve	Branch and Bound: Type of integer processing to be performed	-1
mipPresolve_allowChangeBounds	If node preprocessing is allowed to change bounds on continuous columns	1
mipPresolve_allowTreeRestart	Allow the branch-and-bound tree search to be restarted if it appears to be advantageous	1
mipPresolve_dualReductions	Dual reductions will be performed at each node	1
mipPresolve_globalCoefTightening	Allow global (non-bound) tightening of the problem during the tree search	1
mipPresolve_logicPreprocessing	Primal reductions will be performed at each node	1
mipPresolve_objBasedReductions	Objective function will be used to find reductions at each node	1
mipPresolve_reducedCostFixing	Reduced cost fixing will be performed at each node	1
mipPresolve_symmetryReductions	Allow that symmetry is used to presolve the node problem	1
preAnalyticCenter	Determines if analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs (-1: Auto 0: Off, 1: Fixing, 2: Redcost, 3: Both)	auto
preBasisRed	Determines if a lattice basis reduction algorithm should be attempted as part of presolve	0
preBndRedCone	Determines if second order cone constraints should be used for inferring bound reductions on variables when solving a MIP	auto
preBndRedQuad	Determines if convex quadratic constraints should be used for inferring bound reductions on variables when solving a MIP	auto
preCliqueStrategy	Determines how much effort to spend on clique covers in presolve	-1
preCoefElim	Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem	2
preComponents	Presolve: Determines whether small independent components should be detected and solved as individual subproblems during root node processing	auto
preComponentsEffort	Presolve: Adjusts the overall effort for the independent component presolver	1
preConeDecomp	Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components	auto

Option	Description	Default
preConvertSeparable	Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints	auto
preDomCol	Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem	auto
preDomRow	Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem	auto
preDupRow	Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem	auto
preElimQuad	Presolve: Allows for elimination of quadratic variables via doubleton rows	auto
preFolding	Presolve: Determines if a folding procedure should be used to aggregate continuous columns in an equitable partition	auto
preImplications	Presolve: Determines whether to use implication structures to remove redundant rows	auto
preLinDep	Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem	auto
preObjCutDetect	Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed	1
preProbing	Presolve: Amount of probing to perform on binary variables during presolve	auto
presolve	Determines whether presolving should be performed prior to starting the main algorithm	1
presolveMaxGrow	Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem	0.1
presolveOps	Specifies the operations which are performed during the presolve	511
presolveOps_dualReductions	Dual reductions	1
presolveOps_duplicateColRemoval	Duplicate column removal	1
presolveOps_duplicateRowRemoval	Duplicate row removal	1
presolveOps_forcingRowRemoval	Forcing row removal	1
presolveOps_linDependRowRemoval	Linearly dependant row removal	0
presolveOps_noAdvIpReductions	No advanced IP reductions	0
presolveOps_noGlobalDomainChange	No semi-continuous variable detection	0
presolveOps_noIntVarAndSosDetect	No integer variable and SOS detection	0
presolveOps_noIntVarEliminations	No eliminations on integers	0
presolveOps_noIpReductions	No IP reductions	0
presolveOps_redundantRowRemoval	Redundant row removal	1

Option	Description	Default
presolveOps_singletonColRemoval	Singleton column removal	1
presolveOps_singletonRowRemoval	Singleton row removal	1
presolveOps_strongDualReductions	Strong dual reductions	1
presolveOps_variableEliminations	Variable eliminations	1
presolvePasses	Number of reduction rounds to be performed in presolve	1
rootPresolve	Determines if presolving should be performed on the problem after the global search has finished with root cutting and heuristics	auto
siftPresolveOps	Determines the presolve operations for solving the subproblems during the sifting algorithm	-1

5.45.3.4 Scaling Options

Option	Description	Default
autoScaling	Whether the Optimizer should automatically select between different scaling algorithms	auto
barFreeScale	Defines how the barrier algorithm scales free variables	1e-06
barObjScale	Defines how the barrier scales the objective	auto
barRhsScale	Defines how the barrier scales the right hand side	auto
objScaleFactor	Custom global objective scaling factor, expressed as a power of 2	0
scaling	Determines how the Optimizer will rescale a model internally before optimization	163
scaling_beforePresolve	Scale before presolve	0
scaling_bigM	Treat big-M rows as normal rows	0
scaling_byMaxElemNotGeoMean	0: scale by geometric mean	1
scaling_colScaling	Column scaling	1
scaling_curtisReid	Curtis-Reid	0
scaling_disableGlobalObjScaling	Do not apply automatic global objective scaling	0
scaling_ignoreQuadRowPart	Exclude the quadratic part of constraint when calculating scaling factors	0
scaling_maximum	Maximum	0
scaling_noAggressiveQScaling	Disable aggressive quadratic scaling	0
scaling_noScalingColsDown	Do not scale columns down	0
scaling_noScalingRowsUp	Do not scale rows up	0
scaling_rhsScaling	RHS scaling	0
scaling_rowScaling	Row scaling	1
scaling_rowScalingAgain	Row scaling again	0

Option	Description	Default
scaling_simplexObjScaling	Scale objective function for the simplex method	1
scaling_slackScaling	Enable explicit linear slack scaling	0

5.45.3.5 LP Options

Option	Description	Default
algAfterNetwork	Algorithm to be used for the clean up step after the network simplex solver	auto
autoPerturb	Simplex: Indicates whether automatic perturbation is performed	auto
bigM	Infeasibility penalty used if the "Big M" method is implemented	auto
bigMMethod	Simplex: Whether to use the "Big M" method, or the standard phase I (achieving feasibility) and phase II (achieving optimality)	1
crash	Simplex: Determines the type of crash used when the algorithm begins (only relevant when no advanced basis is available)	2
defaultAlg	Selects the algorithm that will be used to solve the LP	auto
dualGradient	Simplex: Dual simplex pricing method	auto
dualPerturb	Factor by which the problem will be perturbed prior to optimization by dual simplex	auto
dualStrategy	Bit-vector control specifies the dual simplex strategy	1
etaTol	Tolerance on eta elements	1e-13
feasTol	Determines when a solution is treated as feasible	1e-06
feasTolPerturb	Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes	1e-06
feasTolTarget	Target feasibility tolerance for the solution refiner	0
forceParallelDual	Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm	0
invertFreq	Simplex: Frequency with which the basis will be inverted	auto
invertMin	Simplex: Minimum number of iterations between full inversions of the basis matrix	3
lpFlags	Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem	0
lpFlags_barrier	Use the barrier method	0
lpFlags_dual	Use the dual simplex method	0
lpFlags_network	Use the network simplex method	0
lpFlags_primal	Use the primal simplex method	0
lpLog	Simplex: Frequency at which the simplex log is printed	100
lpLogDelay	Time interval between two LP log lines	1
lpLogStyle	Simplex: Style of the simplex log	1
lpThreads	Parameter is deprecated and will be removed in a future release	-1

Option	Description	Default
markowitzTol	Markowitz tolerance used for the factorization of the basis matrix	0.01
matrixTol	Zero tolerance on matrix elements	1e-09
netStallLimit	Limit the number of degenerate pivots of the network simplex algorithm, before switching to either primal or dual simplex, depending on algAfterNetwork	auto
optimalityTol	Simplex: Zero tolerance for reduced costs	1e-06
optimalityTolTarget	Target optimality tolerance for the solution refiner	0
penalty	Minimum absolute penalty variable coefficient	auto
pivotTol	Simplex: Zero tolerance for matrix elements	1e-09
ppFactor	Partial pricing candidate list sizing parameter	1
pricingAlg	Simplex: Determines the primal simplex pricing method	auto
primalPerturb	Factor by which the problem will be perturbed prior to optimization by primal simplex	auto
primalUnshift	Determines whether primal is allowed to call dual to unshift	0
relPivotTol	Simplex: Minimum size of pivot element relative to largest element in column	1e-06
sifting	Determines whether to enable sifting algorithm with the dual simplex method	auto
siftPasses	Determines how quickly we allow to grow the worker problems during the sifting algorithm	4
siftSwitch	Determines which algorithm to use for solving the subproblems during sifting	-1

5.45.3.6 QP Options

Option	Description	Default
eigenvalueTol	Quadratic matrix is considered not to be positive semi-definite, if its smallest eigenvalue is smaller than the negative of this value	1e-06
ifCheckConvexity	Determines if the convexity of the problem is checked before optimization	1
qSimplexOps	Controls the behavior of the quadratic simplex solvers	0
quadraticUnshift	Determines whether an extra solution purification step is called after a solution found by the quadratic simplex (either primal or dual)	auto
repairIndefInitEq	Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible	1

5.45.3.7 Newton-barrier Options

Option	Description	Default
algAfterCrossover	Algorithm to be used for the final clean up step after the crossover	auto
barAlg	Determines which barrier algorithm is to be used to solve the problem	auto

Option	Description	Default
barCrash	Newton barrier: Determines the type of crash used for the crossover	4
barDualStop	Newton barrier: Convergence parameter, representing the tolerance for dual infeasibilities	auto
barFailIterLimit	Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm	auto
barGapStop	Newton barrier: Convergence parameter, representing the tolerance for the relative duality gap	auto
barGapTarget	Newton barrier: Target tolerance for the relative duality gap	auto
barIndefLimit	Newton Barrier: Limits the number of consecutive indefinite barrier iterations that will be performed	15
barIterLimit	Newton barrier: Maximum number of iterations	500
barKernel	Newton barrier: Defines how centrality is weighted in the barrier algorithm	0
barObjPerturb	Defines how the barrier perturbs the objective	1e-06
barOrder	Newton barrier: Controls the Cholesky factorization in the Newton-Barrier	auto
barOutput	Newton barrier: Level of solution output provided	1
barPerturb	Newton barrier: In numerically challenging cases it is often advantageous to apply perturbations on the KKT system to improve its numerical properties	0
barPrimalStop	Newton barrier: Convergence parameter, indicating the tolerance for primal infeasibilities	auto
barRefIter	Newton barrier: After terminating the barrier algorithm, further refinement steps can be performed	0
barRegularize	Determines how the barrier algorithm applies regularization on the KKT system	-1
barStart	Newton barrier: Controls the computation of the starting point for the barrier algorithm	auto
barStepStop	Newton barrier: Convergence parameter, representing the minimal step size	1e-16
choleskyAlg	Newton barrier: Type of Cholesky factorization used	auto
choleskyTol	Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm	1e-15
crossover	Newton barrier: Determines whether the barrier method will cross over to the simplex method when at optimal solution has been found, to provide an end basis and advanced sensitivity analysis information (see XPRSobjsa, XPRSrhssa, XPRSbndsa)	auto
crossoverAccuracyTol	Newton barrier: Determines how crossover adjusts the default relative pivot tolerance	1e-06
crossoverIterLimit	Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates	2147483647
crossoverOps	Newton barrier: Bit vector for adjusting the behavior of the crossover procedure	0
denseColLimit	Newton barrier: Controls trigger point for special treatment of dense columns in Cholesky factorization	auto

5.45.3.8 MIP Options

Option	Description	Default
backTrack	Branch and Bound: Specifies how to select the next node to work on when a full backtrack is performed	3
backtrackTie	Branch and Bound: Specifies how to break ties when selecting the next node to work on when a full backtrack is performed	-1
branchChoice	Once a global entity has been selected for branching, this control determines which of the branches is solved first	0
branchDisj	Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search	auto
branchStructural	Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search	auto
breadthFirst	Number of nodes to include in the best-first search before switching to the local first search (nodeSelection = 4)	11
deterministic	Branch and Bound: Specifies whether the parallel MIP search should be deterministic	1
feasibilityPump	Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node	auto
fixoptfile	name of option file which is read just before solving the fixed problem	
genConsAbsTransformation	Specifies the reformulation method for absolute value general constraints at the beginning of the search	auto
genConsDualReductions	Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs	1
historyCosts	Branch and Bound: How to update the pseudo cost for a global entity when a strong branch or a regular branch is applied	auto
loadMipSol	Loads a MIP solution (the initial point)	0
localChoice	Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree	auto
maxLocalBacktrack	Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node	auto
maxMipSol	Branch and Bound: Limit on the number of integer solutions to be found by the Optimizer	0
maxMipTasks	Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve	auto
maxNode	Branch and Bound: Maximum number of nodes that will be explored	maxint
maxStallTime	Maximum time in seconds that the Optimizer will continue to search for improving solution after finding a new incumbent	0
mipAbsCutoff	Branch and Bound: If the user knows that they are interested only in values of the objective function which are better than some value, this can be assigned to mipAbsCutoff	auto
mipAbsStop	Branch and Bound: Absolute tolerance determining whether the global search will continue or not	0

Option	Description	Default
mipAddCutoff	Branch and Bound: Amount to add to the objective function of the best integer solution found to give the new CURRMIPCUTOFF	0
mipCleanup	Clean up the MIP solution (round-fix-solve) to get duals	1
mipComponents	Determines whether disconnected components in a MIP should be solved as separate MIPs	auto
mipConcurrentNodes	Sets the node limit for when a winning solve is selected when concurrent MIP solves are enabled	auto
mipConcurrentSolves	Selects the number of concurrent solves to start for a MIP	0
mipDualReductions	Branch and Bound: Limits operations that can reduce the MIP solution space	1
mipFracReduce	Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions	auto
mipKappaFreq	Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search	0
mipLog	Global print control	-100
mipRampUp	Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search	auto
mipRefineIterLimit	Defines an effort limit expressed as simplex iterations for the MIP solution refiner	auto
mipRelCutoff	Branch and Bound: Percentage of the LP solution value to be added to the value of the objective function when an integer solution is found, to give the new value of CURRMIPCUTOFF	0
mipRelStop	Branch and Bound: Determines when the global search will terminate	0.0001
mipRestart	Branch and Bound: Controls strategy for in-tree restarts	auto
mipRestartFactor	Branch and Bound: Fine tune initial conditions to trigger an in-tree restart	1
mipRestartGapThreshold	Branch and Bound: Initial gap threshold to delay in-tree restart	0.02
mipstopexpr	Stopping expression for branch and bound	
mipTol	Branch and Bound: Tolerance within which a decision variable's value is considered to be integral	5e-06
mipToltarget	Target mipTol value used by the automatic MIP solution refiner as defined by refineOps	0
mipTrace	Name of MIP trace file	none
mipTraceNode	Node interval between MIP trace file entries	100
mipTraceTime	Time interval, in seconds, between MIP trace file entries	5
miqcpAlg	Determines which algorithm is to be used to solve mixed integer quadratic constrained and mixed integer second order cone problems	auto
nodeProbingEffort	Adjusts the overall level of node probing	1
nodeSelection	Branch and Bound: Determines which nodes will be considered for solution once the current node has been solved	auto

Option	Description	Default
<code>objGoodEnough</code>	Stop once an objective this good is found	<code>none</code>
<code>pseudoCost</code>	Branch and Bound: Default pseudo cost used in estimation of the degradation associated with an unexplored node in the tree search	<code>0.01</code>
<code>qcRootAlg</code>	Determines which algorithm is to be used to solve the root of a mixed integer quadratic constrained or mixed integer second order cone problem, when outer approximation is used	<code>auto</code>
<code>sbBest</code>	Number of infeasible global entities to initialize pseudo costs for on each node	<code>auto</code>
<code>sbEffort</code>	Adjusts the overall amount of effort when using strong branching to select an infeasible global entity to branch on	<code>1</code>
<code>sbEstimate</code>	Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible global entity to branch on	<code>auto</code>
<code>sbIterLimit</code>	Number of dual iterations to perform the strong branching for each entity	<code>auto</code>
<code>sbSelect</code>	Size of the candidate list of global entities for strong branching	<code>-2</code>
<code>sleepOnThreadWait</code>	Determines if the threads should be put into a wait state when waiting for work	<code>auto</code>
<code>sosRefTol</code>	Minimum relative gap between the ordering values of elements in a special ordered set	<code>1e-06</code>
<code>symmetry</code>	Adjusts the overall amount of effort for symmetry detection	<code>1</code>
<code>symSelect</code>	Adjusts the overall amount of effort for symmetry detection	<code>-1</code>
<code>varSelection</code>	Branch and Bound: Determines the formula used to calculate the estimate of each integer variable, and thus which integer variable is selected to be branched on at a given node	<code>auto</code>

5.45.3.9 MIP Cuts Options

Option	Description	Default
<code>autoCutting</code>	Automatically decide whether to generate cutting planes at local nodes in the tree	<code>auto</code>
<code>conflictCuts</code>	Branch and Bound: Specifies how cautious or aggressive the optimizer should be when searching for and applying conflict cuts	<code>auto</code>
<code>coverCuts</code>	Branch and Bound: Number of rounds of lifted cover inequalities at the top node	<code>auto</code>
<code>cutDepth</code>	Branch and Bound: Sets the maximum depth in the tree search at which cuts will be generated	<code>auto</code>
<code>cutFactor</code>	Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during global search	<code>auto</code>
<code>cutFreq</code>	Branch and Bound: Frequency at which cuts are generated in the tree search	<code>auto</code>
<code>cutSelect</code>	Bit vector providing detailed control of the cuts created for the root node of a global solve	<code>-1</code>
<code>cutSelect_clique</code>	Clique cuts	<code>1</code>

Option	Description	Default
<code>cutSelect_cover</code>	Lifted cover cuts	1
<code>cutSelect_disableCutRows</code>	Disable cutting from cut rows	1
<code>cutSelect_flowpath</code>	Flow path cuts	1
<code>cutSelect_gubCover</code>	Lifted GUB cover cuts	1
<code>cutSelect_implication</code>	Implication cuts	1
<code>cutSelect_indicator</code>	Indicator constraint cuts	1
<code>cutSelect_liftAndProject</code>	Turn on automatic Lift-and-Project cutting strategy	1
<code>cutSelect_mir</code>	Mixed Integer Rounding (MIR) cuts	1
<code>cutSelect_mirRowAggregation</code>	Turn on row aggregation for MIR cuts	1
<code>cutSelect_zeroHalf</code>	Zero-half cuts	1
<code>cutStrategy</code>	Branch and Bound: Cut strategy	auto
<code>gomCuts</code>	Branch and Bound: Number of rounds of Gomory or lift-and-project cuts at the top node	auto
<code>lnpBest</code>	Number of infeasible global entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see <code>gomCuts</code>)	50
<code>lnpIterLimit</code>	Number of iterations to perform in improving each lift-and-project cut	auto
<code>maxCutTime</code>	Maximum amount of time allowed for generation of cutting planes and reoptimization	0
<code>netCuts</code>	Determines the addition of multi-commodity network cuts to a problem	0
<code>qcCuts</code>	Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation	auto
<code>treeCoverCuts</code>	Branch and Bound: Number of rounds of lifted cover inequalities generated at nodes other than the top node in the tree	auto
<code>treeCutSelect</code>	Bit vector providing detailed control of the cuts created during the tree search of a global solve	-257
<code>treeCutSelect_clique</code>	Clique cuts	1
<code>treeCutSelect_cover</code>	Lifted cover cuts	1
<code>treeCutSelect_disableCutRows</code>	Disable cutting from cut rows	1
<code>treeCutSelect_flowpath</code>	Flow path cuts	1
<code>treeCutSelect_gubCover</code>	Lifted GUB cover cuts	1
<code>treeCutSelect_implication</code>	Implication cuts	1
<code>treeCutSelect_indicator</code>	Indicator constraint cuts	1
<code>treeCutSelect_liftAndProject</code>	Turn on automatic Lift and Project cutting strategy	1
<code>treeCutSelect_mir</code>	Mixed Integer Rounding (MIR) cuts	1

Option	Description	Default
treeCutSelect_mirRowAggregation	Turn on row aggregation for MIR cuts	0
treeCutSelect_zeroHalf	Zero-half cuts	1
treeGomCuts	Branch and Bound: Number of rounds of Gomory cuts generated at nodes other than the first node in the tree	auto
treeQCCuts	Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation	auto

5.45.3.10 MIP Heuristics Options

Option	Description	Default
heurBeforeLp	Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved	auto
heurDiveIterLimit	Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic	auto
heurDiveRandomize	Level of randomization to apply in the diving heuristic	0
heurDiveSoftRounding	Branch and Bound: Enables a more cautious strategy for the diving heuristic, where it tries to push binaries and integer variables to their bounds using the objective, instead of directly fixing them	auto
heurDiveSpeedUp	Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed	-1
heurDiveStrategy	Branch and Bound: Chooses the strategy for the diving heuristic	auto
heurEmphasis	Branch and Bound: Specifies an emphasis for the search w.r.t. primal heuristics and other procedures that affect the speed of convergence of the primal-dual gap	-1
heurForceSpecialObj	Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer	0
heurFreq	Branch and Bound: Frequency at which heuristics are used in the tree search	-1
heurSearchEffort	Adjusts the overall level of the local search heuristics	1
heurSearchFreq	Branch and Bound: How often the local search heuristic should be run in the tree	auto
heurSearchRootCutFreq	How frequently to run the local search heuristic during root cutting	auto
heurSearchRootSelect	Bit vector control for selecting which local search heuristics to apply on the root node of a global solve	117
heurSearchTreeSelect	Bit vector control for selecting which local search heuristics to apply during the tree search of a global solve	17

5.45.3.11 MIP Solution Pool Options

Option	Description	Default
solnpool	Solution pool file name	none
solnpoolCapacity	Limit on number of solutions to store	999999999
solnpoolCullDiversity	Cull N solutions based on solution diversity	-1
solnpoolCullObj	Cull N solutions based on objective values	-1
solnpoolCullRounds	Terminate solution generation after N culling rounds	999999999
solnpoolDupPolicy	Policy to use when handling storage of duplicate solutions	0
solnpoolmerge	Solution pool file name for merged solutions	none
solnpoolnumsym	Maximum number of variable symbols when writing merged solutions	10
solnpoolPop	Controls method used to populate the solution pool	1
solnpoolPrefix	File name prefix for GDX solution files	soln
solnpoolVerbosity	Controls verbosity of solution pool routines	0

5.45.3.12 General NLP / MINLP Options

Option	Description	Default
knitroOptFile	Option file for NLP solver KNITRO	
xslp_algorithm	Bit map describing the SLP algorithm(s) to be used	166
xslp_algorithm.cascadeBounds	Step bounds are updated to accomodate cascaded values (otherwise cascaded values are pushed to respect step bounds)	0
xslp_algorithm.clampExtendedActiveSB	Apply clamping when converged on extended criteria only with some variables having active step bounds	0
xslp_algorithm.clampExtendedAll	Apply clamping when converged on extended criteria only	0
xslp_algorithm.dynamicDamping	Use dynamic damping	0
xslp_algorithm.escalatePenalties	Escalate penalties	0
xslp_algorithm.estimateStepBounds	Estimate step bounds from early SLP iterations	1
xslp_algorithm.holdValues	Do not update values which are converged within strict tolerance	0
xslp_algorithm.maxCostOption	Continue optimizing after penalty cost reaches maximum	0
xslp_algorithm.noLPPolishing	Skip the solution polishing step if the LP postsolve returns a slightly infeasible, but claimed optimal solution	0
xslp_algorithm.noStepBounds	Do not apply step bounds	0
xslp_algorithm.quickConvergenceCheck	Quick convergence check	1
xslp_algorithm.resetDeltaZ	Reset xslp_delta_z to zero when converged and continue SLP	0

Option	Description	Default
xslp_algorithm_residualErrors	Accept a solution which has converged even if there are still significant active penalty error vectors	0
xslp_algorithm_retainPreviousValue	Retain previous value when cascading if determining row is zero	1
xslp_algorithm_stepBoundsAsRequired	Apply step bounds to SLP delta vectors only when required	1
xslp_algorithm_switchToPrimal	Use the primal simplex algorithm when all error vectors become inactive	0
xslp_calcThreads	Number of threads used for formula and derivatives evaluations	auto
xslp_filter	Bit map for controlling solution updates	3
xslp_filterKeepBest	Retrain solution best according to the merit function	1
xslp_filterZeroLineSearch	Force minimum step sizes in line search	0
xslp_filterZeroLineSearchTR	Accept the trust region step is the line search returns a zero step size	0
xslp_findIV	Option for running a heuristic to find a feasible initial point	auto
xslp_infinity	Value returned by a divide-by-zero in a formula	1e+10
xslp_primalIntegralRef	Reference solution value to take into account when calculating the primal integral	1e+20
xslp_scale	When to re-scale the SLP problem	1
xslp_scaleCount	Iteration limit used in determining when to re-scale the SLP matrix	0
xslp_solver	First order differentiation mode when using analytical derivatives	auto
xslp_threads	Default number of threads to be used	auto
xslp_zero	Absolute tolerance	1e-15

5.45.3.13 NLP Presolve Options

Option	Description	Default
xslp_linQuadBR	Use linear and quadratic constraints and objective function to further reduce bounds on all variables	auto
xslp_postsolve	Determines whether postsolving should be performed automatically	0
xslp_presolve	Determines whether presolving should be performed prior to starting the main algorithm	1
xslp_presolveLevel	Determines the level of changes presolve may carry out on the problem	4
xslp_presolveOps	Bitmap indicating the SLP presolve actions to be taken	2104
xslp_presolveOps_domain	Bound tightening based on function domains	1
xslp_presolveOps_eliminations	Allow eliminations on determined variables	1
xslp_presolveOps_fixAll	Explicitly fix all columns identified as fixed	0

Option	Description	Default
<code>xslp_presolveOps_fixZero</code>	Explicitly fix columns identified as fixed to zero	0
<code>xslp_presolveOps_general</code>	Generic SLP presolve	0
<code>xslp_presolveOps_intBounds</code>	MISLP bound tightening	1
<code>xslp_presolveOps_noCoefficients</code>	Do not presolve coefficients	0
<code>xslp_presolveOps_noDeltas</code>	Do not remove delta variables	0
<code>xslp_presolveOps_noDualSide</code>	Avoid reductions that can not be dual postsolved	0
<code>xslp_presolveOps_noLinear</code>	Avoid performing linear reductions at the nlp level	0
<code>xslp_presolveOps_noSimplifier</code>	Avoid simplifying nonlinear expressions	0
<code>xslp_presolveOps_setBounds</code>	SLP bound tightening	1
<code>xslp_presolveZero</code>	Minimum absolute value for a variable which is identified as nonzero during SLP presolve	1e-09
<code>xslp_probing</code>	Determines whether probing on a subset of variables should be performed prior to starting the main algorithm	auto

5.45.3.14 NLP Augmentation and Linearization Options

Option	Description	Default
<code>xslp_augmentation</code>	Bit map describing the SLP augmentation method(s) to be used	12
<code>xslp_augmentation_allErrorVectors</code>	Penalty error vectors on all non-linear inequality constraints	1
<code>xslp_augmentation_allRowErrorVectors</code>	Penalty error vectors on all constraints	0
<code>xslp_augmentation_aMeanWeight</code>	Use arithmetic means to estimate penalty weights	0
<code>xslp_augmentation_equalityErrorVectors</code>	Penalty error vectors on all non-linear equality constraints	1
<code>xslp_augmentation_evenHanded</code>	Even handed augmentation	0
<code>xslp_augmentation_minimum</code>	Minimum augmentation	0
<code>xslp_augmentation_noUpdateIfOnlyIV</code>	Initial values do not imply an SLP variable	0
<code>xslp_augmentation_penaltyDeltaVectors</code>	Penalty vectors to exceed step bounds	0
<code>xslp_augmentation_sbFromAbsValues</code>	Estimate step bounds from absolute values of row coefficients	0
<code>xslp_augmentation_sbFromValues</code>	Estimate step bounds from values of row coefficients	0
<code>xslp_augmentation_stepBoundRows</code>	Row-based step bounds	0
<code>xslp_delta_x</code>	Minimum absolute value of delta coefficients to be retained	1e-06
<code>xslp_feasTolTarget</code>	When set, this defines a target feasibility tolerance to which the linearizations are solved to	not set
<code>xslp_optimalityTolTarget</code>	When set, this defines a target optimality tolerance to which the linearizations are solved to	not set

Option	Description	Default
xslp_unfinishedLimit	Number of consecutive SLP iterations that may have an unfinished status before the solve is terminated	3
xslp_zeroCriterion	Bitmap determining the behavior of the placeholder deletion procedure	0
xslp_zeroCriterionCount	Number of consecutive times a placeholder entry is zero before being considered for deletion	0
xslp_zeroCriterionStart	SLP iteration at which criteria for deletion of placeholder entries are first activated	0
xslp_zeroCriterion_deltaNBDRRow	Remove placeholders in a basic delta variable if the determining row for the corresponding SLP variable is nonbasic	0
xslp_zeroCriterion_deltaNBUpdateRow	Remove placeholders in a basic delta variable if its update row is nonbasic and the corresponding SLP variable is nonbasic	0
xslp_zeroCriterion_nbDelta	Remove placeholders in nonbasic delta variables	0
xslp_zeroCriterion_nbSLPVar	Remove placeholders in nonbasic SLP variables	0
xslp_zeroCriterion_print	Print information about zero placeholders	0
xslp_zeroCriterion_slpVarNBUpdateRow	Remove placeholders in a basic SLP variable if its update row is nonbasic	0

5.45.3.15 NLP Barrier Options

Option	Description	Default
xslp_barCrossOverStart	Default crossover activation behaviour for barrier start	0
xslp_barLimit	Number of initial SLP iterations using the barrier method	0
xslp_barStallingLimit	Number of iterations to allow numerical failures in barrier before switching to dual	3
xslp_barStallingObjLimit	Number of iterations over which to measure the objective change for barrier iterations with no crossover	3
xslp_barStallingTol	Required change in the objective when progress is measured in barrier iterations without crossover	0.05
xslp_barStartOps	Controls behaviour when the barrier is used to solve the linearizations	-1
xslp_barStartOps_allowInteriorSol	If a non-vertex converged solution found by barrier without crossover can be returned as a final solution	1
xslp_barStartOps_stallingNumerical	Fall back to dual simplex if too many numerical problems are reported by the barrier	1
xslp_barStartOps_stallingObjective	Check objective progress when no crossover is applied	1

5.45.3.16 NLP Penalty Options

Option	Description	Default
xslp_deltaCost	Initial penalty cost multiplier for penalty delta vectors	200

Option	Description	Default
xslp_deltaCostFactor	Factor for increasing cost multiplier on total penalty delta vectors	1.3
xslp_deltaMaxCost	Maximum penalty cost multiplier for penalty delta vectors	1e+20
xslp_enforceCostShrink	Factor by which to decrease the current penalty multiplier when enforcing rows	1e-05
xslp_enforceMaxCost	Maximum penalty cost in the objective before enforcing most violating rows	1e+11
xslp_errorCost	Initial penalty cost multiplier for penalty error vectors	200
xslp_errorCostFactor	Factor for increasing cost multiplier on total penalty error vectors	1.3
xslp_errorMaxCost	Maximum penalty cost multiplier for penalty error vectors	1e+20
xslp_errorTol_a	Absolute tolerance for error vectors	1e-05
xslp_errorTol_p	Absolute tolerance for printing error vectors	0.0001
xslp_escalation	Factor for increasing cost multiplier on individual penalty error vectors	1.25
xslp_eTol_a	Absolute tolerance on penalty vectors	0.0001
xslp_eTol_r	Relative tolerance on penalty vectors	0.0001
xslp_evTol_a	Absolute tolerance on total penalty costs	-1
xslp_evTol_r	Relative tolerance on total penalty costs	-1
xslp_granularity	Base for calculating penalty costs	4
xslp_maxWeight	Maximum penalty weight for delta or error vectors	100
xslp_minWeight	Minimum penalty weight for delta or error vectors	0.01
xslp_objToPenaltyCost	Factor to estimate initial penalty costs from objective function	0
xslp_penaltyInfoStart	Iteration from which to record row penalty information	3

5.45.3.17 NLP Step Bounds Options

Option	Description	Default
xslp_clampShrink	Shrink ratio used to impose strict convergence on variables converged in extended criteria only	0.3
xslp_clampValidationTol_a	Absolute validation tolerance for applying xslp_clampShrink	not set
xslp_clampValidationTol_r	Relative validation tolerance for applying xslp_clampShrink	not set
xslp_defaultStepBound	Minimum initial value for the step bound of an SLP variable if none is explicitly given	16
xslp_djTol	Tolerance on DJ value for determining if a variable is at its step bound	1e-06
xslp_expand	Multiplier to increase a step bound	2
xslp_minSBFactor	Factor by which step bounds can be decreased beneath xslp_aTol_a	1
xslp_sameCount	Number of steps reaching the step bound in the same direction before step bounds are increased	3

Option	Description	Default
<code>xslp_sbStart</code>	SLP iteration after which step bounds are first applied	8
<code>xslp_shrink</code>	Multiplier to reduce a step bound	0.5
<code>xslp_shrinkBias</code>	Defines an overwrite / adjustment of step bounds for improving iterations	not set

5.45.3.18 NLP Variable Update Options

Option	Description	Default
<code>xslp_damp</code>	Damping factor for updating values of variables	1
<code>xslp_dampExpand</code>	Multiplier to increase damping factor during dynamic damping	1
<code>xslp_dampMax</code>	Maximum value for the damping factor of a variable during dynamic damping	1
<code>xslp_dampMin</code>	Minimum value for the damping factor of a variable during dynamic damping	1
<code>xslp_dampShrink</code>	Multiplier to decrease damping factor during dynamic damping	1
<code>xslp_dampStart</code>	SLP iteration at which damping is activated	0
<code>xslp_lsIterLimit</code>	Number of iterations in the line search	0
<code>xslp_lsPatternLimit</code>	Number of iterations in the pattern search preceding the line search	0
<code>xslp_lsStart</code>	Iteration in which to active the line search	8
<code>xslp_lsZeroLimit</code>	Maximum number of zero length line search steps before line search is deactivated	5
<code>xslp_meritLambda</code>	Factor by which the net objective is taken into account in the merit function	0
<code>xslp_sameDamp</code>	Number of steps in same direction before damping factor is increased	3

5.45.3.19 NLP Termination Options

Option	Description	Default
<code>xslp_aTol.a</code>	Absolute delta convergence tolerance	auto
<code>xslp_aTol.r</code>	Relative delta convergence tolerance	auto
<code>xslp_convergenceOps</code>	Bit map describing which convergence tests should be carried out	7167
<code>xslp_convergenceOps_aTol</code>	Execute the delta tolerance checks	1
<code>xslp_convergenceOps_cTol</code>	Execute the closure tolerance checks	1
<code>xslp_convergenceOps_extendedScaling</code>	Take scaling of individual variables / rows into account	0
<code>xslp_convergenceOps_iTol</code>	Execute the impact tolerance checks	1
<code>xslp_convergenceOps_mTol</code>	Execute the matrix tolerance checks	1
<code>xslp_convergenceOps_oTol</code>	Execute the objective range + active step bound check	1

Option	Description	Default
xslp_convergenceOps_sTol	Execute the slack impact tolerance checks	1
xslp_convergenceOps_validation	Execute the validation target convergence checks	1
xslp_convergenceOps_validationK	Execute the first order optimality target convergence checks	1
xslp_convergenceOps_vTol	Execute the objective range checks	1
xslp_convergenceOps_wTol	Execute the convergence continuation check	1
xslp_convergenceOps_xTol	Execute the objective range + constraint activity check	1
xslp_cTol	Closure convergence tolerance	auto
xslp_ecfCheck	Check feasibility at the point of linearization for extended convergence criteria	1
xslp_ecfTol.a	Absolute tolerance on testing feasibility at the point of linearization	auto
xslp_ecfTol.r	Relative tolerance on testing feasibility at the point of linearization	auto
xslp_infeasLimit	Maximum number of consecutive infeasible SLP iterations which can occur before Xpress-SLP terminates	3
xslp_iterLimit	Maximum number of SLP iterations	auto
xslp iTol.a	Absolute impact convergence tolerance	auto
xslp iTol.r	Relative impact convergence tolerance	auto
xslp_mTol.a	Absolute effective matrix element convergence tolerance	auto
xslp_mTol.r	Relative effective matrix element convergence tolerance	auto
xslp_mvTol	Marginal value tolerance for determining if a constraint is slack	auto
xslp_oCount	Number of SLP iterations over which to measure objective function variation for static objective (2) convergence criterion	5
xslp_oTol.a	Absolute static objective (2) convergence tolerance	auto
xslp_oTol.r	Relative static objective (2) convergence tolerance	auto
xslp_sTol.a	Absolute slack convergence tolerance	auto
xslp_sTol.r	Relative slack convergence tolerance	auto
xslp_stopOutOfRange	Stop optimization and return error code if internal function argument is out of range	0
xslp_validationTarget_k	Optimality target tolerance	1e-06
xslp_validationTarget_r	Feasibility target tolerance	1e-06
xslp_vCount	Number of SLP iterations over which to measure static objective (3) convergence	0
xslp_vLimit	Number of SLP iterations after which static objective (3) convergence testing starts	0
xslp_vTol.a	Absolute static objective (3) convergence tolerance	auto

Option	Description	Default
xslp_vTol.r	Relative static objective (3) convergence tolerance	auto
xslp_wCount	Number of SLP iterations over which to measure the objective for the extended convergence continuation criterion	0
xslp_wTol.a	Absolute extended convergence continuation tolerance	auto
xslp_wTol.r	Relative extended convergence continuation tolerance	auto
xslp_xCount	Number of SLP iterations over which to measure static objective (1) convergence	5
xslp_xLimit	Number of SLP iterations up to which static objective (1) convergence testing starts	100
xslp_xTol.a	Absolute static objective function (1) tolerance	auto
xslp_xTol.r	Relative static objective function (1) tolerance	auto

5.45.3.20 NLP Multistart Options

Option	Description	Default
xslp_msMaxBoundRange	Defines the maximum range inside which initial points are generated by multistart presets	1000
xslp_multistartPreset	Enable multistart	0
xslp_multistart_maxSolves	Maximum number of jobs to create during the multistart search	unlimited
xslp_multistart_maxTime	Maximum total time to be spent in the multistart search	unlimited
xslp_multistart_poolsize	Maximum number of problem objects allowed to pool up before synchronization in the deterministic multistart	2
xslp_multistart_seed	Random seed used for the automatic generation of initial point when loading multistart presets	0
xslp_multistart_threads	Maximum number of threads to be used in multistart	auto

5.45.3.21 NLP Derivative Options

Option	Description	Default
xslp_cdTol.a	Absolute tolerance for deducing constant derivatives	1e-08
xslp_cdTol.r	Relative tolerance for deducing constant derivatives	1e-08
xslp_deltaZLimit	Number of SLP iterations during which to apply xslp_delta.z	0
xslp_delta.a	Absolute perturbation of values for calculating numerical derivatives	0.001
xslp_delta.r	Relative perturbation of values for calculating numerical derivatives	0.001
xslp_delta.z	Tolerance used when calculating derivatives	1e-05
xslp_delta_zero	Absolute zero acceptance tolerance used when calculating derivatives	-1
xslp_derivatives	Bitmap describing the method of calculating derivatives	1

Option	Description	Default
xslp_hessian	Second order differentiation mode when using analytical derivatives	-1
xslp_jacobian	First order differentiation mode when using analytical derivatives	-1

5.45.3.22 NLP Log Options

Option	Description	Default
xslp_analyze	Bit map activating additional options supporting model / solution path analysis	0
xslp_analyze_extendedFinalSummary	Include an extended iteration summary	0
xslp_analyze_infeasibleIteration	Run infeasibility analysis on infeasible iterations	0
xslp_analyze_saveFile	Create an Xpress SLP save file at every xslp_autosave iterations	0
xslp_analyze_saveIterBasis	Write the initial basis of the linearizations to disk at every xslp_autosave iterations	0
xslp_analyze_saveLinearizations	Write the linearizations to disk at every xslp_autosave iterations	0
xslp_autosave	Frequency with which to save the model	0
xslp_log	Level of printing during SLP iterations	0
xslp_slpLog	Frequency with which SLP status is printed	1

5.45.3.23 MINLP Options

Option	Description	Default
xslp_cutStrategy	Determines which cuts to apply in the MISLP search when the default SLP-in-MIP strategy is used	0
xslp_heurStrategy	Branch and Bound: MINLP heuristic strategy	auto
xslp_mipAlgorithm	Bitmap describing the MISLP algorithms to be used	17
xslp_mipAlgorithm_finalFixSLP	Fix step bounds according to xslp_mipFixStepBounds after MIP solution is found	0
xslp_mipAlgorithm_finalRelaxSLP	Relax step bounds according to xslp_mipRelaxStepBounds after MIP solution is found	0
xslp_mipAlgorithm_initialFixSLP	Fix step bounds according to xslp_mipFixStepBounds after initial node	0
xslp_mipAlgorithm_initialRelaxSLP	Relax step bounds according to xslp_mipRelaxStepBounds after initial node	0
xslp_mipAlgorithm_initialSLP	Solve initial SLP to convergence	1
xslp_mipAlgorithm_nodeFixSLP	Fix step bounds according to xslp_mipFixStepBounds at each node	0

Option	Description	Default
xslp_mipAlgorithm_nodeLimitSLP	Limit iterations at each node to xslp_mipIterLimit	0
xslp_mipAlgorithm_nodeRelaxSLP	Relax step bounds according to xslp_mipRelaxStepBounds at each node	1
xslp_mipAlgorithm_slpThenMIP	Use MIP on converged SLP solution and then SLP on the resulting MIP solution	0
xslp_mipAlgorithm_withinSLP	Use MIP at each SLP iteration instead of SLP at each node	0
xslp_mipCutOffCount	Number of SLP iterations to check when considering a node for cutting off	5
xslp_mipCutOffLimit	Number of SLP iterations to check when considering a node for cutting off	10
xslp_mipCutOff.a	Absolute objective function cutoff for MIP termination	1e-05
xslp_mipCutOff.r	Absolute objective function cutoff for MIP termination	1e-05
xslp_mipDefaultAlgorithm	Default algorithm to be used during the global search in MISLP	auto
xslp_mipErrorTol.a	Absolute penalty error cost tolerance for MIP cut-off	0
xslp_mipErrorTol.r	Relative penalty error cost tolerance for MIP cut-off	0
xslp_mipFixStepBounds	Bitmap describing the step-bound fixing strategy during MISLP	0
xslp_mipFixStepBounds_coef	Fix step bounds on SLP variables appearing in coefficients	0
xslp_mipFixStepBounds_coefOnly	Fix step bounds on SLP variables appearing only in coefficients	0
xslp_mipFixStepBounds_structAll	Fix step bounds on all structural SLP variables	0
xslp_mipFixStepBounds_structNotCoef	Fix step bounds on structural SLP variables which are not in coefficients	0
xslp_mipIterLimit	Maximum number of SLP iterations at each node	0
xslp_mipLog	Frequency with which MIP status is printed	0
xslp_mipOCount	Number of SLP iterations at each node over which to measure objective function variation	5
xslp_mipOTol.a	Absolute objective function tolerance for MIP termination	1e-05
xslp_mipOTol.r	Relative objective function tolerance for MIP termination	1e-05
xslp_mipRelaxStepBounds	Bitmap describing the step-bound relaxation strategy during MISLP	15
xslp_mipRelaxStepBounds_coef	Relax step bounds on SLP variables appearing in coefficients	1
xslp_mipRelaxStepBounds_coefOnly	Relax step bounds on SLP variables appearing only in coefficients	1
xslp_mipRelaxStepBounds_structAll	Relax step bounds on all structural SLP variables	1
xslp_mipRelaxStepBounds_structNotCoef	Relax step bounds on structural SLP variables which are not in coefficients	1

5.45.4 Detailed Descriptions of XPRESS Options

advBasis (*boolean*): Use advanced basis provided by GAMS ↔

Default: `auto`

algAfterCrossover (*integer*): Algorithm to be used for the final clean up step after the crossover ↔

Default: `auto`

value	meaning
1	Automatically determined.
2	Dual simplex.
3	Primal simplex.
4	Concurrent.

algAfterNetwork (*integer*): Algorithm to be used for the clean up step after the network simplex solver ↔

Default: `auto`

value	meaning
-1	Automatically determined.
2	Dual simplex.
3	Primal simplex.

algorithm (*string*): Choose between simplex and barrier algorithm ↔

This option is used to select the barrier method to solve LPs. By default the barrier method will do a crossover to find a basic solution.

Default: `simplex`

value	meaning
<code>barrier</code>	Use the barrier algorithm
<code>simplex</code>	Use the simplex algorithm

autoCutting (*integer*): Automatically decide whether to generate cutting planes at local nodes in the tree ↔

If the `cutFreq` control is set, no automatic selection will be made and local cutting will be enabled.

Default: `auto`

value	meaning
-1	Automatic.
0	Disabled.
1	Enabled.

autoPerturb (*boolean*): Simplex: Indicates whether automatic perturbation is performed ↔

If this is set to 1, the problem will be perturbed whenever the simplex method encounters an excessive number of degenerate pivot steps, thus preventing the Optimizer being hindered by degeneracies.

Default: `auto`

value	meaning
0	No perturbation performed.
1	Automatic perturbation is performed.

autoScaling (*integer*): Whether the Optimizer should automatically select between different scaling algorithms ↔

If the `scaling` control is set, no automatic scaling will be applied.

Default: `auto`

value	meaning
-1	Automatic.
0	Disabled.
1	Cautious strategy. Non-standard scaling will only be selected if it appears to be clearly superior.
2	Moderate strategy.
3	Aggressive strategy. Standard scaling will only be selected if it appears to be clearly superior.

backTrack (*integer*): Branch and Bound: Specifies how to select the next node to work on when a full backtrack is performed ↔

Note When two nodes are rated the same according to the `backTrack` selection, a secondary rating is performed using the method set by `backtrackTie`.

Default: 3

value	meaning
-1	Automatically determined.
1	Unused.
2	Select the node with the best estimated solution.
3	Select the node with the best bound on the solution.
4	Select the deepest node in the search tree (equivalent to depth-first search).
5	Select the highest node in the search tree (equivalent to breadth-first search).
6	Select the earliest node created.
7	Select the latest node created.
8	Select a node randomly.
9	Select the node whose LP relaxation contains the fewest number of infeasible global entities.
10	Combination of 2 and 9.
11	Combination of 2 and 4.
12	Combination of 3 and 4.

backtrackTie (*integer*): Branch and Bound: Specifies how to break ties when selecting the next node to work on when a full backtrack is performed ↔

The options are the same as for the **backTrack** control.

Default: -1

value	meaning
-1	Default selection.
1	Unused.
2	Select the node with the best estimated solution.
3	Select the node with the best bound on the solution.
4	Select the deepest node in the search tree (equivalent to depth-first search).
5	Select the highest node in the search tree (equivalent to breadth-first search).
6	Select the earliest node created.
7	Select the latest node created.
8	Select a node randomly.
9	Select the node whose LP relaxation contains the fewest number of infeasible global entities.
10	Combination of 2 and 9.
11	Combination of 2 and 4.
12	Combination of 3 and 4.

barAlg (*integer*): Determines which barrier algorithm is to be used to solve the problem ↔

The automatic setting uses 1 for LP and QP problems and 3 for QCQP problems. Usually the detection of primal or dual infeasibility is more robust with settings 2 or 3, therefore, it is advantageous to use one of these values if the model is presumably infeasible.

Default: auto

value	meaning
-1	Determined automatically.
0	Unused.
1	Use the infeasible-start barrier algorithm.
2	Use the homogeneous self-dual barrier algorithm.
3	Start with 2 and optionally switch to 1 during the execution.

barCores (*integer*): If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm ↔

If the value is set to the default value (-1), Xpress will automatically detect the number of cores.

The control is provided for cross-hardware reproducibility purposes. The count does not include logical cores created by Hyper-Threading.

Range: {-1, ..., ∞}

Default: auto

barCrash (*integer*): Newton barrier: Determines the type of crash used for the crossover ↔

During the crash procedure, an initial basis is determined which attempts to speed up the crossover. A good choice at this stage will significantly reduce the number of iterations required to crossover to an optimal solution. The possible values increase proportionally to their time-consumption.

Default: 4

value	meaning
0	Turns off all crash procedures.
1-6	Available strategies with 1 being conservative and 6 being aggressive.

barDualStop (*real*): Newton barrier: Convergence parameter, representing the tolerance for dual infeasibilities [↔](#)

If the difference between the constraints and their bounds in the dual problem falls below this tolerance in absolute value, optimization will stop and the current solution will be returned.

Range: $[0, \infty]$

Default: `auto`

barFailIterLimit (*integer*): Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm [↔](#)

Default: `auto`

value	meaning
0	Determined automatically
>0	Maximum number of consecutive barrier iterations allowed without progress.

barFreeScale (*real*): Defines how the barrier algorithm scales free variables [↔](#)

When using smaller values the barrier algorithm scales free variables more aggressively which can improve performance but may impact numerical stability.

Range: $[0, \infty]$

Default: `1e-06`

barGapStop (*real*): Newton barrier: Convergence parameter, representing the tolerance for the relative duality gap [↔](#)

When the difference between the primal and dual objective function values falls below this tolerance, the Optimizer determines that the optimal solution has been found.

Range: $[0, \infty]$

Default: `auto`

barGapTarget (*real*): Newton barrier: Target tolerance for the relative duality gap [↔](#)

The barrier algorithm will keep iterating until either `barGapTarget` is satisfied or until no further improvements are possible. In the latter case, if `barGapStop` is satisfied, it will declare the problem optimal.

When a solution returned by the barrier algorithm has not converged tightly enough for an application, for example if the dual solution is not accurate enough or crossover is taking too long, setter `barGapTarget` to a small value often resolves the problem, without the risk of the solve failing due to a complementarity level not being numerically achievable. Typical suggested values can be between 1-10 and 1-18.

Range: $[0, \infty]$

Default: `auto`

barIndefLimit (*integer*): Newton Barrier: Limits the number of consecutive indefinite barrier iterations that will be performed \leftrightarrow

The optimizer will try to minimize (resp. maximize) a QP problem even if the Q matrix is not positive (resp. negative) semi-definite. However, the optimizer may detect that the Q matrix is indefinite and this can result in the optimizer not converging. This control specifies how many indefinite iterations may occur before the optimizer stops and reports that the problem is indefinite. It is usual to specify a value greater than one, and only stop after a series of indefinite matrices, as the problem may be found to be indefinite incorrectly on a few iterations for numerical reasons.

Range: $\{1, \dots, \infty\}$

Default: 15

barIterLimit (*integer*): Newton barrier: Maximum number of iterations \leftrightarrow

While the simplex method usually performs a number of iterations which is proportional to the number of constraints (rows) in a problem, the barrier method standardly finds the optimal solution to a given accuracy after a number of iterations which is independent of the problem size. The penalty is rather that the time for each iteration increases with the size of the problem. `barIterLimit` specifies the maximum number of iterations which will be carried out by the barrier.

Range: $\{0, \dots, \infty\}$

Default: 500

barKernel (*real*): Newton barrier: Defines how centrality is weighted in the barrier algorithm \leftrightarrow

Increasing this parameter may increase the number of iterations, therefore the recommended range is $[1,2]$ and $[-2,-1]$.

Default: 0

value	meaning
$\geq +1.0$	Increases the emphasis on centrality when larger value is set.
≤ -1.0	Selects a value adaptively in every iteration from $[+1, -\text{barKernel}]$.

barObjPerturb (*real*): Defines how the barrier perturbs the objective \leftrightarrow

The perturbation scale should be set carefully with consideration to the optimality tolerance. The parameter affects only the barrier solve.

Default: 1e-06

value	meaning
0	Turn off objective perturbation.
>0	Let the optimizer decide if the objective is perturbed or not and use the parameter value as the scale of the perturbation.
<0	Always perturb the objective by the absolute value of the parameter.

barObjScale (*real*): Defines how the barrier scales the objective ↔

The scaling performed by the barrier is applied on top of any other scaling in the problem and only affects the barrier solve.

Default: auto

value	meaning
-1	Let the optimizer decide.
0	Scale by geometric mean.
>=0	Scale such that the largest objective coefficient's largest element does not exceed this number. In quadratic problems, the quadratic diagonal is used as reference values instead of the linear objective.

barOrder (*integer*): Newton barrier: Controls the Cholesky factorization in the Newton-Barrier ↔

Default: auto

value	meaning
0	Choose automatically.
1	Minimum degree method. This selects diagonal elements with the smallest number of nonzeros in their rows or columns.
2	Minimum local fill method. This considers the adjacency graph of nonzeros in the matrix and seeks to eliminate nodes that minimize the creation of new edges.
3	Nested dissection method. This considers the adjacency graph and recursively seeks to separate it into non-adjacent pieces.

barOrderThreads (*integer*): If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton-barrier method ↔

Larger values than `barCores` will be automatically reduced to the value of `barCores`.

Range: {0, ..., ∞}

Default: auto

barOutput (*boolean*): Newton barrier: Level of solution output provided ↔

Output is provided either after each iteration of the algorithm, or else can be turned off completely by this parameter.

Default: 1

value	meaning
0	No output.
1	At each iteration.

barPerturb (*real*): Newton barrier: In numerically challenging cases it is often advantageous to apply perturbations on the KKT system to improve its numerical properties ↔

barPerturb controls how much perturbation is allowed during the barrier iterations. By default no perturbation is allowed. Set this parameter with care as larger perturbations may lead to less efficient iterates and the best settings are problem-dependent.

Range: $[0, \infty]$

Default: 0

barPresolveOps (*integer*): Newton barrier: Controls the Newton-Barrier specific presolve operations ↔

Default: 0

value	meaning
0	Use standard presolve.
1	Extra effort is spent in barrier specific presolve.
2	Do full matrix eliminations (reduce matrix size).

barPrimalStop (*real*): Newton barrier: Convergence parameter, indicating the tolerance for primal infeasibilities ↔

If the difference between the constraints and their bounds in the primal problem falls below this tolerance in absolute value, the Optimizer will terminate and return the current solution.

Range: $[0, \infty]$

Default: `auto`

barRefIter (*integer*): Newton barrier: After terminating the barrier algorithm, further refinement steps can be performed ↔

Such refinement steps are especially helpful if the solution is near to the optimum and can improve primal feasibility and decrease the complementarity gap. It is also often advantageous for the crossover algorithm. **barRefIter** specifies the maximum number of such refinement iterations.

Range: $\{0, \dots, \infty\}$

Default: 0

barRegularize (*integer*): Determines how the barrier algorithm applies regularization on the KKT system ↔

The parameter is a bit set but value -1 (the default value) is treated in a special way: if the parameter is set to -1 then the solver will automatically select the bits it deems most useful.

Default: -1

value	meaning
bit 0 = 1	Standard regularization is turned on/off.
bit 1 = 2	Reduced regularization is turned on/off. This option reduces the perturbation effect of the standard regularization.
bit 2 = 4	Forces to keep dependent rows in the KKT system.
bit 3 = 8	Forces to preserve degenerate rows in the KKT system.

barRhsScale (*real*): Defines how the barrier scales the right hand side ↔

The scaling performed by the barrier is applied on top of any other scaling in the problem and only affects the barrier solve.

Default: `auto`

value	meaning
-1	Let the optimizer decide.
0	Scale by geometric mean.
>=0	Scale such that the largest right hand side coefficient's largest element does not exceed this number.

barStart (*integer*): Newton barrier: Controls the computation of the starting point for the barrier algorithm ↔

Default: `auto`

value	meaning
-1	Uses the available solution for warm-start.
0	Determine automatically.
1	Uses simple heuristics to compute the starting point based on the magnitudes of the matrix entries.
2	Uses the pseudoinverse of the constraint matrix to determine primal and dual initial solutions. Less sensitive to scaling and numerically more robust, but in several case less efficient than 1.
3	Uses the unit starting point for the homogeneous self-dual barrier algorithm.

barStepStop (*real*): Newton barrier: Convergence parameter, representing the minimal step size ↔

On each iteration of the barrier algorithm, a step is taken along a computed search direction. If that step size is smaller than `barStepStop`, the Optimizer will terminate and return the current solution.

If the barrier method is making small improvements on `barGapStop` on later iterations, it may be better to set this value higher, to return a solution after a close approximation to the optimum has been found.

Range: $[0, \infty]$

Default: `1e-16`

barThreads (*integer*): If set to a positive integer it determines the number of threads implemented to run the Newton-barrier algorithm ↔

If the value is set to the default value (-1), the `threads` control will determine the number of threads used.

There is a practical upper limit of 50 on the number of parallel threads the optimizer will create.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

basisOut (*string*): Directs optimizer to output an MPS basis file ↔

In general this option is not used in a GAMS environment, as GAMS maintains basis information for you automatically.

Default: `none`

bigM (*real*): Infeasibility penalty used if the "Big M" method is implemented ↔

Range: $[0, \infty]$

Default: `auto`

bigMMethod (*boolean*): Simplex: Whether to use the "Big M" method, or the standard phase I (achieving feasibility) and phase II (achieving optimality) ↔

In the "Big M" method, the objective coefficients of the variables are considered during the feasibility phase, possibly leading to an initial feasible basis which is closer to optimal. The side-effects involve possible round-off errors due to the presence of the "Big M" factor in the problem.

Default: 1

value	meaning
0	For phase I / phase II.
1	If "Big M" method to be used.

branchChoice (*integer*): Once a global entity has been selected for branching, this control determines which of the branches is solved first ↔

Default: 0

value	meaning
0	Minimum estimate branch first.
1	Maximum estimate branch first.
2	If an incumbent solution exists, solve the branch satisfied by that solution first. Otherwise solve the minimum estimate branch first (option 0).
3	Solve first the branch that forces the value of the branching variable to move farther away from the value it had at the root node. If the branching entity is not a simple variable, solve the minimum estimate branch first (option 0).

branchDisj (*integer*): Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search ↔

Note Split disjunctions are a special form of disjunctions that can be written as $\sum_j m_j x_j \leq m_0 \vee \sum_j m_j x_j \geq m_0+1$. The split disjunctions created by the optimizer will use a combination of binary or integer variables x_j , with integer coefficients m_j . Split disjunctions for branching will always be created with a default priority value of 400 instead of the default value of 500 for regular entity branches.

Default: `auto`

value	meaning
-1	Automatic selection of the strategy.
0	Disabled.
1	Cautious strategy. Disjunctive branches will be created only for general integers with a wide range.
2	Moderate strategy.
3	Aggressive strategy. Disjunctive branches will be created for both binaries and integers.

branchStructural (*integer*): Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search ↔

Structural branches will often involve branching on more than a single global entity at a time. As a result of a structural branch, a parent node could therefore end up with more than two child nodes, unlike the standard single entity branches. Structural branches will always be created with a default priority value of 400 instead of the default value of 500 for regular entity branches.

Default: `auto`

value	meaning
-1	Automatically determined.
0	Disabled.
1	Enabled.

breadthFirst (*integer*): Number of nodes to include in the best-first search before switching to the local first search (`nodeSelection` = 4) ↔

Range: $\{0, \dots, \infty\}$

Default: 11

cacheSize (*integer*): Newton Barrier: L2 or L3 (see notes) cache size in kB (kilobytes) of the CPU ↔

On Intel (or compatible) platforms a value of -1 may be used to determine the cache size automatically. If the CPU model is new then the cache size may not be correctly detected by an older release of the software.

1. Specifying the correct cache size can give a significant performance advantage with the Newton barrier algorithm. If the size is unknown, it is better to specify a smaller size.
2. If the size cannot be determined automatically, a default size of 128kB is assumed.
3. Where present, the L3 cache size should be chosen rather than the L2 cache size.
4. For multi-core CPUs, the cache is shared between a subset of the cores. The Optimizer will divide the `cacheSize` value by the number of cores sharing the cache if >1 Barrier threads are running.
5. Where the CPU is described as having multiple caches ie. 2x6M then the correct cache size to use is 6M not 12M.
6. Examples: Intel Core 2 Duo E6400 (2M Cache, 2.13GHz) `cacheSize`=2048 Intel Xeon x5570 (8M Cache, 2.93GHz) `cacheSize`=8192 Intel Core 2 QX6700 (2x4M Cache, 2.93 GHz) `cacheSize`=4096
7. If in doubt, please contact Xpress Support for advice.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

choleskyAlg (*integer*): Newton barrier: Type of Cholesky factorization used \leftrightarrow

Default: `auto`

value	meaning
bit 0 = 1	Matrix blocking: 0: automatic setting; 1: manual setting.
bit 1 = 2	If manual selection of matrix blocking: 0: multi-pass; 1: single-pass.
bit 2 = 4	Nonseparable QP relaxation: 0: off; 1: on.
bit 3 = 8	Corrector weight: 0: automatic setting; 1: manual setting.
bit 4 = 16	If manual selection of corrector weight: 0: off; 1: on.
bit 5 = 32	Refinement: 0: automatic setting; 1: manual setting.
bit 6 = 64	Preconditioned conjugate gradient method (PCGM): 0: PCGM off; 1: PCGM on.
bit 7 = 128	Preconditioned quasi minimal residual (QMR) to refine solution: 0: QMR off; 1: QMR on.
bit 8 = 256	Perform refinement on the augmented system 0: off; 1: on.
bit 9 = 512	Force highest accuracy in refinement 0: off; 1: on.

choleskyTol (*real*): Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm \leftrightarrow

If the absolute value of the pivot element is less than or equal to `choleskyTol`, it merits special treatment in the Cholesky decomposition process.

Range: $[0, \infty]$

Default: `1e-15`

clamping (*integer*): Allows for the adjustment of returned solution values such that they are always within bounds \leftrightarrow

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `0`

value	meaning
-1	Determined automatically.
0	Equivalent to <code>clamping_primal</code> .
1	Equivalent to <code>clamping_dual</code> .
2	Equivalent to <code>clamping_slacks</code> .
3	Equivalent to <code>clamping_rdj</code> .

clamping_dual (*boolean*): Adjust primal slack values to always be within constraint bounds \leftrightarrow

See also `clamping`.

Default: `0`

clamping_primal (*boolean*): Adjust primal solution to always be within primal bounds \leftrightarrow

Slacks if provided will be adjusted accordingly.

See also [clamping](#).

Default: 0

clamping_rdj (*boolean*): Adjust reduced costs to always be within dual bounds implied by the primal solution ↔

See also [clamping](#).

Default: 0

clamping_slacks (*boolean*): Adjust dual solution to always be within the dual bounds implied by the slacks ↔

Reduced costs, if provided, will be adjusted accordingly.

See also [clamping](#).

Default: 0

concurrentThreads (*integer*): Determines the number of threads used by the concurrent solver ↔

Default: auto

value	meaning
-1	Determined automatically
>0	Number of threads to use.

conflictCuts (*integer*): Branch and Bound: Specifies how cautious or aggressive the optimizer should be when searching for and applying conflict cuts ↔

Conflict cuts are in-tree cuts derived from nodes found to be infeasible or cut off, which can be used to cut off other branches of the search tree.

Default: auto

value	meaning
-1	Automatic.
0	Disable conflict cuts.
1	Cautious application of conflict cuts.
2	Medium application of conflict cuts.
3	Aggressive application of conflict cuts.

coresPerCpu (*integer*): Used to override the detected value of the number of cores on a CPU ↔

The cache size (either detected or specified via the [cacheSize](#) control) used in Barrier methods will be divided by this amount, and this scaled-down value will be the amount of cache allocated to each Barrier thread.

Range: $\{-1, \dots, \infty\}$

Default: auto

coverCuts (*integer*): Branch and Bound: Number of rounds of lifted cover inequalities at the top node
↔

A lifted cover inequality is an additional constraint that can be particularly effective at reducing the size of the feasible region without removing potential integral solutions. The process of generating these can be carried out a number of times, further reducing the feasible region, albeit incurring a time penalty. There is usually a good payoff from generating these at the top node, since these inequalities then apply to every subsequent node in the tree search.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

cpuPlatform (*integer*): Newton Barrier: Selects the AMD or Intel x86 vectorization instruction set that Barrier should run optimized code for ↔

Generic code, SSE2 and AVX optimized code will all result in the same solution path. Using AVX2 might result in a different solution path.

Default: `-1`

value	meaning
-2	Highest supported [Generic, SSE2, AVX or AVX2].
-1	Highest supported solve path consistent code [Generic, SSE2 or AVX].
0	Use generic code compatible with all CPUs.
1	Use SSE2 optimized code.
2	Use AVX optimized code.
3	Use AVX2 optimized code.

cpuTime (*integer*): How time should be measured when timings are reported in the log and when checking against time limits ↔

Default: `0`

value	meaning
-1	Disable the timer.
0	Use elapsed time.
1	Use process time.

crash (*integer*): Simplex: Determines the type of crash used when the algorithm begins (only relevant when no advanced basis is available) ↔

During the crash procedure, an initial basis is determined which is as close to feasibility and triangularity as possible. A good choice at this stage will significantly reduce the number of iterations required to find an optimal solution. The possible values increase proportionally to their time-consumption.

Default: `2`

value	meaning
0	Turns off all crash procedures.
1	For singletons only (one pass).

value	meaning
2	For singletons only (multi pass).
3	Multiple passes through the matrix considering slacks.
4	Multiple (≤ 10) passes through the matrix but only doing slacks at the very end.
$n > 10$	As for value 4 but performing at most $n - 10$ passes.

crossover (*integer*): Newton barrier: Determines whether the barrier method will cross over to the simplex method when at optimal solution has been found, to provide an end basis and advanced sensitivity analysis information (see XPRSobjsa, XPRShssa, XPRsbnds) \leftrightarrow

The full primal and dual solution is available whether or not crossover is used. The crossover must not be disabled if the barrier is used to reoptimize nodes of a MIP. By default crossover will not be performed on QP and MIQP problems.

Default: `auto`

value	meaning
-1	Determined automatically.
0	No crossover.
1	Primal crossover first.
2	Dual crossover first.

crossoverAccuracyTol (*real*): Newton barrier: Determines how crossover adjusts the default relative pivot tolerance \leftrightarrow

When re-inversion is necessary, crossover will compare the recalculated working basic solution with the assumed ones just before re-inversion took place. If the error is above this threshold, crossover will adjust the relative pivot tolerance to address the build-up of numerical inaccuracies.

The full primal and dual solution is available whether or not crossover is used. The crossover must not be disabled if the barrier is used to reoptimize nodes of a MIP. By default crossover will not be performed on QP and MIQP problems.

Range: $[0, \infty]$

Default: `1e-06`

crossoverIterLimit (*integer*): Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates \leftrightarrow

Range: $\{0, \dots, \infty\}$

Default: `2147483647`

crossoverOps (*integer*): Newton barrier: Bit vector for adjusting the behavior of the crossover procedure \leftrightarrow

Default: `0`

value	meaning
bit 0 = 1	Returned solution when the crossover terminates prematurely: 0: Return the last basis from the crossover; 1: Return the barrier solution.
bit 1 = 2	Select the crossover stages to be performed: 0: Perform both crossover stages; 1: Skip second crossover stage.
bit 2 = 4	Set crossover behaviour: 0: Force to perform all pivots; 1: Skip pivots that are numerically less reliable.
bit 3 = 8	Set crossover behaviour: 0: Perform standard crossover; 1: Perform a slower, but numerically more careful crossover.

crossoverThreads (*integer*): Determines the maximum number of threads that parallel crossover is allowed to use ↵

If **crossoverThreads** is set to the default value (-1), the **barThreads** control will determine the number of threads used.

Range: {-1, ..., ∞}

Default: auto

cutDepth (*integer*): Branch and Bound: Sets the maximum depth in the tree search at which cuts will be generated ↵

Generating cuts can take a lot of time, and is often less important at deeper levels of the tree since tighter bounds on the variables have already reduced the feasible region. A value of 0 signifies that no cuts will be generated.

Does not affect cutting on the root node.

Range: {-1, ..., ∞}

Default: auto

cutFactor (*real*): Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during global search ↵

The cuts and cut coefficients are limited by **cutFactor** times the number of rows and coefficients in the initial matrix.

A value of 0.0 prevents cuts from being added, and a value of e.g. 1.0 will allow the problem to grow to twice the initial number of rows and coefficients.

Default: auto

value	meaning
-1	Let the optimizer decide on the maximum amount of cuts based on cutStrategy .
>=0	Multiple of number of rows and coefficients to use.

cutFreq (*integer*): Branch and Bound: Frequency at which cuts are generated in the tree search ↵

If the depth of the node modulo **cutFreq** is zero, then cuts will be generated.

Range: {-1, ..., ∞}

Default: auto

cutSelect (*integer*): Bit vector providing detailed control of the cuts created for the root node of a global solve ↵

Use **treeCutSelect** to control cuts during the tree search.

The default value is -1 which enables all bits. Any bits not listed in the above table should be left in their default 'on' state, since the interpretation of such bits might change in future versions of the optimizer.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -1

value	meaning
bit 5 = 32	Equivalent to cutSelect_clique .
bit 6 = 64	Equivalent to cutSelect_mir .
bit 7 = 128	Equivalent to cutSelect_cover .
bit 8 = 256	Equivalent to cutSelect_mirRowAggregation .
bit 11 = 2048	Equivalent to cutSelect_flowpath .
bit 12 = 4096	Equivalent to cutSelect_implication .
bit 13 = 8192	Equivalent to cutSelect_liftAndProject .
bit 14 = 16384	Equivalent to cutSelect_disableCutRows .
bit 15 = 32768	Equivalent to cutSelect_gubCover .
bit 16 = 65536	Equivalent to cutSelect_zeroHalf .
bit 17 = 131072	Equivalent to cutSelect_indicator .

cutSelect_clique (*boolean*): Clique cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_cover (*boolean*): Lifted cover cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_disableCutRows (*boolean*): Disable cutting from cut rows ↔

See also [cutSelect](#).

Default: 1

cutSelect_flowpath (*boolean*): Flow path cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_gubCover (*boolean*): Lifted GUB cover cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_implication (*boolean*): Implication cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_indicator (*boolean*): Indicator constraint cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_liftAndProject (*boolean*): Turn on automatic Lift-and-Project cutting strategy ↔

See also [cutSelect](#).

Default: 1

cutSelect_mir (*boolean*): Mixed Integer Rounding (MIR) cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_mirRowAggregation (*boolean*): Turn on row aggregation for MIR cuts ↔

See also [cutSelect](#).

Default: 1

cutSelect_zeroHalf (*boolean*): Zero-half cuts ↔

See also [cutSelect](#).

Default: 1

cutStrategy (*integer*): Branch and Bound: Cut strategy ↔

A more aggressive cut strategy, generating a greater number of cuts, will result in fewer nodes to be explored, but with an associated time cost in generating the cuts. The fewer cuts generated, the less time taken, but the greater subsequent number of nodes to be explored.

Default: auto

value	meaning
-1	Automatic selection of the cut strategy.
0	No cuts.
1	Conservative cut strategy.
2	Moderate cut strategy.
3	Aggressive cut strategy.

defaultAlg (*integer*): Selects the algorithm that will be used to solve the LP ↔

Please note that this will affect how the MIP node LP problems are solved during the global search.

Default: auto

value	meaning
1	Automatically determined.
2	Dual simplex.
3	Primal simplex.
4	Newton barrier.

denseColLimit (*integer*): Newton barrier: Controls trigger point for special treatment of dense columns

in Cholesky factorization ↔

Columns with more than `denseColLimit` elements are considered to be dense. Such columns will be handled specially in the Cholesky factorization of this matrix.

Range: $\{0, \dots, \infty\}$

Default: `auto`

deterministic (*integer*): Branch and Bound: Specifies whether the parallel MIP search should be deterministic ↔

Default: 1

value	meaning
0	Use non-deterministic parallel MIP.
1	Use deterministic parallel MIP.
2	Use deterministic parallel MIP, but allow the concurrent root LP solve to be opportunistic.

dualGradient (*integer*): Simplex: Dual simplex pricing method ↔

Default: `auto`

value	meaning
-1	Determine automatically.
0	Devex.
1	Steepest edge.
2	Direct steepest edge.
3	Sparse Devex.

dualize (*integer*): Whether presolve should form the dual of the problem ↔

Default: `auto`

value	meaning
-1	Determine automatically.
0	Solve the primal problem.
1	Solve the dual problem.

dualizeOps (*boolean*): Bit-vector control for adjusting the behavior when a problem is dualized ↔

Default: 1

value	meaning
bit 0 = 1	Swap the simplex algorithm to run. If dual simplex is selected for the original problem then primal simplex will be run on the dualized problem, and similarly if primal simplex is selected.

dualPerturb (*real*): Factor by which the problem will be perturbed prior to optimization by dual simplex ↔

A value of 0.0 results in no perturbation prior to optimization. Note the interconnection to the `autoPerturb` control. If `autoPerturb` is set to 1, the decision whether to perturb or not is left to the Optimizer. When the problem is automatically perturbed in dual simplex, however, the value of `dualPerturb` will be used for perturbation.

Range: $[-\infty, \infty]$

Default: `auto`

dualStrategy (*integer*): Bit-vector control specifies the dual simplex strategy \leftrightarrow

Default: 1

value	meaning
bit 0 = 1	Switch to primal when re-optimization goes dual infeasible and numerically unstable.
bit 1 = 2	When dual intend to switch to primal, stop the solve instead of switching to primal.
bit 2 = 4	Use more aggressive cut-off in MIP search.
bit 3 = 8	Use dual simplex to remove cost perturbations.
bit 4 = 16	Enable more aggressive dual pivoting strategy.
bit 5 = 32	Keep using dual simplex even when it's numerically unstable.

dualThreads (*integer*): Determines the maximum number of threads that dual simplex is allowed to use \leftrightarrow

If `dualThreads` is set to the default value (-1), the `threads` control will determine the number of threads used.

When solving a linear MIP, the dual simplex algorithm will use multiple threads only when solving the initial LP relaxation or when reoptimizing between rounds of cuts on the root node. The parallel dual simplex algorithm differs from the sequential dual simplex algorithm and might follow a different solve path. For `dualThreads` > 1 the solve path is independent of the number of threads used, although the practical limit for observing performance benefits is around `dualThreads` = 8.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

eigenvalueTol (*real*): Quadratic matrix is considered not to be positive semi-definite, if its smallest eigenvalue is smaller than the negative of this value \leftrightarrow

Range: $[0, \infty]$

Default: `1e-06`

elimFillin (*integer*): Amount of fill-in allowed when performing an elimination in presolve \leftrightarrow

Range: $\{0, \dots, \infty\}$

Default: 10

elimTol (*real*): Markowitz tolerance for the elimination phase of the presolve \leftrightarrow

Range: $[0, \infty]$

Default: 0.001

etaTol (*real*): Tolerance on eta elements [↔](#)

During each iteration, the basis inverse is premultiplied by an elementary matrix, which is the identity except for one column - the eta vector. Elements of eta vectors whose absolute value is smaller than **etaTol** are taken to be zero in this step.

Range: $[0, \infty]$

Default: 1e-13

extraPresolve (*integer*): No longer has any effect and will be removed from future releases [↔](#)

Use **presolveMaxGrow** to limit the number of non-zero coefficients in the presolved problem.

Range: $\{0, \dots, \infty\}$

Default: 0

feasibilityPump (*integer*): Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node [↔](#)

Default: auto

value	meaning
-1	Automatic.
0	Turned off.
1	Always try the Feasibility Pump.
2	Try the Feasibility Pump only if other heuristics have failed to find an integer solution.

feasTol (*real*): Determines when a solution is treated as feasible [↔](#)

If the amount by which a constraint's activity violates its right-hand side or ranged bound is less in absolute magnitude than **feasTol**, then the constraint is treated as satisfied. Similarly, if the amount by which a column violates its bounds is less in absolute magnitude than **feasTol**, those bounds are also treated as satisfied.

Range: $[0, \infty]$

Default: 1e-06

feasTolPerturb (*real*): Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes [↔](#)

The tolerance **feasTol** is always considered as an upper limit for the perturbations, but in some cases smaller value can be more desirable.

Range: $[0, \infty]$

Default: 1e-06

feasTolTarget (*real*): Target feasibility tolerance for the solution refiner [↔](#)

Zero and negative values are ignored, and the value of `feasTol` is used.

Use very small values like $1e-100$ to state the refinement should continue as long as an improvement is made. Use very large values like $1e+100$ to disable only this aspect of the refiner.

Refining solutions to match the `feasTolTarget` can influence and worsen their objective value in case the previous objective could only be achieved through slight infeasibilities.

Range: $[-\infty, \infty]$

Default: 0

fixoptfile (*string*): name of option file which is read just before solving the fixed problem ↔

forceParallelDual (*boolean*): Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm ↔

By default, when using a single thread, the dual simplex solver will execute a dedicated sequential simplex algorithm.

Default: 0

value	meaning
0	Disabled.
1	Enabled. Force the dual simplex solver to use the parallel algorithm.

genConsAbsTransformation (*integer*): Specifies the reformulation method for absolute value general constraints at the beginning of the search ↔

Default: auto

value	meaning
-1	Automatic.
0	Use a formulation based on indicator constraints.
1	Use a formulation based on SOS1-constraints.

genConsDualReductions (*boolean*): Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs ↔

Default: 1

value	meaning
0	Disabled. No dual reductions, add columns and rows.
1	Enabled. Only add necessary columns and rows, drop those implied by the objective sense.

gomCuts (*integer*): Branch and Bound: Number of rounds of Gomory or lift-and-project cuts at the top node ↔

Range: $\{-1, \dots, \infty\}$

Default: `auto`

heurBeforeLp (*integer*): Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved ↔

It is possible that a heuristic will find an optimal integer solution that will result in the LP relaxation solution being cut off. If dedicated heuristic threads are enabled through the [heurThreads](#) control, then the initial heuristics will be run in parallel with the LP solve, instead of before.

Default: `auto`

value	meaning
-1	Automatic - let the optimizer decide if heuristics should be run.
0	Disabled.
1	Enabled.

heurDiveIterLimit (*real*): Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic ↔

Default: `auto`

value	meaning
0	No iteration limit.
>=1	Fixed iteration limit.
<0	Automatic selection of the iteration limit based on the problem size. The absolute value is used as a multiplier on the automatic selection.

heurDiveRandomize (*real*): Level of randomization to apply in the diving heuristic ↔

The diving heuristic uses priority weights on rows and columns to determine the order in which to e.g. round fractional columns, or the direction in which to round them. This control determines by how large a random factor these weights should be changed.

Default: 0

value	meaning
0.0-1.0	Amount of randomization (0.0=none, 1.0=full)

heurDiveSoftRounding (*integer*): Branch and Bound: Enables a more cautious strategy for the diving heuristic, where it tries to push binaries and integer variables to their bounds using the objective, instead of directly fixing them ↔

This can be useful when the default diving heuristics fail to find any feasible solutions.

Default: `auto`

value	meaning
-1	Automatic selection.
0	Do not use soft rounding.
1	Cautious use of the soft rounding strategy.
2	More aggressive use of the soft rounding strategy.

heurDiveSpeedUp (*integer*): Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed ↔

Default: -1

value	meaning
-2	Automatic selection biased towards quality
-1	Automatic selection biased towards speed.
0-4	Manual emphasis bias from emphasis on quality (0) to emphasis on speed (4).

heurDiveStrategy (*integer*): Branch and Bound: Chooses the strategy for the diving heuristic ↔

Default: auto

value	meaning
-1	Automatic selection of strategy.
0	Disables the diving heuristic.
1-18	Available pre-set strategies for rounding infeasible global entities and reoptimizing during the heuristic dive.

heurEmphasis (*integer*): Branch and Bound: Specifies an emphasis for the search w.r.t. primal heuristics and other procedures that affect the speed of convergence of the primal-dual gap ↔

For problems where the goal is to achieve a small gap but not necessarily solving them to optimality, it is recommended to set **heurEmphasis** to 1. This setting triggers many additional heuristic calls, aiming for reducing the gap at the beginning of the search, typically at the expense of an increased time for proving optimality.

Default: -1

value	meaning
-1	Optimizer default strategy.
0	Disables all heuristics.
1	Focus on reducing the primal-dual gap in the early part of the search.
2	Extremely aggressive search heuristics.

heurForceSpecialObj (*boolean*): Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer ↔

Deactivated by default.

Default: 0

value	meaning
0	Disabled.
1	Enabled. Run special objective heuristics on large problems and even if incumbent exists.

heurFreq (*integer*): Branch and Bound: Frequency at which heuristics are used in the tree search ↔

Heuristics will only be used at a node if the depth of the node is a multiple of **heurFreq**.

Range: $\{-1, \dots, \infty\}$

Default: -1

heurSearchEffort (*real*): Adjusts the overall level of the local search heuristics [↔](#)

[heurSearchEffort](#) is used as a multiplier on the default amount of work the local search heuristics should do. A higher value means the local search heuristics will be run more often and that they are allowed to search larger neighborhoods.

Range: $[0, \infty]$

Default: 1

heurSearchFreq (*integer*): Branch and Bound: How often the local search heuristic should be run in the tree [↔](#)

Default: auto

value	meaning
-1	Automatic.
0	Disabled in the tree.
n>0	Number of nodes between each run.

heurSearchRootCutFreq (*integer*): How frequently to run the local search heuristic during root cutting [↔](#)

This is given as how many cut rounds to perform between runs of the heuristic. Set to zero to avoid applying the heuristic during root cutting. Branch and Bound: This specifies how often the local search heuristic should be run in the tree.

Default: auto

value	meaning
-1	Automatic.
0	Disabled heuristic during cutting.
n>0	Number of cutting rounds between each run.

heurSearchRootSelect (*integer*): Bit vector control for selecting which local search heuristics to apply on the root node of a global solve [↔](#)

Use [heurSearchTreeSelect](#) to control local search heuristics during the tree search.

Some of the local search heuristics will benefit from having an existing incumbent solution, but it is not required.

Default: 117

value	meaning
bit 0 = 1	Local search with a large neighborhood. Potentially slow but is good for finding solutions that differs significantly from the incumbent.
bit 1 = 2	Local search with a small neighborhood centered around a node LP solution.

value	meaning
bit 2 = 4	Local search with a small neighborhood centered around an integer solution. This heuristic will often provide smaller, incremental improvements to an incumbent solution.
bit 3 = 8	Local search with a neighborhood set up through the combination of multiple integer solutions.
bit 4 = 16	Unused
bit 5 = 32	Local search without an objective function. Called seldom and only when no feasible solution is available.
bit 6 = 64	Local search with an auxiliary objective function. Called seldom and only when no feasible solution is available.

heurSearchTreeSelect (*integer*): Bit vector control for selecting which local search heuristics to apply during the tree search of a global solve ↔

Use [heurSearchRootSelect](#) to control local search heuristics on the root node.

Some of the local search heuristics will benefit from having an existing incumbent solution, but it is not required.

Default: 17

value	meaning
bit 0 = 1	Local search with a large neighborhood. Potentially slow but is good for finding solutions that differs significantly from the incumbent.
bit 1 = 2	Local search with a small neighborhood centered around a node LP solution.
bit 2 = 4	Local search with a small neighborhood centered around an integer solution. This heuristic will often provide smaller, incremental improvements to an incumbent solution.
bit 3 = 8	Local search with a neighborhood set up through the combination of multiple integer solutions.
bit 4 = 16	Unused
bit 5 = 32	Local search without an objective function. Called seldom and only when no feasible solution is available.
bit 6 = 64	Local search with an auxiliary objective function. Called seldom and only when no feasible solution is available.

heurThreads (*integer*): Branch and Bound: Number of threads to dedicate to running heuristics on the root node ↔

When heuristic threads are enable, the heuristics will be run in parallel with the initial LP solve, if possible, and in parallel with the root cutting.

Default: 0

value	meaning
-1	Automatically determined from the threads control.
0	Disabled. Heuristics will be run sequentially with the root LP solve and cutting.
>=1	Number of root threads to dedicate to parallel heuristics.

historyCosts (*integer*): Branch and Bound: How to update the pseudo cost for a global entity when a strong branch or a regular branch is applied ↔

Default: `auto`

value	meaning
-1	Automatically determined.
0	No update.
1	Initialize using only regular branches from the root to the current node.
2	Same as 1, but initialize with strong branching results as well.
3	Initialize using any regular branching or strong branching information from all nodes solves before the current node.

ifCheckConvexity (*boolean*): Determines if the convexity of the problem is checked before optimization
↔

Applies to quadratic, mixed integer quadratic and quadratically constrained problems. Checking convexity takes some time, thus for problems that are known to be convex it might be reasonable to switch the checking off.

Default: 1

value	meaning
0	Turn off convexity checking.
1	Turn on convexity checking.

indLinBigM (*real*): During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough ↔

This control defines the largest BigM for which such a linearized version will be added to the problem in addition to the original constraint. If the BigM is even smaller than `indPreLinBigM`, then the original indicator constraint will additionally be dropped from the problem.

`indLinBigM` should always be at least as large as `indPreLinBigM`. For any value less or equal to `indPreLinBigM`, indicator constraints will never be duplicated and only `indPreLinBigM` is taken into account for linearization.

Range: $[0, \infty]$

Default: 100000

indPreLinBigM (*real*): During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough ↔

This control defines the largest BigM for which the original constraint will be replaced by the linearized version. If the BigM is larger than `indPreLinBigM` but smaller than `indLinBigM`, the linearized row will be added but the original indicator constraint is kept as a numerically stable way to check feasibility.

Replacing an indicator constraint with a BigM row has a side effect on tolerances. In the indicator constraint form, the constraint part is satisfied with `feasTol` tolerance; while after changing it to BigM form, the constraint also includes the binary indicator variable (with a coefficient up to `indPreLinBigM` and an integrality tolerance of `mipTol`), therefore the constraint part of the indicator constraint is satisfied with tolerance `feasTol+mipTol*indPreLinBigM`.

Range: $[0, \infty]$

Default: 100

inputTol (*real*): Tolerance on input values elements ↔

If any value is than or equal to **inputTol** in absolute value, it is treated as zero. The control applies to input functions. For the internal zero tolerance see **matrixTol**.

Range: $[0, \infty]$

Default: 0

invertFreq (*integer*): Simplex: Frequency with which the basis will be inverted ↔

The basis is maintained in a factorized form and on most simplex iterations it is incrementally updated to reflect the step just taken. This is considerably faster than computing the full inverted matrix at each iteration, although after a number of iterations the basis becomes less well-conditioned and it becomes necessary to compute the full inverted matrix. The value of **invertFreq** specifies the maximum number of iterations between full inversions.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

invertMin (*integer*): Simplex: Minimum number of iterations between full inversions of the basis matrix ↔

See the description of **invertFreq** for details.

Range: $\{0, \dots, \infty\}$

Default: 3

ioTimeout (*integer*): Maximum number of seconds to wait for an I/O operation before it is cancelled ↔

Range: $\{0, \dots, \infty\}$

Default: 30

knitroOptFile (*string*): Option file for NLP solver **KNITRO** ↔

l1Cache (*integer*): Newton barrier: L1 cache size in kB (kilo bytes) of the CPU ↔

On Intel (or compatible) platforms a value of -1 may be used to determine the cache size automatically.

Specifying the correct L1 cache size can give a significant performance advantage with the Newton barrier algorithm. If the size is unknown, it is better to specify a smaller size. If the size cannot be determined automatically on Intel (or compatible) platforms, a default size of 8 kB is assumed.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

inpBest (*integer*): Number of infeasible global entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see **gomCuts**) ↔

Range: $\{0, \dots, \infty\}$

Default: 50

lnpIterLimit (*integer*): Number of iterations to perform in improving each lift-and-project cut [↔](#)

By setting the number to zero a Gomory cut will be created instead.

Range: $\{-1, \dots, \infty\}$

Default: auto

loadMipSol (*boolean*): Loads a MIP solution (the initial point) [↔](#)

If true, the initial point provided by GAMS will be passed to the optimizer to be treated as an integer feasible point. The optimizer uses the values for the discrete variables only: the level values for the continuous variables are ignored and are calculated by fixing the integer variables and reoptimizing. In some cases, loading an initial MIP solution can improve performance. In addition, there will always be a feasible solution to return.

Default: 0

localChoice (*integer*): Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree [↔](#)

Default: auto

value	meaning
1	Never backtrack from the first child, unless it is dropped (infeasible or cut off).
2	Always solve both child nodes before deciding which child to continue with.
3	Automatically determined.

lpFlags (*integer*): Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem [↔](#)

When more than one bit is set, then the LP problem will be solved with the concurrent solver. When this control and **algorithm** is set at the same time, **algorithm** will overrule the value of this control.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

value	meaning
bit 0 = 1	Equivalent to lpFlags_dual .
bit 1 = 2	Equivalent to lpFlags_primal .
bit 2 = 4	Equivalent to lpFlags_barrier .
bit 3 = 8	Equivalent to lpFlags_network .

lpFlags_barrier (*boolean*): Use the barrier method [↔](#)

See also [lpFlags](#).

Default: 0

lpFlags_dual (*boolean*): Use the dual simplex method [↔](#)

See also [lpFlags](#).

Default: 0

lpFlags_network (*boolean*): Use the network simplex method [↔](#)

See also [lpFlags](#).

Default: 0

lpFlags_primal (*boolean*): Use the primal simplex method [↔](#)

See also [lpFlags](#).

Default: 0

lpFolding (*integer*): Simplex and barrier: Whether to fold an LP problem before solving it [↔](#)

Default: auto

value	meaning
-1	Automatic.
0	Disable LP folding.
1	Enable LP folding. Attempt to fold all LP problems and MIP initial relaxations.

lpIterLimit (*integer*): Maximum number of iterations that will be performed by primal simplex or dual simplex before the optimization process terminates [↔](#)

Synonym: iterlim

For MIP problems, this is the maximum total number of iterations over all nodes explored by the Branch and Bound method.

Range: {0, ..., ∞}

Default: maxint

lpLog (*integer*): Simplex: Frequency at which the simplex log is printed [↔](#)

This control only has an effect if [lpLogStyle](#) is set to 0.

Default: 100

value	meaning
0	Log displayed at the end of the optimization only.
n<0	Detailed output every - n iterations.
n>0	Summary output every n iterations.

lpLogDelay (*real*): Time interval between two LP log lines [↔](#)

This control only has an effect if [lpLogStyle](#) is set to 1.

Range: $[0, \infty]$

Default: 1

lpLogStyle (*boolean*): Simplex: Style of the simplex log \leftrightarrow

Default: 1

value	meaning
0	Simplex log is printed based on simplex iteration count, at a fixed frequency as specified by the lpLog control.
1	Simplex Log is printed based on an estimation of elapsed time, determined by an internal deterministic timer.

lpRefineIterLimit (*integer*): Simplex iteration limit the solution refiner can spend in attempting to increase the accuracy of an LP solution \leftrightarrow

The solution refiner iteratively attempts to increase the accuracy of the solution until either both [feasTolTarget](#) and [optimalityTolTarget](#) is satisfied, or accuracy cannot further be increased, or the effort limit determined by [lpRefineIterLimit](#) is exhausted.

Range: $\{-1, \dots, \infty\}$

Default: auto

lpThreads (*integer*): Parameter is deprecated and will be removed in a future release \leftrightarrow

This control is provided for compatibility purposes. Please use [concurrentThreads](#) instead.

The value of this control is mirrored by the [concurrentThreads](#) control.

Range: $\{-1, \dots, \infty\}$

Default: -1

markowitzTol (*real*): Markowitz tolerance used for the factorization of the basis matrix \leftrightarrow

Range: $[0, \infty]$

Default: 0.01

matrixTol (*real*): Zero tolerance on matrix elements \leftrightarrow

If the value of a matrix element is less than or equal to [matrixTol](#) in absolute value, it is treated as zero. The control applies when solving a problem, for an input tolerance see [inputTol](#).

Range: $[0, \infty]$

Default: 1e-09

maxCutTime (*integer*): Maximum amount of time allowed for generation of cutting planes and reoptimization \leftrightarrow

The limit is checked during generation and no further cuts are added once this limit has been exceeded.

Default: 0

value	meaning
0	No time limit.
n>0	Stop cut generation after n seconds.

maxImpliedBound (*real*): Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than [maxImpliedBound](#) will be applied to the problem ↔

For numerically challenging MIP problems, it can sometimes help make the solve more stable by reducing the value of [maxImpliedBound](#) to something smaller - e.g. 1.0E+06. It is not recommended to increase this parameter beyond the default of 1.0E+08.

Range: $[0, \infty]$

Default: 1e+08

maxLocalBacktrack (*integer*): Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node ↔

If this control is set to k, then the candidate set of nodes for a local backtrack will consist of all active nodes in the subtree rooted at height k above the current node. For example, a setting of 1 will result in only sibling nodes of the current node being considered.

Default: auto

value	meaning
-1	Automatic.
n>0	Local backtrack limit.

maxMemoryHard (*integer*): Sets the maximum amount of memory in megabytes the optimizer should allocate ↔

If this limit is exceeded, the solve will terminate. This control is designed to make the optimizer stop in a controlled manner, so that the problem object is valid once termination occurs. The solve state will be set to incomplete. This is different to an out of memory condition in which case the optimizer returns an error. The optimizer may still allocate memory once the limit is exceeded to be able to finish the operations and stop in a controlled manner. When [resourceStrategy](#) is enabled, the control also has the same effect as [maxMemorySoft](#) and will cause the optimizer to try preserving memory when possible.

Range: $\{0, \dots, \infty\}$

Default: unlimited

maxMemorySoft (*integer*): When [resourceStrategy](#) is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate ↔

This may change the solving path, but will not cause the solve to terminate early. To set a hard version of the same, please set [maxMemoryHard](#).

Range: $\{0, \dots, \infty\}$

Default: unlimited

maxMipSol (*integer*): Branch and Bound: Limit on the number of integer solutions to be found by the Optimizer ↔

It is possible that during optimization the Optimizer will find the same objective solution from different nodes. However, `maxMipSol` refers to the total number of integer solutions found, and not necessarily the number of distinct solutions.

Setting `maxMipSol=1` can alter the solution path as this will put the emphasis on finding any feasible solution by triggering additional heuristics.

Range: $\{0, \dots, \infty\}$

Default: 0

maxMipTasks (*integer*): Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve ↩

The MIP solver will create smaller tasks from individual active nodes or based on local search heuristics. These are tasks that will be executed in parallel by the number of threads set by `mipThreads`.

If `maxMipTasks` is set to a fixed, positive value, the branch-and-bound tree nodes will always be solved in the same deterministic way, independent of the actual number of executing threads implied by `mipThreads`. How a MIP is solved will still depend on the number of threads used for solving the continuous relaxation and therefore on the settings for the controls `barThreads`, `barCores`, `dualThreads` and `concurrentThreads`). To obtain a MIP solve that is completely independent of the number of threads, it is sufficient to set `maxMipTasks`, `forceParallelDual`, `barThreads` and `barCores`. The concurrent LP solver should be avoided in this case.

The number of MIP tasks that can be defined for a 32-bit system is limited to 32 for performance reasons.

Default: auto

value	meaning
-1	Task limit determined automatically from <code>mipThreads</code> .
>0	Fixed task limit.

maxNode (*integer*): Branch and Bound: Maximum number of nodes that will be explored ↩

Range: $\{0, \dots, \infty\}$

Default: `maxint`

maxScaleFactor (*integer*): Determines the maximum scaling factor that can be applied during scaling ↩

The maximum is provided as an exponent of a power of 2.

Default: 64

value	meaning
0-64	The maximum is provided an exponent of a power of 2.

maxStallTime (*integer*): Maximum time in seconds that the Optimizer will continue to search for improving solution after finding a new incumbent ↩

Default: 0

value	meaning
0	No stall time limit.
n>0	If an integer solution has been found, stop MIP search after n seconds without a new incumbent. No effect as long as no solution was found.

maxTime (*integer*): Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time ↔

For MIP problems, this is the total time taken to solve all the nodes.

Default: 0

value	meaning
0	No time limit.
n<0	Stop in LP or MIP search after n seconds.
n>0	If an integer solution has been found, stop MIP search after n seconds, otherwise continue until an integer solution is finally found.

mipAbsCutoff (*real*): Branch and Bound: If the user knows that they are interested only in values of the objective function which are better than some value, this can be assigned to [mipAbsCutoff](#) ↔

This allows the Optimizer to ignore solving any nodes which may yield worse objective values, saving solution time.

Range: $[-\infty, \infty]$

Default: `auto`

mipAbsStop (*real*): Branch and Bound: Absolute tolerance determining whether the global search will continue or not ↔

It will terminate if $|\text{MIPOBJVAL} - \text{BESTBOUND}| \leq \text{mipAbsStop}$ where MIPOBJVAL is the value of the best solution's objective function, and BESTBOUND is the current best solution bound. For example, to stop the global search when a MIP solution has been found and the Optimizer can guarantee it is within 100 of the optimal solution, set [mipAbsStop](#) to 100.

Range: $[0, \infty]$

Default: 0

mipAddCutoff (*real*): Branch and Bound: Amount to add to the objective function of the best integer solution found to give the new CURRMIPCUTOFF ↔

Once an integer solution has been found whose objective function is equal to or better than CURRMIPCUTOFF, improvements on this value may not be interesting unless they are better by at least a certain amount. If [mipAddCutoff](#) is nonzero, it will be added to CURRMIPCUTOFF each time an integer solution is found which is better than this new value. This cuts off sections of the tree whose solutions would not represent substantial improvements in the objective function, saving processor time. The control [mipAbsStop](#) provides a similar function but works in a different way.

Range: $[-\infty, \infty]$

Default: 0

mipCleanup (*boolean*): Clean up the MIP solution (round-fix-solve) to get duals ↔

If nonzero, clean up the integer solution obtained, i.e. round and fix the discrete variables and re-solve as an LP to get some marginal values for the discrete vars.

Default: 1

mipComponents (*integer*): Determines whether disconnected components in a MIP should be solved as separate MIPs ↔

There can be significant performance benefits from solving disconnected components individual instead of being part of the main branch-and-bound search.

If there are no constraints linking two variables, either directly or indirectly through other variables, they are said to belong to two separate disconnected components. When a problem contains disconnected components of significant size, it can be advantageous to solve each component as a separate MIP. When significant disconnected components are detected in the problem, the solver will switch to a different solve mode where each component is solved separately. This switch will happen after the root node processing has completed and when the solve is about to enter the branch-and-bound search.

Solving disconnected components separately is not compatible with concurrent MIP solves. If concurrent MIP solves has been turned off, disconnected components will be solved as part of the standard branch-and-bound search in each concurrent solve.

Disabling MIP dual reductions through [mipDualReductions](#) will also disable the separate solve of disconnected components.

Default: auto

value	meaning
-1	Automatic - let the solver decide.
0	Disable solving disconnected components separately.
1	Solve disconnected components separately.

mipConcurrentNodes (*integer*): Sets the node limit for when a winning solve is selected when concurrent MIP solves are enabled ↔

When multiple MIP solves are started, they each run up to the [mipConcurrentNodes](#) node limit and only one winning solve is selected for continuing the search with.

Default: auto

value	meaning
-1	Automatic - let the solver decide on a node limit.
>0	Number of nodes each concurrent solve should complete before a winner is selected.

mipConcurrentSolves (*integer*): Selects the number of concurrent solves to start for a MIP ↔

Each solve will use a unique random seed for its random number generator, but will otherwise apply the same user controls. The first concurrent solve to complete will have solved the MIP and all the concurrent solves will be terminated at this point. Using concurrent solves can be advantageous when a MIP displays a high level of performance variability.

A node limit is imposed on each concurrent solve, through [mipConcurrentNodes](#). When a concurrent solve reaches this node limit, it will be suspended until all concurrent solves have reached the limit. At this point a winner will be declared, based on which solve made the most progress towards optimality and only the winning solve will continue, using all threading resources. If a concurrent solve completes its MIP search before reaching the node limit, all solves will be stopped.

Default: 0

value	meaning
-1	Enabled. The number of concurrent solves depends on mipThreads .
n>1	Enabled. The number of concurrent solves to start is given by n.
0, 1	Disabled

mipDualReductions (*integer*): Branch and Bound: Limits operations that can reduce the MIP solution space ↔

The [mipDualReductions](#) control, when set to a value different from 1 will adjust the values of other controls in order to prevent MIP solver operations that can result in the removal of dominated solutions. For example, dual reductions during preprocessing attempts to remove dominated solutions based on objective arguments, assuming that all constraints are known to the Optimizer. If a problem is detected to have symmetries, the solver might also remove some symmetrical solutions from the search space. In both cases, the set of feasible MIP solutions might be reduced. With default settings, it is only guaranteed that at least one optimal solution remains.

When attempting to collect the n-best solutions, it is recommended to set [mipDualReductions](#)=2. This will ensure that the only solutions missed by the enumeration are those that only differ from an existing solution in the values of the continuous variables.

Default: 1

value	meaning
0	Prevent all dual reductions.
1	Allow all dual reductions.
2	Allow dual reductions on continuous variables only.

mipFracReduce (*integer*): Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions ↔

This heuristic is only applicable to problems that are dual degenerate. These are problems that contain multiple solutions with identical objective function value. The more dual degenerate a problem is, the more likely it will be for this heuristic to have an improving effect.

Default: auto

value	meaning
-1	Automatic.
0	Disabled.
1	Run before and after cutting on the root node.
2	Run also during root cutting.
3	Run also during the tree search.

mipKappaFreq (*integer*): Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search ↔

The condition number is calculated as the norm of the basis matrix multiplied by the norm of its inverse. This uses the Froebenius norm.

A summary will be printed at the end of the solve, summarizing the collected condition numbers collected:

- Nodes kappa stable: No. of stable sampled nodes ($\text{kappa} < 10^7$)
- Nodes kappa suspicious: No. of suspicious sampled nodes ($10^7 \leq \text{kappa} < 10^{10}$)
- Nodes kappa unstable: No. of unstable sampled nodes ($10^{10} \leq \text{kappa} < 10^{13}$)
- Nodes kappa ill-posed: No. of ill-posed sampled nodes ($10^{13} \leq \text{kappa}$)
- Largest kappa seen: The largest condition number calculated through all sampled nodes.
- Kappa attention level: A measure of how ill-posed the problem is (between 0 and 1).

Default: 0

value	meaning
0	Do not calculate condition numbers.
1	Calculate conditions numbers on every node, including after each round of root cutting.
n>1	Calculate a condition number once per node of every n'th level of the branch-and-bound tree.

mipLog (*integer*): Global print control ↔

Default: -100

value	meaning
0	No printout in global.
1	Only print out summary statement at the end.
2	Print out detailed log at all solutions found.
3	Print out detailed log at each node.
-n	Print out summary log at each n th node.

mipPresolve (*integer*): Branch and Bound: Type of integer processing to be performed ↔

If set to 0, no processing will be performed.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -1

value	meaning
bit 0 = 1	Equivalent to mipPresolve_reducedCostFixing .
bit 1 = 2	Equivalent to mipPresolve_logicPreprocessing .
bit 2 = 4	[Unused] This bit is no longer used to control probing. Refer to the integer control preProbing for setting probing level during presolve.
bit 3 = 8	Equivalent to mipPresolve_allowChangeBounds .

value	meaning
bit 4 = 16	Equivalent to mipPresolve_dualReductions .
bit 5 = 32	Equivalent to mipPresolve_globalCoefTightening .
bit 6 = 64	Equivalent to mipPresolve_objBasedReductions .
bit 7 = 128	Equivalent to mipPresolve_allowTreeRestart .
bit 8 = 256	Equivalent to mipPresolve_symmetryReductions .

mipPresolve_allowChangeBounds (*boolean*): If node preprocessing is allowed to change bounds on continuous columns [↔](#)

See also [mipPresolve](#).

Default: 1

mipPresolve_allowTreeRestart (*boolean*): Allow the branch-and-bound tree search to be restarted if it appears to be advantageous [↔](#)

See also [mipPresolve](#).

Default: 1

mipPresolve_dualReductions (*boolean*): Dual reductions will be performed at each node [↔](#)

See also [mipPresolve](#).

Default: 1

mipPresolve_globalCoefTightening (*boolean*): Allow global (non-bound) tightening of the problem during the tree search [↔](#)

See also [mipPresolve](#).

Default: 1

mipPresolve_logicPreprocessing (*boolean*): Primal reductions will be performed at each node [↔](#)

Uses constraints of the node to tighten the range of variables, often resulting in fixing their values. This greatly simplifies the problem and may even determine optimality or infeasibility of the node.

See also [mipPresolve](#).

Default: 1

mipPresolve_objBasedReductions (*boolean*): Objective function will be used to find reductions at each node [↔](#)

See also [mipPresolve](#).

Default: 1

mipPresolve_reducedCostFixing (*boolean*): Reduced cost fixing will be performed at each node [↔](#)

This can simplify the node before it is solved, by deducing that certain variables' values can be fixed based on additional bounds imposed on other variables at this node.

See also [mipPresolve](#).

Default: 1

mipPresolve_symmetryReductions (*boolean*): Allow that symmetry is used to presolve the node problem ↔

See also [mipPresolve](#).

Default: 1

mipRampUp (*integer*): Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search ↔

The branch-and-bound tree search starts from the single root node, and only through branching on this root node and the resulting child nodes, are enough active nodes created to produce sufficient tasks to keep all MIP workers busy. This is referred to as the ramp-up phase of a parallel MIP. In a typical MIP solve, the solutions found during the initial dives will typically provide a significant improvement over the root heuristic solutions. It can therefore be advantageous to let these initial dives run as fast as possible, by limiting resource contention. This can be accomplished by restricting the number of parallel tasks and thereby reducing the memory bus contention. The [mipRampUp](#) control can be used to turn this initial task restriction of a parallel MIP solve on or off.

Default: auto

value	meaning
-1	Automatically determined.
0	No special treatment during the ramp-up phase. Always run with the maximal number of tasks.
1	Limit the number of tasks until the initial dives have completed.

mipRefineIterLimit (*integer*): Defines an effort limit expressed as simplex iterations for the MIP solution refiner ↔

The limit is per reoptimizations in the MIP refiner.

Range: $\{-1, \dots, \infty\}$

Default: auto

mipRelCutoff (*real*): Branch and Bound: Percentage of the LP solution value to be added to the value of the objective function when an integer solution is found, to give the new value of CURRMIPCUTOFF ↔

The effect is to cut off the search in parts of the tree whose best possible objective function would not be substantially better than the current solution. The control [mipRelStop](#) provides a similar functionality but works in a different way.

Range: $[0, \infty]$

Default: 0

mipRelStop (*real*): Branch and Bound: Determines when the global search will terminate ↔

Global search will stop if: $| \text{MIPOBJVAL} - \text{BESTBOUND} | \leq \text{mipRelStop} \times \max(| \text{BESTBOUND} |, | \text{MIPOBJVAL} |)$ where MIPOBJVAL is the value of the best solution's objective function and BESTBOUND is the current best solution bound. For example, to stop the global search when a MIP solution has been found and the Optimizer can guarantee it is within 5% of the optimal solution, set **mipRelStop** to 0.05.

This control is a stopping criteria only and different values of the control will not affect the solution path before termination. Unlike other stopping criteria, like time and node count, termination on **mipRelStop** will cause the final solution to be declared optimal and the problem to be returned to its original state.

Tolerances, such as **mipRelCutoff** and **mipAbsCutoff**, determine how much the objective value of a new MIP solution has to differ from the incumbent for it to be accepted. These controls therefore also influence the final gap at the end of a MIP solve.

Range: $[0, \infty]$

Default: 0.0001

mipRestart (*integer*): Branch and Bound: Controls strategy for in-tree restarts ↔

Default: auto

value	meaning
-1	Determined automatically (XPRS_MIPRESTART_DEFAULT).
0	Disable in-tree restarts (XPRS_MIPRESTART_OFF).
1	Allow in-tree restarts at normal aggressiveness (XPRS_MIPRESTART_MODERATE).
2	Allow in-tree restarts at higher aggressiveness (more likely to trigger a restart) (XPRS_MIPRESTART_AGGRESSIVE).

mipRestartFactor (*real*): Branch and Bound: Fine tune initial conditions to trigger an in-tree restart ↔

Use a value > 1 to increase the aggressiveness with which the Optimizer restarts. Use a value < 1 to relax the aggressiveness with which the Optimizer restarts. Note that this control does not affect the initial condition on the gap, which must be set separately.

Range: $[0, \infty]$

Default: 1

mipRestartGapThreshold (*real*): Branch and Bound: Initial gap threshold to delay in-tree restart ↔

The restart is delayed initially if the gap, given as a fraction between 0 and 1, is below this threshold. The optimizer adjusts the threshold every time a restart is delayed. Note that there are other criteria that can delay or prevent a restart.

Range: $[0, 1]$

Default: 0.02

mipstopexpr (*string*): Stopping expression for branch and bound ↔

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: `resusd`, `nodusd`, `objest`, `objval`. Supported operators are: `+`, `-`, `*`, `/`, `^`, `%`, `!=`, `==`, `<`, `<=`, `>`, `>=`, `!`, `&&`, `||`, `(`, `)`, `abs`, `ceil`, `exp`, `floor`, `log`, `log10`, `pow`, `sqrt`. Example:
`nodusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1`

mipThreads (*integer*): If set to a positive integer it determines the number of threads implemented to run the parallel MIP code ↔

If `mipThreads` is set to the default value (-1), the `threads` control will determine the number of threads used.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

mipTol (*real*): Branch and Bound: Tolerance within which a decision variable's value is considered to be integral ↔

Range: $[0, \infty]$

Default: `5e-06`

mipToltarget (*real*): Target `mipTol` value used by the automatic MIP solution refiner as defined by `refineOps` ↔

Negative and zero values are ignored.

Refining solutions to match the `mipToltarget` can influence and worsen their objective value in case the previous objective could only be achieved through slight infeasibilities.

Range: $[-\infty, \infty]$

Default: `0`

mipTrace (*string*): Name of MIP trace file ↔

A `miptrace` file with the specified name will be created. This file records the best integer and best bound values every `mipTraceNode` nodes and at `mipTraceTime`-second intervals.

Default: `none`

mipTraceNode (*integer*): Node interval between MIP trace file entries ↔

Default: `100`

mipTraceTime (*real*): Time interval, in seconds, between MIP trace file entries ↔

Default: `5`

miqcpAlg (*integer*): Determines which algorithm is to be used to solve mixed integer quadratic constrained and mixed integer second order cone problems ↔

Default: `auto`

value	meaning
-1	Determined automatically.
0	Use the barrier algorithm in the branch and bound algorithm.
1	Use outer approximations in the branch and bound algorithm.

mpsNameLength (*integer*): Maximum length of MPS names in characters ↔

Internally it is rounded up to the smallest multiple of 8. MPS names are right padded with blanks. Maximum value is 64.

Range: {0, ..., ∞}

Default: 0

mpsOutputFile (*string*): Name of MPS output file ↔

If specified XPRESS-MP will generate an MPS file corresponding to the GAMS model: the argument is the file name to be used. You can prefix the file name with an absolute or relative path.

Default: none

netCuts (*integer*): Determines the addition of multi-commodity network cuts to a problem ↔

The parameter is defined as a bit string, and values 1, 2, 4 can be summed up if the user wants more classes of cuts to be added.

If the user wants to add both cut-set inequalities and lifted flow-cover inequalities but not node cut-set inequalities, the value of the control should be set to 1+4=5.

Default: 0

value	meaning
-1	Automatically determined.
0	Do not add these cuts.
1	Add cut-set inequalities.
2	Add node cut-set inequalities, i.e., cut-set inequalities that are based on a network cut defined on a single network node.
4	Add lifted flow-cover inequalities.

netStallLimit (*integer*): Limit the number of degenerate pivots of the network simplex algorithm, before switching to either primal or dual simplex, depending on [algAfterNetwork](#) ↔

Default: auto

value	meaning
-1	Automatically determined limit
0	No limit.
n>0	Limit to n network simplex iterations.

nodeProbingEffort (*real*): Adjusts the overall level of node probing ↔

[nodeProbingEffort](#) is used as a multiplier on the default amount of work node probing should do. Setting the control to zero disables node probing.

Range: [0, ∞]

Default: 1

nodeSelection (*integer*): Branch and Bound: Determines which nodes will be considered for solution once the current node has been solved ↔

Default: `auto`

value	meaning
1	Local first: Choose between descendant and sibling nodes if available; choose from all outstanding nodes otherwise.
2	Best first: Choose from all outstanding nodes.
3	Local depth first: Choose between descendant and sibling nodes if available; choose from the deepest nodes otherwise.
4	Best first, then local first: Best first is used for the first <code>breadthFirst</code> nodes, after which local first is used.
5	Pure depth first: Choose from the deepest outstanding nodes.

objGoodEnough (*real*): Stop once an objective this good is found ↔

Default: `none`

objScaleFactor (*integer*): Custom global objective scaling factor, expressed as a power of 2 ↔

When set, it overwrites the automatic global objective scaling factor. A value of 0 means no objective scaling. This control is applied for the full solve, and is independent of any extra scaling that may occur specifically for the barrier or simplex solvers. As it is a power of 2, to scale by 16, set the value of the control to 4.

Range: $\{0, \dots, \infty\}$

Default: 0

optimalityTol (*real*): Simplex: Zero tolerance for reduced costs ↔

On each iteration, the simplex method searches for a variable to enter the basis which has a negative reduced cost. The candidates are only those variables which have reduced costs less than the negative value of `optimalityTol`.

Range: $[0, \infty]$

Default: `1e-06`

optimalityTolTarget (*real*): Target optimality tolerance for the solution refiner ↔

Zero and negative values are ignored, and the value of `optimalityTol` is used.

Use very small values like `1e-100` to state the refinement should continue as long as an improvement is made. Use very large values like `1e+100` to disable only this aspect of the refiner.

Refining solutions to match the `optimalitytoltarget` can influence and increase their infeasibility in case the previous feasibility could only be achieved through slight dual violations.

Range: $[-\infty, \infty]$

Default: 0

outputControls (*boolean*): Toggles the printing of all control settings at the beginning of the search ↔

This includes the printing of controls that have been explicitly assigned to their default value. All unset controls are omitted as they keep their default value.

Setting `outputControls` to 0 has no effect on the function `XPRSDumpcontrols`

Default: 1

value	meaning
0	Turn off printing of user-specified control settings.
1	Print controls.

outputLog (*integer*): Controls the level of output produced by the Optimizer during optimization ↔

Default: 1

value	meaning
0	Turn all output off.
1	Print all messages.
3	Print error and warning messages.
4	Print error messages only.

outputTol (*real*): Zero tolerance on print values ↔

Range: $[0, \infty]$

Default: $1e-05$

penalty (*real*): Minimum absolute penalty variable coefficient ↔

Range: $[0, \infty]$

Default: auto

pivotTol (*real*): Simplex: Zero tolerance for matrix elements ↔

On each iteration, the simplex method seeks a nonzero matrix element to pivot on. Any element with absolute value less than **pivotTol** is treated as zero for this purpose.

Range: $[0, \infty]$

Default: $1e-09$

ppFactor (*real*): Partial pricing candidate list sizing parameter ↔

Range: $[0, \infty]$

Default: 1

preAnalyticCenter (*integer*): Determines if analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs (-1: Auto 0: Off, 1: Fixing, 2: Redcost, 3: Both) ↔

Default: auto

value	meaning
-1	Automatic.
0	Disable analytic center presolving.
1	Use analytic center for variable fixing only.
2	Use analytic center for reduced cost computation only.
3	Use analytic centers for both, variable fixing and reduced cost computation.

preBasisRed (*integer*): Determines if a lattice basis reduction algorithm should be attempted as part of presolve \leftrightarrow

Default: 0

value	meaning
-1	Automatic.
0	Disable basis reduction.
1	Enable basis reduction.

preBndRedCone (*integer*): Determines if second order cone constraints should be used for inferring bound reductions on variables when solving a MIP \leftrightarrow

Default: auto

value	meaning
-1	Automatic.
0	Disable bound reductions from second order cone constraints.
1	Enable bound reductions from second order cone constraints.

preBndRedQuad (*integer*): Determines if convex quadratic constraints should be used for inferring bound reductions on variables when solving a MIP \leftrightarrow

Default: auto

value	meaning
-1	Automatic.
0	Disable bound reductions from quadratic constraints.
1	Enable bound reductions from quadratic constraints.

preCliqueStrategy (*integer*): Determines how much effort to spend on clique covers in presolve \leftrightarrow

Range: $\{-1, \dots, \infty\}$

Default: -1

preCoefElim (*integer*): Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem \leftrightarrow

Default: 2

value	meaning
0	Disabled.
1	Remove as many coefficients as possible.
2	Cautious eliminations. Will not perform a reduction if it might destroy problem structure useful to e.g. heuristics or cutting.

preComponents (*integer*): Presolve: Determines whether small independent components should be detected and solved as individual subproblems during root node processing \leftrightarrow

Default: auto

value	meaning
-1	Automatically determined.
0	Disable detection of independent components.
1	Enable detection of independent components.

preComponentsEffort (*real*): Presolve: Adjusts the overall effort for the independent component presolver [↔](#)

This control affects working limits for the subproblem solving as well as thresholds when it is called. Increase to put more emphasis on component presolving.

Range: $[0, \infty]$

Default: 1

preConeDecomp (*integer*): Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components [↔](#)

Default: auto

value	meaning
-1	Automatically determined.
0	Disable cone decomposition.
1	Enable cone decomposition by replacing large cones with small ones in the presolved problem.
2	Similar to 1, plus decomposition is enabled even if the cone variable is fixed.
3	Cones are decomposed within the Outer Approximation domain only, i.e., the problem maintains the original cones.

preConvertSeparable (*integer*): Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints [↔](#)

This control is only used in MIQPs and MIQCQPs, and has no effect when used on continuous quadratic problems.

Default: auto

value	meaning
-1	Automatically determined.
0	Disable reformulation.
1	Enable reformulation to diagonal quadratic constraints.
2	Similar to 1, plus reduction to second-order cones.
3	Similar to 2, plus the objective function is converted to a constraint and treated as a quadratic constraint.

preDomCol (*integer*): Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem [↔](#)

Only binary columns will be checked.

Default: auto

value	meaning
-1	Automatically determined.
0	Disabled.
1	Cautious strategy.
2	All candidate binaries will be checked for domination.

preDomRow (*integer*): Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem ↔

Default: auto

value	meaning
-1	Automatically determined.
0	Disabled.
1	Cautious strategy.
2	Medium strategy.
3	Aggressive strategy. All candidate row combinations will be considered.

preDupRow (*integer*): Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem ↔

Duplicate rows can also be disabled by clearing the corresponding bit of the [presolveOps](#) integer control.

Default: auto

value	meaning
-1	Automatically determined.
0	Do not eliminate duplicate rows.
1	Eliminate only rows that are identical in all variables.
2	Same as option 1 plus eliminate duplicate rows with simple penalty variable expressions. (MIP only).
3	Same as option 2 plus eliminate duplicate rows with more complex penalty variable expressions. (MIP only).

preElimQuad (*integer*): Presolve: Allows for elimination of quadratic variables via doubleton rows ↔

Default: auto

value	meaning
-1	Automatically determined.
0	Do not eliminate duplicate rows.
1	Eliminate at least one quadratic variable for each doubleton row.

preFolding (*integer*): Presolve: Determines if a folding procedure should be used to aggregate continuous columns in an equitable partition ↔

Default: auto

value	meaning
-1	Automatically determined.
0	Disabled.
1	Enabled.

preImplications (*integer*): Presolve: Determines whether to use implication structures to remove redundant rows ↔

If implication sequences are detected, they might also be used in probing.

Default: `auto`

value	meaning
-1	Automatically determined.
0	Do not use implications for sparsification.
1	Use implications to remove redundant rows.

preLinDep (*integer*): Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem ↔

Default: `auto`

value	meaning
-1	Automatically determined.
0	Do not check for linearly dependent equality constraints.
1	Check for and remove linearly dependent equality constraints.

preObjCutDetect (*boolean*): Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed ↔

This reduction applies to MIPs only.

Default: `1`

value	meaning
0	Disable check and reductions.
1	Enable check and reductions.

preProbing (*integer*): Presolve: Amount of probing to perform on binary variables during presolve ↔

This is done by fixing a binary to each of its values in turn and analyzing the implications.

Default: `auto`

value	meaning
-1	Let the optimizer decide on the amount of probing.
0	Disabled.
1	Light probing — only few implications will be examined.
2	Full probing — all implications for all binaries will be examined.
3	Full probing and repeat as long as the problem is significantly reduced.

presolve (*integer*): Determines whether presolving should be performed prior to starting the main algorithm ↔

Presolve attempts to simplify the problem by detecting and removing redundant constraints, tightening variable bounds, etc. In some cases, infeasibility may even be determined at this stage, or the optimal solution found.

Memory for presolve is dynamically resized. If the Optimizer runs out of memory for presolve, an error message (245) is produced. Presolve settings 2 and 3 can sometimes make the barrier solves more efficient.

Default: 1

value	meaning
-1	Presolve applied, but a problem will not be declared infeasible if primal infeasibilities are detected. The problem will be solved by the LP optimization algorithm, returning an infeasible solution, which can sometimes be helpful.
0	Presolve not applied.
1	Presolve applied.
2	Presolve applied, but redundant bounds are not removed. This can sometimes increase the efficiency of the barrier algorithm.
3	Presolve is applied, and bounds detected to be redundant are always removed.

presolveMaxGrow (*real*): Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem ↔

Range: $[0, \infty]$

Default: 0.1

presolveOps (*integer*): Specifies the operations which are performed during the presolve ↔

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 511

value	meaning
bit 0 = 1	Equivalent to presolveOps_singletonColRemoval .
bit 1 = 2	Equivalent to presolveOps_singletonRowRemoval .
bit 2 = 4	Equivalent to presolveOps_forcingRowRemoval .
bit 3 = 8	Equivalent to presolveOps_dualReductions .
bit 4 = 16	Equivalent to presolveOps_redundantRowRemoval .
bit 5 = 32	Equivalent to presolveOps_duplicateColRemoval .
bit 6 = 64	Equivalent to presolveOps_duplicateRowRemoval .
bit 7 = 128	Equivalent to presolveOps_strongDualReductions .
bit 8 = 256	Equivalent to presolveOps_variableEliminations .
bit 9 = 512	Equivalent to presolveOps_noIpReductions .
bit 10 = 1024	Equivalent to presolveOps_noGlobalDomainChange .
bit 11 = 2048	Equivalent to presolveOps_noAdvIpReductions .
bit 12 = 4096	Equivalent to presolveOps_noIntVarEliminations .
bit 14 = 16384	Equivalent to presolveOps_linDependRowRemoval .
bit 15 = 32768	Equivalent to presolveOps_noIntVarAndSosDetect .

presolveOps_dualReductions (*boolean*): Dual reductions ↔

See also [presolveOps](#).

Default: 1

presolveOps_duplicateColRemoval (*boolean*): Duplicate column removal ↔

See also [presolveOps](#).

Default: 1

presolveOps_duplicateRowRemoval (*boolean*): Duplicate row removal ↔

See also [presolveOps](#).

Default: 1

presolveOps_forcingRowRemoval (*boolean*): Forcing row removal ↔

See also [presolveOps](#).

Default: 1

presolveOps_linDependRowRemoval (*boolean*): Linearly dependant row removal ↔

See also [presolveOps](#).

Default: 0

presolveOps_noAdvIpReductions (*boolean*): No advanced IP reductions ↔

See also [presolveOps](#).

Default: 0

presolveOps_noGlobalDomainChange (*boolean*): No semi-continuous variable detection ↔

See also [presolveOps](#).

Default: 0

presolveOps_noIntVarAndSosDetect (*boolean*): No integer variable and SOS detection ↔

See also [presolveOps](#).

Default: 0

presolveOps_noIntVarEliminations (*boolean*): No eliminations on integers ↔

See also [presolveOps](#).

Default: 0

presolveOps_noIpReductions (*boolean*): No IP reductions ↔

See also [presolveOps](#).

Default: 0

presolveOps_redundantRowRemoval (*boolean*): Redundant row removal ↔

See also [presolveOps](#).

Default: 1

presolveOps_singletonColRemoval (*boolean*): Singleton column removal ↔

See also [presolveOps](#).

Default: 1

presolveOps_singletonRowRemoval (*boolean*): Singleton row removal ↔

See also [presolveOps](#).

Default: 1

presolveOps_strongDualReductions (*boolean*): Strong dual reductions ↔

See also [presolveOps](#).

Default: 1

presolveOps_variableEliminations (*boolean*): Variable eliminations ↔

See also [presolveOps](#).

Default: 1

presolvePasses (*integer*): Number of reduction rounds to be performed in presolve ↔

Range: {0, ..., ∞}

Default: 1

pricingAlg (*integer*): Simplex: Determines the primal simplex pricing method ↔

It is used to select which variable enters the basis on each iteration. In general Devex pricing requires more time on each iteration, but may reduce the total number of iterations, whereas partial pricing saves time on each iteration, but may result in more iterations.

Default: auto

value	meaning
-1	Partial pricing.
0	Determined automatically.
1	Devex pricing.
2	Steepest edge.
3	Steepest edge with unit initial weights.

primalPerturb (*real*): Factor by which the problem will be perturbed prior to optimization by primal simplex ↔

A value of 0.0 results in no perturbation prior to optimization. Note the interconnection to the [autoPerturb](#) control. If [autoPerturb](#) is set to 1, the decision whether to perturb or not is left

to the Optimizer. When the problem is automatically perturbed in primal simplex, however, the value of `primalPerturb` will be used for perturbation.

Range: $[-\infty, \infty]$

Default: `auto`

primalUnshift (*boolean*): Determines whether primal is allowed to call dual to unshift [↔](#)

Default: 0

value	meaning
0	Allow the dual algorithm to be used to unshift.
1	Don't allow the dual algorithm to be used to unshift.

pseudoCost (*real*): Branch and Bound: Default pseudo cost used in estimation of the degradation associated with an unexplored node in the tree search [↔](#)

A pseudo cost is associated with each integer decision variable and is an estimate of the amount by which the objective function will be worse if that variable is forced to an integral value.

Range: $[0, \infty]$

Default: 0.01

qcCuts (*integer*): Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation [↔](#)

This control only has an effect for problems with quadratic or second order cone constraints, and only if outer approximation has not been disabled by setting `miqcpAlg` to 0.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

qcRootAlg (*integer*): Determines which algorithm is to be used to solve the root of a mixed integer quadratic constrained or mixed integer second order cone problem, when outer approximation is used [↔](#)

This control only has an effect if `miqcpAlg` is set to 1.

Default: `auto`

value	meaning
-1	Determined automatically.
0	Use the barrier algorithm.
1	Use the dual simplex on a relaxation of the problem constructed using outer approximation.

qextractalg (*integer*): quadratic extraction algorithm in GAMS interface [↔](#)

Default: 0

value	meaning
0	Automatic
1	ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.
2	DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.

qSimplexOps (*integer*): Controls the behavior of the quadratic simplex solvers ↔

Default: 0

value	meaning
bit 0 = 1	Force traditional primal first phase.
bit 1 = 2	Force BigM primal first phase.
bit 2 = 4	Force traditional dual first phase.
bit 3 = 8	Force BigM dual first phase.
bit 4 = 16	Always use artificial bounds in dual.
bit 5 = 32	Use original problem basis only when warmstarting the KKT.
bit 6 = 64	Skip the primal bound flips for ranged primals (might cause more trouble than good if the bounds are very large).
bit 7 = 128	Also do the single pivot crash.
bit 8 = 256	Do not apply aggressive perturbation in dual.

quadraticUnshift (*integer*): Determines whether an extra solution purification step is called after a solution found by the quadratic simplex (either primal or dual) ↔

Default: auto

value	meaning
-1	Determined automatically.
0	No purification step.
1	Always do the purification step.

randomSeed (*integer*): Sets the initial seed to use for the pseudo-random number generator in the Optimizer ↔

The sequence of random numbers is always reset using the seed when starting a new optimization run.

Range: $\{-\infty, \dots, \infty\}$

Default: 1

refineOps (*integer*): Specifies when the solution refiner should be executed to reduce solution infeasibilities ↔

The refiner will attempt to satisfy the target tolerances for all original linear constraints before presolve or scaling has been applied.

If neither the 7th nor 8th bit is set, the refiner will use the primal simplex if the primal violations are larger than the dual violations, otherwise it will use the dual simplex. If both

the 7th and 8th bit are set then the refiner will split the problem into a primal feasible and dual feasible part, and solve the first with primal simplex and the second with dual simplex.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 19

value	meaning
bit 0 = 1	Equivalent to refineOps_lpOptimal .
bit 1 = 2	Equivalent to refineOps_mipSolution .
bit 3 = 8	Equivalent to refineOps_mipNodeLp .
bit 4 = 16	Equivalent to refineOps_lpPresolve .
bit 5 = 32	Equivalent to refineOps_iterativeRefiner .
bit 6 = 64	Equivalent to refineOps_refinerPrecision .
bit 7 = 128	Equivalent to refineOps_refinerUsePrimal .
bit 8 = 256	Equivalent to refineOps_refinerUseDual .
bit 9 = 512	Equivalent to refineOps_mipFixGlobals .
bit 10 = 1024	Equivalent to refineOps_mipFixGlobalsTarget .

refineOps_iterativeRefiner (*boolean*): Apply the iterative refiner to refine the solution ↔

See also [refineOps](#).

Default: 0

refineOps_lpOptimal (*boolean*): Run the solution refiner on an optimal solution of a non-global problem ↔

See also [refineOps](#).

Default: 1

refineOps_lpPresolve (*boolean*): Run the solution refiner on an optimal solution before postsolve on a non-global problem ↔

See also [refineOps](#).

Default: 1

refineOps_mipFixGlobals (*boolean*): Refine MIP solutions such that rounding them keeps the problem feasible when reoptimized ↔

See also [refineOps](#).

Default: 0

refineOps_mipFixGlobalsTarget (*boolean*): Attempt to refine MIP solutions such that rounding them keeps the problem feasible when reoptimized, but accept integers solutions even if refinement fails ↔

See also [refineOps](#).

Default: 0

refineOps_mipNodeLp (*boolean*): Run the solution refiner on each node of the MIP search ↔

See also [refineOps](#).

Default: 0

refineOps_mipSolution (*boolean*): Run the solution refiner when a new solution is found during a global search \leftrightarrow

The refiner will be applied to the presolved solution before any post-solve operations are applied.

See also [refineOps](#).

Default: 1

refineOps_refinerPrecision (*boolean*): Use higher precision in the iterative refinement \leftrightarrow

See also [refineOps](#).

Default: 0

refineOps_refinerUseDual (*boolean*): If set, the iterative refiner will use the dual simplex algorithm \leftrightarrow

See also [refineOps](#).

Default: 0

refineOps_refinerUsePrimal (*boolean*): If set, the iterative refiner will use the primal simplex algorithm \leftrightarrow

See also [refineOps](#).

Default: 0

reform (*boolean*): Substitute out objective var and equ when possible \leftrightarrow

Default: 1

relaxTreeMemoryLimit (*real*): When the memory used by the branch and bound search tree exceeds the target specified by the [treeMemoryLimit](#) control, the optimizer will try to reduce this by writing nodes to the global file \leftrightarrow

In rare cases, usually where the solve has many millions of very small nodes, the tree structural data (which cannot be written to the global file) will grow large enough to approach or exceed the tree's memory target. When this happens, optimizer performance can degrade greatly as the solver makes heavy use of the global file in preference to memory. To prevent this, the solver will automatically relax the tree memory limit when it detects this case; the [relaxTreeMemoryLimit](#) control specifies the proportion of the previous memory limit by which to relax it. Set [relaxTreeMemoryLimit](#) to 0.0 to force the Xpress Optimizer to never relax the tree memory limit in this way.

While setting higher values of [relaxTreeMemoryLimit](#) can improve performance significantly for a small number of models in low memory situations, the user is advised to use the [treeMemoryLimit](#) control to tune the memory usage of the branch and bound tree, according to the solve characteristics of their problem, rather than increasing [relaxTreeMemoryLimit](#).

Range: $[0, \infty]$

Default: 0.1

relPivotTol (*real*): Simplex: Minimum size of pivot element relative to largest element in column \leftrightarrow

At each iteration a pivot element is chosen within a given column of the matrix. The relative pivot tolerance, [relPivotTol](#), is the size of the element chosen relative to the largest possible pivot element in the same column.

Range: $[0, \infty]$

Default: 1e-06

repairIndefinitEq (*boolean*): Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible \leftrightarrow

Default: 1

value	meaning
0	Repair if possible.
1	Do not repair.

reRun (*boolean*): Rerun with primal simplex when not optimal/feasible ↔

Applies only in cases where presolve is turned on and the model is diagnosed as infeasible or unbounded. If rerun is nonzero, we rerun the model using primal simplex with presolve turned off in hopes of getting better diagnostic information. If rerun is zero, no good diagnostic information exists, so we return no solution, only an indication of unboundedness/infeasibility.

Default: 0

reslim (*real*): Overrides GAMS reslim option ↔

Sets the resource limit. When the solver has used more than this amount of CPU time (in seconds) the system will stop the search and report the best solution found so far. [maxTime](#) overwrites this option.

resourceStrategy (*boolean*): Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve ↔

Available memory (or container limits) are automatically detected but can also be changed by [maxMemorySoft](#) and [maxMemoryHard](#).

Default: 0

value	meaning
1	Allow the optimizer to change the solve path if necessary to preserve memory when getting close to one of the memory limits.

rootPresolve (*integer*): Determines if presolving should be performed on the problem after the global search has finished with root cutting and heuristics ↔

Default: auto

value	meaning
-1	Let the optimizer decide if the problem should be presolved again.
0	Disabled.
1	Always presolve the root problem.

sbBest (*integer*): Number of infeasible global entities to initialize pseudo costs for on each node ↔

By default, strong branching will be performed only for infeasible global entities whose pseudo costs have not otherwise been initialized (see [historyCosts](#)). If [sbBest](#) is set to zero, the control [historyCosts](#) will also be treated as zero and no past branching or strong branching information will be used in the global entity selection.

Default: auto

value	meaning
-1	Determined automatically.
0	Disable strong branching.
n>0	Perform strong branching on up to n entities at each node.

sbEffort (*real*): Adjusts the overall amount of effort when using strong branching to select an infeasible global entity to branch on ↔

sbEffort is used as a multiplier on other strong branching related controls, and affects the values used for **sbBest**, **sbSelect** and **sbIterLimit** when those are set to automatic.

Range: $[0, \infty]$

Default: 1

sbEstimate (*integer*): Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible global entity to branch on ↔

These pseudo costs are used in combination with local strong branching and history costs to select the branch candidate.

Default: auto

value	meaning
-1	Automatically determined.
1-6	Different variants of local pseudo costs.

sbIterLimit (*integer*): Number of dual iterations to perform the strong branching for each entity ↔

This control can be useful to increase or decrease the amount of effort (and thus time) spent performing strong branching at each node. Setting **sbIterLimit**=0 will disable dual strong branch iterations. Instead, the entity at the head of the candidate list will be selected for branching.

Range: $\{-1, \dots, \infty\}$

Default: auto

sbSelect (*integer*): Size of the candidate list of global entities for strong branching ↔

Before strong branching is applied on a node of the branch and bound tree, a list of candidates is selected among the infeasible global entities. These entities are then evaluated based on the local LP solution and prioritized. Strong branching will then be applied to the **sbBest** candidates. The evaluation is potentially expensive and for some problems it might improve performance if the size of the candidate list is reduced.

Default: -2

value	meaning
-2	Automatic (low effort).
-1	Automatic (high effort).
$n \geq 0$	Include n entities in the candidate list (but always at least sbBest candidates).

scaling (*integer*): Determines how the Optimizer will rescale a model internally before optimization ↔

If set to 0, no scaling will take place.

Setting **scaling** to 0 will preserve the current scaling of the problem. Note that the Optimizer might automatically select a different scaling strategy, when the control **autoScaling** is not disabled. However, if **scaling** is set to any value by the user, **autoScaling** will be ignored.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 163

value	meaning
bit 0 = 1	Equivalent to scaling_rowScaling .
bit 1 = 2	Equivalent to scaling_colScaling .
bit 2 = 4	Equivalent to scaling_rowScalingAgain .
bit 3 = 8	Equivalent to scaling_maximum .
bit 4 = 16	Equivalent to scaling_curtisReid .
bit 5 = 32	Equivalent to scaling_byMaxElemNotGeoMean .
bit 6 = 64	Equivalent to scaling_bigM .
bit 7 = 128	Equivalent to scaling_simplexObjScaling .
bit 8 = 256	Equivalent to scaling_ignoreQuadRowPart .
bit 9 = 512	Equivalent to scaling_beforePresolve .
bit 10 = 1024	Equivalent to scaling_noScalingRowsUp .
bit 11 = 2048	Equivalent to scaling_noScalingColsDown .
bit 12 = 4096	Equivalent to scaling_disableGlobalObjScaling .
bit 13 = 8192	Equivalent to scaling_rhsScaling .
bit 14 = 16384	Equivalent to scaling_noAggressiveQScaling .
bit 15 = 32768	Equivalent to scaling_slackScaling .

scaling_beforePresolve (*boolean*): Scale before presolve ↔

See also [scaling](#).

Default: 0

scaling_bigM (*boolean*): Treat big-M rows as normal rows ↔

See also [scaling](#).

Default: 0

scaling_byMaxElemNotGeoMean (*boolean*): 0: scale by geometric mean ↔

1: scale by maximum element.

See also [scaling](#).

Default: 1

scaling_colScaling (*boolean*): Column scaling ↔

See also [scaling](#).

Default: 1

scaling_curtisReid (*boolean*): Curtis-Reid ↔

See also [scaling](#).

Default: 0

scaling_disableGlobalObjScaling (*boolean*): Do not apply automatic global objective scaling ↔

See also [scaling](#).

Default: 0

scaling_ignoreQuadRowPart (*boolean*): Exclude the quadratic part of constraint when calculating scaling factors ↔

See also [scaling](#).

Default: 0

scaling_maximum (*boolean*): Maximum ↔

See also [scaling](#).

Default: 0

scaling_noAggressiveQScaling (*boolean*): Disable aggressive quadratic scaling ↔

See also [scaling](#).

Default: 0

scaling_noScalingColsDown (*boolean*): Do not scale columns down ↔

See also [scaling](#).

Default: 0

scaling_noScalingRowsUp (*boolean*): Do not scale rows up ↔

See also [scaling](#).

Default: 0

scaling_rhsScaling (*boolean*): RHS scaling ↔

See also [scaling](#).

Default: 0

scaling_rowScaling (*boolean*): Row scaling ↔

See also [scaling](#).

Default: 1

scaling_rowScalingAgain (*boolean*): Row scaling again ↔

See also [scaling](#).

Default: 0

scaling_simplexObjScaling (*boolean*): Scale objective function for the simplex method ↔

See also [scaling](#).

Default: 1

scaling_slackScaling (*boolean*): Enable explicit linear slack scaling ↔

See also [scaling](#).

Default: 0

sifting (*integer*): Determines whether to enable sifting algorithm with the dual simplex method ↔

Default: auto

value	meaning
-1	Automatically determined.
0	Disable sifting.
1	Enable sifting.

siftPasses (*integer*): Determines how quickly we allow to grow the worker problems during the sifting algorithm ↵

Using larger values can increase the number of columns added to the worker problem which often results in increased solve times for the worker problems but the number of necessary sifting iterations may be reduced.

Range: {0, ..., ∞}

Default: 4

siftPresolveOps (*integer*): Determines the presolve operations for solving the subproblems during the sifting algorithm ↵

Default: -1

value	meaning
-1	Use the presolveOps setting specified for the original problem.
>=0	Use the value for the presolveOps parameter for solving the subproblems during the sifting algorithm.

siftSwitch (*integer*): Determines which algorithm to use for solving the subproblems during sifting ↵

Default: -1

value	meaning
-1	Dual simplex.
0	Barrier.
>0	Use the barrier algorithm while the number of dual infeasibilities is larger than this value, otherwise use dual simplex.

sleepOnThreadWait (*integer*): Determines if the threads should be put into a wait state when waiting for work ↵

Default: auto

value	meaning
-1	Automatically determined depending on the CPU the Optimizer is running on.
0	Keep the threads busy when waiting for work.
1	Put the threads into a wait state when waiting for work.

solnpool (*string*): Solution pool file name ↵

If set, the integer feasible solutions generated during the global search will be saved to a solution pool. A GDX file whose name is given by this option will be created and will contain an index to separate GDX files containing the individual solutions in the solution pool.

Default: none

solnpoolCapacity (*integer*): Limit on number of solutions to store [↔](#)

Range: {1, ..., ∞}

Default: 999999999

solnpoolCullDiversity (*integer*): Cull N solutions based on solution diversity [↔](#)

When performing a round of culls due to a full solution pool, this control sets the maximum number to cull based on the diversity of the solutions in the pool.

Range: {-1, ..., ∞}

Default: -1

solnpoolCullObj (*integer*): Cull N solutions based on objective values [↔](#)

When performing a round of culls due to a full solution pool, this control sets the maximum number to cull based on the MIP objective function.

Range: {-1, ..., ∞}

Default: -1

solnpoolCullRounds (*integer*): Terminate solution generation after N culling rounds [↔](#)

Limits the rounds of culls performed due to a full solution pool.

Default: 999999999

solnpoolDupPolicy (*integer*): Policy to use when handling storage of duplicate solutions [↔](#)

Default: 0

value	meaning
0	Keep all: All solutions are kept including duplicates.
1	Continuous: All variables are compared with an exact match. Duplicate solutions are discarded.
2	Discrete and continuous separate: Both the discrete component of a solution pair and the continuous solution variables are compared. The continuous variables are compared with an exact match. Duplicate solutions are discarded.
3	Discrete only: Only the discrete component of a solution pair is compared. Duplicate solutions are discarded.

solnpoolmerge (*string*): Solution pool file name for merged solutions [↔](#)

Default: none

solnpoolnumsym (*integer*): Maximum number of variable symbols when writing merged solutions [↔](#)

Range: {1, ..., ∞}

Default: 10

solnpoolPop (*integer*): Controls method used to populate the solution pool ↔

By default the MIP solution pool merely stores the incumbent solutions that are found during the global search, without changing the behavior of the search itself. In contrast, the MIP solution enumerator makes it possible to enumerate all or many of the feasible solutions for the MIP, instead of searching for the best solution.

Default: 1

value	meaning
1	generate solutions using the normal search algorithm
2	invoke the solution enumerator to generate solutions

solnpoolPrefix (*string*): File name prefix for GDX solution files ↔

Default: soln

solnpoolVerbosity (*integer*): Controls verbosity of solution pool routines ↔

Default: 0

value	meaning
-1	no output
0	output only messages coming from the XPRESS libraries
1	add some messages logging the effect of solution pool options
2	debugging mode

sosRefTol (*real*): Minimum relative gap between the ordering values of elements in a special ordered set ↔

The gap divided by the absolute value of the larger of the two adjacent values must be at least **sosRefTol**.

This tolerance must not be set lower than 1.0E-06.

Range: $[0, \infty]$

Default: 1e-06

symmetry (*integer*): Adjusts the overall amount of effort for symmetry detection ↔

Default: 1

value	meaning
0	No symmetry detection.
1	Conservative effort.
2	Intensive symmetry search.

symSelect (*integer*): Adjusts the overall amount of effort for symmetry detection ↔

Default: -1

value	meaning
0	Search the whole matrix (otherwise the 0, 1 and -1 coefficients only).
1	Search all entities (otherwise binaries only).

threads (*integer*): Default number of threads used during optimization ↔

Controls the number of threads to use. Positive values will be compared to the number of available cores detected and reduced if greater than this amount. Non- positive values are interpreted as the number of cores to leave free so setting **threads** to 0 uses all available cores while setting **threads** to -1 leaves one core free for other tasks.

Range: $\{-\infty, \dots, \infty\}$

Default: 1

trace (*integer*): Display the infeasibility diagnosis during presolve ↔

If non-zero, an explanation of the logical deductions made by presolve to deduce infeasibility or unboundedness will be displayed on screen or sent to the message callback function.

Presolve is sometimes able to detect infeasibility and unboundedness in problems. The set of deductions made by presolve can allow the user to diagnose the cause of infeasibility or unboundedness in their problem. However, not all infeasibility or unboundedness can be detected and diagnosed in this way.

Range: $\{0, \dots, \infty\}$

Default: 0

treeCompression (*integer*): When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the global file on disk ↔

The **treeCompression** control determines the strength of the data-compression algorithm used; higher values give superior data- compression at the affect of decreasing performance, while lower values compress quicker but not as effectively. Where **treeCompression** is set to 0, no data compression will be used on the global file.

Range: $\{0, \dots, \infty\}$

Default: 2

treeCoverCuts (*integer*): Branch and Bound: Number of rounds of lifted cover inequalities generated at nodes other than the top node in the tree ↔

Compare with the description for **coverCuts**. A value of -1 indicates the number of rounds is determined automatically.

Range: $\{-1, \dots, \infty\}$

Default: **auto**

treeCutSelect (*integer*): Bit vector providing detailed control of the cuts created during the tree search of a global solve ↔

Use **cutSelect** to control cuts on the root node.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -257

value	meaning
bit 5 = 32	Equivalent to treeCutSelect_clique .
bit 6 = 64	Equivalent to treeCutSelect_mir .
bit 7 = 128	Equivalent to treeCutSelect_cover .
bit 8 = 256	Equivalent to treeCutSelect_mirRowAggregation .
bit 11 = 2048	Equivalent to treeCutSelect_flowpath .
bit 12 = 4096	Equivalent to treeCutSelect_implication .
bit 13 = 8192	Equivalent to treeCutSelect_liftAndProject .
bit 14 = 16384	Equivalent to treeCutSelect_disableCutRows .
bit 15 = 32768	Equivalent to treeCutSelect_gubCover .
bit 16 = 65536	Equivalent to treeCutSelect_zeroHalf .
bit 17 = 131072	Equivalent to treeCutSelect_indicator .

treeCutSelect_clique (*boolean*): Clique cuts ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_cover (*boolean*): Lifted cover cuts ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_disableCutRows (*boolean*): Disable cutting from cut rows ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_flowpath (*boolean*): Flow path cuts ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_gubCover (*boolean*): Lifted GUB cover cuts ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_implication (*boolean*): Implication cuts ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_indicator (*boolean*): Indicator constraint cuts ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_liftAndProject (*boolean*): Turn on automatic Lift and Project cutting strategy ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_mir (*boolean*): Mixed Integer Rounding (MIR) cuts ↔

See also [treeCutSelect](#).

Default: 1

treeCutSelect_mirRowAggregation (*boolean*): Turn on row aggregation for MIR cuts ↔

See also [treeCutSelect](#).

Default: 0

treeCutSelect_zeroHalf (*boolean*): Zero-half cuts ↔

See also [treeCutSelect](#).

Default: 1

treeGomCuts (*integer*): Branch and Bound: Number of rounds of Gomory cuts generated at nodes other than the first node in the tree ↔

Compare with the description for [gomCuts](#). A value of -1 indicates the number of rounds is determined automatically.

Range: $\{-1, \dots, \infty\}$

Default: auto

treeMemoryLimit (*integer*): Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree ↔

This doesn't include memory used for presolve, heuristics, solving the LP relaxation, etc. When set to 0 (the default), the optimizer will calculate a limit automatically based on the amount of free physical memory detected in the machine. When the memory used by the branch and bound tree exceeds this limit, the optimizer will try to reduce the memory usage by writing lower-rated sections of the tree to a file called the "global file". Though the solve can continue if it cannot bring the tree memory usage below the specified limit, performance will be inhibited and a message will be printed to the log.

Range: $\{0, \dots, \infty\}$

Default: auto

treeMemorySavingTarget (*real*): When the memory used by the branch-and-bound search tree exceeds the limit specified by the [treeMemoryLimit](#) control, the optimizer will try to save memory by writing lower-rated sections of the tree to the global file ↔

The target amount of memory to save will be enough to bring memory usage back below the limit, plus enough extra to give the tree room to grow. The `treeMemorySavingTarget` control specifies the extra proportion of the tree's size to try to save; for example, if the tree memory limit is 1000Mb and `treeMemorySavingTarget` is 0.1, when the tree size exceeds 1000Mb the optimizer will try to reduce the tree size to 900Mb. Reducing the value of `treeMemorySavingTarget` will cause less extra nodes of the tree to be written to the global file, but will result in the memory saving routine being triggered more often (as the tree will have less room in which to grow), which can reduce performance. Increasing the value of `treeMemorySavingTarget` will cause additional, more highly-rated nodes, of the tree to be written to the global file, which can cause performance issues if these nodes are required later in the solve.

Range: $[0, \infty]$

Default: 0.4

treeQCCuts (*integer*): Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation ↔

This control only has an effect for problems with quadratic or second order cone constraints, and only if outer approximation has not been disabled by setting `miqcpAlg` to 0.

Range: $\{-1, \dots, \infty\}$

Default: auto

varSelection (*integer*): Branch and Bound: Determines the formula used to calculate the estimate of each integer variable, and thus which integer variable is selected to be branched on at a given node ↔

The variable selected to be branched on is the one with the maximum estimate.

Default: auto

value	meaning
-1	Determined automatically.
1	The minimum of the 'up' and 'down' pseudo costs.
2	The 'up' pseudo cost plus the 'down' pseudo cost.
3	The maximum of the 'up' and 'down' pseudo costs, plus twice the minimum of the 'up' and 'down' pseudo costs.
4	The maximum of the 'up' and 'down' pseudo costs.
5	The 'down' pseudo cost.
6	The 'up' pseudo cost.
7	A weighted combination of the 'up' and 'down' pseudo costs, where the weights depend on how fractional the variable is.
8	The product of the 'up' and 'down' pseudo costs.

writePrtSol (*boolean*): Directs optimizer to output a "printsol" file ↔

Default: 0

xslp_algorithm (*integer*): Bit map describing the SLP algorithm(s) to be used ↔

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 166

value	meaning
bit 0 = 1	Equivalent to <code>xslp_algorithm_noStepBounds</code> .
bit 1 = 2	Equivalent to <code>xslp_algorithm_stepBoundsAsRequired</code> .
bit 2 = 4	Equivalent to <code>xslp_algorithm_estimateStepBounds</code> .
bit 3 = 8	Equivalent to <code>xslp_algorithm_dynamicDamping</code> .
bit 4 = 16	Equivalent to <code>xslp_algorithm_holdValues</code> .
bit 5 = 32	Equivalent to <code>xslp_algorithm_retainPreviousValue</code> .
bit 6 = 64	Equivalent to <code>xslp_algorithm_resetDeltaZ</code> .
bit 7 = 128	Equivalent to <code>xslp_algorithm_quickConvergenceCheck</code> .
bit 8 = 256	Equivalent to <code>xslp_algorithm_escalatePenalties</code> .
bit 9 = 512	Equivalent to <code>xslp_algorithm_switchToPrimal</code> .
bit 11 = 2048	Equivalent to <code>xslp_algorithm_maxCostOption</code> .
bit 12 = 4096	Equivalent to <code>xslp_algorithm_residualErrors</code> .
bit 13 = 8192	Equivalent to <code>xslp_algorithm_noLPPolishing</code> .
bit 14 = 16384	Equivalent to <code>xslp_algorithm_cascadeBounds</code> .
bit 15 = 32768	Equivalent to <code>xslp_algorithm_clampExtendedActiveSB</code> .
bit 16 = 65536	Equivalent to <code>xslp_algorithm_clampExtendedAll</code> .

`xslp_algorithm_cascadeBounds` (*boolean*): Step bounds are updated to accomodate cascaded values (otherwise cascaded values are pushed to respect step bounds) \leftrightarrow

Normally, cascading will respect the step bounds of the SLP variable being cascaded. However, allowing the cascaded value to fall outside the step bounds (i.e. expanding the step bounds) can lead to better linearizations, as cascading will set better values for the SLP variables regarding their determining rows; note, that this later strategy might interfere with convergence of the cascaded variables.

See also [xslp_algorithm](#).

Default: 0

`xslp_algorithm_clampExtendedActiveSB` (*boolean*): Apply clamping when converged on extended criteria only with some variables having active step bounds \leftrightarrow

When clamping is applied, then in any iteration when the solution would normally be deemed converged on extended criteria only, an extra step bound shrinking step is applied to help imposing strict convergence. In this variant, clamping is only applied on variables that have converged on extended criteria only and have active step bounds.

See also [xslp_algorithm](#).

Default: 0

`xslp_algorithm_clampExtendedAll` (*boolean*): Apply clamping when converged on extended criteria only \leftrightarrow

When clamping is applied, then in any iteration when the solution would normally be deemed converged on extended criteria only, an extra step bound shrinking step is applied to help imposing strict convergence. In this variant, clamping is applied on all variables that have converged on extended criteria only.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_dynamicDamping (*boolean*): Use dynamic damping ↔

Dynamic damping is sometimes an alternative to step bounding as a means of encouraging convergence, but it does not have the same power to force convergence as do step bounds.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_escalatePenalties (*boolean*): Escalate penalties ↔

Constraint penalties are increased after each SLP iteration where penalty vectors are present in the solution. Escalation applies an additional scaling factor to the penalty costs for active errors. This helps to prevent successive solutions becoming "stuck" because of a particular constraint, because its cost will be raised so that other constraints may become more attractive to violate instead and thus open up a new region to explore.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_estimateStepBounds (*boolean*): Estimate step bounds from early SLP iterations ↔

If initial step bounds are not being explicitly provided, this gives a good method of calculating reasonable values. Values will tend to be larger rather than smaller, to reduce the risk of infeasibility caused by excessive tightness of the step bounds.

See also [xslp_algorithm](#).

Default: 1

xslp_algorithm_holdValues (*boolean*): Do not update values which are converged within strict tolerance ↔

Models which are numerically unstable may benefit from this setting, which does not update values which have effectively hardly changed. If a variable subsequently does move outside its strict convergence tolerance, it will be updated as usual.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_maxCostOption (*boolean*): Continue optimizing after penalty cost reaches maximum ↔

Normally if the penalty cost reaches its maximum (by default the value of infinity), the optimization will terminate with an unconverged solution. If the maximum value is set to a smaller value, then it may make sense to continue, using other means to determine when to stop.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_noLPPolishing (*boolean*): Skip the solution polishing step if the LP postsolve returns a slightly infeasible, but claimed optimal solution ↔

Due to the nature of the SLP linearizations, and in particular because of the large differences in the objective function (model objective against penalty costs) some dual reductions in the linear presolver might introduce numerically instable reductions that cause slight infeasibilities to appear in postsolve. It is typically more efficient to remove these infeasibilities with an extra call to the linear optimizer; compared to switching these reductions off, which usually has a significant cost in performance. This bit is provided for numerically very hard problems, when the polishing step proves to be too expensive (Xpress SLP will report these if any in the final log summary).

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_noStepBounds (*boolean*): Do not apply step bounds ↔

The default algorithm uses step bounds to force convergence. Step bounds may not be appropriate if dynamic damping is used.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_quickConvergenceCheck (*boolean*): Quick convergence check ↔

Normally, each variable is checked against all convergence criteria until either a criterion is found which it passes, or it is declared "not converged". Later (extended convergence) criteria are more expensive to test and, once an unconverged variable has been found, the overall convergence status of the solution has been established. The quick convergence check carries out checks on the strict criteria, but omits checks on the extended criteria when an unconverged variable has been found.

See also [xslp_algorithm](#).

Default: 1

xslp_algorithm_resetDeltaZ (*boolean*): Reset [xslp_delta_z](#) to zero when converged and continue SLP ↔

One of the mechanisms to avoid local optima is to retain small non-zero coefficients between delta vectors and constraints, even when the coefficient should strictly be zero. If this option is set, then a converged solution will be continued with zero coefficients as appropriate.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_residualErrors (*boolean*): Accept a solution which has converged even if there are still significant active penalty error vectors ↔

Normally, the optimization will continue if there are active penalty vectors in the solution. However, it may be that there is no feasible solution (and so active penalties will always be present). Setting bit 12 means that, if other convergence criteria are met, then the solution will be accepted as converged and the optimization will stop.

See also [xslp_algorithm](#).

Default: 0

xslp_algorithm_retainPreviousValue (*boolean*): Retain previous value when cascading if determining row is zero ↔

If the determining row is zero (that is, all the coefficients interacting with it are either zero or in columns with a zero activity), then it is impossible to calculate a new value for the vector being cascaded. The choice is to use the solution value as it is, or to revert to the assumed value

See also [xslp_algorithm](#).

Default: 1

xslp_algorithm_stepBoundsAsRequired (*boolean*): Apply step bounds to SLP delta vectors only when required [↔](#)

Step bounds can be applied to all vectors simultaneously, or applied only when oscillation of the delta vector (change in sign between successive SLP iterations) is detected.

See also [xslp_algorithm](#).

Default: 1

xslp_algorithm_switchToPrimal (*boolean*): Use the primal simplex algorithm when all error vectors become inactive [↔](#)

The primal simplex algorithm often performs better than dual during the final stages of SLP optimization when there are relatively few basis changes between successive solutions. As it is impossible to establish in advance when the final stages are being reached, the disappearance of error vectors from the solution is used as a proxy.

See also [xslp_algorithm](#).

Default: 0

xslp_analyze (*integer*): Bit map activating additional options supporting model / solution path analysis [↔](#)

In most cases, the value of this control does not affect the solution process itself. However, bit 3 (extended summary) will cause SLP to do more function evaluations, and the presence of non-deterministic user functions might cause changes in the solution process. These options are off by default due to performance considerations.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

value	meaning
bit 3 = 8	Equivalent to xslp_analyze_extendedFinalSummary .
bit 4 = 16	Equivalent to xslp_analyze_infeasibleIteration .
bit 6 = 64	Equivalent to xslp_analyze_saveLinearizations .
bit 7 = 128	Equivalent to xslp_analyze_saveIterBasis .
bit 8 = 256	Equivalent to xslp_analyze_saveFile .

xslp_analyze_extendedFinalSummary (*boolean*): Include an extended iteration summary [↔](#)

See also [xslp_analyze](#).

Default: 0

xslp_analyze_infeasibleIteration (*boolean*): Run infeasibility analysis on infeasible iterations ↔

See also [xslp_analyze](#).

Default: 0

xslp_analyze_saveFile (*boolean*): Create an Xpress SLP save file at every [xslp_autosave](#) iterations ↔

See also [xslp_analyze](#).

Default: 0

xslp_analyze_saveIterBasis (*boolean*): Write the initial basis of the linearizations to disk at every [xslp_autosave](#) iterations ↔

See also [xslp_analyze](#).

Default: 0

xslp_analyze_saveLinearizations (*boolean*): Write the linearizations to disk at every [xslp_autosave](#) iterations ↔

See also [xslp_analyze](#).

Default: 0

xslp_aTol_a (*real*): Absolute delta convergence tolerance ↔

The absolute delta convergence criterion assesses the change in value of a variable (δX) against the absolute delta convergence tolerance. If $\delta X < \text{xslp_aTol_a}$ then the variable has converged on the absolute delta convergence criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget_r](#). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: auto

xslp_aTol_r (*real*): Relative delta convergence tolerance ↔

The relative delta convergence criterion assesses the change in value of a variable (δX) relative to the value of the variable (X), against the relative delta convergence tolerance. If $\delta X < X * \text{xslp_aTol_r}$ then the variable has converged on the relative delta convergence criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget_r](#). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: auto

xslp_augmentation (*integer*): Bit map describing the SLP augmentation method(s) to be used ↔

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 12

value	meaning
bit 0 = 1	Equivalent to xslp_augmentation_minimum .
bit 1 = 2	Equivalent to xslp_augmentation_evenHanded .
bit 2 = 4	Equivalent to xslp_augmentation_equalityErrorVectors .
bit 3 = 8	Equivalent to xslp_augmentation_allErrorVectors .
bit 4 = 16	Equivalent to xslp_augmentation_penaltyDeltaVectors .
bit 5 = 32	Equivalent to xslp_augmentation_aMeanWeight .
bit 6 = 64	Equivalent to xslp_augmentation_sbFromValues .
bit 7 = 128	Equivalent to xslp_augmentation_sbFromAbsValues .
bit 8 = 256	Equivalent to xslp_augmentation_stepBoundRows .
bit 9 = 512	Equivalent to xslp_augmentation_allRowErrorVectors .
bit 10 = 1024	Equivalent to xslp_augmentation_noUpdateIfOnlyIV .

xslp_augmentation_allErrorVectors (*boolean*): Penalty error vectors on all non-linear inequality constraints ↩

The linearization of a nonlinear constraint is inevitably an approximation and so may not be feasible except at the point of linearization. Adding penalty error vectors allows the linear approximation to be violated at a cost and so ensures that the linearized constraint is feasible.

See also [xslp_augmentation](#).

Default: 1

xslp_augmentation_allRowErrorVectors (*boolean*): Penalty error vectors on all constraints ↩

If the linear portion of the underlying model may actually be infeasible, then applying penalty vectors to all rows may allow identification of the infeasibility and may also allow a useful solution to be found.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_aMeanWeight (*boolean*): Use arithmetic means to estimate penalty weights ↩

Penalty weights are estimated from the magnitude of the elements in the constraint or interacting rows. Geometric means are normally used, so that a few excessively large or small values do not distort the weights significantly. Arithmetic means will value the coefficients more equally.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_equalityErrorVectors (*boolean*): Penalty error vectors on all non-linear equality constraints ↩

The linearization of a nonlinear equality constraint is inevitably an approximation and so will not generally be feasible except at the point of linearization. Adding penalty error vectors allows the linear approximation to be violated at a cost and so ensures that the linearized constraint is feasible.

See also [xslp_augmentation](#).

Default: 1

xslp_augmentation_evenHanded (*boolean*): Even handed augmentation ↔

Standard augmentation treats variables which appear in non-constant coefficients in a different way from those which contain non-constant coefficients. Even-handed augmentation treats them all in the same way by replacing each non-constant coefficient C in a vector V by a new coefficient $C*V$ in the "equals" column (which has a fixed activity of 1) and creating delta vectors for all types of variable in the same way.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_minimum (*boolean*): Minimum augmentation ↔

Standard augmentation includes delta vectors for all variables involved in nonlinear terms (in non-constant coefficients or as vectors containing non-constant coefficients). includes delta vectors only for variables in non-constant coefficients. This produces a smaller linearization, but there is less control on convergence, because convergence control (for example, step bounding) cannot be applied to variables without deltas.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_noUpdateIfOnlyIV (*boolean*): Initial values do not imply an SLP variable ↔

Having an initial value will not cause the augmentation to include the corresponding delta variable; i.e. treat the variable as an SLP variable. Useful to provide initial values necessary in the first linearization in case of a minimal augmentation, or as a convenience option when it's easiest to set an initial value for all variables for some reason.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_penaltyDeltaVectors (*boolean*): Penalty vectors to exceed step bounds ↔

Although it has rarely been found necessary or desirable in practice, Xpress-SLP allows step bounds to be violated at a cost. This may help with feasibility but it generally slows down or prevents convergence, so it should be used only if found absolutely necessary.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_sbFromAbsValues (*boolean*): Estimate step bounds from absolute values of row coefficients ↔

If step bounds are to be imposed from the start, the best approach is to provide explicit values for the bounds. Alternatively, Xpress-SLP can estimate the values from the largest estimated magnitude of the coefficients in the relevant rows.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_sbFromValues (*boolean*): Estimate step bounds from values of row coefficients ↔

If step bounds are to be imposed from the start, the best approach is to provide explicit values for the bounds. Alternatively, Xpress-SLP can estimate the values from the range of estimated coefficient sizes in the relevant rows.

See also [xslp_augmentation](#).

Default: 0

xslp_augmentation_stepBoundRows (*boolean*): Row-based step bounds ↔

Step bounds are normally applied as bounds on the delta variables. Some applications may find that using explicit rows to bound the delta vectors gives better results.

See also [xslp_augmentation](#).

Default: 0

xslp_autosave (*integer*): Frequency with which to save the model ↔

A value of zero means that the model will not automatically be saved. A positive value of n will save model information at every n th SLP iteration as requested by [xslp_analyze](#).

Range: $\{0, \dots, \infty\}$

Default: 0

xslp_barCrossOverStart (*integer*): Default crossover activation behaviour for barrier start ↔

When [xslp_barLimit](#) is set, [xslp_barCrossOverStart](#) offers an overwrite control on when crossover is applied. A positive value indicates that crossover should be disabled in iterations smaller than [xslp_barCrossOverStart](#) and should be enabled afterwards, or when stalling is detected as described in [xslp_barStartOps](#). A value of 0 indicates to respect the value of [crossover](#) and only overwrite its value when stalling is detected. A value of -1 indicates to always rely on the value of [crossover](#).

Range: $\{0, \dots, \infty\}$

Default: 0

xslp_barLimit (*integer*): Number of initial SLP iterations using the barrier method ↔

Particularly for larger models, using the Newton barrier method is faster in the earlier SLP iterations. Later on, when the basis information becomes more useful, a simplex method generally performs better. [xslp_barLimit](#) sets the number of SLP iterations which will be performed using the Newton barrier method.

Range: $\{0, \dots, \infty\}$

Default: 0

xslp_barStallingLimit (*integer*): Number of iterations to allow numerical failures in barrier before switching to dual ↔

On large problems, it may be beneficial to warm start progress by running a number of iterations with the barrier solver as specified by [xslp_barLimit](#). On some numerically difficult problems, the barrier may stop prematurely due to numerical issues. Such solves can sometimes be finished if crossover is applied. After [xslp_barStallingLimit](#) such attempts, SLP will automatically switch to use the dual simplex.

Range: $\{0, \dots, \infty\}$

Default: 3

xslp_barStallingObjLimit (*integer*): Number of iterations over which to measure the objective change for barrier iterations with no crossover ↔

On large problems, it may be beneficial to warm start progress by running a number of iterations with the barrier solver without crossover by setting [xslp_barLimit](#) to a positive value and setting [crossover](#) to 0. A potential drawback is slower convergence due to the interior point provided by the barrier solve keeping a higher number of variables active. This may lead to stalling in progress, negating the benefit of using the barrier. When in the last [xslp_barStallingObjLimit](#) iterations no significant progress has been made, crossover is automatically enabled.

Range: {0, ..., ∞}

Default: 3

xslp_barStallingTol (*real*): Required change in the objective when progress is measured in barrier iterations without crossover ↔

Minimum objective variability change required in relation to control [xslp_barStallingObjLimit](#) for the iterations to be regarded as making progress. The net objective, error cost and error sum are taken into account.

Range: [0, ∞]

Default: 0.05

xslp_barStartOps (*integer*): Controls behaviour when the barrier is used to solve the linearizations ↔

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -1

value	meaning
bit 0 = 1	Equivalent to xslp_barStartOps_stallingObjective .
bit 1 = 2	Equivalent to xslp_barStartOps_stallingNumerical .
bit 2 = 4	Equivalent to xslp_barStartOps_allowInteriorSol .

xslp_barStartOps_allowInteriorSol (*boolean*): If a non-vertex converged solution found by barrier without crossover can be returned as a final solution ↔

See also [xslp_barStartOps](#).

Default: 1

xslp_barStartOps_stallingNumerical (*boolean*): Fall back to dual simplex if too many numerical problems are reported by the barrier ↔

See also [xslp_barStartOps](#).

Default: 1

xslp_barStartOps_stallingObjective (*boolean*): Check objective progress when no crossover is applied ↔

See also [xslp_barStartOps](#).

Default: 1

xslp_calcThreads (*integer*): Number of threads used for formula and derivatives evaluations ↔

When beneficial, SLP can calculate formula values and partial derivative information in parallel.

Range: $\{-1, \dots, 1\}$

Default: `auto`

xslp_cdTol_a (*real*): Absolute tolerance for deducing constant derivatives ↔

The absolute tolerance test for constant derivatives is used as follows: If the value of the user function at point X_0 is Y_0 and the values at $(X_0 - \delta X)$ and $(X_0 + \delta X)$ are Y_d and Y_u respectively, then the numerical derivatives at X_0 are: "down" derivative $D_d = (Y_0 - Y_d) / \delta X$ "up" derivative $D_u = (Y_u - Y_0) / \delta X$ If $\text{abs}(D_d - D_u) \leq \text{xslp_cdTol_a}$ then the derivative is regarded as constant.

Range: $[0, \infty]$

Default: `1e-08`

xslp_cdTol_r (*real*): Relative tolerance for deducing constant derivatives ↔

The relative tolerance test for constant derivatives is used as follows: If the value of the user function at point X_0 is Y_0 and the values at $(X_0 - \delta X)$ and $(X_0 + \delta X)$ are Y_d and Y_u respectively, then the numerical derivatives at X_0 are: "down" derivative $D_d = (Y_0 - Y_d) / \delta X$ "up" derivative $D_u = (Y_u - Y_0) / \delta X$ If $\text{abs}(D_d - D_u) \leq \text{xslp_cdTol_r} * \text{abs}(Y_d + Y_u) / 2$ then the derivative is regarded as constant.

Range: $[0, \infty]$

Default: `1e-08`

xslp_clampShrink (*real*): Shrink ratio used to impose strict convergence on variables converged in extended criteria only ↔

If the solution has converged but there are variables converged on extended criteria only, the [xslp_clampShrink](#) acts as a shrinking ratio on the step bounds and the problem is optimized (if necessary multiple times), with the purpose of expediting strict convergence on all variables. [xslp_algorithm](#) controls if this shrinking is applied at all, and if shrinking is applied to of the variables converged on extended criteria only with active step bounds only, or if on all variables.

Range: $[0, 1]$

Default: `0.3`

xslp_clampValidationTol_a (*real*): Absolute validation tolerance for applying [xslp_clampShrink](#) ↔

If set and the absolute validation value is larger than this value, then control [xslp_clampShrink](#) is checked once the solution has converged, but there are variables converged on extended criteria only.

Range: $[0, \infty]$

Default: `not set`

xslp_clampValidationTol_r (*real*): Relative validation tolerance for applying [xslp_clampShrink](#) ↔

If set and the relative validation value is larger than this value, then control [xslp_clampShrink](#) is checked once the solution has converged, but there are variables converged on extended criteria only.

Range: $[0, \infty]$

Default: `not set`

xslp_convergenceOps (*integer*): Bit map describing which convergence tests should be carried out ↔

Provides fine tuned control (over setting the related convergence tolerances) of which convergence checks are carried out.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `7167`

value	meaning
bit 0 = 1	Equivalent to <code>xslp_convergenceOps_cTol</code> .
bit 1 = 2	Equivalent to <code>xslp_convergenceOps_aTol</code> .
bit 2 = 4	Equivalent to <code>xslp_convergenceOps_mTol</code> .
bit 3 = 8	Equivalent to <code>xslp_convergenceOps iTol</code> .
bit 4 = 16	Equivalent to <code>xslp_convergenceOps_sTol</code> .
bit 5 = 32	Check for user provided convergence.
bit 6 = 64	Equivalent to <code>xslp_convergenceOps_vTol</code> .
bit 7 = 128	Equivalent to <code>xslp_convergenceOps_xTol</code> .
bit 8 = 256	Equivalent to <code>xslp_convergenceOps_oTol</code> .
bit 9 = 512	Equivalent to <code>xslp_convergenceOps_wTol</code> .
bit 10 = 1024	Equivalent to <code>xslp_convergenceOps_extendedScaling</code> .
bit 11 = 2048	Equivalent to <code>xslp_convergenceOps_validation</code> .
bit 12 = 4096	Equivalent to <code>xslp_convergenceOps_validationK</code> .

xslp_convergenceOps_aTol (*boolean*): Execute the delta tolerance checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_cTol (*boolean*): Execute the closure tolerance checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_extendedScaling (*boolean*): Take scaling of individual variables / rows into account ↔

See also [xslp_convergenceOps](#).

Default: 0

xslp_convergenceOps iTol (*boolean*): Execute the impact tolerance checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_mTol (*boolean*): Execute the matrix tolerance checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_oTol (*boolean*): Execute the objective range + active step bound check ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_sTol (*boolean*): Execute the slack impact tolerance checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_validation (*boolean*): Execute the validation target convergence checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_validationK (*boolean*): Execute the first order optimality target convergence checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_vTol (*boolean*): Execute the objective range checks ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_wTol (*boolean*): Execute the convergence continuation check ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_convergenceOps_xTol (*boolean*): Execute the objective range + constraint activity check ↔

See also [xslp_convergenceOps](#).

Default: 1

xslp_cTol (*real*): Closure convergence tolerance ↔

The closure convergence criterion measures the change in value of a variable (δX) relative to the value of its initial step bound (B), against the closure convergence tolerance. If $\delta X < B * \text{xslp_cTol}$ then the variable has converged on the closure convergence criterion. If no explicit initial step bound is provided, then the test will not be applied and the variable can never converge on the closure criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget_r](#). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp_cutStrategy (*integer*): Determines which cuts to apply in the MISP search when the default SLP-in-MIP strategy is used ↔

Cuts are derived from the linearizations and are local cuts in that they are valid in the linearization and not necessarily valid for the full problem. The values mirror that of XPRS_CUTSTRATEGY.

Range: $\{-1, \dots, 3\}$

Default: 0

xslp_damp (*real*): Damping factor for updating values of variables ↔

The damping factor sets the next assumed value for a variable based on the previous assumed value (X_0) and the actual value (X_1). The new assumed value is given by $X_1 * \text{xslp_damp} + X_0 * (1 - \text{xslp_damp})$

Range: [0, 1]

Default: 1

xslp_dampExpand (*real*): Multiplier to increase damping factor during dynamic damping ↔

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are `xslp_sameDamp` successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to $D * \text{xslp_dampExpand} + \text{xslp_dampMax} * (1 - \text{xslp_dampExpand})$

Range: [0, 1]

Default: 1

xslp_dampMax (*real*): Maximum value for the damping factor of a variable during dynamic damping ↔

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are `xslp_sameDamp` successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to $D * \text{xslp_dampExpand} + \text{xslp_dampMax} * (1 - \text{xslp_dampExpand})$

Range: [0, 1]

Default: 1

xslp_dampMin (*real*): Minimum value for the damping factor of a variable during dynamic damping ↔

If dynamic damping is enabled, the damping factor for a variable will be decreased if successive changes are in the opposite direction. More precisely, the damping factor (D) for the variable will be reset to $D * \text{xslp_dampShrink} + \text{xslp_dampMin} * (1 - \text{xslp_dampExpand})$

Range: [0, 1]

Default: 1

xslp_dampShrink (*real*): Multiplier to decrease damping factor during dynamic damping ↔

If dynamic damping is enabled, the damping factor for a variable will be decreased if successive changes are in the opposite direction. More precisely, the damping factor (D) for the variable will be reset to $D * \text{xslp_dampShrink} + \text{xslp_dampMin} * (1 - \text{xslp_dampExpand})$

Range: [0, 1]

Default: 1

xslp_dampStart (*integer*): SLP iteration at which damping is activated ↔

If damping is used as part of the SLP algorithm, it can be delayed until a specified SLP iteration. This may be appropriate when damping is used to encourage convergence after an un-damped algorithm has failed to converge.

Range: {0, ..., ∞}

Default: 0

xslp_defaultStepBound (*real*): Minimum initial value for the step bound of an SLP variable if none is explicitly given ↔

If no initial step bound value is given for an SLP variable, this will be used as a minimum value. If the algorithm is estimating step bounds, then the step bound actually used for a variable may be larger than the default. A default initial step bound is ignored when testing for the closure tolerance [xslp.cTol](#): if there is no specific value, then the test will not be applied.

Range: $[0, \infty]$

Default: 16

xslp_deltaCost (*real*): Initial penalty cost multiplier for penalty delta vectors ↔

If penalty delta vectors are used, this parameter sets the initial cost factor. If there are active penalty delta vectors, then the penalty cost may be increased.

Range: $[0, \infty]$

Default: 200

xslp_deltaCostFactor (*real*): Factor for increasing cost multiplier on total penalty delta vectors ↔

If there are active penalty delta vectors, then the penalty cost multiplier will be increased by a factor of [xslp_deltaCostFactor](#) up to a maximum of [xslp_deltaMaxCost](#)

Range: $[1, \infty]$

Default: 1.3

xslp_deltaMaxCost (*real*): Maximum penalty cost multiplier for penalty delta vectors ↔

If there are active penalty delta vectors, then the penalty cost multiplier will be increased by a factor of [xslp_deltaCostFactor](#) up to a maximum of [xslp_deltaMaxCost](#)

Range: $[0, \infty]$

Default: $1e+20$

xslp_deltaZLimit (*integer*): Number of SLP iterations during which to apply [xslp_delta_z](#) ↔

[xslp_delta_z](#) is used to retain small derivatives which would otherwise be regarded as zero. This is helpful in avoiding local optima, but may make the linearized problem more difficult to solve because of the number of small nonzero elements in the resulting matrix. [xslp_deltaZLimit](#) can be set to a nonzero value, which is then the number of iterations for which [xslp_delta_z](#) will be used. After that, small derivatives will be set to zero. A negative value indicates no automatic perturbations to the derivatives in any situation.

Range: $\{0, \dots, \infty\}$

Default: 0

xslp_delta_a (*real*): Absolute perturbation of values for calculating numerical derivatives ↔

First-order derivatives are calculated by perturbing the value of each variable in turn by a small amount. The amount is determined by the absolute and relative delta factors as follows: `xslp_delta_a + abs(X)*xslp_delta_r` where (X) is the current value of the variable. If the perturbation takes the variable outside a bound, then the perturbation normally made only in the opposite direction.

Range: $[0, \infty]$

Default: 0.001

xslp_delta_r (*real*): Relative perturbation of values for calculating numerical derivatives \leftrightarrow

First-order derivatives are calculated by perturbing the value of each variable in turn by a small amount. The amount is determined by the absolute and relative delta factors as follows: `xslp_delta_a + abs(X)*xslp_delta_r` where (X) is the current value of the variable. If the perturbation takes the variable outside a bound, then the perturbation normally made only in the opposite direction.

Range: $[0, \infty]$

Default: 0.001

xslp_delta_x (*real*): Minimum absolute value of delta coefficients to be retained \leftrightarrow

If the value of a coefficient in a delta column is less than this value, it will be reset to zero. Larger values of `xslp_delta_x` will result in matrices with fewer elements, which may be easier to solve. However, there will be increased likelihood of local optima as some of the small relationships between variables and constraints are deleted. There may also be increased difficulties with singular bases resulting from deletion of pivot elements from the matrix.

Range: $[0, \infty]$

Default: 1e-06

xslp_delta_z (*real*): Tolerance used when calculating derivatives \leftrightarrow

If the absolute value of a variable is less than this value, then a value of `xslp_delta_z` will be used instead for calculating derivatives. If a nonzero derivative is calculated for a formula which always results in a matrix coefficient less than `xslp_delta_z`, then a larger value will be substituted so that at least one of the coefficients is `xslp_delta_z` in magnitude. If `xslp_deltaZLimit` is set to a positive number, then when that number of iterations have passed, values smaller than `xslp_delta_z` will be set to zero.

Range: $[0, \infty]$

Default: 1e-05

xslp_delta_zero (*real*): Absolute zero acceptance tolerance used when calculating derivatives \leftrightarrow

Provides an override value for the `xslp_delta_z` behavior. Derivatives smaller than `xslp_delta_zero` will not be substituted by `xslp_delta_z`, defining a range in which derivatives are deemed nonzero and are affected by `xslp_delta_z`. A negative value means that this tolerance will not be applied.

Range: $[-\infty, \infty]$

Default: -1

xslp_derivatives (*boolean*): Bitmap describing the method of calculating derivatives \leftrightarrow

If no bits are set then numerical derivatives are calculated using finite differences. Analytic derivatives cannot be used for formulae involving discontinuous functions. They may not work well with functions which are not smooth (such as MAX), or where the derivative changes very quickly with the value of the variable (such as LOG of small values). Both first and second order analytic derivatives can either be calculated as symbolic formulas, or by the means of auto-differentiation, with the exception that the second order symbolic derivatives require that the first order derivatives are also calculated using the symbolic method.

Default: 1

value	meaning
bit 0 = 1	Analytic derivatives where possible
bit 1 = 2	Avoid embedding numerical derivatives of instantiated functions into analytic derivatives

xslp_djTol (*real*): Tolerance on DJ value for determining if a variable is at its step bound ↔

If a variable is at its step bound and within the absolute delta tolerance [xslp_aTol.a](#) or closure tolerance [xslp_cTol](#) then the step bounds will not be further reduced. If the DJ is greater in magnitude than [xslp_djTol](#) then the step bound may be relaxed if it meets the necessary criteria.

Range: $[0, \infty]$

Default: 1e-06

xslp_ecfCheck (*integer*): Check feasibility at the point of linearization for extended convergence criteria ↔

The extended convergence criteria measure the accuracy of the solution of the linear approximation compared to the solution of the original nonlinear problem. For this to work, the linear approximation needs to be reasonably good at the point of linearization. In particular, it needs to be reasonably close to feasibility. [xslp_ecfCheck](#) is used to determine what checking of feasibility is carried out at the point of linearization. If the point of linearization at the start of an SLP iteration is deemed to be infeasible, then the extended convergence criteria are not used to decide convergence at the end of that SLP iteration. If all that is required is to decide that the point of linearization is not feasible, then the search can stop after the first infeasible constraint is found (parameter is set to 1). If the actual number of infeasible constraints is required, then [xslp_ecfCheck](#) should be set to 2, and all constraints will be checked. The number of infeasible constraints found at the point of linearization is returned in XSLP_ECFCOUNT.

Default: 1

value	meaning
0	No check (extended criteria are always used);
1	Check until one infeasible constraint is found;
2	Check all constraints.

xslp_ecfTol.a (*real*): Absolute tolerance on testing feasibility at the point of linearization ↔

The extended convergence criteria test how well the linearization approximates the true problem. They depend on the point of linearization being a reasonable approximation — in particular, that it should be reasonably close to feasibility. Each constraint is tested at the point of linearization, and the total positive and negative contributions to the constraint from the columns in the problem are calculated. A feasibility tolerance is calculated as the largest of [xslp_ecfTol.a](#) and $\max(\text{abs}(\text{Positive}), \text{abs}(\text{Negative})) * \text{xslp_ecfTol.r}$. If the calculated infeasibility is greater than the tolerance, the point of linearization is regarded as infeasible and the extended convergence criteria will not be applied. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget.r](#). Good values for the control are usually fall between 1e-1 and 1e-6.

Range: $[-\infty, \infty]$

Default: auto

xslp_ecfTol_r (*real*): Relative tolerance on testing feasibility at the point of linearization ↔

The extended convergence criteria test how well the linearization approximates the true problem. They depend on the point of linearization being a reasonable approximation — in particular, that it should be reasonably close to feasibility. Each constraint is tested at the point of linearization, and the total positive and negative contributions to the constraint from the columns in the problem are calculated. A feasibility tolerance is calculated as the largest of [xslp_ecfTol_a](#) and $\max(\text{abs}(\text{Positive}), \text{abs}(\text{Negative})) * \text{xslp_ecfTol_r}$. If the calculated infeasibility is greater than the tolerance, the point of linearization is regarded as infeasible and the extended convergence criteria will not be applied. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget_r](#). Good values for the control are usually fall between 1e-1 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp_enforceCostShrink (*real*): Factor by which to decrease the current penalty multiplier when enforcing rows ↔

When feasibility of a row cannot be achieved by increasing the penalty cost on its error variable, removing the variable (fixing it to zero) can force the row to be satisfied, as set by [xslp_enforceMaxCost](#). After the error variables have been removed (which is equivalent to setting to row to be enforced) the penalties on the remaining error variables are rebalanced to allow for a reduction in the size of the penalties in the objective in order to achieve better numerical behaviour.

Range: $[0, 1]$

Default: `1e-05`

xslp_enforceMaxCost (*real*): Maximum penalty cost in the objective before enforcing most violating rows ↔

When feasibility of a row cannot be achieved by increasing the penalty cost on its error variable, removing the variable (fixing it to zero) can force the row to be satisfied. After the error variables have been removed (which is equivalent to setting to row to be enforced) the penalties on the remaining error variables are rebalanced to allow for a reduction in the size of the penalties in the objective in order to achieve better numerical behaviour, controlled by [xslp_enforceCostShrink](#).

Range: $[0, \infty]$

Default: `1e+11`

xslp_errorCost (*real*): Initial penalty cost multiplier for penalty error vectors ↔

If penalty error vectors are used, this parameter sets the initial cost factor. If there are active penalty error vectors, then the penalty cost may be increased.

Range: $[0, \infty]$

Default: `200`

xslp_errorCostFactor (*real*): Factor for increasing cost multiplier on total penalty error vectors ↔

If there are active penalty error vectors, then the penalty cost multiplier will be increased by a factor of [xslp_errorCostFactor](#) up to a maximum of [xslp_errorMaxCost](#)

Range: $[1, \infty]$

Default: 1.3

xslp_errorMaxCost (*real*): Maximum penalty cost multiplier for penalty error vectors \leftrightarrow

If there are active penalty error vectors, then the penalty cost multiplier will be increased by a factor of [xslp_errorCostFactor](#) up to a maximum of [xslp_errorMaxCost](#)

Range: $[0, \infty]$

Default: 1e+20

xslp_errorTol_a (*real*): Absolute tolerance for error vectors \leftrightarrow

The solution will be regarded as having no active error vectors if one of the following applies: every penalty error vector and penalty delta vector has an activity less than [xslp_errorTol_a](#); the sum of the cost contributions from all the penalty error and penalty delta vectors is less than [xslp_evTol_a](#); the sum of the cost contributions from all the penalty error and penalty delta vectors is less than [xslp_evTol_r](#) * Obj where Obj is the current objective function value.

Range: $[0, \infty]$

Default: 1e-05

xslp_errorTol_p (*real*): Absolute tolerance for printing error vectors \leftrightarrow

The solution log includes a print of penalty delta and penalty error vectors with an activity greater than [xslp_errorTol_p](#).

Range: $[0, \infty]$

Default: 0.0001

xslp_escalation (*real*): Factor for increasing cost multiplier on individual penalty error vectors \leftrightarrow

If penalty cost escalation is activated in [xslp_algorithm](#) then the penalty cost multiplier will be increased by a factor of [xslp_escalation](#) for any active error vector up to a maximum of [xslp_maxWeight](#).

Range: $[1, \infty]$

Default: 1.25

xslp_eTol_a (*real*): Absolute tolerance on penalty vectors \leftrightarrow

For each penalty error vector, the contribution to its constraint is calculated, together with the total positive and negative contributions to the constraint from other vectors. If its contribution is less than [xslp_eTol_a](#) or less than Positive*[xslp_eTol_r](#) or less than abs(Negative)*[xslp_eTol_r](#) then it will be regarded as insignificant and will not have its penalty increased. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget_r](#). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: 0.0001

xslp_eTol_r (*real*): Relative tolerance on penalty vectors ↔

For each penalty error vector, the contribution to its constraint is calculated, together with the total positive and negative contributions to the constraint from other vectors. If its contribution is less than **xslp_eTol_a** or less than $\text{Positive} * \text{xslp_eTol_r}$ or less than $\text{abs}(\text{Negative}) * \text{xslp_eTol_r}$ then it will be regarded as insignificant and will not have its penalty increased. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target **xslp_validationTarget_r**. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: 0.0001

xslp_evTol_a (*real*): Absolute tolerance on total penalty costs ↔

The solution will be regarded as having no active error vectors if one of the following applies: every penalty error vector and penalty delta vector has an activity less than **xslp_errorTol_a**; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than **xslp_evTol_a**; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than $\text{xslp_evTol_r} * \text{Obj}$ where Obj is the current objective function value. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target **xslp_validationTarget_r**. Good values for the control are usually fall between 1e-2 and 1e-6, but normally a magnitude larger than **xslp_eTol_a**.

Range: $[-\infty, \infty]$

Default: -1

xslp_evTol_r (*real*): Relative tolerance on total penalty costs ↔

The solution will be regarded as having no active error vectors if one of the following applies: every penalty error vector and penalty delta vector has an activity less than **xslp_errorTol_a**; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than **xslp_evTol_a**; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than $\text{xslp_evTol_r} * \text{Obj}$ where Obj is the current objective function value. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target **xslp_validationTarget_r**. Good values for the control are usually fall between 1e-2 and 1e-6, but normally a magnitude larger than **xslp_eTol_r**.

Range: $[-\infty, \infty]$

Default: -1

xslp_expand (*real*): Multiplier to increase a step bound ↔

If step bounding is enabled, the step bound for a variable will be increased if successive changes are in the same direction. More precisely, if there are **xslp_sameCount** successive changes reaching the step bound and in the same direction for a variable, then the step bound (B) for the variable will be reset to $B * \text{xslp_expand}$.

Range: $[1, \infty]$

Default: 2

xslp_feasTolTarget (*real*): When set, this defines a target feasibility tolerance to which the linearizations are solved to ↔

This is a soft version of XPRS_FEASTOL, and will dynamically revert back to XPRS_FEASTOL if the desired accuracy could not be achieved.

Range: $[0, \infty]$

Default: `not set`

xslp_filter (*integer*): Bit map for controlling solution updates \leftrightarrow

Bits 0 determine if XSLPgetspsol should return the final converged solution, or the solution which had the best value according to the merit function. If bit 1 is set, a cascaded solution which does not improve the merit function will be rejected (Xpress SLP will revert to the solution of the linearization). Bits 2-3 determine the strategy for when the step direction is not improving according to the merit function.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 3

value	meaning
bit 0 = 1	Equivalent to xslp_filterKeepBest .
bit 1 = 2	Check cascaded solutions against improvements in the merit function.
bit 2 = 4	Equivalent to xslp_filterZeroLineSearch .
bit 3 = 8	Equivalent to xslp_filterZeroLineSearchTR .

xslp_filterKeepBest (*boolean*): Retrain solution best according to the merit function \leftrightarrow

See also [xslp_filter](#).

Default: 1

xslp_filterZeroLineSearch (*boolean*): Force minimum step sizes in line search \leftrightarrow

See also [xslp_filter](#).

Default: 0

xslp_filterZeroLineSearchTR (*boolean*): Accept the trust region step is the line search returns a zero step size \leftrightarrow

See also [xslp_filter](#).

Default: 0

xslp_findIV (*integer*): Option for running a heuristic to find a feasible initial point \leftrightarrow

The procedure uses bound reduction (and, up to an extent, probing) to obtain a point in the initial bounding box that is feasible for the bound reduction techniques. If an initial point is already specified and is found not to violate bound reduction, then the heuristic is not run and the given point is used as the initial solution.

Default: `auto`

value	meaning
-1	Automatic (default).
0	Disable the heuristic.
1	Enable the heuristic.

xslp_granularity (*real*): Base for calculating penalty costs ↔

If **xslp_granularity** > 1, then initial penalty costs will be powers of **xslp_granularity**.

Range: [1, ∞]

Default: 4

xslp_hessian (*integer*): Second order differentiation mode when using analytical derivatives ↔

Symbolic mode differentiation for the second order derivatives is only available when **xslp_jacobian** is also set to symbolic mode.

Default: -1

value	meaning
1	Numerical derivatives (finite difference)
2	Symbolic differentiation
3	Automatic differentiation
-1,0	Automatic selection

xslp_heurStrategy (*integer*): Branch and Bound: MINLP heuristic strategy ↔

On some problems it is worth trying more comprehensive heuristic strategies by setting HEURSTRATEGY to 2 or 3. Note that HEURSTRATEGY is deprecated, use **heurEmphasis** instead.

Default: auto

value	meaning
-1	Automatic selection of heuristic strategy.
0	No heuristics.
1	Basic heuristic strategy.
2	Enhanced heuristic strategy.
3	Extensive heuristic strategy.
4	Run all heuristics without effort limits.

xslp_infeasLimit (*integer*): Maximum number of consecutive infeasible SLP iterations which can occur before Xpress-SLP terminates ↔

An infeasible solution to an SLP iteration means that is likely that Xpress-SLP will create a poor linear approximation for the next SLP iteration. Sometimes, small infeasibilities arise because of numerical difficulties and do not seriously affect the solution process. However, if successive solutions remain infeasible, it is unlikely that Xpress-SLP will be able to find a feasible converged solution. **xslp_infeasLimit** sets the number of successive SLP iterations which must take place before Xpress-SLP terminates with a status of "infeasible solution".

Range: {0, ..., ∞}

Default: 3

xslp_infinity (*real*): Value returned by a divide-by-zero in a formula ↔

Range: $[0, \infty]$

Default: `1e+10`

xslp_iterLimit (*integer*): Maximum number of SLP iterations \leftrightarrow

If Xpress-SLP reaches **xslp_iterLimit** without finding a converged solution, it will stop. For MISLP, the limit is on the number of SLP iterations at each node.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

xslp iTol a (*real*): Absolute impact convergence tolerance \leftrightarrow

The absolute impact convergence criterion assesses the change in the effect of a coefficient in a constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. $E = X * C$ where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as $E1 = X * C0 + \delta X * C'0$ where X is as before, $C0$ is the value of the coefficient C calculated using the assumed values for the variables and $C'0$ is the value of $\partial C / \partial X$ calculated using the assumed values for the variables. If $C1$ is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by $\delta E = X * C1 - (X * C0 + \delta X * C'0)$. If $\delta E < \text{xslp iTol a}$ then the variable has passed the absolute impact convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target **xslp_validationTarget.r**. Good values for the control are usually fall between $1e-3$ and $1e-6$.

Range: $[-\infty, \infty]$

Default: `auto`

xslp iTol r (*real*): Relative impact convergence tolerance \leftrightarrow

The relative impact convergence criterion assesses the change in the effect of a coefficient in a constraint in relation to the magnitude of the constituents of the constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. $E = X * C$ where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as $E1 = X * C0 + \delta X * C'0$ where X is as before, $C0$ is the value of the coefficient C calculated using the assumed values for the variables and $C'0$ is the value of $\partial C / \partial X$ calculated using the assumed values for the variables. If $C1$ is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by $\delta E = X * C1 - (X * C0 + \delta X * C'0)$. All the elements of the constraint are examined, excluding delta and error vectors: for each, the contribution to the constraint is evaluated as the element multiplied by the activity of the vector in which it appears; it is then included in a total positive contribution or total negative contribution depending on the sign of the contribution. If the predicted effect of the coefficient is positive, it is tested against the total positive contribution; if the effect of the coefficient is negative, it is tested against the total negative contribution. If $T0$ is the total positive or total negative contribution to the constraint (as appropriate) and $\delta E < T0 * \text{xslp iTol r}$ then the variable has passed the relative impact convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target **xslp_validationTarget.r**. Good values for the control are usually fall between $1e-3$ and $1e-6$.

Range: $[-\infty, \infty]$

Default: `auto`

xslp_jacobian (*integer*): First order differentiation mode when using analytical derivatives ↔

Symbolic mode differentiation for the second order derivatives is only available when **xslp_jacobian** is set to symbolic mode.

Default: -1

value	meaning
1	Numerical derivatives (finite difference)
2	Symbolic differentiation
3	Automatic differentiation
-1,0	Automatic selection

xslp_linQuadBR (*integer*): Use linear and quadratic constraints and objective function to further reduce bounds on all variables ↔

While bound reduction is effective when performed on nonlinear, nonquadratic constraints and objective function, it can be useful to obtain tightened bounds from linear and quadratic constraints, as the corresponding variables may appear in other nonlinear constraints. This option then allows for a slightly more expensive bound reduction procedure, at the benefit of further reduction in the problem's bounds.

Default: auto

value	meaning
-1	Automatic selection
0	Disable
1	Enable

xslp_log (*integer*): Level of printing during SLP iterations ↔

Default: 0

value	meaning
-1	None
0	Minimal
1	Normal: iteration, penalty vectors
2	Omit from convergence log any variables which have converged
3	Omit from convergence log any variables which have already converged (except variables on step bounds)
4	Include all variables in convergence log
5	Include user function call communications in the log

xslp_lsIterLimit (*integer*): Number of iterations in the line search ↔

The line search attempts to refine the step size suggested by the trust region step bounds. The line search is a local method; the control sets a maximum on the number of model evaluations during the line search.

Range: {0, ..., ∞}

Default: 0

xslp_lsPatternLimit (*integer*): Number of iterations in the pattern search preceding the line search ↔

When positive, defines the number of samples taken along the step size suggested by the trust region step bounds before initiating the line search. Useful for highly non-convex problems.

Range: {0, ..., ∞}

Default: 0

xslp_lsStart (*integer*): Iteration in which to active the line search ↔

Range: {0, ..., ∞}

Default: 8

xslp_lsZeroLimit (*integer*): Maximum number of zero length line search steps before line search is deactivated ↔

When the line search repeatedly returns a zero step size, counteracted by bits set on [xslp_filter](#), the effort spent in line search is redundant, and line search will be deactivated after [xslp_lsZeroLimit](#) consecutive such iteration.

Range: {0, ..., ∞}

Default: 5

xslp_maxWeight (*real*): Maximum penalty weight for delta or error vectors ↔

When penalty vectors are created, or when their weight is increased by escalation, the maximum weight that will be used is given by [xslp_maxWeight](#).

Range: [0, ∞]

Default: 100

xslp_meritLambda (*real*): Factor by which the net objective is taken into account in the merit function ↔

The merit function is evaluated in the original, non-augmented / linearized space of the problem. A solution is deemed improved, if either feasibility improved, or if feasibility is not deteriorated but the net objective is improved, or if the combination of the two is improved, where the value of the [xslp_meritLambda](#) control is used to combine the two measures. A nonpositive value indicates that the combined effect should not be checked.

Range: [0, ∞]

Default: 0

xslp_minSBFactor (*real*): Factor by which step bounds can be decreased beneath [xslp_aTol.a](#) ↔

Normally, step bounds are not decreased beneath [xslp_aTol.a](#), as such variables are treated as converged. However, it may be beneficial to decrease step bounds further, as individual variable value changes might affect the convergence of other variables in the model, even if the variable itself is deemed converged.

Range: [0, ∞]

Default: 1

xslp_minWeight (*real*): Minimum penalty weight for delta or error vectors ↔

When penalty vectors are created, the minimum weight that will be used is given by [xslp_minWeight](#).

Range: $[0, \infty]$

Default: 0.01

xslp_mipAlgorithm (*integer*): Bitmap describing the MISLP algorithms to be used ↔

[xslp_mipAlgorithm](#) determines the strategy of XSLPglobal for solving MINLP problems. The recommended approach is to solve the problem first without reference to the global variables. This can be handled automatically by setting bit 0 of [xslp_mipAlgorithm](#); if done manually, then optimize using the "P" option to prevent the Optimizer presolve from changing the problem. Some versions of the optimizer re-run the initial node as part of the global search; it is possible to initiate a new SLP optimization at this point by relaxing or fixing step bounds (use bits 2 and 3). If step bounds are fixed for a class of variable, then the variables in that class will not change their value in any child node. At each node, it is possible to relax or fix step bounds. It is recommended that step bounds are relaxed, so that the new problem can be solved starting from its parent, but without undue restrictions caused by step bounding (use bit 4). Exceptionally, it may be preferable to restrict the freedom of child nodes by relaxing fewer types of step bound or fixing the values of some classes of variable (use bit 5). When the optimal node has been found, it is possible to fix the global variables and then re-optimize with SLP. Step bounds can be relaxed or fixed for this optimization as well (use bits 7 and 8). Although it is ultimately necessary to solve the optimal node to convergence, individual nodes can be truncated after [xslp_mipIterLimit](#) SLP iterations. Set bit 6 to activate this feature. The normal MISLP algorithm uses SLP at each node. One alternative strategy is to use the MIP optimizer for solving each SLP iteration. Set bit 9 to implement this strategy ("MIP within SLP"). Another strategy is to solve the problem to convergence ignoring the nature of the global variables. Then, fixing the linearization, use MIP to find the optimal setting of the global variables. Then, fixing the global variables, but varying the linearization, solve to convergence. Set bit 10 to implement this strategy ("SLP then MIP"). For mode details about MISLP algorithms and strategies, see the separate section.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 17

value	meaning
bit 0 = 1	Equivalent to xslp_mipAlgorithm_initialSLP .
bit 2 = 4	Equivalent to xslp_mipAlgorithm_initialRelaxSLP .
bit 3 = 8	Equivalent to xslp_mipAlgorithm_initialFixSLP .
bit 4 = 16	Equivalent to xslp_mipAlgorithm_nodeRelaxSLP .
bit 5 = 32	Equivalent to xslp_mipAlgorithm_nodeFixSLP .
bit 6 = 64	Equivalent to xslp_mipAlgorithm_nodeLimitSLP .
bit 7 = 128	Equivalent to xslp_mipAlgorithm_finalRelaxSLP .
bit 8 = 256	Equivalent to xslp_mipAlgorithm_finalFixSLP .
bit 9 = 512	Equivalent to xslp_mipAlgorithm_withinSLP .
bit 10 = 1024	Equivalent to xslp_mipAlgorithm_slpThenMIP .

xslp_mipAlgorithm_finalFixSLP (*boolean*): Fix step bounds according to [xslp_mipFixStepBounds](#) after MIP solution is found ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipAlgorithm_finalRelaxSLP (*boolean*): Relax step bounds according to [xslp_mipRelaxStepBounds](#) after MIP solution is found ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipAlgorithm_initialFixSLP (*boolean*): Fix step bounds according to [xslp_mipFixStepBounds](#) after initial node ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipAlgorithm_initialRelaxSLP (*boolean*): Relax step bounds according to [xslp_mipRelaxStepBounds](#) after initial node ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipAlgorithm_initialSLP (*boolean*): Solve initial SLP to convergence ↔

See also [xslp_mipAlgorithm](#).

Default: 1

xslp_mipAlgorithm_nodeFixSLP (*boolean*): Fix step bounds according to [xslp_mipFixStepBounds](#) at each node ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipAlgorithm_nodeLimitSLP (*boolean*): Limit iterations at each node to [xslp_mipIterLimit](#) ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipAlgorithm_nodeRelaxSLP (*boolean*): Relax step bounds according to [xslp_mipRelaxStepBounds](#) at each node ↔

See also [xslp_mipAlgorithm](#).

Default: 1

xslp_mipAlgorithm_slpThenMIP (*boolean*): Use MIP on converged SLP solution and then SLP on the resulting MIP solution ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipAlgorithm_withinSLP (*boolean*): Use MIP at each SLP iteration instead of SLP at each node ↔

See also [xslp_mipAlgorithm](#).

Default: 0

xslp_mipCutOffCount (*integer*): Number of SLP iterations to check when considering a node for cutting off ↔

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last [xslp_mipCutOffCount](#) SLP iterations are all worse than the best obtained so far, and the difference is greater than [xslp_mipCutOff_a](#) and $\text{OBJ} * \text{xslp_mipCutOff_r}$ where OBJ is the best integer solution obtained so far. The test is not applied until at least [xslp_mipCutOffLimit](#) SLP iterations have been carried out at the current node.

Range: {0, ..., ∞}

Default: 5

xslp_mipCutOffLimit (*integer*): Number of SLP iterations to check when considering a node for cutting off ↔

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last [xslp_mipCutOffCount](#) SLP iterations are all worse than the best obtained so far, and the difference is greater than [xslp_mipCutOff_a](#) and $\text{OBJ} * \text{xslp_mipCutOff_r}$ where OBJ is the best integer solution obtained so far. The test is not applied until at least [xslp_mipCutOffLimit](#) SLP iterations have been carried out at the current node.

Range: {0, ..., ∞}

Default: 10

xslp_mipCutOff_a (*real*): Absolute objective function cutoff for MIP termination ↔

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last [xslp_mipCutOffCount](#) SLP iterations are all worse than the best obtained so far, and the difference is greater than [xslp_mipCutOff_a](#) and $\text{OBJ} * \text{xslp_mipCutOff_r}$ where OBJ is the best integer solution obtained so far. The MIP cutoff tests are only applied after [xslp_mipCutOffLimit](#) SLP iterations at the current node.

Range: [0, ∞]

Default: 1e-05

xslp_mipCutOff_r (*real*): Absolute objective function cutoff for MIP termination ↔

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last [xslp_mipCutOffCount](#) SLP iterations are all worse than the best obtained so far, and the difference is greater than [xslp_mipCutOff_a](#) and $\text{OBJ} * \text{xslp_mipCutOff_r}$ where OBJ is the best integer solution obtained so far. The MIP cutoff tests are only applied after [xslp_mipCutOffLimit](#) SLP iterations at the current node.

Range: [0, ∞]

Default: 1e-05

xslp_mipDefaultAlgorithm (*integer*): Default algorithm to be used during the global search in MISLP ↔

The default algorithm used within SLP during the MISLP optimization can be set using [xslp_mipDefaultAlgorithm](#). It will not necessarily be the same as the one best suited to the initial SLP optimization.

Range: {1, ..., 5}

Default: auto

xslp_mipErrorTol_a (*real*): Absolute penalty error cost tolerance for MIP cut-off ↔

The penalty error cost test is applied at each node where there are active penalties in the solution. If [xslp_mipErrorTol_a](#) is nonzero and the absolute value of the penalty costs is greater than [xslp_mipErrorTol_a](#), the node will be declared infeasible. If [xslp_mipErrorTol_a](#) is zero then no test is made and the node will not be declared infeasible on this criterion.

Range: [0, ∞]

Default: 0

xslp_mipErrorTol_r (*real*): Relative penalty error cost tolerance for MIP cut-off ↔

The penalty error cost test is applied at each node where there are active penalties in the solution. If [xslp_mipErrorTol_r](#) is nonzero and the absolute value of the penalty costs is greater than [xslp_mipErrorTol_r](#) * abs(Obj) where Obj is the value of the objective function, then the node will be declared infeasible. If [xslp_mipErrorTol_r](#) is zero then no test is made and the node will not be declared infeasible on this criterion.

Range: [0, ∞]

Default: 0

xslp_mipFixStepBounds (*integer*): Bitmap describing the step-bound fixing strategy during MISLP ↔

At any node (including the initial and optimal nodes) it is possible to fix the step bounds of classes of variables so that the variables themselves will not change. This may help with convergence, but it does increase the chance of a local optimum because of excessive artificial restrictions on the variables.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

value	meaning
bit 0 = 1	Equivalent to xslp_mipFixStepBounds_structNotCoef .
bit 1 = 2	Equivalent to xslp_mipFixStepBounds_structAll .
bit 2 = 4	Equivalent to xslp_mipFixStepBounds_coefOnly .
bit 3 = 8	Equivalent to xslp_mipFixStepBounds_coef .

xslp_mipFixStepBounds_coef (*boolean*): Fix step bounds on SLP variables appearing in coefficients ↔

See also [xslp_mipFixStepBounds](#).

Default: 0

xslp_mipFixStepBounds_coefOnly (*boolean*): Fix step bounds on SLP variables appearing only in coefficients ↔

See also [xslp_mipFixStepBounds](#).

Default: 0

xslp_mipFixStepBounds_structAll (*boolean*): Fix step bounds on all structural SLP variables ↔

See also [xslp_mipFixStepBounds](#).

Default: 0

xslp_mipFixStepBounds_structNotCoef (*boolean*): Fix step bounds on structural SLP variables which are not in coefficients ↔

See also [xslp_mipFixStepBounds](#).

Default: 0

xslp_mipIterLimit (*integer*): Maximum number of SLP iterations at each node ↔

If bit 6 of [xslp_mipAlgorithm](#) is set, then the number of iterations at each node will be limited to [xslp_mipIterLimit](#).

Range: {0, ..., ∞}

Default: 0

xslp_mipLog (*integer*): Frequency with which MIP status is printed ↔

By default (zero or negative value) the MIP status is printed after synchronization points. If [xslp_mipLog](#) is set to a positive integer, then the current MIP status (node number, best value, best bound) is printed every [xslp_mipLog](#) nodes.

Range: {0, ..., ∞}

Default: 0

xslp_mipOCount (*integer*): Number of SLP iterations at each node over which to measure objective function variation ↔

The objective function test for MIP termination is applied only when step bounding has been applied (or [xslp_sbStart](#) SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last [xslp_mipOCount](#) SLP iterations is within [xslp_mipOTol_a](#) or within $\text{OBJ} * \text{xslp_mipOTol}_r$ where OBJ is the average value of the objective function over those iterations.

Range: {0, ..., ∞}

Default: 5

xslp_mipOTol_a (*real*): Absolute objective function tolerance for MIP termination ↔

The objective function test for MIP termination is applied only when step bounding has been applied (or `xslp_sbStart` SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last `xslp_mipOCount` SLP iterations is within `xslp_mipOTol_a` or within `OBJ * xslp_mipOTol_r` where `OBJ` is the average value of the objective function over those iterations.

Range: $[0, \infty]$

Default: `1e-05`

`xslp_mipOTol_r` (*real*): Relative objective function tolerance for MIP termination ↔

The objective function test for MIP termination is applied only when step bounding has been applied (or `xslp_sbStart` SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last `xslp_mipOCount` SLP iterations is within `xslp_mipOTol_a` or within `OBJ * xslp_mipOTol_r` where `OBJ` is the average value of the objective function over those iterations.

Range: $[0, \infty]$

Default: `1e-05`

`xslp_mipRelaxStepBounds` (*integer*): Bitmap describing the step-bound relaxation strategy during MISLP ↔

At any node (including the initial and optimal nodes) it is possible to relax the step bounds of classes of variables so that the variables themselves are completely free to change. This may help with finding a global optimum, but it may also increase the solution time, because more SLP iterations are necessary at each node to obtain a converged solution.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `15`

value	meaning
bit 0 = 1	Equivalent to <code>xslp_mipRelaxStepBounds_structNotCoef</code> .
bit 1 = 2	Equivalent to <code>xslp_mipRelaxStepBounds_structAll</code> .
bit 2 = 4	Equivalent to <code>xslp_mipRelaxStepBounds_coefOnly</code> .
bit 3 = 8	Equivalent to <code>xslp_mipRelaxStepBounds_coef</code> .

`xslp_mipRelaxStepBounds_coef` (*boolean*): Relax step bounds on SLP variables appearing in coefficients ↔

See also `xslp_mipRelaxStepBounds`.

Default: `1`

`xslp_mipRelaxStepBounds_coefOnly` (*boolean*): Relax step bounds on SLP variables appearing only in coefficients ↔

See also `xslp_mipRelaxStepBounds`.

Default: `1`

`xslp_mipRelaxStepBounds_structAll` (*boolean*): Relax step bounds on all structural SLP variables ↔

See also [xslp_mipRelaxStepBounds](#).

Default: 1

xslp_mipRelaxStepBounds_structNotCoef (*boolean*): Relax step bounds on structural SLP variables which are not in coefficients \leftrightarrow

See also [xslp_mipRelaxStepBounds](#).

Default: 1

xslp_msMaxBoundRange (*real*): Defines the maximum range inside which initial points are generated by multistart presets \leftrightarrow

This is the maximum range in which initial points are generated; the actual range is expected to be smaller as bounds and domains are also considered.

Range: $[0, \infty]$

Default: 1000

xslp_mTol_a (*real*): Absolute effective matrix element convergence tolerance \leftrightarrow

The absolute effective matrix element convergence criterion assesses the change in the effect of a coefficient in a constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. $E = X * C$ where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as $E = X * C_0 + \delta X * C'_0$ where V is as before, C_0 is the value of the coefficient C calculated using the assumed values for the variables and C'_0 is the value of $\partial C / \partial X$ calculated using the assumed values for the variables. If C_1 is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by $\delta E = X * C_1 - (X * C_0 + \delta X * C'_0)$. If $\delta E < X * \text{xslp_mTol_a}$ then the variable has passed the absolute effective matrix element convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget_r](#). Good values for the control are usually fall between $1e-3$ and $1e-6$.

Range: $[-\infty, \infty]$

Default: auto

xslp_mTol_r (*real*): Relative effective matrix element convergence tolerance \leftrightarrow

The relative effective matrix element convergence criterion assesses the change in the effect of a coefficient in a constraint relative to the magnitude of the coefficient. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. $E = X * C$ where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as $E_1 = X * C_0 + \delta X * C'_0$ where V is as before, C_0 is the value of the coefficient C calculated using the assumed values for the variables and C'_0 is the value of $\partial C / \partial X$ calculated using the assumed values for the variables. If C_1 is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by $\delta E = X * C_1 - (X * C_0 + \delta X * C'_0)$. If $\delta E < E_1 * \text{xslp_mTol_r}$ then the variable has passed the relative effective matrix element convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget_r](#). Good values for the control are usually fall between $1e-3$ and $1e-6$.

Range: $[-\infty, \infty]$

Default: auto

xslp_multistartPreset (*integer*): Enable multistart \leftrightarrow

Default: 0

value	meaning
0	Disable multistart preset.
1	Generate <code>xslp_multistart_maxSolves</code> number of random base points.
2	Generate <code>xslp_multistart_maxSolves</code> number of random base points, filtered by a merit function centred on initial feasibility.
3	Load the most typical SLP tuning settings. A maximum of <code>xslp_multistart_maxSolves</code> jobs are loaded.
4	Load a comprehensive set of SLP tuning settings. A maximum of <code>xslp_multistart_maxSolves</code> jobs are loaded.

xslp_multistart_maxSolves (*integer*): Maximum number of jobs to create during the multistart search ↩

This control can be increased on the fly during the multistart search: for example, if a job gets refused by a user callback, the callback may increase this limit to account for the rejected job.

Range: $\{-1, \dots, \infty\}$

Default: `unlimited`

xslp_multistart_maxTime (*integer*): Maximum total time to be spent in the multistart search ↩

XSLP_MAXTIME applies on a per job instance basis. There will be some time spent even after `xslp_multistart_maxTime` has elapsed, while the running jobs get terminated and their results collected.

Range: $\{0, \dots, \infty\}$

Default: `unlimited`

xslp_multistart_poolsize (*integer*): Maximum number of problem objects allowed to pool up before synchronization in the deterministic multistart ↩

Deterministic multistart is ensured by guaranteeing that the multistart solve results are evaluated in the same order every time. Solves that finish too soon can be pooled until all earlier started solves finish, allowing the system to start solving other multistart instances in the meantime on idle threads. Larger pool sizes will provide better speedups, but will require larger amounts of memory. Positive values are interpreted as a multiplier on the maximum number of active threads used, while negative values are interpreted as an absolute limit (and the absolute value is used). A value of zero will mean no result pooling.

Range: $\{0, \dots, \infty\}$

Default: 2

xslp_multistart_seed (*integer*): Random seed used for the automatic generation of initial point when loading multistart presets ↩

Range: $\{-\infty, \dots, \infty\}$

Default: 0

xslp_multistart_threads (*integer*): Maximum number of threads to be used in multistart ↩

The current hard upper limit on the number of threads to be used in multistart is 64.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

xslp_mvTol (*real*): Marginal value tolerance for determining if a constraint is slack \leftrightarrow

If the absolute value of the marginal value of a constraint is less than `xslp_mvTol`, then (1) the constraint is regarded as not constraining for the purposes of the slack tolerance convergence criteria; (2) the constraint is not regarded as an active constraint when identifying unconverged variables in active constraints. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target `xslp_validationTarget.r`. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp_objToPenaltyCost (*real*): Factor to estimate initial penalty costs from objective function \leftrightarrow

The setting of initial penalty error costs can affect the path of the optimization and, indeed, whether a solution is achieved at all. If the penalty costs are too low, then unbounded solutions may result although Xpress-SLP will increase the costs in an attempt to recover. If the penalty costs are too high, then the requirement to achieve feasibility of the linearized constraints may be too strong to allow the system to explore the nonlinear feasible region. Low penalty costs can result in many SLP iterations, as feasibility of the nonlinear constraints is not achieved until the penalty costs become high enough; high penalty costs force feasibility of the linearizations, and so tend to find local optima close to an initial feasible point. Xpress-SLP can analyze the problem to estimate the size of penalty costs required to avoid an initial unbounded solution. `xslp_objToPenaltyCost` can be used in conjunction with this procedure to scale the costs and give an appropriate initial value for balancing the requirements of feasibility and optimality. Not all models are amenable to the Xpress-SLP analysis. As the analysis is initially concerned with establishing a cost level to avoid unboundedness, a model which is sufficiently constrained will never show unboundedness regardless of the cost. Also, as the analysis is done at the start of the optimization to establish a penalty cost, significant changes in the coefficients, or a high degree of nonlinearity, may invalidate the initial analysis. A setting for `xslp_objToPenaltyCost` of zero disables the analysis. A setting of 3 or 4 has proved successful for many models. If `xslp_objToPenaltyCost` cannot be used because of the problem structure, its effect can still be emulated by some initial experiments to establish the cost required to avoid unboundedness, and then manually applying a suitable factor. If the problem is initially unbounded, then the penalty cost will be increased until either it reaches its maximum or the problem becomes bounded.

Range: $[0, \infty]$

Default: 0

xslp_oCount (*integer*): Number of SLP iterations over which to measure objective function variation for static objective (2) convergence criterion \leftrightarrow

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least `xslp_mvTol`) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where `Iter` is the `xslp_oCount` most recent SLP iterations and `Obj` is the

corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{xslp_oTol_a}$ then the problem has converged on the absolute static objective (2) convergence criterion. The static objective function (2) test is applied only if `xslp_oCount` is at least 2.

Range: $\{0, \dots, \infty\}$

Default: 5

xslp_optimalityTolTarget (*real*): When set, this defines a target optimality tolerance to which the linearizations are solved to \leftrightarrow

This is a soft version of `optimalityTol`, and will dynamically revert back to `optimalityTol` if the desired accuracy could not be achieved.

Range: $[0, \infty]$

Default: not set

xslp_oTol_a (*real*): Absolute static objective (2) convergence tolerance \leftrightarrow

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least `xslp_mvTol`) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where `Iter` is the `xslp_oCount` most recent SLP iterations and `Obj` is the corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{xslp_oTol_a}$ then the problem has converged on the absolute static objective (2) convergence criterion. The static objective function (2) test is applied only if `xslp_oCount` is at least 2. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target `xslp_validationTarget.k`. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: auto

xslp_oTol_r (*real*): Relative static objective (2) convergence tolerance \leftrightarrow

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least `xslp_mvTol`) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where `Iter` is the `xslp_oCount` most recent SLP iterations and `Obj` is the corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{AVGIter}(\text{Obj}) * \text{xslp_oTol_r}$ then the problem has converged on the relative static objective (2) convergence criterion. The static objective function (2) test is applied only if `xslp_oCount` is at least 2. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target `xslp_validationTarget.k`. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: auto

xslp_penaltyInfoStart (*integer*): Iteration from which to record row penalty information \leftrightarrow

Information about the size (current and total) of active penalties of each row and the number of times a penalty vector has been active is recorded starting at the SLP iteration number given by [xslp_penaltyInfoStart](#).

Range: $\{0, \dots, \infty\}$

Default: 3

xslp_postsolve (*boolean*): Determines whether postsolving should be performed automatically [↔](#)

Default: 0

value	meaning
0	Do not automatically postsolve.
1	Postsolve automatically.

xslp_presolve (*integer*): Determines whether presolving should be performed prior to starting the main algorithm ↔

The Xpress NonLinear nonlinear presolve (which is carried out once, before augmentation) is independent of the Optimizer presolve (which is carried out during each SLP iteration).

Default: 1

value	meaning
0	Disable SLP presolve.
1	Activate SLP presolve.
2	Low memory presolve. Original problem is not restored by postsolve and dual solution may not be completely postsolved.

xslp_presolveLevel (*integer*): Determines the level of changes presolve may carry out on the problem ↔

[xslp_presolveOps](#) controls the operations carried out in presolve. [xslp_presolveLevel](#) controls how those operations may change the problem.

Default: 4

value	meaning
1	Individual rows only presolve, no nonlinear transformations.
2	Individual rows and bounds only presolve, no nonlinear transformations.
3	Presolve allowing changing problem dimension, no nonlinear transformations.
4	Full presolve.

xslp_presolveOps (*integer*): Bitmap indicating the SLP presolve actions to be taken ↔

The Xpress NonLinear nonlinear presolve (which is carried out once, before augmentation) is independent of the Optimizer presolve (which is carried out during each SLP iteration). Linear reductions are performed according to [presolveOps](#) if bit 12 is not set.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 2104

value	meaning
bit 0 = 1	Equivalent to xslp_presolveOps_general .
bit 1 = 2	Equivalent to xslp_presolveOps_fixZero .
bit 2 = 4	Equivalent to xslp_presolveOps_fixAll .
bit 3 = 8	Equivalent to xslp_presolveOps_setBounds .
bit 4 = 16	Equivalent to xslp_presolveOps_intBounds .
bit 5 = 32	Equivalent to xslp_presolveOps_domain .
bit 8 = 256	Equivalent to xslp_presolveOps_noCoefficients .
bit 9 = 512	Equivalent to xslp_presolveOps_noDeltas .

value	meaning
bit 10 = 1024	Equivalent to xslp_presolveOps_noDualSide .
bit 11 = 2048	Equivalent to xslp_presolveOps_eliminations .
bit 12 = 4096	Equivalent to xslp_presolveOps_noLinear .
bit 13 = 8192	Equivalent to xslp_presolveOps_noSimplifier .

xslp_presolveOps_domain (*boolean*): Bound tightening based on function domains [↔](#)

See also [xslp_presolveOps](#).

Default: 1

xslp_presolveOps_eliminations (*boolean*): Allow eliminations on determined variables [↔](#)

See also [xslp_presolveOps](#).

Default: 1

xslp_presolveOps_fixAll (*boolean*): Explicitly fix all columns identified as fixed [↔](#)

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_fixZero (*boolean*): Explicitly fix columns identified as fixed to zero [↔](#)

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_general (*boolean*): Generic SLP presolve [↔](#)

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_intBounds (*boolean*): MISLP bound tightening [↔](#)

See also [xslp_presolveOps](#).

Default: 1

xslp_presolveOps_noCoefficients (*boolean*): Do not presolve coefficients [↔](#)

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_noDeltas (*boolean*): Do not remove delta variables [↔](#)

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_noDualSide (*boolean*): Avoid reductions that can not be dual postsolved [↔](#)

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_noLinear (*boolean*): Avoid performing linear reductions at the nlp level ↔

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_noSimplifier (*boolean*): Avoid simplifying nonlinear expressions ↔

See also [xslp_presolveOps](#).

Default: 0

xslp_presolveOps_setBounds (*boolean*): SLP bound tightening ↔

See also [xslp_presolveOps](#).

Default: 1

xslp_presolveZero (*real*): Minimum absolute value for a variable which is identified as nonzero during SLP presolve ↔

During the SLP (nonlinear)presolve, a variable may be identified as being nonzero (for example, because it is used as a divisor). A bound of plus or minus [xslp_presolveZero](#) will be applied to the variable if it is identified as non-negative or non-positive.

Range: $[0, \infty]$

Default: 1e-09

xslp_primalIntegralRef (*real*): Reference solution value to take into account when calculating the primal integral ↔

When a global optimum is known, this can be used to calculate a globally valid primal integral. It can also be used to indicate the target objective value still to be taken into account in the integral.

Range: $[-\infty, \infty]$

Default: 1e+20

xslp_probing (*integer*): Determines whether probing on a subset of variables should be performed prior to starting the main algorithm ↔

Probing runs multiple times bound reduction in order to further tighten the bounding box.

The Xpress NonLinear nonlinear probing, which is carried out once, is independent of the Optimizer presolve (which is carried out during each SLP iteration). The probing level allows for probing on an expanding set of variables, allowing for probing on all variables (level 5) or only those for which probing is more likely to be useful (binary variables).

Default: auto

value	meaning
-1	Automatic.
0	Disable SLP probing.
1	Activate SLP probing only on binary variables.
2	Activate SLP probing only on binary or unbounded integer variables.
3	Activate SLP probing only on binary or integer variables.
4	Activate SLP probing only on binary, integer variables, and unbounded continuous variables.
5	Activate SLP probing on any variable.

xslp_sameCount (*integer*): Number of steps reaching the step bound in the same direction before step bounds are increased ↔

If step bounding is enabled, the step bound for a variable will be increased if successive changes are in the same direction. More precisely, if there are **xslp_sameCount** successive changes reaching the step bound and in the same direction for a variable, then the step bound (B) for the variable will be reset to $B * \text{xslp_expand}$.

Range: {0, ..., ∞}

Default: 3

xslp_sameDamp (*integer*): Number of steps in same direction before damping factor is increased ↔

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are **xslp_sameDamp** successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to $D * \text{xslp_dampExpand} + \text{xslp_dampMax} * (1 - \text{xslp_dampExpand})$.

Range: {0, ..., ∞}

Default: 3

xslp_sbStart (*integer*): SLP iteration after which step bounds are first applied ↔

If step bounds are used, they can be applied for the whole of the SLP optimization process, or started after a number of SLP iterations. In general, it is better not to apply step bounds from the start unless one of the following applies: (1) the initial estimates are known to be good, and explicit values can be provided for initial step bounds on all variables; or (2) the problem is unbounded unless all variables are step-bounded.

Range: {0, ..., ∞}

Default: 8

xslp_scale (*integer*): When to re-scale the SLP problem ↔

During the SLP optimization, matrix entries can change considerably in magnitude, even when the formulae in the coefficients are not very nonlinear. Re-scaling of the matrix can reduce numerical errors, but may increase the time taken to achieve convergence.

Default: 1

value	meaning
0	No re-scaling.
1	Re-scale every SLP iteration up to xslp_scaleCount iterations after the end of barrier optimization.
2	Re-scale every SLP iteration up to xslp_scaleCount iterations in total.
3	Re-scale every SLP iteration until primal simplex is automatically invoked.
4	Re-scale every SLP iteration

xslp_scaleCount (*integer*): Iteration limit used in determining when to re-scale the SLP matrix ↔

If **xslp_scale** is set to 1 or 2, then **xslp_scaleCount** determines the number of iterations (after the end of barrier optimization or in total) in which the matrix is automatically re-scaled.

Range: {0, ..., ∞}

Default: 0

xslp_shrink (*real*): Multiplier to reduce a step bound ↔

If step bounding is enabled, the step bound for a variable will be decreased if successive changes are in opposite directions. The step bound (B) for the variable will be reset to $B * \text{xslp_shrink}$. If the step bound is already below the strict (delta or closure) tolerances, it will not be reduced further.

Range: [0, 1]

Default: 0.5

xslp_shrinkBias (*real*): Defines an overwrite / adjustment of step bounds for improving iterations ↔

Positive values overwrite **xslp_shrink** only if the objective is improving. A negative value is used to scale all step bounds in improving iterations.

Range: $[-\infty, \infty]$

Default: not set

xslp_slpLog (*integer*): Frequency with which SLP status is printed ↔

If **xslp_log** is set to zero (minimal logging) then a nonzero value for **xslp_slpLog** defines the frequency (in SLP iterations) when summary information is printed out.

Range: {0, ..., ∞}

Default: 1

xslp_solver (*integer*): First order differentiation mode when using analytical derivatives ↔

The presence of **KNITRO** is detected automatically. **KNITRO** can be used to solve any problem loaded into XSLP, independently from how the problem was loaded. **xslp_solver** is set to automatic, Xpress SLP will be selected if any SLP specific construct has been loaded (these are ignored if **KNITRO** is selected manually).

Default: auto

value	meaning
-1	Automatic selection, based on model characteristics and solver availability
0	Use Xpress-SLP (always available)
1	Use Knitro if available

xslp_sTol_a (*real*): Absolute slack convergence tolerance ↔

The slack convergence criterion is identical to the impact convergence criterion, except that the tolerances used are **xslp_sTol_a** (instead of **xslp_iTol_a**) and **xslp_sTol_r** (instead of **xslp_iTol_r**).

See [xslp iTol a](#) for a description of the test. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget r](#). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp_sTol_r (*real*): Relative slack convergence tolerance \leftrightarrow

The slack convergence criterion is identical to the impact convergence criterion, except that the tolerances used are [xslp_sTol a](#) (instead of [xslp iTol a](#)) and [xslp_sTol_r](#) (instead of [xslp iTol_r](#)). See [xslp iTol_r](#) for a description of the test. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target [xslp_validationTarget r](#). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp_stopOutOfRange (*boolean*): Stop optimization and return error code if internal function argument is out of range \leftrightarrow

If [xslp_stopOutOfRange](#) is set to 1, then if an internal function receives an argument which is out of its allowable range (for example, LOG of a negative number), an error code is set and the optimization is terminated.

Default: 0

xslp_threads (*integer*): Default number of threads to be used \leftrightarrow

Overall thread control value, used to determine the number of threads used where parallel calculations are possible.

Range: $\{-1, \dots, \infty\}$

Default: `auto`

xslp_unfinishedLimit (*integer*): Number of consecutive SLP iterations that may have an unfinished status before the solve is terminated \leftrightarrow

If the optimization of the current linear approximation terminates with an "unfinished" status, then first a number of strategies are applied to attempt a successful solve of the same linearization. If this fails, then a new iteration is started to change the linearization itself. This control limits the number of such repeated attempts.

Range: $\{0, \dots, \infty\}$

Default: 3

xslp_validationTarget_k (*real*): Optimality target tolerance \leftrightarrow

Primary optimality control for SLP. When the relevant optimality based convergence controls are left at their default values, SLP will adjust their value to match the target. The control defines a target value, that may not necessarily be attainable for problem with no strong constraint qualifications.

Range: $[0, \infty]$

Default: `1e-06`

xslp_validationTarget_r (*real*): Feasibility target tolerance ↔

Primary feasibility control for SLP. When the relevant feasibility based convergence controls are left at their default values, SLP will adjust their value to match the target. The control defines a target value, that may not necessarily be attainable.

Range: $[0, \infty]$

Default: 1e-06

xslp_vCount (*integer*): Number of SLP iterations over which to measure static objective (3) convergence ↔

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where Iter is the **xslp_vCount** most recent SLP iterations and Obj is the corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{xslp_vTol_a}$ then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least **xslp_vLimit** + **xslp_sbStart** SLP iterations have taken place and only if **xslp_vCount** is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced.

Range: $\{0, \dots, \infty\}$

Default: 0

xslp_vLimit (*integer*): Number of SLP iterations after which static objective (3) convergence testing starts ↔

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where Iter is the **xslp_vCount** most recent SLP iterations and Obj is the corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{xslp_vTol_a}$ then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least **xslp_vLimit** + **xslp_sbStart** SLP iterations have taken place and only if **xslp_vCount** is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced.

Range: $\{0, \dots, \infty\}$

Default: 0

xslp_vTol_a (*real*): Absolute static objective (3) convergence tolerance ↔

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where Iter is the `xslp.vCount` most recent SLP iterations and Obj is the corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{xslp.vTol.a}$ then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least `xslp.vLimit` + `xslp.sbStart` SLP iterations have taken place and only if `xslp.vCount` is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target `xslp.validationTarget.k`. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp.vTol.r (*real*): Relative static objective (3) convergence tolerance ↔

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where Iter is the `xslp.vCount` most recent SLP iterations and Obj is the corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{AVGIter}(\text{Obj}) * \text{xslp.vTol.r}$ then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least `xslp.vLimit`

- `xslp.sbStart` SLP iterations have taken place and only if `xslp.vCount` is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target `xslp.validationTarget.k`. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp.wCount (*integer*): Number of SLP iterations over which to measure the objective for the extended convergence continuation criterion ↔

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. The extended convergence continuation criterion is applied after a converged solution has been found where at least one variable has converged on extended criteria and is at its step bound limit. The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the last converged solution is given by: $\delta\text{Obj} = \text{Obj} - \text{LastConvergedObj}$ For a minimization problem, the sign is reversed. If $\delta\text{Obj} > \text{xslp.wTol.a}$ and $\delta\text{Obj} > \text{ABS}(\text{ConvergedObj}) * \text{xslp.wTol.r}$

then the solution is deemed to have a significantly better objective function value than the converged solution. When a solution is found which converges on extended criteria and with active step bounds, the solution is saved and SLP optimization continues until one of the following: (1) a new solution is found which converges on some other criterion, in which case the SLP optimization stops with this new solution; (2) a new solution is found which converges on extended criteria and with active step bounds, and which has a significantly better objective function, in which case this is taken as the new saved solution; (3) none of the `xslp_wCount` most recent SLP iterations has a significantly better objective function than the saved solution, in which case the saved solution is restored and the SLP optimization stops. If `xslp_wCount` is zero, then the extended convergence continuation criterion is disabled.

Range: $\{0, \dots, \infty\}$

Default: 0

xslp_wTol_a (*real*): Absolute extended convergence continuation tolerance \leftrightarrow

The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the

last converged solution is given by: $\delta\text{Obj} = \text{Obj} - \text{LastConvergedObj}$ For a minimization problem, the sign is reversed. If $\delta\text{Obj} > \text{xslp_wTol.a}$ and $\delta\text{Obj} > \text{ABS}(\text{ConvergedObj}) * \text{xslp_wTol.r}$ then the solution is deemed to have a significantly better objective function value than the converged solution. If xslp_wCount is greater than zero, and a solution is found which converges on extended criteria and with active step bounds, the solution is saved and SLP optimization continues until one of the following: (1) a new solution is found which converges on some other criterion, in which case the SLP optimization stops with this new solution; (2) a new solution is found which converges on extended criteria and with active step bounds, and which has a significantly better objective function, in which case this is taken as the new saved solution; (3) none of the xslp_wCount most recent SLP iterations has a significantly better objective function than the saved solution, in which case the saved solution is restored and the SLP optimization stops. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target $\text{xslp_validationTarget.k}$. Good values for the control are usually fall between $1e-4$ and $1e-6$.

Range: $[-\infty, \infty]$

Default: auto

xslp_xCount (*integer*): Number of SLP iterations over which to measure static objective (1) convergence
 ↩

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. However, if the objective function has already been stable for several SLP iterations, then there is less likelihood of an improved result, and the converged solution can be accepted. The static objective function (1) test measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. Because all the variables have converged, the solution is already converged but the fact that some variables are at their step bound limit suggests that the objective function could be improved by going further. The variation in the objective function is defined as $\delta\text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj})$ where Iter is the xslp_xCount most recent SLP iterations and Obj is the corresponding objective function value. If $\text{ABS}(\delta\text{Obj}) \leq \text{xslp_xTol.a}$ then the objective function is deemed to be static according to the absolute static objective function (1) criterion. If $\text{ABS}(\delta\text{Obj}) \leq \text{AVGIter}(\text{Obj}) * \text{xslp_xTol.r}$ then the objective function is deemed to be static according to the relative static objective function (1) criterion. The static objective function (1) test is applied only until xslp_xLimit SLP iterations have taken place. After that, if all the variables have converged on strict or extended criteria, the solution is deemed to have converged. If the objective function passes the relative or absolute static objective function (1) test then the solution is deemed to have converged.

Range: $\{0, \dots, \infty\}$

Default: 5

xslp_xLimit (*integer*): Number of SLP iterations up to which static objective (1) convergence testing starts
 ↩

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. Good values for the control are usually fall between 1e-4 and 1e-6.

Range: $[-\infty, \infty]$

Default: `auto`

xslp_zero (*real*): Absolute tolerance ↔

If a value is below `xslp_zero` in magnitude, then it will be regarded as zero in certain formula calculations: an attempt to divide by such a value will give a "divide by zero" error; an exponent of a negative number will produce a "negative number, fractional exponent" error if the exponent differs from an integer by more than `xslp_zero`.

Range: $[0, \infty]$

Default: `1e-15`

xslp_zeroCriterion (*integer*): Bitmap determining the behavior of the placeholder deletion procedure ↔

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `0`

value	meaning
bit 0 = 1	Equivalent to <code>xslp_zeroCriterion_nbSLPVar</code> .
bit 1 = 2	Equivalent to <code>xslp_zeroCriterion_nbDelta</code> .
bit 2 = 4	Equivalent to <code>xslp_zeroCriterion_slpVarNBUpdateRow</code> .
bit 3 = 8	Equivalent to <code>xslp_zeroCriterion_deltaNBUpdateRow</code> .
bit 4 = 16	Equivalent to <code>xslp_zeroCriterion_deltaNBDRRow</code> .
bit 5 = 32	Equivalent to <code>xslp_zeroCriterion_print</code> .

xslp_zeroCriterionCount (*integer*): Number of consecutive times a placeholder entry is zero before being considered for deletion ↔

Range: $\{0, \dots, \infty\}$

Default: `0`

xslp_zeroCriterionStart (*integer*): SLP iteration at which criteria for deletion of placeholder entries are first activated ↔

Range: {0, ..., ∞}

Default: 0

xslp_zeroCriterion_deltaNBDRRow (*boolean*): Remove placeholders in a basic delta variable if the determining row for the corresponding SLP variable is nonbasic ↔

See also [xslp_zeroCriterion](#).

Default: 0

xslp_zeroCriterion_deltaNBUpdateRow (*boolean*): Remove placeholders in a basic delta variable if its update row is nonbasic and the corresponding SLP variable is nonbasic ↔

See also [xslp_zeroCriterion](#).

Default: 0

xslp_zeroCriterion_nbDelta (*boolean*): Remove placeholders in nonbasic delta variables ↔

See also [xslp_zeroCriterion](#).

Default: 0

xslp_zeroCriterion_nbSLPVar (*boolean*): Remove placeholders in nonbasic SLP variables ↔

See also [xslp_zeroCriterion](#).

Default: 0

xslp_zeroCriterion_print (*boolean*): Print information about zero placeholders ↔

See also [xslp_zeroCriterion](#).

Default: 0

xslp_zeroCriterion_slpVarNBUpdateRow (*boolean*): Remove placeholders in a basic SLP variable if its update row is nonbasic ↔

See also [xslp_zeroCriterion](#).

Default: 0

5.45.5 Helpful Hints

The comments below should help both novice and experienced GAMS users to better understand and make use of GAMS/XPRESS.

- **Infeasible and unbounded models** The fact that a model is infeasible/unbounded can be detected at two stages: during the presolve and during the simplex or barrier algorithm. In the first case we cannot recover a solution, nor is any information regarding the infeasible/unbounded constraint or variable provided (at least in a way that can be returned to GAMS). In such a situation, the GAMS link will automatically rerun the model using primal simplex with presolve turned off (this can be avoided by setting the rerun option to 0). It is possible (but very unlikely) that the simplex method will solve a model to optimality while the presolve claims the model is infeasible/unbounded (due to feasibility tolerances in the simplex and barrier algorithms).
- The barrier method does not make use of `iterlim`. Use `bariterlim` in an options file instead. The number of barrier iterations is echoed to the log and listing file. If the barrier iteration limit is reached during the barrier algorithm, XPRESS continues with a simplex algorithm, which will obey the `iterlim` setting.
- Semi-integer variables are not implemented in the link, nor are they supported by XPRESS; if present, they trigger an error message.
- SOS1 and SOS2 variables are required by XPRESS to have lower bounds of 0 and nonnegative upper bounds.

5.45.6 Setting up a GAMS/XPRESS-Link license

To use the GAMS/XPRESS solver with a GAMS/XPRESS-Link license you have to set up the XPRESS portion of the licensing. To do so, copy your XPRESS license `xpauth.xpr` to the GAMS system directory. As of version 24.2 GAMS already comes with a file `xpauth.xpr`. You might consider copying this file to `xpauth.xpr.bak` or similar before overwriting it with your own XPRESS license file.

Chapter 6

Tools Manuals

A large number of tools are included in GAMS distribution. Below are a functional [categorization of all tools](#), an alphabetically sorted [list of all tools](#), and a brief description of each tool with their [Supported Platforms](#).

6.1 Tools Category

All tools included in GAMS distribution are categorized as

6.1.1 GAMS Integrated Development Environments

There are two integrated model development environments including a general text editor with the ability to launch and monitor the compilation and execution of GAMS models: The [GAMS IDE](#) and [GAMS Studio](#).

6.1.2 Data Exchange

A collection of tools that provide functionality to exchange data between GAMS and other data sources. This category contains tools for popular data sources and high-level programming environment and like databases ([GDX2ACCESS](#), [GDX2SQLITE](#), [MDB2GMS](#), [SQL2GMS](#)), Matlab ([GDXMRW](#)), and R ([GDXRRW](#)). There are also tools for specialized systems like HAR ([GDX2HAR](#) and [HAR2GDX](#)), TROLL ([GDXTROLL](#)), and VEDA ([GDX2VEDA](#)).

6.1.2.1 Excel

Tools to exchange data with Microsoft Excel are grouped in a subcategory [Excel](#). The tools in this category are [GDX2XLS](#), [GDXXRW](#), [MSAPPAVAIL](#), [XLS2GMS](#), [XLSDUMP](#), and [XLSTALK](#). Many of the tools described here use the GAMS Data eXchange facility [GAMS Data eXchange \(GDX\)](#).

6.1.3 GDX Service

A collection of tools that operate directly on [GAMS Data eXchange \(GDX\)](#) containers to e.g. compare ([GDXDIFF](#)), copy ([GDXCOPY](#)), merge ([GDXMERGE](#)), and rename ([GDXRENAME](#)).

6.1.4 Data Transformation

A collection of tools that perform very specific tasks that are awkward or inefficient to implement in GAMS directly. Through [GAMS Data eXchange \(GDX\)](#) and the execution of the tools in this category allow to perform complex tasks from a GAMS model like identifying eigenvalues or the inverse of a matrix.

The tools in this category are [CHOLESKY](#), [CSDP](#), [EIGENVECTOR](#), [EIGENVALUE](#), [GDXRANK](#), [MessageReceiverWindow](#), [INVERT](#), [MCFILTER](#), [SCENRED](#), and [SCENRED2](#).

6.1.5 Other Tools

A collection of more exotic tools that can become handy in some some special circumstances. The tools in this category are [ASK](#), [CHK4UPD](#), [ENDECRYPT](#), [FINDTHISGAMS](#), [GAMS Posix Utilities](#), [MODEL2TEX](#), and [ShellExecute](#). Most notably, the collection contains the tool [MODEL2TEX](#) to document the model algebra in LaTeX format.

6.2 List of Tools

The following table gives an alphabetically sorted list of all available tools.

Tool	Description
ASK	The utility can be used to get input from an user interactively.
CHK4UPD	Checks whether the user can update to a more recent GAMS version.
CHOLESKY	Calculates the Choleksy decomposition of a symmetric positive definite matrix.
CSDP	The semidefinite programming CSDP solver from COIN-OR. The communication with CSDP requires the setup of matrix data structures in a CSDP input file. In a sense a GAMS model functions as a matrix generator.
CSV2GDX	Reads a CSV file (comma separated values) and writes to a GDX file.
EIGENVALUE	Calculates eigenvalues of a symmetric matrix.
EIGENVECTOR	Calculates eigenvector of a symmetric matrix.
ENDECRYPT	A tool to encrypt and decrypt text files.
FINDTHISGAMS	Windows command line tool for modifying GAMS specific registry entries created by the GAMS installer.
GAMS IDE	Classic Integrated Development Environment.
GAMS STUDIO	Integrated Development Environment.
GDX2ACCESS	Converts GDX data to MS Access tables.
GDX2HAR	Translates files between GDX and HAR format.
GDX2SQLITE	Dumps the complete contents of a GDX file into a SQLite2 database. From Amsterdam Optimization Modeling Group.
GDX2VEDA	Translates a GDX file into the VEDA format.
GDX2XLS	Converts GDX data into a MS Excel spreadsheet.
GDXCOPY	Converts a GDX file into different GDX formats.
GDXDIFF	Compares the data of symbols with the same name, type and dimension in two GDX files and writes the differences to a third GDX file.

Tool	Description
GDxDUMP	Writes scalars, sets and parameters (tables) to standard output formatted as a GAMS program with data statements.
GDxMERGE	Combines multiple GDx files into one file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.
GDxMRW	A suite of utilities to import/export data between GAMS and MATLAB and to call GAMS models from MATLAB and get results back into MATLAB .
GDxRANK	Reads one or more one dimensional parameters from a GDx file, sorts each parameter and writes the sorted indices as a one dimensional parameters to the output GDx file.
GDxRENAME	Replaces UEL strings in GDx files.
GDxRRW	An interface between GAMS and R . It includes functions to transfer data between GDx and R and a function to call GAMS from R .
GDxTROLL	Translates a GDx file into the TROLL format.
GDxVIEWER	Views and converts data contained in GDx files.
GDxXRW	Preferred utility to read and write MS Excel spreadsheet data.
GMSUNZIP	A copy of the decompression tool unzip from Info-ZIP prefixed with "gms" for clear identification.
GMSZIP	A copy of the compression and archiving tool zip from Info-ZIP prefixed with "gms" for clear identification.
HAR2GDx	Translates files between GDx and HAR format.
IDECMDS	Sends commands to the GAMSIDE.
INVERT	Inverts a matrix.
MCFILTER	Removal of duplicate and dominated points in a multi-criteria solution set.
MDB2GMS	Converts data from an MS Access database into a GAMS readable format.
MESSAGE RECEIVER WINDOW	A graphical tool that receives and displays Windows messages.
MODEL2TEX	Translates a GAMS model into LaTeX
MPS2GMS	Translates an MPS file into an equivalent short generic GAMS program using a GDx file to store data.
MSAPPAVAIL	Checks if a MS Office Application is available.
POSIX	A collection of POSIX utilities which are usually available for Windows and the different Unix systems and therefore help to write platform independent scripts.
SCENRED	A tool for the reduction of scenarios that model random data processes of a stochastic program. From Humboldt-University Berlin.
SCENRED2	Scenred2 is a fundamental update of Scenred and offers a scenario tree construction algorithm. From Humboldt-University Berlin.
SHELLEXECUTE	Launches external programs from the command line.
SQL2GMS	Converts data from an SQL database into a GAMS readable format.
XLS2GMS	Converts spreadsheet data from a MS Excel spreadsheet into a GAMS readable format.
XLSDUMP	Writes all worksheets of a MS Excel workbook to a GDx file. Unlike gdxxrw , the program does not require that Excel is installed.
XLSTALK	Open/Close/Run macro in MS Excel.

- awk, cat, cksum, cmp, comm, cp, cut, diff, expr, fold, gdate, grep, gsort, gunzip, gzip, head, join, make, mkdir, mv, od, paste, printf, rm, sed, sleep, tail, tar, tee, test, touch, tr, uniq, wc, xargs

6.4 ASK

Writing a GUI (Graphical User Interface) for a GAMS application requires some serious programming, and therefore place a burden on the knowledge and time of the modeler. In this section we show how extremely simple user interfaces can be built using a few simple tools. The main purpose of these tools is to allow a developer quickly put an application together such that an end-user does not have to edit GAMS files. We assume the end-user runs a GAMS model from the GAMS-IDE.

The ASK utility can be used to get input from an end-user and the GDXViewer tool can be used to present end-results. Together these tools allow you to build a minimalist GUI without any programming.

6.4.1 Usage

ask <options>

where the **options** are

T=string

where the **string** identifies the type of input item to go after and can be

- **integer** - when one wants an integer number
- **float** - when one wants a real number
- **radiobutton** - when one wants a radio button choice
- **combobox** - when one wants a combo (drop down choice) box
- **checkboxlistbox** - when one wants a check list box
- **fileopenbox** - when one wants the name of a file to open
- **filesavebox** - when one wants the name of a file to save

Example: **T=integer**

M="string"

where the **string** is the text to in the box.

Example: **M="Enter a number"**

O="filename"

where the **filename** is the name of a file in which to place the results for subsequent inclusion into GAMS

Example: **O="file.inc"**

D="string 1|string 2..."

where the "string 1|string 2|string 3|...|string n" gives the n strings to be associated with multiple choices when using checkbox, radiobutton, combobox, or checkboxlistbox. The individual strings are separated by the delimiter "|"

Example: **D="Small data set|Medium data set|Large data set"**

E="number 1|number 2..."

where the "number 1|number 2|number 3|...|number n" gives the n numbers to be returned to GAMS associated with the choices made when using checkbox, radiobutton, combobox, or checklistbox. The individual numbers are separated by the delimiter "|"

Example: E="1|2|3|4|5"

I="filepath"

where **filepath** gives the path in which to look for the file under the fileopenbox and filesavebox dialogues. If not specified this is the project directory

Example: I="C:\gams\mine"

F="filemask"

where **filemask** gives the mask for acceptable files under the fileopenbox and filesavebox dialogues. If not specified this is *.*.

Example: I="*.gdx"

R="string"

where the **string** gives a line of GAMS code to place in the include file.

This can contain a s parameter in which the information to return is substituted

Example: R="\$include '%s'" or R="set i /1990*%s/;"

C="string"

A title for the dialogue box being used

Example: C="Box to ask for a file"

L=number

where the **number** gives a lower bound on a numeric entry

Example: L=15

U=number

where the **number** gives an upper bound on a numeric entry

Example: U=15

@ "filename"

where **filename** gives the name of a file of input instructions containing the options above in this table

Example: @ask.opt

In addition a number by itself can be entered to put multiple entries into columns under the **checkbox**, **radiobutton**, **combobox**, or **checkboxlistbox** entries.

6.4.2 Calling ASK utility from GAMS

The ASK utility is a simple tool to ask simple interactive questions to the end-user. For instance, if your model requires a scalar to be changed regularly, instead of letting the end-user change the .gms source file, it may be better to pop up a window, with a question text, where the required number can be entered. The ASK tool allows you to do this. As the ASK tool generates a standard GAMS include file, this file can then be used through a \$include statement:

```
$call =ask T=integer M="Enter number of cities" o=n.inc
Scalar n 'number of cities' /
$include n.inc
/;
display n;
```

The \$call statement will invoke the ASK tool. If ASK.EXE is not located in the GAMS system directory but placed somewhere else you may have to provide a path, as in:

```
$call =d:\util\ask T=integer M="Enter number of cities" o=n.inc
```

The parameter T=integer indicates we want to ask for an integer number (T means type). The parameter M="text" specifies the question text. Finally O=filename sets the name of the include file that ASK should create.

When we run this GAMS fragment from the IDE, we will see:

After enter a number and hitting the OK button GAMS will continue. The listing file will demonstrate clearly how the include file was formed:

```

2 scalar n 'number of cities' /
INCLUDE D:\GAMS PROJECTS\ASK\N.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 12
7 /;
8 display n;
Include File Summary
SEQ GLOBAL TYPE PARENT LOCAL FILENAME
1 1 INPUT 0 0 D:\GAMS PROJECTS\ASK\X.GMS
2 1 CALL 1 1 =ask T=integer M="Enter number of cities" o=n.inc
3 3 INCLUDE 1 3 .D:\GAMS PROJECTS\ASK\N.INC

```

In this case 12 was entered and the OK button was pressed. If the user pressed the CANCEL button, an error will be generated and the listing file will show that the CANCEL button was pressed:

```

2 scalar n 'number of cities' /
INCLUDE D:\GAMS PROJECTS\ASK\N.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 * Cancel was pressed
7 /;
* **** $1
* **** LINE 4 INPUT D:\GAMS PROJECTS\ASK\X.GMS
* **** 1 Real number expected
8 display n;

```

In case you want to limit the integer that the user is allowed to enter you can specify a lower and an upperbound as in:

```

$call =ask T=integer M="Give integer, between 0 and 5" L=0 U=5 O=n1.inc
Scalar n1 'an integer 0..5' /
$include n1.inc
/;
display n1;

```

This will only accept values between 0 and 5.

To allow the user to specify a floating point number, we can use T=float. An example is:

```

$call =ask T=float M="Give floating point number, no bounds" O=x.inc
Scalar x 'real' /
$include x.inc
/;
display x;

```

The floating point popup window can be told to make sure the number entered is within certain bounds, using the L=lowerbound and U=upperbound syntax:

```

$call =ask T=float M="Give floating point number, between 0 and 5" L=0 U=5.0 O=x1.inc
Scalar x1 'real' /
$include x1.inc
/;
display x1;

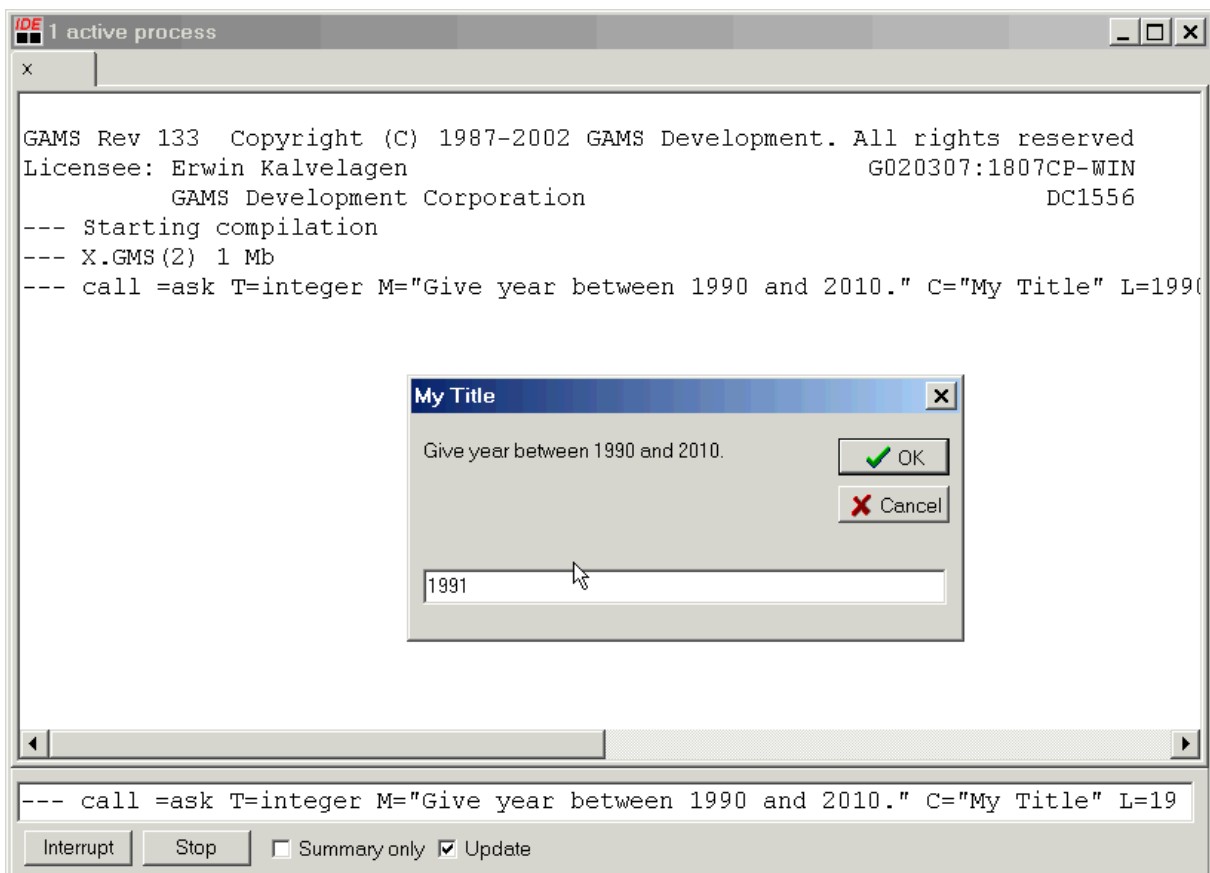

```

Up to now, the include file generated by ASK just contained a single number. ASK can generate more complicated include files. Consider the example:

```

* import a set
$call =ask T=integer M="Give year between 1990 and 2010." C="My Title" L=1990 U=2010 R="set i /1990*"
$include i.inc
display i;

```

The parameters `C="caption"` and `R="resultstring"` are new. The caption is simple: it sets the name of the window. The result string is a string that is returned after ASK has substituted `s` for the result. I.e. if we enter 1991, then the result written to the include file is `set i /1990*1991/;`.

The listing file can be used to check the correct behavior:

```

1 * import a set
INCLUDE D:\GAMS PROJECTS\ASK\I.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 set i /1990*1991/;

```

```

7 display i;
Include File Summary
SEQ  GLOBAL TYPE      PARENT  LOCAL  FILENAME
  1      1 INPUT        0       0  D:\GAMS PROJECTS\ASK\X.GMS
  2      2 CALL          1       2  =ask T=integer M="Give year between 1990 and 2010." C="My Ti
      R="set i /1990*%/s/;" O=i.inc
  3      3 INCLUDE      1       3  .D:\GAMS PROJECTS\ASK\I.INC

```

6.4.3 Radio Button

Radio buttons can be used through the parameter `T=radiobuttons` as in:

```

* import a number through radio buttons
$call =ask T=radiobuttons M="Choose single option" D="option 1|option 2|option 3|option 4|option 5"
$include n2.inc
display n2;

```

The parameter `D="option 1|option 2|option 3|option 4|option 5"` specifies the text of the options shown. The list `E="1|2|3|4|5"` gives the return (exit) strings when a certain option is chosen. I.e. if the second option is chosen in the list specified with the `D` parameter, then the second string in the `E` list is returned. The result is again substituted in the string specified in the `R` parameter if it exists.

In this example the command line became rather long and difficult to handle. In addition some Windows systems have restrictive maximum lengths for the command line. Therefore we offer the possibility to specify the command line arguments in a separate external text file. This text file is passed using

```
@filename
```

. Assume the file `ask.opt` looks like:

```

T=radiobuttons
M=Choose single option
D=option 1|option 2|option 3|option 4|option 5|option 6|option 7|option 8|option 9|option 10
E=1|2|3|4|5|6|7|8|9|10
2
R=scalar n3 option /%/s/;
O=n3.inc

```

Every command line parameter is specified on a separate line. Notice the strange option 2; this tells ASK to display the radio buttons in two columns. We can use this option file as follows:

```
* id, now 2 columns and using a parameter file
$call =ask @"ask.opt"
$include n3.inc
display n3;
```

The quotes around the filename are optional, and really only needed if the filename contains blanks.

If you want to keep all the logic in one place, then one can use GAMS to generate the option file. It is noted that it is not possible to use the PUT facility for this. I.e.:

```
File f /asktest.opt/;
put f;
put 'T=checkboxlistbox'/
'M=Choose multiple options'/
'D=option 1|option 2|option 3|option 4|option 5'/
'E=1|2|3|4|5'/
'R=%s checked list box choice'/
'O=k2.inc'/;
putClose;
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

is not correct: the `$call` is handled at compile time, before the `PUT` statement has done its work. However, one could use the following:

```
$echo 'T=checkboxlistbox' > asktest.opt
$echo 'M=Choose multiple options' >> asktest.opt
$echo 'D=option 1|option 2|option 3|option 4|option 5' >> asktest.opt
$echo 'E=1|2|3|4|5' >> asktest.opt
$echo 'R=%s checked list box choice' >> asktest.opt
$echo 'O=k2.inc' >> asktest.opt
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

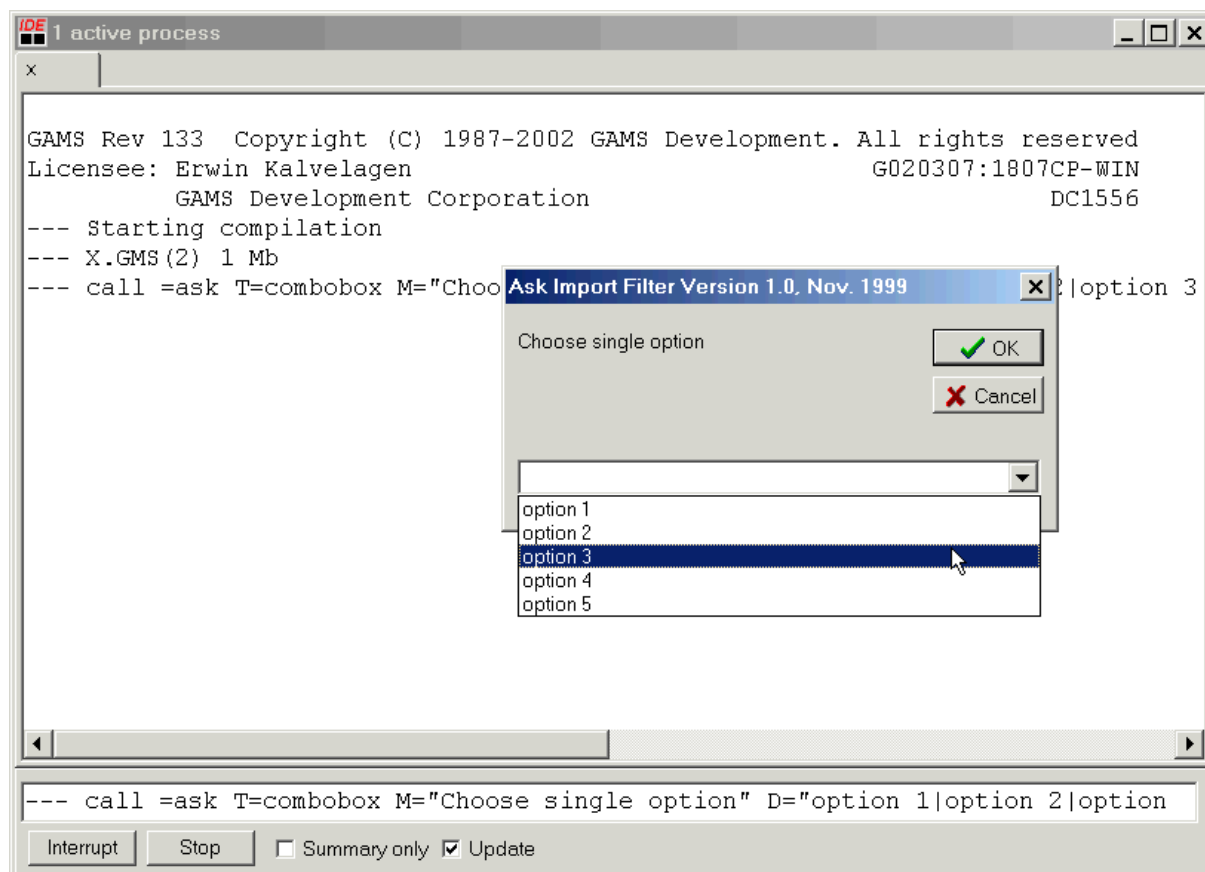

or better:

```
$onEcho > asktest.opt
T=checkboxlistbox
M=Choose multiple options
D=option 1|option 2|option 3|option 4|option 5
E=1|2|3|4|5
R=%s checked list box choice
O=k2.inc
$offEcho
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

6.4.4 Combo Box

The next type is `T=combo` which also allows a single selection:

```
* import a number through a combo box
$call =ask T=combo M="Choose single option" D="option 1|option 2|option 3|option 4|option 5" E="1
$include n4.inc
display n4;
```

As an example consider the case where the model comes with three data sets: a small one, a medium sized one and a large data set. Each data set is stored in a separate include file: `small.inc`, `medium.inc` and `large.inc`. We want to ask the user which data set should be used and the correct include file should be used. This can be accomplished by:

```
$echo 'T=combobox' > ask.opt
$echo 'M=choose data set' >> ask.opt
$echo 'D=Small data set|Medium data set|Large data set' >> ask.opt
$echo 'E=small.inc|medium.inc|large.inc' >> ask.opt
$echo 'R=$include %s' >> ask.opt
$echo 'O=dataset.inc' >> ask.opt
$call =ask @ask.opt
$include dataset.inc
```

Newer GAMS systems allow:

```
$onEcho > ask.opt
T=combobox
M=choose data set
D=Small data set|Medium data set|Large data set
E=small.inc|medium.inc|large.inc
R=$include %s
O=dataset.inc
$offEcho
$call =ask @ask.opt
$include dataset.inc
```

In this case `dataset.inc` will contain a single line: another include statement, which is either `$include small.inc`, `$include medium.inc` or `$include large.inc`.

6.4.5 List and Checklist Box

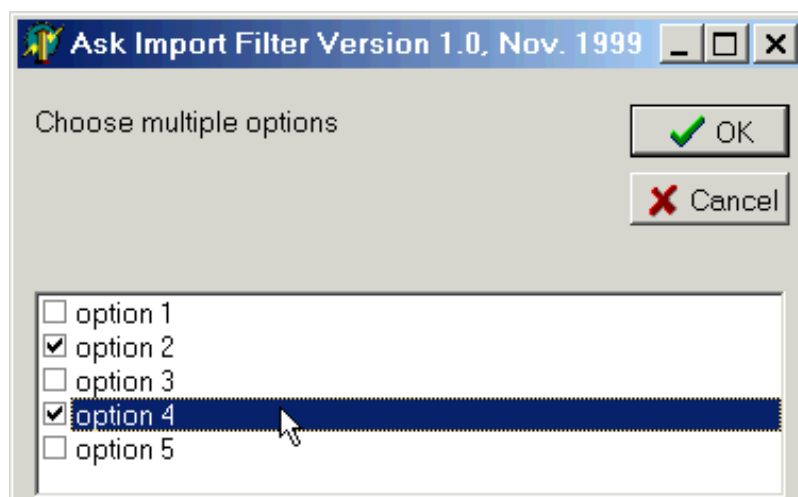

In some cases it may be useful to be able to select multiple items from a list. This can be done with `T=listbox`:

```
* import a set through a listbox
$call =ask T=listbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option 5" E=
Set k /
$include k.inc
/;
display k;
```

Selecting multiple entries involves holding down the CTRL key. Sometimes a convenient alternative is `T=checkboxlistbox`:

```
* import a set through a checked listbox
$call =ask T=checkboxlistbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option 5" E=
Set k2 /
$include k2.inc
/;
display k2;
```

When we select options 1, 3 and 5, the following include file is generated:

```
* Ask Import Filter Version 1.1, Aug. 2002
* Erwin Kalvelagen, GAMS Development Corp.
1 'checked list box choice'
3 'checked list box choice'
5 'checked list box choice'
```

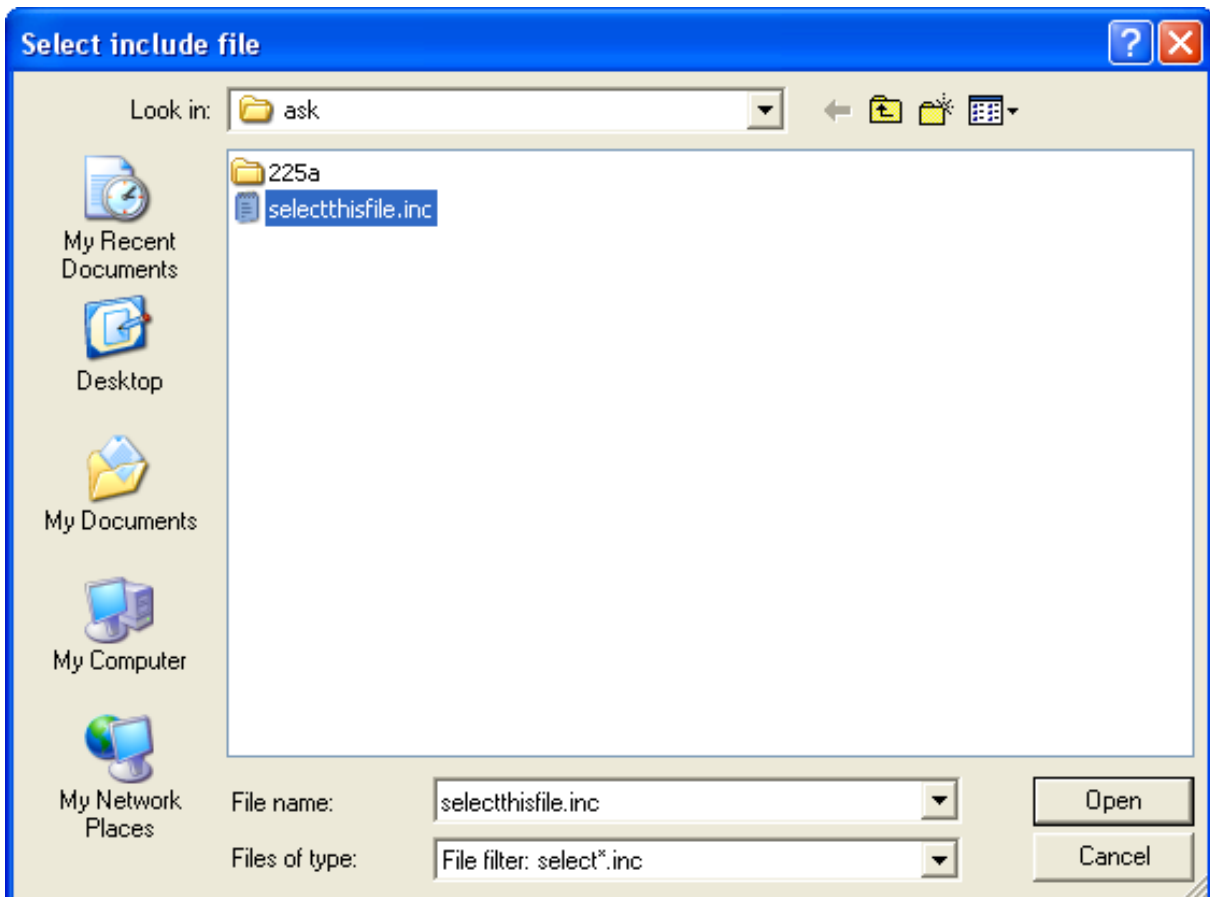

which will populate the set k2 as follows:

```
1 * import a set through a checked listbox
3 set k2 /
INCLUDE D:\GAMS PROJECTS\ASK\K2.INC
5 * Ask Import Filter Version 1.1, Aug. 2002
6 * Erwin Kalvelagen, GAMS Development Corp.
7 1 'checked list box choice'
8 3 'checked list box choice'
9 5 'checked list box choice'
10 /;
11 display k2;
----      11 SET k2
1,      3,      5
```

The last type is the generic string type: `T=string`. This allows the user to enter any string, which is then copied to an include file as is.

6.4.6 File Open Dialog Box

The type `T=fileopenbox` will display a file open dialog box from which the user can select a file.

Related options are `I=InitialDirectory` and `F=Filter`. A complete example to ask for an include file could be:

```
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$include '%s'" C="Select include file"
$include fln.inc
```

This will open a file open dialog box with the starting directory being the `GAMS project/working` directory (this is also where GAMS looks for include files by default). Only files with mask `SELECT*.INC` are shown. The file `FLN.INC` will contain an include statement with the file the user has selected.

A related method would be:

```
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$setglobal incfile '%s'" C="Select include file"
$include fln.inc
$include %incfile%
```

where we use a `$setglobal` to set the macro `incfile` to contain the user-specified file name.

To let the user choose from a set of related GDX files, one could use something like:

```
$call =ask T=fileopenbox I="%system.fp%" F="myproject*.gdx" o=setgdxname.inc R="$setglobal gdxfile '%s'" C="Select gdx file"
$include setgdxname.inc
$gdxIn %gdxfile%
$load i
$load j
```

In case you want to ask for a filename of a file to be written, use the type `T=filesavebox`. E.g.:

```
$call =ask T=filesavebox I="%system.fp%" o=fln.inc R="$setglobal gdxfile '%s'" C="Specify gdx file"
$include fln.inc
Set i / a, b, c /;
execute_unload '%gdxfile%', i;
```

In case you want to ask for a directory, use the type `T=selectdirectory`. In this case the filter option `F` is ignored. E.g.:

```
$call =ask T=selectdirectory I="%system.fp%" o=fln.inc R="$setglobal myInputdir '%s'" C="Select directory"
$include fln.inc
$log Selected directory "%myInputdir%"
```

6.5 CHK4UPD

The tool `chk4upd` checks if there is a newer version of GAMS available than the one you are running. It checks for the most recent version available as well as for the newest version you can run with your license in case your maintenance and support is expired.

By default it reads `gamslice.txt` located in a GAMS [standard location](#). Alternatively, you can specify another license on the command line. In addition to the command line tool you will find an integration in [GAMS Studio](#) and the [GAMS IDE](#) in the `Help` menu.

6.6 CHOLESKY

CHOLESKY calculates the Cholesky decomposition of a symmetric positive definite matrix. Matrix decomposition $A=LL^T$.

6.6.1 Usage

```
cholesky gdxin i a gdxout L
```

where

gdxin

name of gdxfile with matrix

i

name of set used in matrix

a

name of 2 dimensional parameter inside gdxin

gdxout

name of gdxfile for results (factor L)

L

name of 2 dimensional parameter inside gdxout

Calculates the Cholesky decomposition $A=LL^t$ of a symmetric positive definite matrix $A=a(i,j)$ where i and j are aliased sets. L will contain the Cholesky factor $L(i,j)$.

6.6.2 Example

```
$onText
```

```
Finds the Cholesky decomposition  $A=LL'$  of a positive definite symmetric matrix  
A through an external program.
```

```
Erwin Kalvelagen, may 2008
```

```
$offText
```

```
Set i / i1*i5 /;
```

```
Alias (i,j);
```

```
Table a(i,j) 'original matrix'
```

	i1	i2	i3	i4	i5
i1	64	48	24	8	8
i2	48	72	42	54	36
i3	24	42	89	107	95
i4	8	54	107	210	186
i5	8	36	95	186	187;

```

Parameter L(i,j) 'cholesky factor';

execute_unload 'a.gdx', i, a;
execute '=cholesky.exe a.gdx i a b.gdx L';
execute_load 'b.gdx', L;

display a, L;

*
* only lower triangular part of A is used
*
Table a2(i,j) 'original matrix'
      i1  i2  i3  i4  i5
i1    64
i2    48  72
i3    24  42  89
i4     8  54 107 210
i5     8  36  95 186 187;

Parameter L2(i,j) 'cholesky factor';

execute_unload 'a.gdx', i, a2;
execute '=cholesky.exe a.gdx i a2 b.gdx L2';
execute_load 'b.gdx', L2;

display a2, L2;

```

6.7 CSDP

The semidefinite programming [CSDP](#) solver from COIN-OR. The communication with CSDP requires the setup of matrix data structures in a CSDP input file. In a sense a GAMS model functions as a matrix generator.

6.7.1 Usage

```
csdp <input problem> [<final solution>] [<initial solution>]
```

<input problem>

the name of a file containing the SDP problem in SDPA sparse format.

<final solution>

the optional name of a file in which to save the final solution.

<initial solution>

the optional name of a file from which to take the initial solution.

See [CSDP User's Guide](#) for more information.

6.8 CSV2GDX

CSV2GDX is a tool that reads a CSV file and writes to a GDX file. There are multiple ways to read CSV files (Comma Separated Values) inside GAMS (see [Data Exchange with Text Files](#) for instance), but a number of features available in CSV2GDX make it possible to read a CSV file where GAMS itself cannot be used. In addition to the syntax explanation and the basic functionalities demonstrated on some examples, this tutorial also discusses some advantages and disadvantages of CSV2GDX compared to the GAMS internal table statement.

6.8.1 Usage

CSV2GDX is called by specifying the CSV file and several options to define how to read the data.

```
csv2gdx filename {options}
```

Filename

The input file; the .csv file extension is assumed when no extension has been specified.

Parameters can also be read from a text file; the use of an external file for parameters is indicated by preceding the file name with a @ (at sign). When reading parameters from a text file, lines starting with an asterisk (*) will be ignored. See also [Example 8](#).

6.8.2 Options

The following options can be used when calling CSV2GDX:

Option	Default	Description
acceptBadUels	N	Indicate if bad UELs are accepted or result in an error return code.
autoCol	none	Generate automatic UELs for each column.
autoRow	none	Generate automatic UELs for each row.
checkDate	N	Write GDX file only if the CSV file is more recent than the GDX file.
colCount	none	Number of columns in the input file.
decimalSep	Period	Specify a decimal separator.
fieldSep	Comma	Specify a field separator.
id	none	Identifier for the symbol in the GDX file.
index	none	Identify columns to get UELs from.
output	<CSVFilename>.gdx	Optional output filename.
password	none	Password for an encrypted input file.
storeZero	N	Indicate how zero values are handled.
text	none	Specify the column to get explanatory text from.
trace	1	Controls the amount of information written to the log.
useHeader	N	Indicate if the first row is a header row.
value	none	Specify the column to get the values from.
valueDim	N	Adds an extra dimension for values.
values	none	Specify the columns to get the values from.

Note

- The user has to specify an identifier for the symbol in the GDX file within the parameter `id`, regardless of the data structure in the CSV file.
- `CSV2GDX` determines the number of columns in the CSV file from the header row or from the user defined input specified in the parameter `colCount`. Therefore, the user must enable the option `useHeader` or has to specify the number of columns within `colCount` in any case.

Some more detailed remarks on the options:

acceptBadUels = *boolean* (default=N)

This option specifies how to proceed, when a bad UEL (e.g. too long) is encountered. If set to N, reading is stopped, and an error is signaled. When set to Y, a valid UEL is made up and reading is continued.

autoCol = *string*

Generate automatic UELs for each column. The `autoCol` string is used as the prefix for the column label numbers. This option overrides the use of a header row. However, if there is a header row, one must skip the row by enabling `useHeader`. This option is demonstrated in [Example 3](#).

autoRow = *string*

Generate automatic UELs for each row. The `autoRow` string is used as the prefix for the row label numbers. The generated unique elements will be used in the first index position shifting other elements to the right. Using `autoRow` can be helpful when there are no labels that can be used as unique elements but also to store entries that would be a duplicate entry without an unique row label. This option is demonstrated in [Example 3](#).

checkDate = *boolean* (default=N)

Write GDX file only if the CSV file is more recent than the GDX file to save resources when running the model containing the `CSV2GDX` call multiple times. This option is demonstrated in [Example 5](#).

colCount = *integer*

Number of columns in the input file. This parameter is required if there is no header row, since `CSV2GDX` determines the number of columns from the header row. This option is demonstrated in [Example 3](#). Note that the `lastCol` constant cannot be used for the `colCount` option.

decimalSep = [Period, Comma] (default=Period)

Specify a decimal separator. The decimal is normally a period, but this parameter allows a comma as the decimal separator, too. Special values recognized are `Eps`, `NA` resp. `N/A`, `Inf`, `True`, `False`, `None`, `Null` and `Undef` (case insensitive). A string that is not recognized as a valid number will be stored as `Undef`. This option is demonstrated in [Example 2](#) and [Example 6](#) (focusing on reading special values) for instance.

fieldSep = [Comma, SemiColon, Tab] (default=Comma)

Specify a field separator. Fields are normally separated by a comma, but this parameter allows some additional choices. Using tabs as delimiter should be avoided, since text editors act different on handling them. For instance, one must specify tabs in the GAMS IDE explicitly using `%system.tab%`:

```
$onEcho > tabSeparated.csv
USA%system.tab%100
GER%system.tab%70
$offEcho
```

```
$call csv2gdx tabSeparated.csv id=x fieldSep=tab index=1 colCount=2 value=lastCol
```

This option is demonstrated in [Example 2](#) and [Example 3](#) for instance.

id = *string*

Identifier for the symbol in the GDX file. Additional symbols, `Dim1`, `Dim2`, ... for the domain sets of the symbol `id` will be added automatically to the GDX file. Executing `CSV2GDX` without specifying an identifier will fail.

index = *list of columns*

Identify columns to get UELs from. The columns are represented as a list of integers separated by comma. For example `index=1,2,3,4` resp. `index=(1,2,3,4)`; in this case the notation `1..4` is allowed. Brackets can only be used on Windows systems. The `index` option is used in all examples.

output = *filename* (default=<CSVFilename>.gdx)

Optional output filename. If no output file is specified, `CSV2GDX` will use the input filename and change the file extension to `.gdx`. If no path is specified, the output file will be created in the current directory. This option is demonstrated in [Example 2](#) for instance.

password = *string*

Password for an encrypted input file. Use `ENDECRYPT` to encrypt a file. This option is demonstrated in [Example 7](#).

storeZero = *boolean* (default=N)

Indicate if zero values are ignored or written as `EPS`; an empty field is always ignored. This option is demonstrated in [Example 6](#).

text = *integer*

Specify the column to get explanatory text from when reading a set. For example `text=5`. This option is demonstrated in [Example 9](#).

trace = *integer* (default=1)

Controls the amount of information written to the log. Higher values will generate more output. Valid range is `0..3`. Set `trace=0` to prevent writing any information to the log. This feature is demonstrated in [Example 6](#).

useHeader = *boolean* (default=N)

Indicate if the first row is a header row. The fields in the header row of the columns specified within the `values` option will be used as UELs. A header row is not needed or should be ignored when using the `colCount` or `autoCol` option. To skip one existing header row while using `autoCol`, enable `useHeader`. This option is demonstrated in [Example 1](#) and [Example 2](#) for instance.

value = *integer*

Specify the column to get the values from. For example `value=5`. This option is demonstrated in [Example 2](#).

valueDim = *boolean* (default=N)

Indicate if an extra dimension for values is added to the parameter even if there is just one value column. This is ignored, if there is no value column. This feature is demonstrated in [Example 2](#).

values = *list of columns*

Specify the columns to get the values from. When using a list of columns for the values and `useHeader` enabled, each field in the first row of the columns is used as UEL to identify the values in those columns. See also `useHeader` and `autoCol` below. If the number of columns is unknown, the symbolic constant `lastCol` can be useful: `values=2..lastCol`. This option is demonstrated in [Example 1](#) and [Example 5](#) for instance.

6.8.3 Advances and limitations

Advances

- `CSV2GDX` enables the user to read CSV data where the table statement cannot be used without doing further preprocessing, e.g. in case of semicolon- or tab separated data or comma separated decimals.
- In general, `CSV2GDX` is a quite performant tool compared to the GAMS internal table statement.

Limitations

- Suppose we want to skip some rows while reading the data. For example, if the CSV file contains some reference information in a specific row which we do not want to be stored in the domain sets or in the parameter. However, skipping rows cannot be done with `CSV2GDX`.
- There might be CSV files with no header and varying, unknown length of rows. Since `CSV2GDX` determines the number of columns based on the header row or by setting the `colCount` option in advance, `CSV2GDX` might return incorrect results or the execution is aborted.
- Reading several parameters from a CSV file cannot be done directly within the `CSV2GDX` call. The data must be split later on as demonstrated in [Example 4](#).
- `CSV2GDX` cannot read CSV files containing line breaks within a (quoted) field. You will either get an error message - "Quoted field not terminated with closing quote" - or the result might not be correct for unquoted fields, because the field content will be cut by the line break.

6.8.4 Getting Started

We introduce the basic functionalities of CSV2GDX on some simple examples. Note that many CSV files can be read inside GAMS directly using a table statement, but a number of features available in CSV2GDX enable the user to read a CSV file where the table statement cannot be used, e.g. reading files with semicolon separated data or if the decimals are separated by comma instead of a period.

6.8.4.1 Example 1 - Reading CSV Files with CSV2GDX

The first example of this collection demonstrates the key commands of CSV2GDX. For instance, consider the table statement of the model `[transport]` from the GAMS Model Library:

```
Table d(i,j) 'distance in thousands of miles'
      new-york  chicago  topeka
seattle      2.5      1.7      1.8
san-diego    2.5      1.8      1.4;
```

The data can be stored in `distance.csv` like this:

```
,new-york,chicago,topeka
seattle,2.5,1.7,1.8
san-diego,2.5,1.8,1.4
```

First of all, CSV2GDX is called now, to generate `distance.gdx` by processing the input file `distance.csv`:

```
csv2gdx distance.csv id=d index=1 values=2..lastCol useHeader=y
```

CSV2GDX generates one single parameter `d` and two domain sets from the input file. The name of the parameter in the GDX file must be declared within the `id` option, while the domain sets for this parameter will be labeled with `Dim1` and `Dim2` automatically. Column number one is specified as the first domain set within the `index` option. The `values` option is used to specify the column numbers 2,3,4 containing the data values. By enabling the `useHeader` option, the fields of the first row of the columns specified within the `values` option will be handled as the second domain set. If the number of columns is unknown in advance, one can use the `lastCol` constant in the `values` or `index` option.

However, to complete the declaration of the sets and parameter for the model `transport`, one must load the data from `distance.gdx`:

```

Set
  i 'canning plants'
  j 'markets';

$gdxIn distance.gdx
$load i = Dim1
$load j = Dim2

Parameter d(i,j) 'distance in thousands of miles';
$load d
$gdxIn
display i, j, d;

```

This example is also part of the GAMS Data Utilities Library, see model `[csv2gdx2]` for reference.

6.8.4.2 Example 2 - Reading Semicolon separated Data

In this example, the distances from the previous example are stored as a list. We want to read the cities and the column containing the miles measurement. Note, that the fields are separated by semicolon and the decimals by comma. As described in [Data Exchange with Text Files](#) the CSV file must be preprocessed with the POSIX tools in advance to replace commas by dots and semicolons by commas to read the data directly using a simple table statement.

```

i;j;miles
seattle;new-york;2,5
seattle;chicago;1,7
seattle;topeka;1,8
san-diego;new-york;2,5
san-diego;chicago;1,8
san-diego;topeka;1,4

```

The data will be stored as `distanceOut.gdx` by adding the `output` file option. One can specify the field and decimal separators within the `fieldSep` and `decimalSep` option. Domain sets for the parameter to be read are declared by `index=1,2`.

```
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHeader
```

In order to load the data from the GDX file, execute the commands from the [previous example](#). However, note that `Dim2` does not contain the UELs from the header row this time, but the unique elements of the second column specified in the `index` option. The option `useHeader` is enabled to indicate that there is a header row to be skipped when reading the values. Also note, that the symbol `d` in the GDX file has exactly two dimensions. It may be useful to add an additional dimension to the parameter `dmod`, e.g. if different measurement units for the distances may become relevant later on and need to be calculated (kilometer for instance).

This can be done by adding the option `valueDim`:

```
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHeader valueDim
```

The option adds a third dimension to `d`. Now we want to add the distances in kilometer by calculating the values inside the model:

```
Set m 'measurement unit' / miles, km /;

Parameter dmod(i,j,m);

$gdxIn distanceOut.gdx
$load dmod = d
$gdxIn
display dmod;

dmod(i,j,'km') = 1.852*dmod(i,j,'miles');
display dmod;
```

Parameter `d` (`valueDim` disabled):

```
----      36 PARAMETER d  distance in thousands of miles

                new-york      chicago      topeka
seattle         2.500         1.700         1.800
san-diego       2.500         1.800         1.400
```

Parameter `dmod` resp. `d` with `valueDim` enabled before calculating further measurements:

```
----      49 PARAMETER dmod

                                miles
seattle .new-york                2.500
seattle .chicago                1.700
seattle .topeka                 1.800
san-diego.new-york              2.500
san-diego.chicago              1.800
san-diego.topeka                1.400
```

Parameter `dmod` with `valueDim` enabled after calculating the distances in kilometer inside the GAMS model:

```
----      52 PARAMETER dmod

                                miles      km
seattle .new-york                2.500     4.630
seattle .chicago                1.700     3.148
seattle .topeka                 1.800     3.334
san-diego.new-york              2.500     4.630
san-diego.chicago              1.800     3.334
san-diego.topeka                1.400     2.593
```

This example is also part of the GAMS Data Utilities Library, see model `[csv2gdx3]` for reference.

6.8.4.3 Example 3 - Dealing with missing Labels and Duplicates

Missing Labels

The file EUCData.csv contains the extracted euclidean coordinates of the first nine cities of berlin52.tsp from [TSPLib](#). You might want to import the data to calculate a complete distance matrix inside GAMS to find an optimal traveling salesman tour for instance.

```
565.0;575.0
25.0;185.0
345.0;750.0
945.0;685.0
845.0;655.0
880.0;660.0
25.0;230.0
525.0;1000.0
580.0;1175.0
```

There is no header row, neither a column with labels to serve as domain sets for the coordinates of the cities. However, CSV2GDX automatically generates UELs for columns and rows by adding ascending numbers to an user-defined prefix specified within the [autoCol](#) and [autoRow](#) option. Also note, because of the missing header, the number of columns in the file must be manually determined and declared within [colCount](#).

```
csv2gdx EUCData.csv id=coord fieldSep=semiColon autoCol=x autoRow=city colCount=2 values=1,2
```

The rows will be labeled with city1...city9, the columns with x1 and x2.

Load the parameter and sets from the GDX file to calculate the complete distance matrix. The set Dim1 contains the UELs city1...city9 for the set i of cities, Dim2 is the set of axes/coordinates i.e. containing the elements x1 and x2 to represent the x-axis and y-axis:

```
Set
  i      'cities'
  axes  'x1 and x2 axes';

$gdxIn EUCData.gdx
$load i      = Dim1
$load axes  = Dim2

Parameter coord(i,axes) 'coordinate of city i';
$load coord
$gdxIn
display coord;
```

The display statement generates the following output:

```
----      43 PARAMETER coord  coordinate of city i

           x1          x2
city1     565.000     575.000
city2     25.000     185.000
```

city3	345.000	750.000
city4	945.000	685.000
city5	845.000	655.000
city6	880.000	660.000
city7	25.000	230.000
city8	525.000	1000.000
city9	580.000	1175.000

One could now easily proceed calculating a complete distance matrix:

```
Alias (i,j);
```

```
Parameter c(i,j) 'euclidean distance between city i and j';
c(i,j) = eDist(coord(i,"x1") - coord(j,"x1"),coord(i,"x2") - coord(j,"x2"));
```

Duplicates

In the previous example, using the `autoCol` and `autoRow` option had an additional benefit as we declared the set of the cities on the fly. However, one major advantage/purpose of these options is to prevent error messages or loss of data when reading rows with duplicate keys.

Consider the input file `duplicates.csv`:

```
red,red,1
red,red,2
red,green,3
blue,blue,4
```

Note the duplicate key in the first two rows. By the use of the `autoRow` parameter in the `CSV2GDX` call unique labels are added to each row. This way a GAMS program can store all data with duplicate keys and prepare for better error messages.

```
csv2gdx duplicates.csv id=data index=1,2 value=3 colCount=3 autoRow=row
```

Ascending numbers will be added to the 'row' prefix specified.

The data can be easily loaded into sets and parameter by executing the following lines:

```
Set
  row 'UEls generated by autoRow'
  color 'set of colors';
```

```
$gdxIn duplicates.gdx
$load row = Dim1
$load color = Dim2
$loadm color = Dim3
```

```
Parameter data(row,color,color);
$load data
$gdxIn
display row, color, data;
```

Note the usage of the `$loadm` command to merge all colors into one set of colors. The display statement generates the following output in the listing file:

```

----      77 SET row  UELs generated by autoRow

row1,    row2,    row3,    row4

----      77 SET color  set of colors

red  ,    blue  ,    green

----      77 PARAMETER data

                red        blue        green

row1.red        1.000
row2.red        2.000
row3.red                3.000
row4.blue                4.000

```

The complete example is also part of the GAMS Data Utilities Library, see model `[csv2gdx4]` for reference.

6.8.4.4 Example 4 - Reading several Parameters from a single Input File

This example demonstrates how to read the data from a single input file into different parameters. However, this cannot be done directly using the CSV2GDX tool, since CSV2GDX writes to a single parameter (see section [limitations](#)). For instance, an energy supplier plans to build new transmission lines from their power plants to some distribution stations. There are different stages for the transmissions lines. The relevant data to be read are the plant and station identifiers, the capacity bounds per transmissions line on a certain stage and the associated cost. The data is all stored in a single file:

```

plant;station;length;minCap;maxCap;stage;cost
p1;s1;100;50;100;1;1200
p1;s2;75;35;65;1;500
p1;s1;100;100;150;2;1800
p2;s1;150;50;100;1;1400
p2;s1;150;100;150;2;2000
p2;s1;150;150;200;3;2350
p2;s2;75;25;50;1;600
p2;s2;75;50;75;2;800
p3;s1;80;40;100;1;1050

```

Read networkData.csv with CSV2GDX by calling:

```

csv2gdx networkData.csv id=dataPar useHeader=y fieldSep=semiColon index=1,2,6 values=4,5,7

```

Note that the stage stored in column six is a domain set, too, while the length of the transmission line in the third column is of no interest. Since CSV2GDX writes to a single parameter, one must split the data later on into minCap, maxCap and cost for instance:

```

Parameter
  dataPar
  minCap(plant,station,stage)
  maxCap(plant,station,stage)
  cost(plant,station,stage);

$gdxIn networkData.gdx
$load plant    = Dim1
$load station  = Dim2
$load stage    = Dim3
$load dataPar
$gdxIn

minCap(plant,station,stage) = dataPar(plant,station,stage,'minCap');
maxCap(plant,station,stage) = dataPar(plant,station,stage,'maxCap');
cost(plant,station,stage)   = dataPar(plant,station,stage,'cost');

```

This example is also part of the GAMS Data Utilities Library, see model `[csv2gdx5]` for reference.

6.8.4.5 Example 5 - Reading economic Data from the World Bank Data Catalog

This example demonstrates how to read some real CSV data from the [World Bank Data Catalog](#). Suppose we want to read some time series data, e.g. GDP growth rates. The data is structured as follows (rows shortened for presentation):

```

"Country Name","Country Code","Indicator Name","Indicator Code","1999","2000","2001","2002","2003","2004","2005","2006","2007","2008","2009","2010","2011","2012","2013","2014","2015"
"East Asia and Pacific","EAA","GDP growth, constant 2010 USD","NYGDPMKTPKDZ","","","","","","","","","","","","","","","","","",""

```

We are not interested in the "Country Code", "Indicator Name" and "Indicator Code". Since the annual GDP rate per country is unique, the CSV2GDX call is quite easy despite the large number of columns. Note that there are only a few limitations of CSV2GDX, discussed in the section [Advances and limitations](#). Empty fields in the data will always be ignored, causing no trouble at all if the field separators are set correctly.

```
csv2gdx GDPData.csv id=GDPG index=1 values=5..lastCol useHeader=y checkDate=y
```

The option `checkDate` is enabled to save resources if you run the model multiple times, as the GDX file is only written if the CSV file is more recent than the GDX file. To load the sets and parameter from the GDX file, execute the following commands:

```

Set country, year;
$gdxIn GDPData.gdx
$load country = Dim1
$load year    = Dim2

Parameter GDPRate(country,year);
$load GDPRate
$gdxIn
display country, year, GDPRate;

```

The display statement generates the following output in the listing file. Obviously, double quotes are removed from the fields of the value columns, but also from the index columns:

```
----      12 SET country
```

```
East Asia and Pacific, Europe and Central Asia, Latin America and the Caribbean, Middle East and North Africa,
Afghanistan          , Albania          , Algeria          , Angola
```

```
----      12 SET year
```

```
2015,      2016,      2017,      2018,      2019,      2020
```

```
----      12 PARAMETER GDP
```

	2015	2016	2017	2018	2019	2020
East Asia and Pacific	6.504	6.327	6.449	6.182	6.065	5.948
Europe and Central Asia	0.963	1.672	3.782	2.901	3.029	2.915
Latin America and the Caribbean	-0.562	-1.526	0.902	2.044	2.586	2.712

Note that the listings have been shortened for presentation. However, there is no data for the years 1999-2014.

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx6] for reference.

6.8.5 Additional Examples for extended Use

The examples in this section discuss some special features. Some topics were already mentioned briefly in the previous section like reading compressed and encrypted files or reading the CSV2GDX options from an external file.

6.8.5.1 Example 6 - Reading special Values

To illustrate how special values are interpreted, consider the following data:

```
one,two,three,four,five,six
red,red,,Undef,'3.3',red
red,red,"4.4",5.5,Eps,green
"red",'green',7.7e+02,8.8°,-Inf,blue
blue,blue,10,0,NA,purple
brown,blue,true,false,N/A,green
black,red,None,Null,"True",blue
```

Calling CSV2GDX to read the data and write to GDX:

```
csv2gdx data.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3
```

The GAMS log reports three occurrences of undefined values. Note that the amount of information written to the log was increased by setting the option `trace=3`.

```

--- call csv2gdx specialValues.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3
CSV2GDX          25.2.0 r67638 ALFA Released 15Aug18 WEI x86 64bit/MS Windows
Header enabled, number of columns = 6
  1: one
  2: two
  3: three
  4: four
  5: five
  6: six
  2: |red|, |red|, ||, |Undef|, |'3.3'|, |red|
  3: |red|, |red|, |4.4|, |5.5|, |Eps|, |green|
  4: |red|, |'green'|, |7.7e+02|, |8.8°|, |-Inf|, |blue|
  5: |blue|, |blue|, |10|, |0|, |NA|, |purple|
Undef Count = 3, No errors, CSV2GDX time = 157ms

```

As mentioned in [decimalSep](#), CSV2GDX fails to recognize the number 8.8 from the string 8.8° because of the unknown special character, while 7.7e+02 is interpreted as a number of course. Watch out if there are quotes in the values or index columns. The number 4.4 enclosed by double quotes is interpreted as a number, while '3.3' is not (as you can see in the log, the double quotes are eliminated, while the single quotes remain). In the first column, the double quotes enclosing the string red are removed, while the single quotes in the second column enclosing the string green are not removed. The zero value is stored as EPS by setting `storeZero=y`. Note that no error was reported, even though some of the values stored as `Undef` may cause some trouble in your model later on (use `$onUndef` to enable loading parameters with undefined values).

The booleans `true` and `false` in the second last row are represented by the numerals 1 resp. 0 within GAMS. The special values `None` and `Null` will be converted to 0. Since `storeZore` is enabled in this example, the value displayed for `false`, `None` and `Null` is EPS.

Suppose we want to declare the parameter A as: A(color,color,color,number). We can proceed as follows:

```

Set color, number;
$gdxIn data.gdx
$load color = Dim1
$loadm color = Dim2
$loadm color = Dim3
$load number = Dim4

Parameter A(color,color,color,number);
$onUndef
$load A
$offUndef
$gdxIn
display A;

```

Loading undefined values is enabled by adding `$onUndef`. This example is also part of the GAMS Data Utilities Library, see model [\[csv2gdx7\]](#) for reference.

6.8.5.2 Example 7 - Reading a compressed encrypted Input File

Reading a compressed input file is supported by CSV2GDX. The `gzip` program in the `gbin` sub-directory or [ENDECRYPT](#) must be used for compression. Call `gzip` to compress the CSV file by running the following command:

```
gzip compressMe.csv -c > compressedFile.csv.gz
```

Gzip writes to standard output by appending `-c` to keep the original file unchanged. The output is then redirected to `compressedFile.csv.gz`. To read the compressed file, call CSV2GDX with the same options as for processing the uncompressed file.

```
csv2gdx compressedFile.csv.gz output=unCompressedGzipFile.gdx id=d index=1 useHeader=y values=2..las
```

The data in this example is taken from [Example 1](#).

While the main purpose of Endencrypt is about encrypting and decrypting files, it also compresses the file. If you want to compress a file with Endencrypt, do not specify a password file:

```
cat compressMe.csv | endencrypt -W compressedFile.csv
```

The option `-W` encrypts standard input and writes to `compressedFile.csv`. Although there will be no encryption because of the missing password file, one must set the option `-W`. You can read the compressed file with CSV2GDX:

```
csv2gdx compressedFile.csv output=unCompressedEndycriptFile.gdx id=d index=1 useHeader=y values=2..1
```

Note that there is no further file extension added.

By adding a password file (containing the password in the first line), Endencrypt encrypts and compresses the input file:

```
cat compressMe.csv | endencrypt -W compressedEncryptedFile.csv passwordFile.txt
```

The password file will be deleted. Execute the following command to read the compressed and encrypted file with CSV2GDX:

```
csv2gdx compressedEncryptedFile.csv output=unCompressedDecryptedFile.gdx password=Anton id=d index=1
```

The password option is added. You must set the password directly within the option, in this case "Anton", not the password file. Note that CSV2GDX does not support `.gz`, `.7z` etc. compressed files!

This example is also part of the GAMS Data Utilities Library, see model `[csv2gdx8]` for reference.

6.8.5.3 Example 8 - Reading Options from an external File

This example demonstrates how to read the options from an external text file as already mentioned in section [Filename](#). The file `distance.csv` from the Getting Started [Example 1](#) will be processed with `CSV2GDX` while reading the options from an external text file named `howToRead.txt`.

```
csv2gdx distance.csv @howToRead.txt
```

Swapping the order of the CSV filename and the instructions filename inside the call statement will cause an error. Note the leading @ (at sign) on the instructions file, containing the following options:

```
* These lines are interpreted as a comment
* This file specifies the options for reading distance.csv using CSV2GDX
```

```
id           = d
fieldSep     = semiColon
decimalSep   = comma
index        = 1
useHeader    = y
values       = 2..lastCol
```

This example is also part of the GAMS Data Utilities Library, see model `[csv2gdx9]` for reference.

6.8.5.4 Example 9 - Reading Set Elements with explanatory Text

In this example, we will demonstrate how to read explanatory text of set elements using the `CSV2GDX` option `text`.

Consider the input file `data.csv`:

```
a1,b1,explanatory text of a1.b1,10
a1,b2,explanatory text of a1.b2,20
a2,b1,explanatory text of a2.b1,30
a2,b2,explanatory text of a2.b2,40
```

The set elements are stored in the first and second column, the explanatory text is stored in the third column and there is a fourth column containing some values. Suppose we want to read a two-dimensional set with explanatory text. By default, `CSV2GDX` does not read explanatory text, i.e. by running the following command:

```
csv2gdx data.csv id=abOnlyUEls index=1,2 colCount=4
```

`CSV2GDX` creates a GDX file containing the two-dimensional set `abOnlyUEls` without explanatory text (needless to say, we did not specify a column to get the explanatory text from). By specifying the third column within the `index` option, i.e. `index=1..3`, the result will be a three-dimensional set (without explanatory text, too). Using the `value` option is not suitable, as the data type will be a parameter instead of a set (in addition, `CSV2GDX` expects numeric data, potentially leading to undefined values). We can read the explanatory text easily by specifying column three within the `text` option:

```
csv2gdx data.csv id=abWithExpText index=1,2 text=3 colCount=4
```

The figure shows the set `abOnlyUEls` on the left without explanatory text and the set `abWithExpText` on the right:

Note that the `text` and `value(s)` options cannot be used at the same time (instead, use multiple `CSV2GDX` calls in scenarios when you wish to read set elements with explanatory text and parameters from a single data set).

6.9 EIGENVALUE

EIGENVALUE calculates eigenvalues of a symmetric matrix.

6.9.1 Usage

```
eigenvalue gdxin i a gdxout ev
```

where

gdxin

name of gdxfile with matrix

i

name of set used in matrix

a

name of 2 dimensional parameter inside gdxin

gdxout

name of gdxfile for results (eigenvalues)

ev

name of 1 dimensional parameter inside gdxout

Calculates eigenvalues of symmetric matrix $a(i, j)$ where i and j are aliased sets.

6.9.2 Example

\$onText

Eigenvalue example.

```
octave:1> a=[9 1 1; 1 9 1; 1 1 9]
```

```
a =
```

```
 9  1  1
 1  9  1
 1  1  9
```

```
octave:2> eig(a)
```

```
ans =
```

```
 8
 8
11
```

\$offText

```
Set i / i1*i3 /;
```

```

Alias (i,j);

Table a(i,j)
      i1  i2  i3
i1    9   1   1
i2    1   9   1
i3    1   1   9;

Parameter e(i) 'eigenvalues';

execute_unload 'mat.gdx', i, a;
execute '=eigenvalue.exe mat.gdx i a ev.gdx e';
execute_load 'ev.gdx', e;

display a, e;

```

6.10 EIGENVECTOR

EIGENVECTOR calculates eigenvalues/vectors of a symmetric matrix.

6.10.1 Usage

```
eigenvector gdxin i a gdxout eval evec
```

where

gdxin

name of gdxfile with matrix

i

name of set used in matrix

a

name of 2 dimensional parameter inside gdxin

gdxout

name of gdxfile for results (eigenvalues)

eval

name of 1 dimensional parameter inside gdxout

evec

name of 2 dimensional parameter inside gdxout

Calculates eigenvalues/vectors of symmetric matrix $a(i,j)$ where i and j are aliased sets. `eval` will contain the eigenvalues and `evec` will contain the eigenvectors.

6.10.2 Example

\$onText

Eigenvector example.

```
octave:1> a = [1 2 4 7 11; 2 3 5 8 12; 4 5 6 9 13; 7 8 9 10 14; 11 12 13 14 15]
```

a =

evec(i,j) 'eigenvectors';
```

```
execute_unload 'mat.gdx', i, a;
```

```
execute '=eigenvector.exe mat.gdx i a ev.gdx eval evec';
execute_load 'ev.gdx', eval, evec;

display a, eval, evec;
```

6.11 ENDECRYPT

A tool to encrypt and decrypt text files.

6.11.1 Usage

```
endencrypt option xfile [passwdfile]
```

option

-W

to encrypt standard input and write to **xfile**

-R

to decrypt **xfile** and write to standard output

xfile

Text file to encrypt or decrypt.

passwdfile (optional)

First line is used as password; will be deleted after use

6.12 FINDTHISGAMS

6.12.1 Introduction

The Windows command line tool `findthisgams` is used for modifying GAMS specific registry entries created by the GAMS installer. These registry entries are primarily used for Windows file associations for GAMS related files (`*.gms`, `*.gdx`, `*.gpr`) and for the Object-oriented GAMS APIs which use the registry key `gams.location` for finding a valid GAMS system directory. This documentation uses the following registry hive abbreviations:

- HKCU: HKEY_CURRENT_USER
- HKLM: HKEY_LOCAL_MACHINE
- HKCR: HKEY_CLASSES_ROOT

Attention

This tool should be used with caution and only when necessary, as it changes the state of the registry. Reading this documentation carefully before use is advised.

6.12.2 Usage

```
findthisgams.exe [-q] [ list | delete (HKLM|HKCU) | write (HKLM|HKCU) ] [ide]
```

Without arguments: When `findthisgams.exe` is run without arguments, the tool tries to register the current GAMS system directory by either writing to HKCU (which takes precedence over HKLM) or by deleting entries in HKCU that hide the correct entries (current system directory) in HKLM.

-q: Run quietly. No pop-ups.

list: Print a summary of GAMS related registry entries (old and new).

delete (HKLM|HKCU): Deletes the registry entries in either HKLM or HKCU. The tool tries to delete both the old and the new style registry entries.

write (HKLM|HKCU): Writes the registry entries for the current GAMS system directory either to HKLM or HKCU.

ide: Per default, when `findthisgams.exe` writes to the registry, it uses [GAMS Studio](#) for file associations. Specifying `ide` will register the GAMS IDE instead.

6.12.3 Registry Keys

The registry entries created by the Windows installer have changed with [GAMS 32](#). When running `findthisgams` with command line parameter `list`, the registry is queried for both the old and the new style registry keys. This gives a good overview of the current state of the registry before initiating any actual modifications to the registry:

Old registry keys (up to GAMS 31):

```
[HKCR|HKCU] \.gms
[HKCR|HKCU] \.gdx
[HKCR|HKCU] \gamside.file
[HKCR|HKCU] \gamside.file\shell\open\command
[HKCR|HKCU] \.gpr
[HKCR|HKCU] \gamside.project
[HKCR|HKCU] \gamside.project\shell\open\command
[HKCR|HKCU] \gams.location
```

New registry keys (GAMS 32 and later):

```
[HKLM|HKCU] \Software\Classes\.gms
[HKLM|HKCU] \Software\Classes\.gdx
[HKLM|HKCU] \Software\Classes\gamside.file
[HKLM|HKCU] \Software\Classes\gamside.file\DefaultIcon
[HKLM|HKCU] \Software\Classes\gamside.file\shell\open\command
[HKLM|HKCU] \Software\Classes\.gpr
[HKLM|HKCU] \Software\Classes\gamside.project
[HKLM|HKCU] \Software\Classes\gamside.project\DefaultIcon
[HKLM|HKCU] \Software\Classes\gamside.project\shell\open\command
[HKLM|HKCU] \Software\Classes\gams.location
```

Additional registry keys (GAMS 37 and later):

```
[HKLM|HKCU] \Software\Classes\.gsp
[HKLM|HKCU] \Software\Classes\gamsstudio.project
[HKLM|HKCU] \Software\Classes\gamsstudio.project\DefaultIcon
[HKLM|HKCU] \Software\Classes\gamsstudio.project\shell\open\command
```

Note

In order to access registry entries in HKLM, `findthisgams` needs to be run with administrative privileges.

6.13 GAMS Studio

GAMS Studio is a completely new integrated development environment for GAMS, which is available for Windows, Mac OS X, and Linux. It is based on C++ and Qt.

Note

In addition to this technical documentation, there is also a [tutorial](#) about the usage of GAMS Studio.

6.13.1 Motivation

The classic [GAMS IDE](#) has been shipped with the GAMS system for the last 20 years and is still the workhorse for many GAMS programmers. However, the existing IDE does not provide all the features we see in modern development environments. Due to its underlying software technology, implementing new features in the current IDE turned out to be a poor option, so work on a new development environment started from scratch. GAMS Studio is based on C++ and Qt, which makes it fast, reliable, and platform independent (Windows, Mac OS X, and Linux). An overview about the differences between GAMS Studio and the classic GAMS IDE can be seen at [the end](#) of this chapter (for long-time GAMSIDE users, especially the difference between [IDE projects and Studio projects](#) might be interesting).

6.13.2 Central Widgets

6.13.2.1 Welcome Page

The Welcome page is the starting point of GAMS Studio. It is designed to give quick access to common actions and to offer helpful information. It is divided into three columns.

On the very left there is a column labeled "Last Files" which lists all files that have been opened recently in Studio with the most recent file on top. A simple left click on an item in this list opens the corresponding file. The middle column named "Getting Started" offers useful actions and links for new users. The upper half contains shortcuts to create new files in user defined locations, open the [GAMS Model Library Explorer](#) or load the Transport example. The lower half has a link to the Studio introduction video on YouTube and two further links that open the [integrated help view](#) showing either this Studio documentation or the page with the GAMS tutorial overview. The rightmost column "Further Help" contains a link to the recent changes of GAMS Studio, the latest GAMS release notes, the GAMS World Forum for support and information about how to contact GAMS.

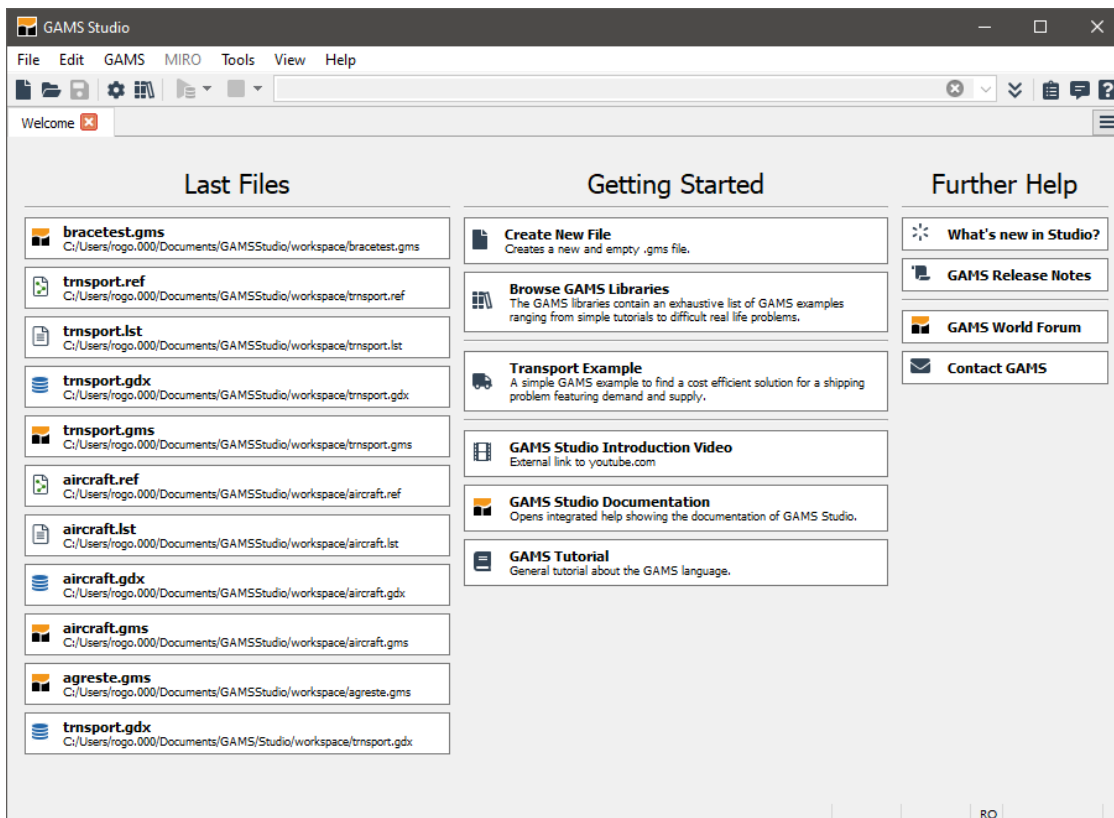

Figure 6.1 Welcome page

6.13.2.2 Code Editor

The Code Editor provides common functionality for editing with GAMS specific syntax highlighting. On the left side there is a special area displaying the line numbers and icons for links and errors generated by the compiler.

Action	Shortcut	macOS	Description
Copy	Ctrl - C	Command - C	Copy selected text
Cut	Ctrl - X	Command - X	Cut selected text
Paste	Ctrl - V	Command - V	Paste text from clipboard
Select All	Ctrl - A	Command - A	Select whole document
Switch Comment	Ctrl - *	Command - *	(Un)Comment all lines in selection
Undo	Ctrl - Z	Command - Z	Reverts the latest text change
Redo	Ctrl - Y or Ctrl - Shift - Z	Command - Shift - Z	Restores a previous Undo

6.13.2.2.1 1. Basic Text Manipulation

Action	Shortcut	macOS	Description
Remove Line	Shift - Del		Removes the current line
Duplicate Line	Ctrl - D	Command - D	Duplicates the current line(s)
Lowercase	Alt - Shift - L	Option - Shift - L	Toggle selection to lower case

Action	Shortcut	macOS	Description
Uppercase	Alt - Shift - U	Option - Shift - U	Toggle selection to upper case
Tab	Tab	Tab	Add spaces till next tab size
Untab	Shift - Tab	Shift - Tab	Remove spaces till previous tab size
Indent	Ctrl - I	Command - I	Indent complete line
Outdent	Ctrl - Shift - I	Command - Shift - I	Outdent complete line
Find	Ctrl - F	Command - F	Open Search & Replace window, filling search field with selected text if there is any.
Find Next	F3	F3	Jump to next search result if
Find Previous	Shift - F3	Shift - F3	Jump to previous search result

6.13.2.2.2 2. Advanced Text Manipulation

Action	Shortcut	macOS	Description
Zoom In	Ctrl - + or Ctrl - = or Ctrl - Wheel Up	Command - + or Command - = or Command - Wheel Up	Zoom in
Zoom Out	Ctrl - - or Ctrl - Wheel Down	Command - - or Command - Wheel Down	Zoom out
Reset Zoom	Ctrl - 0	Command - 0	Reset zoom
Match Parentheses	Ctrl - B	Command - B	Jump to matching parenthesis
Select Parentheses	Ctrl - Shift - B	Command - Shift - B	Select to matching parenthesis
Toggle Bookmark	Ctrl - M	Ctrl - M	Toggle bookmark
Previous Bookmark	Ctrl - ,	Ctrl - ,	Go to previous bookmark
Next Bookmark	Ctrl - .	Ctrl - .	Go to next bookmark
Toggle Folding	Alt - L	Alt - L	Toggles the folding state of the current section
Fold all Sections	Alt - O	Alt - O	Folds all foldable sections
Fold DCO Sections	Alt - I	Alt - I	Folds all foldable DCO sections
Unfold all Sections	Alt - Shift - O	Alt - Shift - O	Unfolds all foldable sections
Open Code Completer	Ctrl - Space	Ctrl - Space	Opens the Code Completer
Jump to include	Ctrl - Left Mouse Button or F2	Command - Left Mouse Button or F2	Jumps to file referenced by \$include
Scroll Up	Ctrl - Up	Command - Up	Scroll up (keeping cursor position)
Scroll Down	Ctrl - Down	Command - Down	Scroll down (keeping cursor position)
Scroll Page Up	Ctrl - PageUp	Fn - Up	Scroll page up (keeping cursor position)

Action	Shortcut	macOS	Description
Scroll Page Down	Ctrl - PageDown	Fn - Down	Scroll page down (keeping cursor position)
Start of Line	Home	Command - Left	Go to the start of line (or lines content)
End of Line	End	Command - Right	Go to the end of the line
Start of Document	Ctrl - Home	Fn - Left	Go to the start of the document
End of Document	Ctrl - End	Fn - Right	Go to the end of the document
Previous Word	Ctrl - Left	Option - Left	Go to previous start of word (or character class)
Next Word	Ctrl - Right	Option - Right	Go to next start of word (or character class)
Start/Change Block Edit	Alt - Shift - Arrow Key	Option - Shift - Arrow Key	Start/Change block edit selection
Start/Change Block Edit	Alt - Left Mouse Button	Option - Shift - Left Mouse Button	Draw block edit selection
Start/Change Block Edit	Alt - Shift - Left Mouse Button	Option - Shift - Left Mouse Button	Span block edit selection from text cursor to mouse click
Change Block Edit by Word	Ctrl - Shift - Left / Right	Command - Shift - Left / Right	Change block edit selection by word bounds
Change Block Edit by Word	Ctrl - Left / Right	Command - Left / Right	Change block edit position by word bounds (skip selection)
Change Block Edit Anchor	Shift - Arrow Key	Shift - Arrow Key	Change block edits anchor (start position)
Move Block Edit	Arrow Key	Arrow Key	Move block edit selection
Move Lines Up or Down	Ctrl - Shift - Up / Down	Command - Shift - Up / Down	Move line(s) up or down

6.13.2.2.3 3. Navigation & Selection The Code Editor looks for parenthesis to the right then to the left of the cursor and marks valid and invalid nesting. Hitting **Ctrl - B** moves the cursor to the matching parenthesis keeping the state inside/outside. To select the block to the matching parenthesis hit **Ctrl - Shift - B**.

To support navigating to files included by the gams source, place the mouse cursor over the file name and press the **Ctrl - Left Mousebutton** or place the cursor at the filename and hit **F2**. If found, Studio will add the file to the current project and open it. Only plain text filenames can be detected this way, symbols are not resolved.

6.13.2.2.4 Code Folding The Code Editor detects several kinds of sections in the source code that can be folded. These sections include all kinds of matching parentheses that extend over more than one line plus several $\$$ -control options that needs to come in pairs. To toggle the folding state of a section either the fold-marker can be clicked or the shortcut **Alt - L** can be pressed when the cursor is in a foldable line. To fold or unfold all foldable sections the main menu contains entries in the **View** menu. Additionally the shortcuts **Alt - 0** to fold and **Alt - Shift - 0** to unfold can be used. To define individual blocks of folding the [Dollar Control Options](#) `$onFold` and `$offFold` can be added to the source.

List of $\$$ -control options that create a fold section:

- `$OnText / $OffText`
- `$OnEmbeddedCode[V/S] / $OffEmbeddedCode`
- `$OnEcho[V/S] / $OffEcho`
- `$OnPut[V/S] / $OffPut`
- `$OnExternalInput / $OffExternalInput`
- `$OnExternalOutput / $OffExternalOutput`
- `$ifThen[I/E] / $endif`
- `$onFold / $offFold`

6.13.2.2.5 Syntax Highlighting The GAMS Studio syntax highlighter recognizes different kinds of source code like

- **\$control option** with some special treatments (like `$OffText`, `$OnText`, etc.)
- **comments**, e.g. line comments and comment block
- **keywords** like declarations or loops
- **description** as descriptive text for identifiers
- **data statements** for identifiers or table data
- ...

To get the best highlight result it is recommended to use strict GAMS syntax.

6.13.2.2.6 Code Completion GAMS Studio offers a static code completion for fixed internal keywords known by the compiler. The code completer pops up after pressing `Ctrl - Space` and shows keywords that matches the current syntax and starts with the already typed characters of the word to the left of the cursor. Moving the cursor to the left shortens the matching pattern while moving the cursor to the right extends it. The keys `up/down`, `pageUp/pageDown`, and `home/end` are processed by the results list during the completer is visible. The selected word can be inserted with the keys `tab` or `enter/return` or by double clicking a word in the list. To hide the completer, hit `esc` or click outside of the completer window. Additionally the completer hides if there is no match for the current start of word.

6.13.2.2.7 Automatic closing of brackets and quote characters This feature is meant to improve convenience for users typing source code. In GAMS, as in pretty much every other programming language, opening brackets or quote characters are followed at some point by a closing equivalent. So when a user types one of the following characters the matching closing character will also be inserted after the text cursor. This allows the user to easily type the content in between. When typing the closing character which should be right after the cursor the already existing character will be jumped over. So when a user types the closing character by force of habit the autoclose feature does not interfere or causes syntax errors. Also possible is to make a text selection and then type a bracket or quote character. The selected text will then be surrounded by the chosen character pair. In the GAMS Studio under **Settings > Editor > "Auto close opening brackets and quotes"** a switch is available to turn this auto-close feature off.

List of characters that trigger insertion of a closing character:

- `(`
- `{`

- [
- ”
- '

Other editors also close the < character but in the GAMS language context it is used in a different way, making it unnecessary to be closed automatically (e.g. as a comparison operator). In some cases user might not like the closing character to be inserted automatically however, this is hard to predict. Other editors - like Qt Creator - check what the next character after the cursor is. Only a limited set of characters allows the automatic insertion of the closing character.

Following characters allow auto closing when being the next char after the text cursor:

- **Whitespaces**
- ,
- ;
-)
-]
- {
- }

All others will prevent the insertion of characters.

6.13.2.2.8 File Encoding When opening a file Studio tries to assume the valid file-encoding. As it is not possible to safely determine the encoding the **Edit > Encoding** menu assists. To reload a file using another codec the **reload with ...** submenu can be used. With the **convert to ...** submenu the current file can be converted to another codec. A selection of encodings is preselected. This selection can be changed using the **Select encoding** submenu. It opens a dialog where the active encodings can be selected. One of them is marked as the **Default** encoding. Initially is is set to **utf-8**.

6.13.2.2.9 Bookmarks The **Code Editor** provides the ability to set temporary **bookmarks** in the text files opened in main tabs. If Studio is closed they are dropped. Also if a file tab is closed the bookmarks for this file are dropped. A bookmark is placed at the current position of the current file using the **toggle bookmark** key. A line in the editor can only carry one bookmark. If this line has a bookmark already the existing one is removed. The keys for next/previous bookmark allow to navigate through the bookmarks beyond file bounds.

6.13.2.3 Listing Viewer

The Listing Viewer is used for displaying a [GAMS output or listing file](#) (*.lst) which is generated when running a GAMS (.gms) file. The Listing Viewer consists of two sides. On the left side, the content of the listing file is presented in a tree structure that allows for convenient navigation within the listing file. The right side shows the listing file itself.

By clicking on a specific item in the tree on the left hand side, the listing file will automatically jump to the corresponding location. Changes of the cursor position in the listing file are dynamically reflected in the tree by selecting the item that belongs to the current section of the listing file.

Figure 6.3 Listing Viewer showing `blend.lst` generated by running a modified `blend.gms`

6.13.2.4 GDX Viewer

The GDX Viewer is used to open and inspect [GDX \(GAMS Data eXchange\)](#) files. A GDX file contains GAMS symbols such as sets, parameters, variables, and equations in a binary format that serves as input and output to GAMS. The GDX Viewer component consists of two sides. The left side displays the symbol table of the open GDX file in a table format. Every entry represents a symbol and consists of the following information:

- **Entry:** The index of the symbol
- **Name:** The identifier of the symbol
- **Type:** The type of the symbol (Alias, Equation, Parameter, Set, or Variable)
- **Dim:** The dimension of the symbol
- **Records:** The number of records of the symbol
- **Text:** The explanatory text of the symbol

Entry	Name	Type	Dim	Records	Text
3	a	Parameter	1	2	capacity of plant i in cases
4	b	Parameter	1	3	demand at market j in cases
7	c	Parameter	2	6	transport cost in thousands of dollars per case
10	cost	Equation	0	1	define objective function
5	d	Parameter	2	6	distance in thousands of miles
12	demand	Equation	1	3	satisfy demand at market j
6	f	Parameter	0	1	freight in dollars per case per thousand miles
1	i	Set	1	2	canning plants
2	j	Set	1	3	markets
11	supply	Equation	1	2	observe supply limit at plant i
8	x	Variable	2	6	shipment quantities in cases
9	z	Variable	0	1	total transportation costs in thousands of dollars

Figure 6.4 Symbol table showing `transport.gdx` generated by running `transport.gms` from the GAMS Model Library

A specific column can be sorted by clicking on the respective column header. Clicking again toggles the sorting direction. The **Filter** facility provides dynamic filtering of the list of symbols contained in the GDX file using wildcard syntax. By default, only the **Name** column is taken into account by the filter. By selecting the **All Columns** check box, the search considers all other columns as well. The right side of the GDX Viewer displays the actual data of the symbol that is selected in the symbol table. Data can be displayed in either the **List View** or the **Table View** which can be toggled using the corresponding button in the upper part of the GDX Viewer.

6.13.2.4.1 List View The **List View** is the default representation when looking at data using the GDX Viewer. The data is presented in the form of a table in which each row represents a record of the symbol. Each record consists of key columns corresponding to the symbols dimension. The value columns vary according to symbol type:

- **Set/Alias:** Column **Text** contains the explanatory text of a record, Y if no explanatory text is available.
- **Parameter:** Column **Value** contains the numerical value of a record.
- **Variable/Equation:** Five numerical columns: (**Level**, **Marginal**, **Lower**, **Upper**, **Scale**).

 i^1	 j^2	 Value
seattle	new-york	2.5
seattle	chicago	1.7
seattle	topeka	1.8
san-diego	new-york	2.5
san-diego	chicago	1.8
san-diego	topeka	1.4

Figure 6.5 Right side of GDX Viewer showing the parameter d from the transport model

The header displays the individual domains as well as the original index position using superscript notation which is especially useful if the column order has been changed. Furthermore it allows to manipulate the displayed data in several ways. By left clicking on a column header, the corresponding column is sorted using a stable sort mechanism that does not change the order of equal entries. Clicking again changes the sorting direction. Due to the [Extended Range Arithmetic](#) used by GAMS, columns containing numerical data can contain special values. Those values are treated in a special way when being sorted:

- **-INF**: Smallest numerical value.
- **EPS**: Treated as value very close but different from 0.
- **+INF**: Largest numerical value.
- **NA**: Treated as first non-numerical value (sorted as being greater than +INF).
- **UNDEF**: Sorted as being greater than NA.
- **ACRONYMS**: Sorted as being greater than UNDEF. Relative order of acronyms is by their internal number.

The order of columns can be changed by dragging a column header and dropping it at a different position. Dragging the border between column headers allows for resizing the widths of the involved columns. The columns in the **List View** offer a [filter facility](#) which can be opened either by right clicking on the column header or by left clicking on the filter icon. The **Reset** button in the top right corner can be used to reset the view to defaults. This removes all filters, resets the applied sorting as well as the applied numerical format and switches back to the **List View** in case the **Table View** was active.

The button **Preferences** opens a menu containing different settings for the current symbol. **Squeeze Defaults** can be used on variables and equations in order to hide all columns that have the default value of the respective variable or equation type. **Squeeze Trailing Zeroes** allows to turn on/off the truncation of trailing zeroes. The displaying format of numerical values can be specified using the **Format** drop down menu and the **Precision** spin box.

The available options for the **Format** are as follows:

- **g-format**: The display format is chosen automatically: **f-format** for numbers closer to one and **e-format** otherwise. The value in the **Precision** spin box specifies the number of significant digits. When precision is set to **Full**, the number of digits used is the least possible such that the displayed value would convert back to the value stored in GDX. Trailing zeros do not exist when **precision=Full**.

desk ¹	Level	Marginal	Lower	Upper	Scale
d1	1333.33	0	0	+INF	1
d2	0	-6.66667	0	+INF	1
d3	0	-3.33333	0	+INF	1
d4	66.6667	0	0	+INF	1

Figure 6.6 Variable mix from the prodmix model using g-format with precision=6

desk ¹	Level	Marginal	Lower	Upper	Scale
d1	1333.3333333333333	0	0	+INF	1
d2	0	-6.666666666666665	0	+INF	1
d3	0	-3.3333333333333317	0	+INF	1
d4	66.66666666666666	0	0	+INF	1

Figure 6.7 Variable mix from the prodmix model using g-format with precision=Full

- **f-format:** Values are displayed in fixed format as long as appropriate. Large numbers are still displayed in scientific format. The value in the Precision spin box specifies the number of decimals.

desk ¹	Level	Marginal	Lower	Upper	Scale
d1	1333.333333	0	0	+INF	1
d2	0	-6.666667	0	+INF	1
d3	0	-3.333333	0	+INF	1
d4	66.666667	0	0	+INF	1

Figure 6.8 Variable mix from the prodmix model using f-format with precision=6

- **e-format:** Values are displayed in scientific format. The value in the Precision spin box specifies the number of significant digits. When precision is set to Full, the number of digits used is the least possible such that the displayed value would convert back to the value stored in GDX. Trailing zeros do not exist when precision=Full.

desk ¹	Level	Marginal	Lower	Upper	Scale
d1	1.33333e+03	0e+00	0e+00	+INF	1e+00
d2	0e+00	-6.66667e+00	0e+00	+INF	1e+00
d3	0e+00	-3.33333e+00	0e+00	+INF	1e+00
d4	6.66667e+01	0e+00	0e+00	+INF	1e+00

Figure 6.9 Variable mix from the prodmix model using e-format with precision=6

The value in the **Precision** spin box specifies the number of decimals or the number of significant digits depending on the chosen format:

- **g-format:** Significant digits [1..17, Full]
- **f-format:** Decimals [0..14]
- **e-format:** Significant digits [1..17, Full]

Next to Preferences is the **Attributes** button. This button opens a menu that allows to hide certain attribute columns of variables and equations explicitly. This is especially useful when using the **Table View**.

6.13.2.4.2 Table View Switching to the **Table View** is possible for symbols that have at least two dimensions. This mode consists of two parts: A separate header view that shows the domains and attributes of the symbol as well as the actual data. The header view also allows to access the **filter facility** and highlights the positions of specific domains by using visual separators (from left to right: rows, columns, attributes). The data itself is reshaped into a format where the labels of the last dimension are moved into the column header while the remaining dimensions go into the row header. The entries in the table are the numerical values (or explanatory text in case of GAMS sets) of the record with the corresponding labels of the headers. The following image shows the **List View** of a GAMS Parameter on the left side and its representation in the **Table View** on the right side:

\uparrow i ¹	\uparrow j ²	\uparrow Value	\uparrow i ¹	\uparrow j ²	\uparrow Value
seattle	new-york	2.5			
seattle	chicago	1.7		new-york	chicago
seattle	topeka	1.8	seattle	2.5	1.7
san-diego	new-york	2.5	san-diego	2.5	1.8
san-diego	chicago	1.8			topeka
san-diego	topeka	1.4			

Figure 6.10 Two dimensional parameter as List View and Table View

In case of GAMS variables and equations, a virtual dimension for the five numerical values (Level, Marginal, Lower Bound, Upper Bound, Scale) is introduced and displayed in the column header. When looking at the data of variables or equations it is most of the time useful to visualize only a specific attribute like the variable levels. This can be achieved by using the **Attributes** menu in the upper part of the GDX Viewer. The menu allows to hide specific attributes explicitly by disabling the corresponding checkboxes.

Both column and row header dimensions can be moved into different positions in order to reshape the table view. This can be done by performing a drag-and-drop operation that starts by clicking (and holding) the left mouse button while the mouse cursor is located on the index that should be moved. Moving the mouse to an arbitrary location will bring up a drop indicator (in the form of a thin line) that previews the position in which the index will be dropped as soon as the mouse button is released. In general all index positions can be moved to arbitrary new locations, but there are a few restrictions:

- The (virtual) numerical dimension of variables and equations (Level, Marginal, Lower Bound, Upper Bound, Scale) can not be moved and is always the last dimension in the column header.

- If a header (column or row) runs out of dimensions, a dummy header (Value, Text) is introduced which can not be moved but can be used as a drop target for further drag-and-drop operations.

Figure 6.11 The table view representation of a GAMS parameter during a drag-and-drop operation that will move the dragged dimension into the position indicated by the drop indicator (thin black line)

While filters that have been applied in the **List View** will also be applied to the **Table View** and vice versa, sorting does not have any effect. The labels are sorted using the internal order which can not be changed by the user. For large data it is recommended to reduce the amount of visible records by applying filters in the **List View** and by disabling certain value columns in case of variables and equations. Once the data has been reduced, switching to the **Table View** allows to look at the data in a compact format.

6.13.2.4.3 Filter Facility Filters can be applied in both the **List View** and the **Table View** through the header view that contains the domains as well as the (numerical) attributes. In the **List View**, the header is part of the data view itself, while the **Table View** offers a separate header view above the actual data. The filter dialog can be opened either by right clicking on the header or by left clicking on the filter icon. Depending on the type of the column (key or value), the appropriate filter dialog for labels or numerical values is opened.

The filter dialog for a specific key column shows all occurring labels of that column in a list. Per default all labels in all columns are visible. Shrinking the displayed data can be achieved by unchecking one or more labels. The filter is applied by clicking the **Apply** button. Instead of selecting labels manually one can also use the wildcard string filter in the upper part of the filter dialog. The filter is automatically applied to the list of labels. Matching labels will be selected while all others will be deselected. The **Hide unselected items** checkbox can be used to automatically hide all deselected labels. This is especially useful for larger amounts of labels in combination with the wildcard string filter as only the matching labels will remain in the list while typing. The **Select All** and **Deselect All** buttons allow for selecting/deselecting all labels.

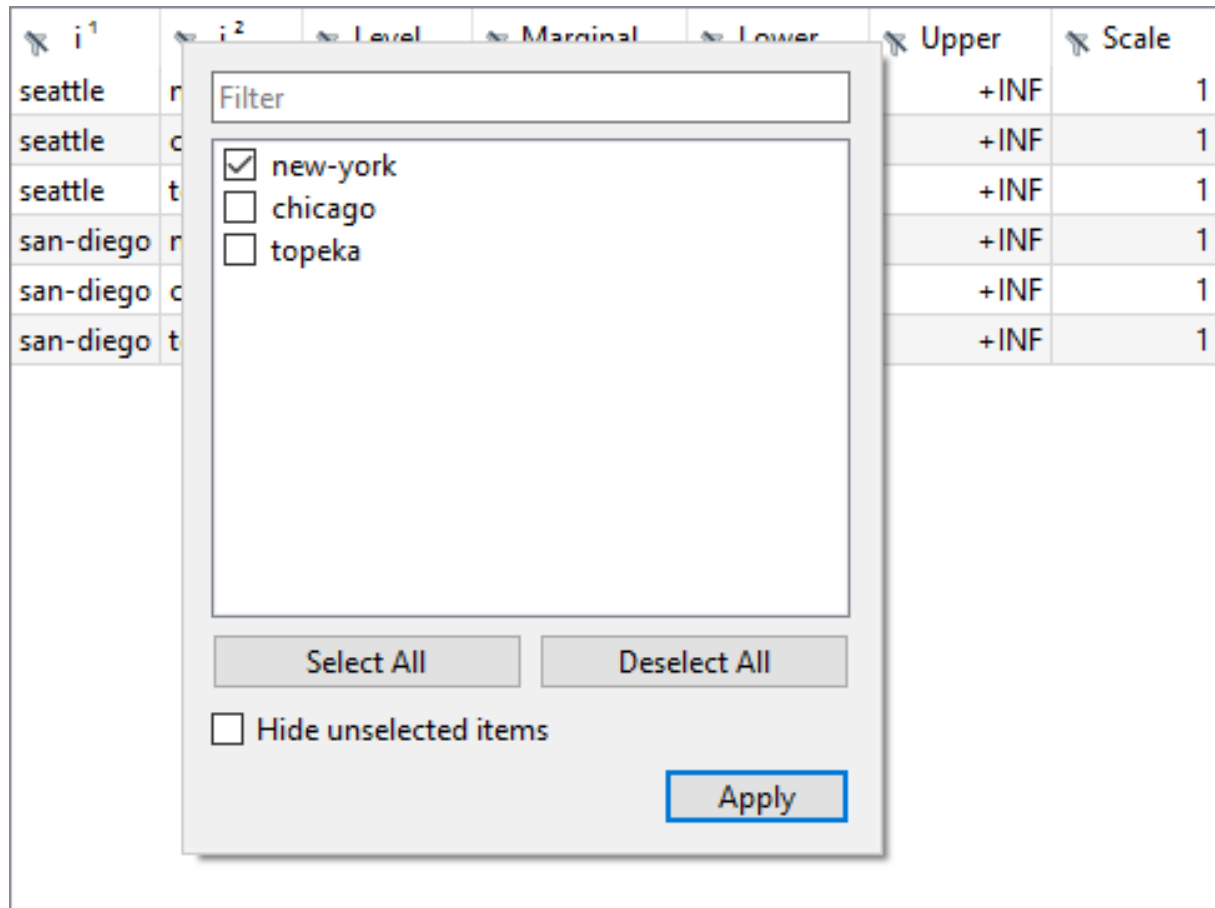

Figure 6.12 Filter dialog on column j for variable x in `trnsport.gdx`

Numerical columns offer a different filter type that allows to specify an interval for values that should be included or excluded in the view for this specific column. The **Min** value is the lowest and the **Max** value is the largest one still included in the view. When the **Exclude** check box is activated, the specified range is excluded from the view instead of included. The lower part of the filter contains check boxes for special values like **+INF** or **EPS**. Checking/unchecking will show/hide the corresponding values in the view. Clicking the **Apply** button adds the filter to the column and refreshes the view accordingly. The **Reset** button removes an active filter.

Note

When a filter on a numerical column is applied, the values used for comparison are the actual values from the GDX file. Since the displayed values are influenced by the **Format** and the **Precision** setting, they can differ from the internal ones from the GDX file. Here is an example: Let's assume we have a parameter $p(i)$ with $p("i1")=1.34$ and $p("i2")=2$. With format set to **g-format** and precision set to 2, the values are displayed as 1.3 and 2. When applying a filter with the bounds (**Min**, **Max**) set to 1.33 and 2 both records are still shown even though 1.33 is greater than 1.3 (number shown in the GDX Viewer) since the internal GDX value used for comparison is actually 1.34.

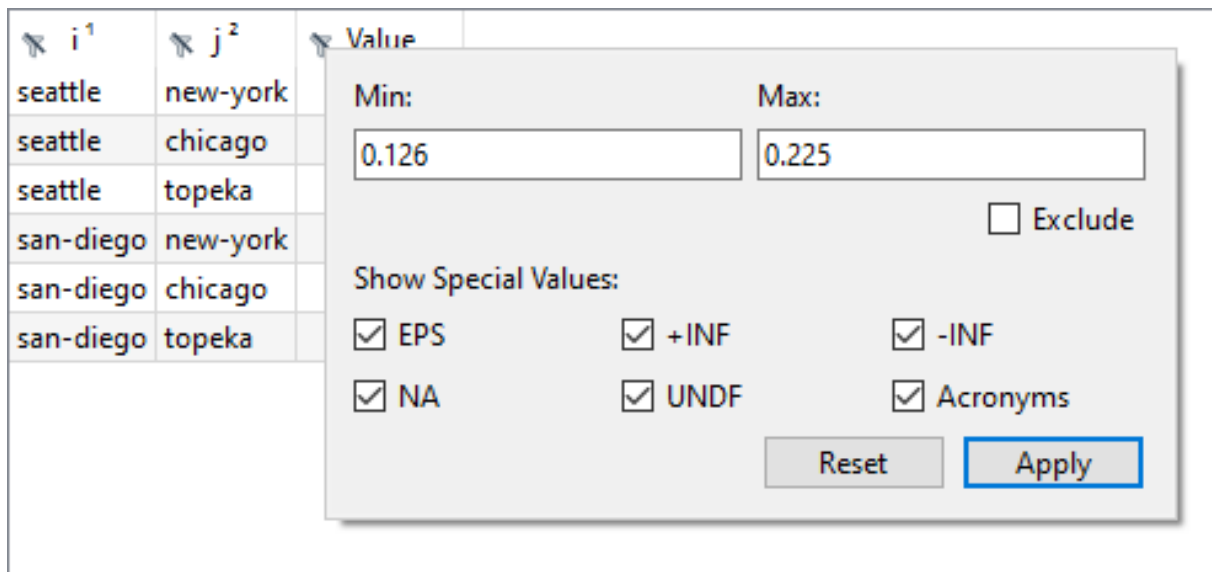

Figure 6.13 Filter dialog on numerical column Value for parameter c in `trnsport.gdx`

Action	Shortcut	macOS	Description
Jump to Symbol Search	Ctrl - F	Command - F	Moves the focus to the Symbol Search input field located above the symbol table
Select All	Ctrl - A	Command - A	Selects all data (right side only)
Copy (comma-separated)	Ctrl - C	Command - C	Copy selection to clipboard using comma as separator
Copy (tab-separated)	Ctrl - Shift - C	Command - Shift - C	Copy selection to clipboard using tab as separator (right side only)
Copy Without Labels (comma-separated)	context menu only	context menu only	Copy selection without labels to clipboard using comma as separator (Table View only)
Copy Without Labels (tab-separated)	context menu only	context menu only	Copy selection without labels to clipboard using tab as separator (Table View only)
Auto Resize Columns	Ctrl - R	Command - R	Resizes all columns to content (right side only)

6.13.2.4.4 Summary of Actions and Shortcuts

6.13.2.5 Reference File Viewer

The Reference File Viewer is a useful tool to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS model and is created using the `rf` parameter when running the model.

Figure 6.14 Parameter to create a symbol reference file when running the model

When the model is compiled, the reference file with ".ref" extension is created and can be opened either using the menu: **File > Open** or double-clicking the "RefFile" entry in the [Process Log](#):

```

--- Starting compilation
--- trnsport.gms(66) 3 Mb
--- RefFile /home/jeed/Documents/GAMS/Studio/workspace/trnsport.ref
--- Starting execution: elapsed 0:00:00.002
--- trnsport.gms(43) 4 Mb
--- Generating LP model transport
--- trnsport.gms(64) 4 Mb

```

Figure 6.15 Process Log showing clickable entry for the reference file

The Reference Viewer is categorized by a number of tabs:

Set (2)	Entry	Name	Type	Dim	Domain	Text	Location	Line	Column
Acronym (0)	137	a	Parameter	1	(i)	capacity of plant i in cases	(1) Declared in trnsport.gms	54	10
Variable (2)	138	b	Parameter	1	(j)	demand at market j in cases	(1) Defined in trnsport.gms	60	16
Parameter (5)	141	c	Parameter	2	(i,j)	transport cost in thousands...	(0) Assigned (1) Implicitly Assigned in trnsport.gms	64	39
Equation (3)	144	cost	Equation	0		define objective function	(0) Controlled (1) Referenced in trnsport.gms	62	22
Model (1)	139	d	Parameter	2	(i,j)	distance in thousands of mi...			
File (0)	146	demand	Equation	1	(j)	satisfy demand at market j			
Function (0)	140	f	Parameter	0		freight in dollars per case p...			
Unused (0)	135	i	Set	1		canning plants			
File Used (1)	136	j	Set	1		markets			
	145	supply	Equation	1	(i)	observe supply limit at pla...			
	147	transport	Model	0					
	142	x	Variable	2	(i,j)	shipment quantities in cases			
	143	z	Variable	0		total transportation costs i...			

Figure 6.16 Reference File Viewer showing tabs and reference file information

- **All Symbols** shows an alphabetical listing of all symbols used in the model.
- **Set, Acronym, Variable, Parameter, Equation, and Model** shows an alphabetical listing of symbols of the same type. See [Data Types and Definitions](#) for more details on GAMS data types.
- **File** shows an alphabetical listing of all [file statements](#) used in the model.
- **Function** shows a list of [GAMS built-in functions](#) that has been used in the model.
- **Unused** shows an alphabetical listing of all symbols that have been declared in the model but are not used anywhere.
- **File used** shows an alphabetical listing of all files used in the model including the full file path. A double-click on an file entry of the table will jump to the beginning of the reference file.

The number next to the tab name indicates how many symbols in the category, where the number of [All Symbols](#) tab sums up the number of symbols in all other tabs except [Unused](#) tab and [File used](#) tab. A click on a symbol entry of the table in every tab (except [File used](#) tab) will show the detailed reference list containing the reference location in the right hand side of the reference viewer. A mouse-over on an entry of the reference list will show the tooltip of file location and position with the file that has been referenced. A double-click on an entry of the reference list will jump to the position in the corresponding file that has been referenced.

The reference list is organized by the following reference types:

Reference Type	Description
declared	Declaration of the symbol.
defined	Defined using a data statement.
assigned	When the symbol appears on the left side of an assignment statement.
implicitly assigned	Implicit assignment like a variable in a model.
control	When the set is used as a control set.
reference	Referenced in a statement.

The detailed description of the reference types and their shorthand symbols can be found in [Reference Types](#) in [GAMS Output](#).

6.13.2.5.1 Sort and Filter referenced symbols

- **Sort** : A click on a table column header in the reference table will sort the symbol in the table by either Entry, Name, Type, Dim(ension), Domain, or Text.
- **Filter** : An input in the **Filter** box will search and display the symbol in the reference table by Name. A search in all columns can be enabled by checking **All Columns** next to the **Filter** box.

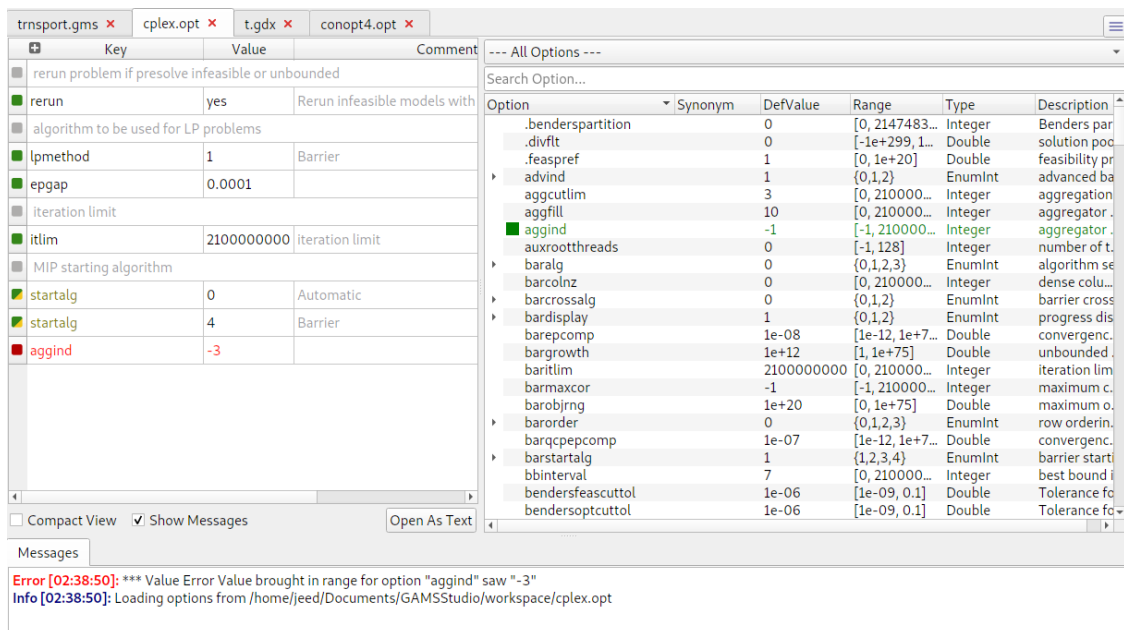

Action	Shortcut	macOS	Description
Symbol Search	Ctrl - F	Command - F	Jump to the focus to the Symbol Search input field located above the symbol table
Auto Resize Columns	Ctrl - R	Command - R	Resize all columns to content (right side only)

6.13.2.5.2 Summary of Actions and Shortcuts

6.13.2.6 Solver Option Editor

The Solver Option Editor is used to view and edit a solver-specific option file for controlling solver and interpreting results. See usage of [The Solver Options File](#) in [Solver Usage](#) and how to set `optFile` parameter to instruct gams to read an option file in [The GAMS Call and Command Line Parameters](#). The Solver Option Editor provides an editor to edit the file contents in a table form where a row entry corresponds to a line in the solver option file. The Solver Option Editor also provides a browser of solver option definitions which can be displayed in group or be filtered by search and where the option can be directly added into or deleted from the editor.

The Solver Option Editor consists of the contents editor in the left pane, option definition browser in the right pane, as well as message and configuration tab in the bottom pane.

- The left pane shows the contents editor of solver option file in a table form. Each row entry is either an option entry containing the option key, option value, as well as end-of-line comment (shown if there is definition of end-of-line comment characters for a solver option file) or a comment entry. Below the editor shows **Compact View** checkbox and **Open As Text** button
 - An option key and value are shown in green color when defined correctly according to the definition, otherwise in red color when there is an error. An end-of-line comment (if defined) and a comment entry are shown in grey color. (see section [Toggle comment/option selection](#) on how to turn an option entry into a comment entry and vice versa)
 - A comment row entry is shown in a merged cell as differences between option key and value are not identified in a comment line of a solver option file.
 - The **Compact View** checkbox enables the editor to display the file contents without comments. Note that some editing actions are suppressed when the editor is in compact view (see section [Compact View](#) for more details).
 - The **Show Messages** checkbox allows to display or hide the messages log at the bottom pane.
 - The **Open As Text** button allows to reopen the file in the text editor once contents of the file has been saved (see [Open an existing solver option file](#) and [Save a solver option file](#) in section [Basic Operations](#) for more details).
- The right pane shows a browser of solver option definitions.
 - The lower part of the browser lists all option definitions, each contains **Option Name**, **Synonym**, **Default Value**, **Range**, **Type**, and **Description**. The list can be sorted alphabetically in ascending or descending order by clicking the **Option Name** header. A checkbox in front of an option entry indicates whether there is an option of this definition entry defined in the left pane editor. An entry with enumeration type (**EnumStr** or **EnumInt**) can be expanded to show all enumerated values of the option by clicking the bullet in front of the option entry, clicking the bullet again hides all enumerated values of the option. By double clicking the entry or dragging the entry and dropping in the left pane editor adds the option key with the default value defined by this option definition in the left pane editor (See section [Summary of Actions and Shortcuts](#) on how to add or insert an option).
 - Above the list of all option definitions is a group of options and a search box. Option groups filter the list of option definitions by group name. By default all option definitions are displayed. Search box with placeholder text **Search Option...** allows a simple search through all option definitions. As a search keyword has been typed into the search box the results are displayed in the list of option definitions below. The search performs case insensitively on all fields of option definitions including enumerated values.

- The bottom pane shows the message log which reports the operations that have been carried out such as the contents have been loaded and saved as well as errors resulting from editing the contents. By default the message log is shown unless the **Show Messages** checkbox in the left pane has been unmarked to hide the message log.

6.13.2.6.1 Basic Operations
